¹Hospital Lariboisiere, Department of Cardiology, Paris, France; ²Inserm UMR-S 942, Paris, France

Background: Serelaxin (RLX), the recombinant form of human relaxin 2, is a vasoactive peptide hormone with interesting endocrine and paracrine properties, especially for cardiovascular system. Serelaxin is currently tested in clinical trials as a treatment of acute heart failure and may improve the cardiovascular prognosis of patients.

Purpose: We aimed to explore the effects of an extended administration of serelaxin in a murine model of chronic heart failure with myocardial injuries resulting from the association of isoproterenol and aldosterone.

Methods: Wild type (WT) or transgenic Aldosterone synthase (AS, overexpressing cardiac aldosterone synthase) 3-month old FVB male mice, beforehand injected twice a day for 2 days with subcutaneous isoproterenol (150mg/kg/injection) to induce systolic heart failure, were treated for 28 days with continuous serelaxin infusion (24µg/day), released by osmotic minipumps (WT or AS ISO RLX mice). These 2 groups were compared to control mice which were not treated by serelaxin and had been previously injected (WT or AS ISO mice) or not (WT or AS mice) with isoproterenol. Fractional shortening (FS) was assessed by transthoracic echocardiography along the course of treatment. Evaluation of myocardial fibrosis by sirius red coloration and quantification of mRNA expression by quantitative PCR after reverse transcription were performed at day 31.

Results: After isoproterenol injections, AS ISO mice developed a cardiac hypertrophy (heart weight/tibia length ratio +9.4% versus AS mice, $p < 0.05$) and a systolic dysfunction (decrease in FS from 44% to 36%, $p < 0.01$), which persisted 28 days later with major myocardial fibrosis (+300% versus AS mice at day 31, $p < 0.01$). Compared to AS ISO mice, a treatment with serelaxin induced in AS ISO RLX mice an early and persistent improvement in FS ($p < 0.01$ at day 10, 17, 24, 31, FS 44% for AS ISO RLX mice versus 38% for AS ISO mice at day 31), a decrease in cardiac fibrosis formation at day 31 (-46%, $p < 0.01$), a decrease in mRNA overexpression of pro-inflammatory MCP 1 (-60%, $p < 0.05$) and a restoration of altered expression of mRNA of pro-angiogenic VEGFα and anti-fibrotic MMP 9 in AS ISO mice to similar AS mice levels at day 31. WT ISO mice developed a transient systolic dysfunction after isoproterenol. Serelaxin induced in WT ISO RLX mice an earlier recovery of their initial FS at day 10 (versus day 17 for WT ISO mice) and a decrease in mRNA overexpression of ANP at day 31 (-38% for WT ISO RLX versus WT ISO mice, $p < 0.05$).

Conclusions: An extended 28-day treatment with serelaxin improved cardiac function in mice with a systolic dysfunction induced by isoproterenol and cardiac overexpression of aldosterone, through anti-fibrotic, anti-inflammatory and pro-angiogenic properties.

18

Why treatment with natriuretic peptide analogs failed to fulfill our expectations? - receptor expression and function in a failing heart.

Institute of Cardiology Research Grant

K Katarzyna Kodziszewska¹; P Leszek¹; B Sochanowicz²; K Brzoska²; W Piotrowski¹; T Zielinski¹

¹Institute of Cardiology, Warsaw, Poland; ²Institute of Nuclear Chemistry and Technology, Centre for Radiobiology and Biological Dosimetry, Warsaw, Poland

Background: Natriuretic peptide (NP) receptors are targets for both native NPs and their analogs used in heart failure (HF) therapy due to antifibrotic and antiproliferative actions. However, in large-scale studies BNP analogs failed to reverse cardiac remodeling and improve patient prognosis. Guanylyl cyclase (GC)-bound receptors (NPR-A, NPR-B) mediate the majority of biological actions of NPs, binding peptides with various affinities. NPR-A binds predominantly with ANP ≥ BNP ≥ CNP, while NPR-B affinity is greatest to CNP ≥ ANP ≥ BNP.

Purpose: To demonstrate differences in expression of NPs (ANP, BNP, CNP) and their receptors (NPR-A, NPR-B, NPR-C) on the level of transcription and translation, as well as the GC activity in healthy vs. failing hearts.

Method: RT-PCR and ELISA tests were performed on 43 hearts from patients undergoing heart transplantation and 12 healthy donor hearts not allotted to transplantation in order to determine the expressions of natriuretic peptides and their receptors

on mRNA and protein level. GC activity was assessed by stimulating receptors with increasing concentrations of their respective peptides (ANP for NPR-A and CNP for NPR-B).

Results: Expression of myocardium-derived natriuretic peptides (ANP, BNP) in the hearts of heart failure patients was increased on the levels of both mRNA (fold change: 24.4, $p=0.0003$; 13.3, $p=0.0440$, respectively) as well as protein levels (1.2 vs. 3.4, $p=0.001$; 26.2 vs. 94.1 ng/mg of protein, $p>0.0001$, respectively). CNP mRNA level was reduced (fold change: 0.1; $p=0.019$), while protein level was increased in a failing myocardium (7.6 vs. 12.1 ng/mg of protein; $p=0.01$). NPR-A and NPR-B levels remained unchanged on the level of both mRNA (fold change: 0.9, $p=0.393$; and 1.0, $p=0.444$, respectively) and protein (22.8 vs. 21.5, $p=0.579$; 11.1 vs. 10.5 ng/mg of protein, $p=0.168$). NPR-C mRNA levels were raised (fold change: 2.9, $p=0.00001$), while protein expression was reduced (7.5 vs. 4.8 ng/mg of protein, $p=0.001$) in myocardium of HF patients. Stimulation of NPR-A and NPR-B revealed reduced activity of NPR-A (0.45 vs. 1.98 pmol/min/mg of protein, $p=0.022$) in failing vs healthy hearts, while NPR-B function remained unchanged (0.87 vs. 1.45 pmol/min/mg of protein, $p=0.202$).

Conclusions: While the levels of both NP receptors exhibiting guanylyl cyclase activity remain unchanged in healthy and failing heart tissues, function of NPR-A, the main target of BNP-based therapeutics, is reduced. On the other hand, the activity of its sister receptor, NPR-B, stays the same, indicating that it might be a better therapeutic target. As expected, expression of ANP and BNP is increased in failing myocardium. Level of CNP mRNA is reduced in the disease, while its protein levels are elevated, likely due to increased production outside the myocardium (vessels) or reduced breakdown. NPR-C (clearance receptor) protein levels are reduced despite elevated mRNA expression, suggesting posttranslational alterations.

19

ORM-3819 promotes cardiac contractility on a dual mechanism of action: troponin-C dependent calcium sensitization is supported by selective PDE III inhibition

MEDIA-261409, TÁMOP-4.2.2.A-11/1/KONV-2012-0045, OTKA: K 109083
L Nagy¹; B Bodi²; P Pollesello³; A Vegh⁴; T Sorsa⁵; J Levijoki³; A Toth²;
I Edes¹; JGY Papp⁶; Z Papp²

¹University of Debrecen, Faculty of Medicine, Department of Cardiology, Debrecen, Hungary; ²University of Debrecen, Faculty of Medicine, Division of Clinical Physiology, Debrecen, Hungary; ³Orion Pharma, Drug Discovery and Pharmacology, Espoo, Finland; ⁴Department of Pharmacology and Pharmacotherapy, University of Szeged, Szeged, Hungary; ⁵MTA-SZTE Research Group of Cardiovascular Pharmacology, Hungarian Academy of Sciences, Szeged, Hungary

Introduction: ORM-3819 (L-6-[4-[N'-(4-Hydroxy-3-methoxy-2-nitro-benzylidene)-hydrazino]-phenyl]-5-methyl-4,5-dihydro-2H-pyridazin-3-one) is a novel chemical entity with a molecular structure similar to that of levosimendan.

Purpose: This study is the first pharmacological characterization of ORM-3819, focusing primarily on its cardiotoxic effects deriving from its binding to the cardiac troponin C (cTnC) and inhibition of phosphodiesterase (PDE) isozymes.

Methods: The binding of ORM-3819 to cTnC was followed by nuclear magnetic resonance spectroscopy (NMR). In vitro enzyme assays on purified PDE III and IV isozymes were carried out to reveal the PDE inhibitory effect of ORM-3819. The cardiotoxic effect of ORM-3819 was evaluated in vitro in permeabilized myocyte-sized preparations from guinea pig left ventricles (LV), ex vivo in Langendorff-perfused guinea pig hearts, in vivo after intravenous drug administration in healthy guinea pigs and mongrel dogs with myocardial stunning induced by the ligation and then reperfusion of the left anterior descending coronary artery.

Results: NMR spectroscopy confirmed the binding of ORM-3819 to cTnC by detecting chemical shift changes in the presence of ORM-3819. The selective inhibition of the PDE III and IV isozymes (IC₅₀: 3.88±0.3 nM for the PDE III and 4.95±0.02 µM for the PDE IV isozyme) was revealed during in vitro enzyme assays. The Ca²⁺-sensitizing effect of ORM-3819 was demonstrated in vitro in permeabilized myocyte-sized preparations from LV of guinea pig hearts (ΔpCa₅₀: 0.12±0.01; EC₅₀: 2.88±0.14 µM). ORM-3819 increased the maximal rate of LV pressure development (+dP/dt_{max}) (EC₅₀: 8.9±1.7 nM) and LV systolic pressure (EC₅₀: 7.63±1.74 nM) in Langendorff-perfused guinea pig hearts. Intravenous

administration of ORM-3819 increased LV +dP/dt_{max} (EC₅₀: 0.13±0.05 µM/kg) and improved the rate of LV pressure decrease (-dP/dt_{max}); (EC₅₀: 0.03±0.02 µM/kg) in healthy guinea pigs. In an in vivo dog model of myocardial stunning, ORM-3819 restored the depressed LV +dP/dt_{max} and improved % segmental shortening (%SS) in the ischaemic area (to 18.8±3), which was reduced after the ischaemia-reperfusion insult (from 24.1±2.1 to 11.0±2.4).

Conclusion: Our data demonstrate ORM-3819 as a potent positive inotropic agent exerting its cardiotoxic effect by a cTnC-dependent Ca²⁺-sensitizing mechanism in combination with the selective inhibition of the PDE III isozyme. This dual mechanism of action results in the concentration-dependent augmentation of the contractile performance under control conditions and in the postschaemic failing myocardium.

20

Vepoloxamer (purified poloxamer-188) improves LV function, limits cardiomyocyte calcium overload and restores integrity of calcium cycling proteins in myocardium of dogs with advanced heart failure

HN Hani Sabbah¹; V Gupta¹; V Gupta¹; M Emanuele²

¹Henry Ford Hospital, Detroit, United States of America; ²Mast Therapeutics, Inc., San Diego, United States of America

Background: Calcium overload occurs in cardiomyocytes (CMs) of the failing heart and contributes to cell death and progressive LV dysfunction. Vepoloxamer (VEPO), purified poloxamer-188, is a rheologic agent that improves microvascular blood flow and repairs damaged cell membranes. It is under investigation in a phase-3 trial in patients with acute sickle cell crisis and in phase-2a trial in patients with heart failure (HF).

Purpose: We examined the effects of multiple acute infusions of VEPO on LV function in dogs with (HF) (LV ejection fraction, EF~30%) and tested the hypothesis that the membrane reparative properties of VEPO attenuate calcium overload in failing CMs by inhibiting unregulated calcium entry into cells and, in doing so, reverses abnormalities of sarcoplasmic reticulum (SR) calcium cycling proteins.

Methods: 14 HF dogs were randomized to 2, 2 hrs infusions of VEPO (450 mg/kg, n=7) or saline (control, n=7) given 3 weeks (W) apart. LV EF and plasma troponin-I (TnI) were measured at baseline, at end of infusion and at 1 and 3W after each infusion. LV tissue obtained at end of study was used to assess calcium ATPase activity (CaAA) and protein levels of phosphorylated (p) ryanodine receptors at serine-2808 (p-RYR-s2808) and p-sodium-calcium-exchanger 1 (p-NCX-1) by Western blotting. Tissue from 7 normal (NL) dogs was used for comparisons. Separately, freshly isolated CMs from 6 control dogs were incubated for 2 hrs with VEPO (4.5 mg/ml) or saline and then treated with 10 µM Fura-2 AM to fluorometrically assess intracellular calcium concentration.

Results: VEPO increased EF by 6.0±0.7%* at 2 hrs; 7.0±0.7%* at 1W; 1.0±0.6% at 3W; 6.0±1.3%* at 4W and 5.9±1.3%* at 6W and reduced TnI by 0.02±0.04 ng/ml at 2hrs; 0.18±0.04* ng/ml at 1W; 0.13±0.03* ng/ml at 3W; 0.23±0.03* ng/ml at 4W and 0.17±0.03* ng/ml at 6W (*p<0.05 vs. control). CaAA was reduced and p-RYR-s2808 and p-NCX-1 levels increased in HF-Controls compared to NL. VEPO therapy normalized all SR proteins (Table). Treatment of isolated CMs with VEPO reduced intracellular calcium compared to saline (2.32±0.05 vs. 3.14±0.32 relative fluorometric units, p<0.05).

Conclusions: VEPO attenuates calcium overload and normalizes SR calcium cycling. This leads to lowering of TnI along with improvement of LV function. The results support the development of VEPO for treatment of patients with HF.

MODERATED POSTER SESSION 1 – ACUTE HEART FAILURE

Saturday 21 May 2016 10:00–11:00

Location: Poster Area

22

Hypochloraemia during hospitalization for acute heart failure is strongly associated with poor decongestion and mortality

J M Jozine Ter Maaten¹; K Damman¹; MM Givertz²; M Metra³; JG Cleland⁴; DM Bloomfield⁵; P Ponikowski⁶; DJ Van Veldhuisen¹; JM Testani⁷; AA Voors¹

¹University Medical Center Groningen, Groningen, Netherlands; ²Brigham and Women's Hospital, Boston, United States of America; ³University of Brescia, Brescia, Italy; ⁴Imperial College London, London, United Kingdom; ⁵Merck Research Laboratories, Rahway, United States of America; ⁶Wroclaw Medical University, Wroclaw, Poland; ⁷Yale University, New Haven, United States of America

Background: Chloride plays a key role in renal salt sensing, neurohormonal activation and regulation of diuretic targets and hypochloraemia predicts mortality in acute heart failure (AHF). AHF therapies such as diuretics alter chloride homeostasis.

Purpose: We studied the association between (changes in) serum chloride concentration and diuretic responsiveness, decongestion, and mortality in patients with AHF.

Methods: Patients hospitalized for AHF in the PROTECT trial (n=2033) who had serum chloride measured within 24 hours of admission and 14 days later were studied (n=1960). Hypochloraemia was defined as chloride <96 mEq/L. Results Median baseline chloride was 101.0 [97.0-104.0] mEq/L. Low baseline chloride was associated with high bicarbonate, poor diuretic response, less haemoconcentration, and more worsening heart failure (all P < 0.01). Newly developed hypochloraemia at day 14 was common and associated with a decline in renal function, and increase in serum urea (P < 0.01). In multivariable analyses, chloride measured at day 14, but not baseline chloride was strongly and independently associated with 180-day mortality (HR per SD decrease: 1.33 [1.17-1.50], P < 0.001). In comparison, sodium was not significantly associated with mortality after multivariable adjustment at any time point. Hypochloraemia at baseline that resolved was not associated with mortality (p=0.55), but new or persistent hypochloraemia at day 14 was associated with increased mortality (HR: 3.11 [2.17-4.46], P < 0.001).

Conclusion: Hypochloraemia at AHF hospital admission was strongly associated with impaired decongestion. New or persistent hypochloraemia 14 days later was independently associated with reduced survival, whereas hypochloraemia that resolved by day 14 was not.

Adjusted HRs 180-day mortality

24

Red cell distribution width (RDW) predicts long term prognosis in patients hospitalized with acute heart failure: the RDW in Acute Heart Failure (REAHF) study.

E Testa¹; R Remo Melchior¹; G Rinaldi²; S Leccardi¹; A Silvestri¹; C Serraino¹; C Bracco¹; L Spadafora¹; A Giraudo¹; LM Fenoglio¹

¹Santa Croce E Carle Hospital, Internal Medicine, Cuneo, Italy; ²University of Turin, School of Medicine, Turin, Italy

Background: RDW has been proposed as a sensitive biomarker of chronic hypoxic burden via the hypoxia-> erythropoietin -> anysocite-> RDW model. The role of RDW in predicting prognosis in acute heart failure (AHF) and his relationship with comorbidities is not fully elucidated.

Purpose: To evaluate the long-term prognostic value of RDW in a broad population of patients hospitalized for AHF.

Methods: in a retrospective cohort observational study, 436 consecutive patients admitted in 2013 for AHF in a urban hospital were categorized in patients with low RDW (<14.5) and high RDW (> 14.5). Hemoglobin, NT-proBNP values along with clinical and biochemical variables were recorded. Charlson comorbidity score was calculated. The rate of death from all causes was determined after a median follow up of 18 months.

Results: Overall population has a median age of 80 years (IQR 72-85), 228 patients (52%) were males. At follow up 185 patients (42%) had died: in the cohort with low RDW (n=189) 52 patients had died (27%) whereas in the cohort with high RDW (n=247), 133 patients (53%) had died. The unadjusted risk ratio of patients with high RDW was 2.26 (log rank test p < 0.0001, Figure) In a multivariate Cox regression model, the hazard ratio for death from any cause for the patients with high RDW as compared with those with low RDW was 2.0 (95 percent confidence interval, 1.3 to 2.9; P < 0.001); the RDW added prognostic information beyond that provided by conventional risk factors, including the patient's age; sex; the presence or absence of a history of coronary artery disease, hypertension, diabetes, systolic dysfunction, anemia, hyponatremia; estimated glomerular filtration rate; high NT-pro BNP levels, Charlson comorbidity score.

Conclusion: RDW is a powerful marker of long-term mortality in patients with AHF and his prognostic value is maintained beyond that provided by hemoglobin levels, comorbidity score or other well-established risk factors or biomarkers.

Survival curve

25

Admission and discharge prognostic value of Galectin-3 and its relationship with echocardiographic parameters in patients hospitalized for acute heart failure

B Benedetta De Berardinis¹; S Santarelli¹; V Russo¹; C Bongiovanni¹; L Magrini¹; G Salerno¹; R Marino¹; P Cardelli¹; S Di Somma¹

¹Sapienza University of Rome, Sant'Andrea Hospital, 2nd Faculty of Medicine, Rome, Italy

Background: Galectine-3 (Gal-3), is biomarker involved in different body processes such as inflammation and fibrosis, which play a central role in the development of Heart Failure (HF).

Purpose: Aim of this study was to evaluate in patients hospitalized for acute heart failure (AHF), Gal-3 prognostic role also to systolic and diastolic functions related to echocardiographic data.

Methods: We enrolled 143 consecutive AHF patients presenting to our emergency department from January 2014 to March 2015. In all studied patients, at hospital admission, together with echocardiographic assessment Gal-3 and Brain Natriuretic Peptide (BNP) were performed and repeated at discharge. A 60 days follow up phone call was made to evaluating cardiovascular events (death and rehospitalization).

Results: No statistically significant difference for Gal-3 values at admission and at discharge in patients with events and neither in patients without events and in the whole group. At ROC analysis Gal-3 at discharge showed to be able to predict 60 days events: AUC 0.67, 95% CI 0.533 to 0.793, $p < 0.05$. Considering patients with a value of Gal-3 at admission > 17.8 ng/ml, we found a statistically significant correlation with events, while patients who had a Gal-3 median value < 17.8 ng/ml had better prognosis ($p < 0.001$). BNP mean value at arrival was 1140 ± 1115 pg/ml, and at t test it showed prognostic relevance for events (mean value in patients without events 971 ± 781 pg/ml, and 1644 ± 1678 pg/ml in patients with events, $p < 0.001$). At ROC analysis, BNP at arrival showed prognostic value for events (AUC 0.619, $p < 0.05$). The combined ROC curve of BNP and Gal-3 at discharge showed prognostic power for events (AUC 0.75, $p < 0.05$). At echocardiographic assessment, there was no statistically significant difference between patients with reduced and preserved left ventricular ejection fraction in relation with Gal-3. There was a significant inverse correlation between Gal-3 and the deceleration time ($r = -0.35$; $p < 0.05$) in patients with sinus rhythm as result of diastolic dysfunction.

Conclusions: In patients admitted with AHF, Gal-3 evaluation at hospital discharge allows to identify those subjects who are at higher risk for events (death and rehospitalization) in the following 60 days; in particular for those ones that presented a value of Gal 3 greater than 17.8 ng/ml. The combined use of BNP and Gal-3 at hospital discharge seems to be useful for predicting future 60 days prognostic value. The prognostic value of Gal-3 could be referred to its effect on left ventricle diastolic function.

26

Acute decompensated heart failure syndrome in patients with myocardial infarction as the predictor of the development of multiple organ dysfunction syndrome

MV Krestjanyanov¹; AYU Yevstigneeva²; VA Razin²

¹Ulyanovsk Regional Hospital of War Veterans, Radiology department, Ulyanovsk, Russian Federation; ²Ulyanovsk State University, Ulyanovsk, Russian Federation

Myocardial Infarction (MI) complicated with Multiple Organ Dysfunction Syndrome (MODS) is the serious life-threatening condition leading to high mortality.

The purpose of the study was evaluation the cardiologic status of patients with MI due to Acute Decompensated Heart Failure (ADHF) complicated with MODS, investigating the structure of MODS and the contribution of known risk factors to its development. Were examined 76 patients with MI complicated with ADHF syndrome; 48 patients of this group revealed MODS (the 1st group; mean age is 64 (7) years). MODS was not diagnosed in 28 patients (the 2nd group; mean age is 59 (2) years). Heart Function Deficiency (HFD) severity was estimated with the following scales: "CHOCKS" scale, "US" classification, Killip/Kimball scale of 1967, Forrester/Stevenson scale of 1977, patient's model with Heart Failure (HF) "Seattle HF Model", "EFFECT" scale. ADHF Syndrome was revealed in 17 patients in both groups. Severity of Coronary stenosis was estimated by "SYNTAX" scale. Risk factors were estimated with GRACE scale; MODS – with MODS, SOFA scales. The 2,3,4,5 component MODS was determined. Statistical significance was defined at the level of methods for $p < 0.05$.

All patients had chronic extra-cerebral pathology prior to the development of severe forms of MI (75% had polymorbidity). 90% of all cases with MODS included the Pathology of the Respiratory system. More often (37%) MODS included 2 components, and only 3% included 5 components. Cardiac Function Deficiency prevailed in patients with MODS ($p < 0.05$). Positive dynamic of HFD was revealed in the 2nd group of patients with all scales ($p < 0.05$). Dependence of the degree of HFD in patients with MODS and severity of coronary atherosclerosis (AS) was assessed as the highest in patients with MI and ACHD in the presence of severe coronary stenosis ("SYNTAX" ≥ 23) and as the least in patients with moderate coronary stenosis ("SYNTAX" ≤ 22) ($p < 0.05$). Executing the discriminant analysis had shown the most significant risk factors of MODS: Hypertension, AS, rheumatism, coronary heart disease, chronic intoxication. Carrying out the canon analysis revealed that only hypertension was statistically significant. Defining of the standardized variables for comparison of importance of arterial hypertension as risk factor was found that it contributes to 78% of variability, so, its contribution to the development of MODS is maximal, and then the severity of AH is higher, the more components lead to MODS. Besides AS was found to contribute to 5-component MODS.

Thus, the most common MODS component is the acute pathology of the Respiratory System that does not depend on the MI type with ADHF. More often was found MODS with 3-component. The higher degree of cardiac function deficiency is also found in patients with MODS. Hypertension makes the greatest contribution to the

development of MODS, the severity of hypertension is directly proportional to the number of MODS components.

Five years monitoring of pulmonary congestion in chronic heart failure patients in outpatient clinic. Randomized controlled trial (IMPEDANCE-HF).

M Michael Shochat¹; A Shotan¹; M Kazatsker¹; I Kleiner²; J Weinstein²; I Dahan¹; D Blondheim¹; S Meisel¹

¹Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; ²Saroka Medical Center, Cardiology, Beer Sheva, Israel

Assessment dynamic of pulmonary congestion in patients with congestive heart failure for long period of time by noninvasive technique may help understand mechanisms of Acute Heart Failure development and Heart Failure (HF) associated hospitalizations. In this study we used a new type of impedance technique based on calculated lung impedance (LI) rather than on the traditionally measured transthoracic impedance for monitoring HF patients. Aim To determine the dynamics of pulmonary congestion development in HF patients.

Method and Results: LI change is adequately reflects dynamics of pulmonary congestion and decreasing LI reflects increasing lung fluid. In "Non-invasive Lung IMPEDANCE-Guided Preemptive Treatment in Chronic Heart Failure Patients: a Randomized Controlled Trial (IMPEDANCE-HF trial)" 256 CHF patients with LVEF $< 35\%$ were randomized (1:1) to a control group treated by clinical assessment and a monitored group whose therapy was also assisted by Lung Impedance (LI). Was found that LI-guided treatment reduced HF hospitalizations by 45% and HF associated death by 58% during 48 months of treatment. Signs, LI and ratio of the instantaneous LI to the calculated baseline LI (ΔLI) were monitored monthly in the outpatient clinic. For assessment dynamics of pulmonary congestion in long standing follow up we introduced an additional parameter, the mean annual DLI Ratio (DLIR/year). DLIR/year was calculated as the arithmetic average of all available monthly measurements within the same year. Of 256 study patients, 190 were admitted for HF, 31 for non-AHF causes only and 35 were not hospitalized at all during the follow up period. The average number of HF hospitalizations was 1.05/year. 221 of 256 patients had follow up period > 5 years. Results calculation DLIR/year were for patients without HF hospitalizations (-11%; -8%; -8%; -7%; -8%), (group 1), for patients with HF hospitalizations < 1.05 /year (-17%; -15%; -16%; -15%; -16%), (group 2) and for patients with HF hospitalizations > 1.05 /year (-24%; -23%; -30%; -33%; -37%), (group 3), ($p < 0.01$ between groups). In group 1 and 2 there were not changes in pulmonary congestion between years ($p = NS$), but in group 3 was a significant increasing in pulmonary congestion since third year follow up, $p < 0.01$. Conclusion From our findings follows that a degree of pulmonary congestion (reflected by degree of DLIR/year decrease) is a main predictor of multiple HF hospitalizations.

28

Management of heart failure in the real-world: does the setting make the difference? Findings from the ARNO administrative database.

This work was partially supported by an unrestricted grant from Novartis Pharma Italy

F Orso¹; E Rossi²; S Calabria³; E Cinconze²; S Baldasseroni⁴; N Martini⁵; A P Aldo Pietro Maggioni⁶

¹Azienda Ospedaliero-Universitaria Careggi, Department of Geriatrics, Section of Geriatric Medicine and Cardiology, Firenze, Italy; ²CINECA Interuniversity Consortium, Casalecchio di Reno, Italy; ³CORE, Collaborative Outcome Research, Bologna, Italy; ⁴Azienda Ospedaliero-Universitaria Careggi, Department of Heart and Vessel, Section Internal Medicine and Cardiology, Firenze, Italy; ⁵Accademia Nazionale di Medicina, Roma, Italy; ⁶ANMCO Research Center, Florence, Italy

Background: The natural course of patients with chronic heart failure (HF) is characterised by frequent rehospitalisations that are cause of morbidity and mortality and are responsible for a large part of HF costs. Patients included in randomized clinical trials and registries are generally enrolled in cardiology wards, but in the real-world these patients are frequently managed also in non-cardiology settings.

Purpose: The purpose of this study is to describe the real world clinical epidemiology of acute heart failure analysing a large administrative database and describing the main differences in terms of clinical characteristics, treatments, one-year outcomes and costs across the different settings of care.

Methods: Data came from the ARNO Observatory that includes nearly 3,000,000 in-habitants of 7 Local Health Authorities of the Italian National Health Service (NHS). Patients with HF were selected when discharged for HF (from January 1, 2008 to December 31 2012) and prescribed on at least one specific HF treatment. We compared patients managed in cardiology vs those managed in internal medicine/geriatric wards. Results. The study population was composed by 37,242 patients discharged alive for HF from the above described specific settings and prescribed on HF treatments. Just 26.6% were managed in a cardiology setting and nearly two thirds of the patients (63.3%) were managed in internal medicine (49.7%) and geriatrics (13.6%) wards. Compared to those discharged from internal medicine/geriatrics settings, HF patients managed in cardiology setting were younger (mean age 73 vs 80 years), with a lower prevalence of females (39.8% vs 56.6). Less co-morbidities such as COPD (26.3 vs 32.0%)

or depression (12.9 vs 24.4%) were reported as well as a higher prescription rate of ACE-inhibitors/Angiotensin Receptor Blockers, Beta-Blockers and Mineralocorticoid antagonists (72.2 vs 63.9 %, 68.6 vs 46.6% and 47.3 vs 40.4%). During the 1-year follow-up, patients managed in cardiology had at least one re-hospitalization in 57.4% vs 56.8% and less frequently due to non-cardiovascular causes (31.1 vs 53.5%). NHS's total direct cost per year were higher in cardiology (15,664€) than in the internal medicine/geriatric wards (10,516 €). p values for all above differences <0.01.

Conclusions: Real world evidence show that only a minority of patients are managed in a cardiology setting and that, according to management setting, patient's characteristics are very different in terms of clinical characteristics, treatments, costs and outcomes.

29

Risk assessment of re-hospitalizations for heart failure during 30 days after discharge for heart failure in randomized controlled IMPEDANCE-HF trial

M Michael Shochat¹; A Shotan¹; I Kleiner²; I Dahan¹; J Weinstein²; D Blondheim¹; S Meisel¹

¹Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; ²Saroka Medical Center, Cardiology, Beer Sheva, Israel

Background: Prevention of re-hospitalization for heart failure (HF) is an unresolved issue. Aim Evaluate the ability of a new non-invasive method for lung impedance monitoring to predict HF re-admissions within 30 days after previous HF hospitalization.

Methods: In "Non-invasive Lung IMPEDANCE-Guided Preemptive Treatment in Chronic Heart Failure Patients: a Randomized Controlled Trial (IMPEDANCE-HF trial)" 256 CHF patients with LVEF<35% were randomized (1:1) to a control group treated by clinical assessment and a monitored group whose therapy was also assisted by Lung Impedance (LI). Was found that LI-guided treatment reduced HF hospitalizations by 45% and HF associated death by 58% during 48 months of treatment. There were 211 and 386 HF hospitalizations in monitoring and control group within 48 months of follow up. LI was measured in all patients at admission and discharge and calculated as a part from normal LI impedance for each patient and presented in percent. Improvement in LI impedance at discharge (decreasing in pulmonary congestion) in compare with admission was divided in 4 categories: A: 0< DLI< 5%; B: 5 < DLI < 10%; C: 10 < DLI < 20% and D: DLI > 20%. Results We found that percent of re-admissions for HF was in categories A: 60 and 64% (NS), B: 30 and 35% (NS), C: 10 and 27% (p < 0.05), D: 6 and 6.1days (NS) in monitored and control group correspondingly. Length of hospital stay was in categories A: 5.4 and 4.9 days (NS), B: 3.7 and 5 days (p < 0.05), C: 5.2 and 5 days (NS), D: 4 and 19% (p < 0.05) in monitored and control group correspondingly.

Conclusions: Noninvasive LI monitoring may be used to evaluate effectiveness of therapy in hospitalized HF patients. Small (less 5%) improvement in LI during hospitalization is a very strong predictor for re-hospitalization during next month in both groups. LI improvement in categories A and B was so small that even LI-guided treatment was ineffective to prevent re-admissions during next month. On the other side, LI improvement in categories C and D was enough powerful to enable to LI-guided treatment significantly improves rate of HF hospitalizations.

Dynamic transcatheter mitral valve repair: first in man experience with a novel concept to treat patients with severe heart failure and functional mitral regurgitation

N Nicou¹; M Miriam Silaschi¹; TA McDonagh²; M Eskandari³; N Walker³; R Dworakowski²; J Byrne²; P Maccarthy²; M Monaghan³; O Wendler¹

¹King's College Hospital, Cardiothoracic Surgery, London, United Kingdom;

²King's College Hospital, Cardiology, London, United Kingdom; ³King's College Hospital, Non-invasive Cardiology, London, United Kingdom

Introduction: We report the case of a 58-year-old man, transferred to our centre following an out of hospital cardiac arrest with acute ST-elevation myocardial infarction and cardiogenic shock. An Impella was inserted and primary percutaneous intervention performed using two drug-eluting stents into left anterior descending and right coronary artery. The patient had a prolonged stay on intensive care unit. Echocardiography demonstrated a significantly impaired left ventricular ejection fraction (LVEF 20%) and severe functional mitral regurgitation. The patient remained hypotensive and dialysis-dependent making treatment with heart failure medication challenging. He was not suitable or ineligible for alternative treatments, including percutaneous edge-to-edge mitral valve repair, re-synchronisation therapy and heart transplantation. Therefore, approval was sought from the Medicine and Health Care Products Regulatory, to insert a spacer balloon, a new device, on compassionate grounds.

Device Procedure: This spacer balloon is a novel device for dynamic transcatheter mitral valve repair (DTMVR). It is a fluid-filled balloon, implanted via transapical access into the mitral valve orifice, and aims to improve leaflet coaptation during systole. Its size is adjustable after implantation through a subcutaneous port to enable optimal performance. The patient underwent implantation under general anaesthesia, guided by echocardiography and fluoroscopy. The balloon was filled stepwise, until Swan-Ganz catheter measurements confirmed optimal haemodynamics and echocardiography showed optimal reduction of MR. Post procedure, the patient was no longer dialysis dependent and was discharged home. Improved blood pressure allowed for initiation of heart failure medication. While LVEF improved to 45% and the patients NYHA status increased to II, MR decreased to moderate degree. Thus, at six months, the balloon was topped up (+2.5ml) under echocardiographic guidance during an outpatient appointment, which reduced MR to mild degree. At seven months, the patient developed some small thrombi on the device. Given that his surgical risk had dramatically decreased, mitral valve replacement was performed and the device explanted. The patient had an uneventful postoperative course, has been discharged home and is stable in NYHA class I.

Conclusion: This spacer balloon offers a new treatment option of dynamic TMVR. Patients with acute heart failure and MR may benefit as demonstrated. How the spacer balloon would perform as destination therapy in patients with chronic heart failure, remains to be seen.

31

Avoiding heart failure admission - high dose bolus IV Furosemide & CKD stage 4/5

J Jacqueline Hunt¹; H Church¹; N Patel¹; A Marshall¹

¹Eastbourne District General Hospital, Eastbourne, United Kingdom

Heart failure is one of the most common causes of admission to hospital. Studies have demonstrated day case IV Furosemide to be a successful treatment in avoiding admission to hospital. This case study demonstrates high dose IV Furosemide in a complex heart failure patient with chronic kidney disease stage 4/5 can be effective in avoiding admission.

Background: An 82 year old male had a past medical history of CKD stage 4/5, COPD, CRTP, EF 10-15%, PAF, Type II DM chronic back pain. He would be outside criteria for many IV Furosemide regimes due to renal failure, GFR 18 and the dose

required. He had 5 admissions over the past year due to heart failure. The patient presented with SOB, weight gain of 4lbs, ankle oedema and abdominal distention. He no longer responded to oral titrations of diuretics. He was on maximum tolerated medication. He was aware of his prognosis, however he valued any time which he could have at home. Day case diuretics within the cardiology department were administered by a heart failure specialist nurse and with support from the cardiology team if required. The dose was determined by previous admission requirements. Furosemide 240mg was administered over 2 hours via syringe driver. Observations were monitored every 15minutes until 1 hour post infusion. Renal function was checked the following morning.

Results: The patient required IV diuretics Monday, Thursday & Friday and achieved dry weight, without any deterioration in blood pressure or renal function. The patient was able to go home each evening. This regime was successful because of early implementation of IV Furosemide at large doses. Average duration of previous admissions were 7 days at a cost of £2000 approx. Conclusion : High dose day case IV Furosemide should be considered for complex heart failure patients with stage 4/5 renal disease. Regimes need to be flexible to adapt to individuals requirements, however this needs to be within an environment where the expert clinicians are well known to the care needs of the patient.

32

Gene expression profiling to identify giant cell myocarditis in a patient with clinical suspicion but no histological evidence of the disease

F M Friedrich Fruhwald¹; D Lassner²; S Fruhwald¹; O Dapunt¹; U Gross²; HP Schultheiss²

¹Medical University of Graz, Graz, Austria; ²Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany

A previously healthy female (26 years) was admitted due to sudden onset of massive dyspnoea, nausea and vomiting following a respiratory infection two weeks ago. At admission the patient had no fever. Due to the acute beginning of dyspnoea pulmonary embolism was excluded by computed tomography. The patient was then admitted to the intensive care unit for treatment. She was intubated and mechanically ventilated with initially high positive end expiratory pressure (PEEP) which led to respiratory stabilisation. However, she was catecholamine-dependent (norepinephrine). Echocardiography revealed a massive depression of left ventricular function with an ejection fraction (LV-EF) of 25%.

Endomyocardial biopsy (EMB) was taken the following day under the suspicion of giant cell myocarditis. After EMB echo showed an even more depressed LV-EF (15%), the patient was even more norepinephrine-dependent and cardiogenic shock was deteriorating as well (INTERMACS-1). This prompted the implantation of an extracorporeal membrane oxygenation (ECMO) in a veno-arterial manner. After five days on ECMO preliminary results of EMB showed no infection of viral genome, no giant cells in histology (although lymphocytes and macrophages were present) while immunohistological staining showed a massive elevation of lymphocytes and macrophages. However, due to the suspicion of giant cell myocarditis a gene expression profiling was done which confirmed the suspicion.

With this information a high-dose cortisone-therapy was started at 10mg/kg body-weight for 3 days followed by 4 weeks at 1mg/kg bodyweight. This was supported by cyclosporine. After 3 days of high-dose cortisone LV-EF increased from 15% to 55% and ECMO was explanted. The patient was extubated and transferred to the normal ward after another 4 days. Overall, the patient left the hospital after 4 weeks to start cardiac rehabilitation. Treatment at discharge consisted of methylprednisolone (1mg/kg for 4 weeks, followed by a decline of 10mg every 2 weeks until 10mg will be reached), cyclosporine (trough level 100-150), pantoprazol 40mg, calcium plus vitamin D, ramipril, eplerenon and bisoprolol.

Giant cell myocarditis is a rapid progressive disease with an enormously high mortality due to pump failure or arrhythmias. Immunosuppression including cortisone

and cyclosporine is the treatment option saving lives. Therefore, every effort must be made to get a definite diagnosis out of the EMB-specimen as soon as possible. In cases where no focal granulomas of giant cells can be found in histology these findings may oppose the clinical suspicion. Therefore, gene expression profiling as reported earlier is an excellent tool to identify the disease and get certainty about the underlying disease.

33

Life-saving role of ECMO in aggressive multidisciplinary treatment strategy for catastrophic antiphospholipid syndrome

F Bevilacqua¹; M E Maria Enrica Antoniucci¹; M Calabrese¹; G Arlotta¹; A Scapigliati¹; S Guarneri¹; F Cavaliere¹

¹Catholic University of the Sacred Heart, cardiovascular department, Rome, Italy

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is a rapidly progressive life-threatening disease characterized by multiple organ failure in presence of antiphospholipid antibodies. Therapy is based on anticoagulation with intravenous (IV) heparin, immunosuppressors, IV immunoglobulins, and plasmapheresis. Nevertheless, the course of the disease is sometimes hyperacute and the high mortality rate is primarily due to acute cardiopulmonary failure. Veno-arterial extracorporeal membrane oxygenation (VA-ECMO) may effectively support cardiorespiratory function and acts as a bridge to recovery.

Description: A 29-year-old woman with history of Antiphospholipid Syndrome (APS), past pulmonary, cerebral and skin vasculitis, presented to our hospital with epigastric pain and fever. After 7 days she had chest pain with ECG sinus tachycardia, anterolateral ST segment depression, serum Troponin T elevation and global hypokinesia with 40% left ventricular ejection fraction (LVEF) on echocardiography. The clinical scenario rapidly deteriorated with severe acute respiratory failure with cardiogenic shock (LVEF 20%) and acute kidney injury with anuria, refractory to mechanical ventilation, inotropes, and diuretics. Coronary angiography yielded normal results and myocardial biopsy was performed. Femoro-femoral VA-ECMO was initiated. Blood flow was 2.5 L/min/m². After initial hemodynamic stabilization, we tried to identify the heart failure (HF) etiology. Differential diagnosis included lupus myocarditis, infective and Libman-Sacks endocarditis, thrombotic thrombocytopenic purpura and CAPS. We diagnosed CAPS on the basis of the following criteria: evidence of involvement of 3 or more organs, systems, and/or tissues (pulmonary, cardiac and kidney); development of manifestations simultaneously in a week; confirmation by histopathology of small vessel occlusion in myocardial biopsy; and laboratory confirmation of the antiphospholipid antibodies presence. Pulse steroid therapy with intravenous (IV) methylprednisolone, 1 g daily for 3 days, and IV immunoglobulin 1 mg/kg/d, for 3 days were given. She also underwent 3 plasmapheresis cycles. Heparin infusion, started before ECMO administration, was continued to maintain constant anticoagulation. The patient progressively recovered and ECMO was stopped 10 days later. Steroid therapy was tapered to 120 mg daily associated to immunosuppression with mycophenolate mofetil 1 g twice/daily. Warfarin was started for oral anticoagulation. The patient was discharged 4 weeks after ECMO interruption with specialist follow-up from cardiologists and rheumatologists.

Conclusion: CAPS has a high mortality rate, requiring early aggressive treatment managed by a multidisciplinary team. In this case, ECMO device played a key role as a bridge to recovery of cardiac function in a heart failure rare etiology.

34

Hemodynamics and cerebral oximetry in a case of severe heart failure based on amyloidosis

H Holm¹; M Magnusson¹; G Tasevska¹; A Fedorowski¹; E Erasmus Bachus¹

¹Skane University Hospital, Malmö, Sweden

Introduction: We report a 65-year-old male diagnosed with heart failure in 2011. The ultrasonic cardiography (UCG) showed a left ventricular ejection fraction (LVEF) of 40%. Examination with magnetic resonance tomography (MRT), cardiac and subcutaneous biopsies revealed cardiac AL-amyloidosis. The patient was discharged in New York Heart Association (NYHA) class 3a, mean arterial pressure (MAP) 75 mmHg and heart rate (HR) 71 bpm. UCG in 2013 was unchanged. In 2014 the patient was readmitted because of pleural effusion. The UCG was unchanged. Hemodynamic parameters were stable, NYHA class worsened to 3b. The patient was discharged in NYHA class 3a. In October 2014 the patient was examined with head-up tilt test (HUT) and absolute cerebral oximetry. Two weeks later the patient received emergency treatment due to hyper dynamic sepsis. MAP at admission was 58 mmHg, NYHA class 4. Despite adequate treatment with antibiotics and inotropes the patient remained hemodynamically unstable. LVEF was stable. Even with ventilation and hemofiltration the hemodynamic parameters were unchanged with insufficient circulation and vasoplegia. The patient died in hemodynamic chock after 25 days at the ICU.

Objectives: The patient showed an unexpected BP response during HUT. During postural change induced by HUT, MAP increased from 59 mmHg at base line in supine position to 68 mmHg in 60 degrees HUT where it remained stable until it returned to base line level after tilt back. HR (atrial fibrillation) was unchanged during HUT. Absolute cerebral tissue oxygenation (SctO₂) decreased slightly during HUT parallel to increasing MAP. Peripheral oxygen saturation (SpO₂) remained stable during HUT. Two weeks later the patient died in hemodynamic chock despite adequate treatment for sepsis and stable LVEF. HUT was performed according to a protocol adopted from current guidelines. SctO₂ was assessed by an absolute cerebral oximeter. BP and SpO₂ were recorded by a beat-to-beat monitor.

Clinical question:

Does cardiac AL-amyloidosis cause pathological changes in BP and HR response, not explained by heart failure, leading to an impaired ability to adequately respond on hemodynamic challenges?

Discussion: The increase of MAP from hypotension to normal values during HUT was unexpected. SctO₂ decreased with increasing MAP, which might reflect impaired end organ perfusion, HR did not change notably. This might reflect the patients inability to respond to hemodynamic challenges which might have caused circulatory failure during sepsis.

Conclusions: Cardiac AL-amyloidosis might lead to pathological hemodynamic patterns. Amyloid infiltration into the subendocardium is discussed to be the pathophysiological mechanism. Dysautonomia may contribute. HUT could be used to identify patients with autonomic and hemodynamic failure. We promote close follow-ups and generous hospitalization for these patients to early detect and avoid hemodynamically challenging situations.

Total circulatory support using isolated left ventricular assist device in a patient with acquired Fontan physiology

J G Juan Guillermo Duero Posada¹; S Bhagra¹; F Billia¹; M Badiwala¹; HJ Ross¹

¹Toronto General Hospital, Cardiology, Toronto, Canada

RV failure remains an important cause of increased morbidity and mortality following LVAD implantation and management includes volume optimization, inotropic and mechanical RV support. 55 year female, blood group O, 36% Class I and 93% Class II PRA, with 1year history of DCM was referred for consideration of advanced

therapies in the context of progressive symptomatic deterioration, deranged liver enzymes and high BNP (2012 pg/ml). Her coronaries were unobstructed; cardiac MRI showed nonspecific delayed enhancement with LVEF of 13%, and moderate RV impairment, her QRS was narrow and primary prevention ICD was put in place. Resting hemodynamics were left-sided limited (table 1). Isolated continuous-flow left ventricular assist device was implanted as a bridge to transplant with successful discharge on postoperative day 25. 18 days later, she developed progressive RV failure requiring IV diuretics and milrinone and was listed high status for heart transplantation.

ECG's showed progressive QRS widening and, 30 days after admission, asystole with failure to capture by the pacemaker. Echocardiogram confirmed cardiac standstill. Flow was non-pulsatile and hemodynamics were in keeping with Fontan physiology (table 1). There was no evidence of end organ damage and she was supported on LVAD alone. She was physically active until her transplant 22 days following cardiac standstill. She is well post-transplant with no significant rejection and normal graft function.

To the best of our knowledge only one case has previously been reported using LV assist device alone to provide total circulatory support for 7 days. We considered additional RV mechanical support, but, with satisfactory hemodynamics and no end organ damage, it was felt that the additional risk of surgery for RV support was not warranted. The LVAD alone was providing satisfactory circulatory support in the context of acquired Fontan physiology.

We highlight the difficulties in deciding between isolated LVAD and BiVAD support and demonstrate that total circulatory support with isolated LV assist device is possible in the context of low trans pulmonary gradient and pulmonary vascular resistance.

Untreatable amyloidosis? Definitive therapy with double transplantation.

Z Zoltan Tarjanyi¹; B Sax¹; I Hartyanszky¹; L Gopcsa²; A Assabiny¹; A Hajas¹; K Racz¹; ZS Szelenyi¹; N Nyolczas³; B Merkely¹

¹Semmelweis University Heart Center, Budapest, Hungary; ²Szent Laszlo Hospital, Budapest, Hungary; ³Medical Centre, Hungarian Defence Forces, Budapest, Hungary

We report the case of a young female patient, born in 1966, lived an active life, without any symptoms. Her medical history is negative. In September, 2014, she was admitted with progressive fatigue. Echocardiography showed severe left ventricular wall wall thickening (septal and posterior wall thickness 16 and 15 mm, respectively) and granular myocardial pattern with signs of restrictive cardiomyopathy. A cardiac MRI was performed, which confirmed the diagnosis of cardiac amyloidosis. Her heart failure rapidly progressed, and she was hospitalized in October 2014. The indication for heart transplantation was established, but her untreatable disease contraindicated her transplantation.

Further investigations of the etiology of amyloidosis revealed kappa light chain producing multiple myeloma (MM). After a multidisciplinary consultation including cardiologists and hematologists, the decision for a double, heart and bone marrow transplantation was made. In November 2014 a dose reduced chemotherapy was started and patient reached partial remission of MM. In March 2015, a successful

heart transplantation was performed. She was discharged home after an uneventful postoperative period in April 2015 without any signs of rejection in a good overall condition. After the complete recovery from the cardiac transplant, the hematologist performed a successful autologous stem cell transplantation in September 2015.

Now our patient is in an excellent medical condition. Her routine biopsies revealed no rejection and echocardiography examinations showed good left ventricular function. The multiple myeloma is in complete remission as confirmed by immunoserology and bone marrow biopsy tests.

In conclusion we can say that the multidisciplinary cooperation was able to develop an effective treatment plan to save a patient with a mostly untreatable disease.

37

An unusual approach in a patient with pacemaker lead-related tricuspid regurgitation

CM Angelescu¹; C Iorgulescu¹; A Radu¹; A Nastasa¹; R Vataescu¹

¹Emergency Clinical Hospital Floreasca, cardiology, Bucharest, Romania

There are few data in the literature regarding severe tricuspid regurgitation induced by RV pacemaker leads, although such cases are not rare in clinical practice. PM and ICD leads may be the cause of tricuspid regurgitation or may worsen existing tricuspid regurgitation. Severe tricuspid regurgitation is an independent predictor of mortality. The treatment of choice is surgical tricuspid valve repair. A 61 year old female was referred to our hospital with shortness of breath and peripheral edema. Her history revealed that a single chamber transvenous permanent pacemaker had been implanted 4 years before for third degree atrio-ventricular block. The ECG showed AFib and VVI pacing. TTE revealed mild LV systolic dysfunction (LVEF 40-45%) and severe tricuspid regurgitation with right heart dilation and volume overload. 2D and 3D TTE showed that the RV lead (active fixation in the basal septum) was responsible for the severe tricuspid regurgitation (due to interference with septal leaflet coaptation). Our strategy was RV lead extraction and re-implantation in a low septal position under TTE guidance, thus reducing the tricuspid valve closure impairment and upgrade to resynchronization therapy device. Medical treatment included loop diuretic, ACE inhibitor, beta-blocker and vitamin K antagonist. Follow-up at one month showed NYHA class II, normal LVEF (55%) with improved mobility and coaptation of the tricuspid leaflets, moderate tricuspid regurgitation and decreased right ventricular pressures compared with the previous examination.

Conclusion: This case reveals the importance of careful risk-benefit estimation when establishing the management of pacemaker lead induced tricuspid regurgitation. Complete assessment of valve anatomy is important to decide whether it is better to extract the pacemaker lead or to repair the tricuspid valve without lead extraction. Upgrading to CRT due to LV systolic dysfunction was an argument towards interventional treatment in this case.

Therapeutics alternatives in failing Fontan

S Prado Diaz¹; SC Valbuena²; T Lopez²; A Gonzalez²; J Ruiz Cantador²; A Sanchez Recalde²; F Dominguez²; G Guzman Martinez²; M Moreno Yanguela²; JL Lopez Sendon²

¹University Hospital Ramon y Cajal de Madrid, Department of Cardiology, Madrid, Spain; ²University Hospital La Paz, Department of Cardiology, Madrid, Spain

A 40-year-old woman, who had undergone to total cavopulmonary connection (TCPC), was admitted with severe heart failure. She had a history of double inlet left ventricle with normally-related great vessels. She underwent pulmonary artery banding at 4 months old and Glenn procedure when she was 12 years old. Total cavopulmonary anastomosis with an intra-atrial lateral tunnel was completed at 26 years old.

She kept in functional class (FC) II until one year ago, however during last year she significantly worsened, remaining in FC IIIb. At admission the patient was in anasarca, showing massive pleural effusion, ascites and generalized edema. She weighed 4 Kg more, liver was enlarged and jugular venous pressure was elevated. Her legs were absolutely swollen and oxygen saturation was 81%. Transthoracic echocardiogram showed a single ventricle with mildly decreased ejection fraction (46%). There were no stenosis nor images suggesting thrombi and cardiac magnetic resonance confirmed complications absence. Thoracentesis and paracentesis were required; however, right pleural effusion soon reappeared. After high doses of intravenous diuretics, peripheral edema persisted and kidney function was impaired, requiring veno-venous hemofiltration with slight edema improvement. Protein-losing enteropathy was diagnosed and treatment with corticoid therapy was started. High transpulmonary pressure gradient was confirmed in cardiac catheterization, and pulmonary vasodilators were initiated.

After 20 days on optimum medical treatment, situation was not improved. Then a fenestration of the intracardiac tunnel Fontan was proposed. Percutaneously, an intraatrial tunnel puncture with Brokenburg needle was performed and a stent was implanted to maintain open the new right-to-left shunt. Systemic arterial desaturation was remote and venous pressure significantly decreased.

In "single ventricular physiology", chronic elevation of the pulmonary pressures leads to significant venous congestion. When medical treatment is ineffective, creation of right-to-left shunt could be considered in order to decompress venous system and to increase ventricular filling pressure, improving cardiac output. However, fenestration relieves one of the main aims of Fontan circulation, keeping away circulations, impairing systemic arterial oxygenation. Protein-losing enteropathy is a major complication of total cavopulmonary anastomosis, related to chronically-elevated venous pressures and associated with high mortality. Clinically it could present as peripheral edema, pleural effusions, ascites, dyspnoea and chronic diarrhea. Usually, response to medical treatment is poor, and percutaneous fenestration is a valid alternative prior to heart transplantation.

decided to stop further attempts of RFA. Bilateral renal denervation was performed 2 days after procedure. Further 10 nonsustained VT episodes occurred within the next 48 h. During next 3months an ICD interrogation showed nonsustained VTs, terminated by ATP, no documented episodes of syncopal VT/VF with ICD shocks occurred with oral Amiodarone (200 mg/day). Discussion. In our patient we can see decreasing amount of VTs and no recorded ICD shocks after RDN. VT in this case was developed on dilated myocardium of LV, and has multiple sites of origin and was difficult to map, which greatly hinders its approach. It remains unclear the question of the primacy of heart failure in this patient, because when ICD was implanted 2 years ago the Echo showed a slight decrease in ejection fraction and moderate enlargement of the heart chambers. On the one hand the progression of heart failure may cause recurrent VT and ICD shocks as a consequence, but on the other hand a frequent occurrence of the VT itself may worsen heart failure. It is possible that, to the effect on the autonomic tone, RSD may result in beneficial effects by improving heart failure, because after procedure there were no symptoms of pulmonary congestion/edema, which suggests that arrhythmia reduction was probably related to heart failure improvement.

Conclusion: VTs with multiple ICD shocks might be controlled by renal sympathetic denervation. In our patient with ICD and electrical storm renal sympathetic denervation reduced the arrhythmia load and consequently ICD shocks.

Fig.1 Sustained ventricular tachycardia

39

Renal sympathetic denervation for electrical storm as polymorphic ventricular tachycardia in dilated cardiomyopathy

S Sevda Bayramova¹; A Yakubov¹; D Losik¹; V Shabanov¹; A Romanov¹

¹State Research Institute of Circulation Pathology, Arrhythmia Department, Novosibirsk, Russian Federation

Introduction: Despite a continuous improvement in technology, patients with ICDs can experience frequent ICD shocks, delivered for recurrent ventricular tachycardia (VT) or VF. Activation of the autonomic nervous system contribute to the increased mortality in these patients. A 59-year-old male was admitted to the hospital after several episodes of syncope and multiple ICD shocks (around 20 a day). 12 lead ECG was done showing VT (Fig.1). Coronary artery disease had been excluded previously. At admission to the hospital ICD interrogation revealed a plenty of episodes of VTs terminated by a multiple shocks 17 J as cause of the syncope. The Echo showed severely reduced systolic LV-function (EF 37%) and dilated left ventricle (LV). Reversible causes were excluded. Intravenous treatment with amiodarone (1.2 g per day) was initiated. Despite the heart-failure therapy, device reprogramming, recurrent episodes of VT occurred. Patient was taken to EP study. Several sustained polymorphic VTs were induced, activation mapping for first VT morphology revealed the earliest site at the LVOT, the zone was treated with RF, the next slow VT (130/bpm) with another morphology was induced with the earliest ventricular activation at the basal lateral part of the LV, which was also exposed by RFA. Then again VT with another morphology and ongoing changing of cycle was induced. Considering high amount of VTs like electrical storm was

40

Best management of aortic root thrombus in LVAD patients?

C Costin Radu¹; MA Piscitelli¹; S Guendouz²; W Abdi³; J Suos¹; D Tixier¹; A Fiore¹; E Bergeend¹; T Damy²; JP Couetil¹

¹University Hospital Henri Mondor, Cardiac Surgery, Creteil, France; ²University Hospital Henri Mondor, Cardiology, Creteil, France; ³University Hospital Henri Mondor, Anesthesia and Surgical Intensive Care, Creteil, France

Introduction: Success obtained with bridge-to-transplant and destination therapy has established left ventricular assist devices (LVAD) as an important option for treatment of advanced heart failure. However, LVAD generate significant pathophysiological changes that can interfere with their benefits. One of these changes is permanent closure of the aortic valve (AV) and aortic root thrombus formation. The aim of our study was to review the patients with aortic root thrombus formation early after LVAD implantation for better clinical understanding and to develop strategies to prevent unfavorable outcome.

Description: A review of our patients identified 3 cases with aortic root thrombus early after LVAD implantation.

Case 1: A 49 years old patient developed a "hyper dense image" suggesting thrombus in the non-coronary sinus on transthoracic echocardiography (TTE) 72 hours after LVAD implantation. Anticoagulation was initiated at h 12 and reached target level at h 48. AV was not opening. A decrease in pump speed allowed partial AV opening at every third beat and the image was no longer present at the next TTE. Patient had an uneventful postoperative course.

Case 2: A 65 years old patient developed a "hyper dense image" in the non-coronary sinus on TTE 24 hours after LVAD implantation. Anticoagulation was initiated at h 12 and reached target level at h 24. AV was not opening. A decrease in pump speed allowed partial AV opening every forth to fifth beat. At h 48, while awake and in good condition, the patient experienced sudden unconsciousness, hemodynamic deterioration and abrupt increase in pump power. TTE showed decreased LV unloading with AV opening at every beat and disappearance of the non-coronary sinus image, suggesting the thrombus has been aspirated in the LV and into the pump. A "ramp test" confirmed pump thrombosis. Patient underwent emergently pump exchange and a subsequent CT scan confirmed multiple ischemic strokes.

Case 3: A 44 years old patient developed a "hyper dense image" in the non-coronary sinus on TTE 48 hours after LVAD implantation. Anticoagulation was initiated at h 12 and reached target level at h 72. AV was not opening. An increase in pump speed insured good LV unloading. TTE showed a permanently closed AV without aortic insufficiency. A CT scan performed 2 weeks later confirmed a large thrombus in the non-coronary sinus, without obstruction of the coronary ostia (Figure 1). Patient had uneventful postoperative course. Two months later patient underwent cardiac rehabilitation and TTE showed thrombus regression and partial AV opening (Figure 1 C, D)

Conclusion: A permanently closed AV early after LVAD implantation is not uncommon and exposes patients to risk of aortic root thrombus with subsequent thrombo-embolism and pump obstruction. If valve opening can't be obtained and development of an aortic root thrombus can't be prevented, complete LV unloading by increased pump speed might be a safer option.

Managing patients with advanced heart failure: the importance of the heart team in a case of severe functional mitral regurgitation

A Antonella Fontana¹; A. Ciro²; A. Vincenzi²; V. Colombo²; P. Camisasca²; G. Trocino²; L. Avalli³; F. Achilli²

¹San Gerardo Hospital, Monza, Italy; ²San Gerardo Hospital, Department of Cardiology, Monza, Italy; ³San Gerardo Hospital, Cardiac Surgery Intensive Care Unit, Monza, Italy

In 2003, a man experienced his first episode of congestive heart failure (HF) with diagnosis of idiopathic dilated cardiomyopathy, and he was implanted ICD for primary prevention. Therapy up-titration was regularly scheduled, with subsequent upgrading of ICD to cardiac resynchronization therapy (CRT/D). The patient (pt) persisted in good conditions until 2011 (NYHA II), when one episode of acute HF occurred. After stabilization, he persisted in good conditions until the beginning of 2014, when two subsequent episodes of acute decompensation occurred. Following these events, he progressively deteriorated, with NYHA class persistently worsened to III-IV. Eccentric hypertrophy with severe LV dilation, ejection fraction (EF) 27%, pseudo-normalized diastolic pattern, mild aortic and tricuspid regurgitation, and severe mitral regurgitation (MR) with leaflets tethering were the main echo findings. Surgical correction of MR was discussed, but logistic EuroScore and STS scores were 29.40% and 8.17% respectively, so the pt was excluded from surgery by the Heart Team. The percutaneous edge-to-edge correction of MR was proposed after trans-oesophageal echocardiography (TOE) confirmed suitability of the MV for the procedure. Inclusion criteria as requested by the EVEREST II trial were fulfilled, so the intervention was performed in September 2014 (pt aged 79). Swan-Ganz catheterization at the beginning of the intervention showed cardiac output (CO) 2.5 l/min, cardiac index (CI) 1.3 l/min, pulmonary capillary wedge pressure (PCWP) 22 mmHg, pulmonary artery pressure (PAP) systolic/diastolic 35/20 mmHg. The procedure was successfully performed under general anaesthesia and TOE guidance, with deployment of one clip; a total of 1300cc of saline solution and 40 mg of intravenous furosemide were administered, in three hours. At the end of the procedure MR was mild (1+). No mitral stenosis occurred. The following clinical course was regular: three days in the intensive coronary care unit and four days in the cardiology ward. Daily haemodynamic evaluation showed improvement in CO and CI (2.97 l/min and 1.87 l/min respectively), and reduction in PCWP (13 mmHg), with no significant difference in PAP (36/16 mmHg) and systemic and pulmonary vascular resistances. The patient was discharged home without changes in home therapy, with ambulatory follow up planned within a month. Three months later he was

re-hospitalized for acute HF, because of severe MR. He was treated with continuous infusion of intravenous furosemide 1 ml/h and 24-h levosimendan with slow but constant improvement. Two weeks after this re-admission, MR again improved to mild, and he was discharged home in good and stable clinical conditions. Few days after ambulatory visit in late January 2015, the patient experienced several subntrant episodes of ventricular tachycardia and ventricular fibrillation. Conducted to the emergency room, he required hospitalization for arrhythmic storm, but died 10 days later.

Unconventional cannulation strategy in peripheral ECMO to prevent differential hypoxia

F. Bevilacqua¹; M. E. Maria Enrica Antonucci¹; S. De Paulis¹; R. Zamparelli¹; M. Corrado¹; L. Martinelli¹; F. Cavaliere¹

¹Catholic University of the Sacred Heart, cardiovascular department, Rome, Italy

Introduction: Veno-arterial extracorporeal membrane oxygenation (VA ECMO) is a therapy in cardiac and respiratory failure, refractory to conventional treatment. But, when the heart recovers and lung function remains poor, may present differential hypoxia with insufficient oxygen supply to the brain and the heart. To solve this problem many strategies have been suggested. We report an unconventional cannulation way. **Description:** A young woman, with history of mitral valve replacement was admitted to our hospital with chest pain and dyspnea. Echocardiography showed mitral valve prosthesis dysfunction caused by a thrombus with reduced left ventricular function, severe pulmonary hypertension and tricuspid regurgitation. An emergent mitral valve replacement and tricuspid annuloplasty were performed. After a few hours she developed severe hypoxemia due to massive pulmonary edema, with cardiogenic shock, refractory to inotropes and ventilation. We decided to put her on ECMO. Peripheral cannulation could be rapidly achieved and re-sternotomy avoided, limiting infections and major bleeding complications. However central cannulation could provide higher circuit blood flow and oxygen delivery, avoiding differential hypoxia. Axillary or subclavian artery cannulation was impossible for their small caliber. We performed a peripheral VA ECMO with a 19 Fr drainage venous cannula through right femoral vein and, to prevent differential hypoxia, a 17 French venous long cannula was inserted into the left femoral artery and advanced until the distal aortic arch, under ecocardiographic guidance. A back flow femoral cannula was placed to avoid limb ischaemia. With ECMO hemodynamic stabilized. Peripheral oxygen saturation measured at the right arm was 100%. Mean cerebral tissue oxygen saturation measured by near infrared spectroscopy was 60% bilateral. Cardiac function gradually recovered. By day seven, she was successfully weaned from ECMO. Mechanical ventilation was removed 18 days later. After 46 days she was discharged from the intensive care unit with no neurological sequelae.

Discussion and conclusion: Potential solutions to prevent upper body hypoxemia in peripheral VA ECMO include: (1) increasing pump flows (2) switching to VV ECMO, (3) adding an additional return cannula to the internal jugular vein, (4) switching to central placement of the arterial cannula. In our case axillary or subclavian artery cannulation was impossible, there was a high bleeding risk for a re-sternotomy. We then decided to undertake an unconventional arterial cannulation for ECMO through a long venous cannula inserted in the femoral artery and placed in the proximal descending thoracic aorta. In this way, proximal perfusion was achieved despite a distal cannulation site being used. The main contraindication to the use of the long cannula is severe atherosclerotic disease of the aorta, but in a young woman with no atherosclerosis it can represent a viable option.

43

a case of severe functional mitral regurgitation in patient with left ventricular non-compaction treated by mitral repair using minimally invasive approach

YH Park¹; HG Je¹; JS Kim¹; JH Kim¹; KJ Chun¹

¹Pusan National University Yangsan Hospital, Yangsan, Korea Republic of

Introduction: Noncompaction of the left ventricle is a rare congenital cardiomyopathy characterized by prematurely arrested compaction of myocardial fibers. The prognosis is poor when the left ventricular function deteriorates.

Case report description: A 18-year-old woman presented with a 6-month history of severe cough, nausea, vomiting and dyspnea despite of maximal medical therapy. Chest X-ray revealed marked cardiomegaly with consolidation of right lower lung field (Figure, left upper). Transthoracic echocardiography revealed multiple prominent left ventricular trabeculations with deep recesses, marked mitral annular dilatation with coaptation failure causing very severe functional mitral regurgitation and depressed left ventricular ejection fraction of 38% (Figure, right). Computed tomographic coronary angiography revealed normal coronary anatomy and confirmed the diagnosis of isolated noncompaction of the left ventricle (Figure, left lower). The patient refused cardiac transplantation due to poor economic status but was amenable to nontransplant surgical options.

Question: What can be offered as an option for the treatment of this patient?

Answer and discussion: Mitral repair with ringed annuloplasty was planned for this

young women. Mitral exposure was obtained through right anterolateral minithoracotomy via 4th intercostal space and a left atriotomy. Mitral annuloplasty with 28 mm Physio ring and left atrial reduction by left atrial inferior wall resection were done. Postoperative transesophageal echocardiography demonstrated no mitral regurgitation. The patient was discharged on postoperative day 7 after an uneventful hospital stay. Her ejection fraction decreased to 20%, but estimated systolic right ventricular pressure also markedly decreased from 98 to 26 mm Hg. The patient's symptoms improved to New York Heart Association functional class II by her clinic visit at postoperative month 6. Clinical and echocardiographic follow-up was performed every 6 months thereafter has shown gradual improvement in ventricular function. The latest echocardiogram at 5 yrs postoperatively revealed trace mitral regurgitation and an ejection fraction of 30%. The patient's symptom improved to New York Heart Association functional class I and she can go exercise to the gym.

Comment: In this case, the 5-year results of sustainable clinical improvement supports that correction of mitral regurgitation by annuloplasty alone may result in progressive ventricular remodeling. In patients with left ventricular noncompaction and severe mitral regurgitation, mitral annuloplasty using minimally invasive approach might be a surgical alternative to traditional medical therapy or transplantation.

Percutaneous LVAD for high risk angioplasty. Why use support?

I Wojtkowska¹; K Kukula²; M Demkow³; J Jastrzebski²; P Tyczynski²; A Witkowski²; J Stepinska¹

¹Institute of Cardiology, Intensive Cardiac Therapy Clinic, Warsaw, Poland;

²Institute of Cardiology, Department of Interventional Cardiology and Angiology, Warsaw, Poland; ³Institute of Cardiology, Coronary Artery and Structural Heart Disease Department, Warsaw, Poland

A 62-year-old patient with severe post infarction heart failure (CHF) due to previous anterolateral STEMI complicated by cardiogenic shock treated with primary PCI of LAD with DES implantation one year before, post ICD implantation, was admitted with NSTEMI. His additional risk factors included obesity, DM and AF. Patient status on admission to CCU was poor. Symptoms of CHF were dominant, with dyspnea, bilateral rales, peripheral edema and recurrent chest pain. Signs of pulmonary congestion were noted on chest X-ray. Heart rate on admission was 80/min and blood pressure 110/70 mmHg. ECG showed sinus rhythm of 78/min, precordial Q waves and signs of lateral ischemia (Fig.1). Echocardiography revealed dilated left ventricle-62 mm with severely impaired contractility and EF of 15%. Non-significant mitral regurgitation was present (Fig.2). Coronary angiography showed borderline LAD lesions distally to previously implanted stents, borderline lesion in mid-RCA and tight lesion in mid-LCx originating from RCA. The patient was primarily treated conservatively for HF according to ESC guidelines and dual antiplatelet therapy was introduced. Due to severely impaired LV systolic function in our patient, PCI was associated with significantly increased periprocedural risk. Thus, the periprocedural support with Heart Mate PHP was decided. The device was introduced through right femoral access and the PCI procedure was performed through right radial access. The pump was run at 2.5 l/min. Direct implantation of Xience Pro DES (3,0x18 mm) into mid-LCx was performed. Right femoral access was closed with the ProStar system. The patient's hemodynamic status promptly improved. He was discharged at day 10 post procedure. No major adverse events were observed during 13-months follow-up.

Crossing all bridges after acute myocardial infarction

E Zatarain¹; I Sousa-Casasnovas¹; P Navas Tejedor¹; M Martinez-Selles¹; J Velasquez Rodriguez¹; M Ruiz Fernandez²; A Villa-Arranz¹; J Hortal-Iglesias³; A Gonzalez-Pinto²; F Fernandez-Aviles¹

¹University Hospital Gregorio Marañon, Cardiology, Madrid, Spain; ²University Hospital Gregorio Marañon, Cardiac Surgery, Madrid, Spain; ³University Hospital Gregorio Marañon, Anaesthesiology, Madrid, Spain

Description: A 49 years-old woman, smoker and overweighted, was admitted to ER due to atypical chest pain that had started with short episodes one week ago. Her EKG showed extensive ischaemia with RBBB and she was referred to our center for primary PCI. At the cath-lab she presented signs of cardiogenic shock. Norepinephrine, dobutamine and IABP were started at the time of PCI. A thrombotic obstruction in main-left artery was observed and a drug-eluting stent was deployed 8h after the onset of symptoms. Before transfer, she suffered an electrical storm refractory to antiarrhythmic drugs requiring several electric shocks. Treatment, problems and techniques used: Mechanical ventilation (MV) and percutaneous VA-ECMO were started in the cath-lab by the hemodynamist as a bridge to decision (Picture, left). She arrived at the cardiology intensive-care unit with hemodynamic stability, the VA-ECMO was set at 3200 revolution-per-minute giving 2.5-3 L/min outflow and normal pressures. After 12h of support, the flow started to decrease, lactic acid to rise up and deep-negative pressure was registered in the inner cannula. Transesophageal echocardiography revealed heart tamponade with complete collapse of right ventricle (picture middle, arrows). She underwent surgical replacement of VA-ECMO with a short-term centrifugal LVAD (left ventricular assist device) and drainage of pericardial effusion. Due to broad extension of necrosis the inner cannula was placed in the left atrium (picture right, asterisk). Neither suction nor thrombotic or hemorrhagic events were registered. Anticoagulation was achieved with non-fractionated heparine controlled by activated clotting time test (range 180-200 s). Successfully assisted, the LVEF did not recovered during next week and several attempts failed to wean her from LVAD. After heart transplant (HT) work-up without contraindication and favourable sedation window the patient was listed for urgent heart transplantation. The 9th day after LVAD, HT was successfully performed. No significant surgical bleeding occurred and the main complication was weaning from MV due to delirium and sedation requirements. After 18 days in postoperative intensive care unit she was discharged to hospitalization area and 54 days after admission she was discharged home. After HT she has suffered a cytomegalovirus reactivation that need valganciclovir 900 mg tid. Today she continues ambulatory follow-up without complications.

Conclusion and clinical implications: VA-ECMO can be safely implanted by percutaneous approach, specially in emergency situations in the cath-lab as a bridge to decision. Short-term centrifugal LVAD can successfully rescue the patient from ECMO support when it fails. LVAD cannulation through left atrium is a good choice in those short-term centrifugal devices when extensive necrosis affects LV apex. Short-term centrifugal LVAD can be used as a bridge to recovery or a bridge to transplant in those acute heart failure settings.

Supporting the right heart in pulmonary oedema post-LVAD implantH S Hoong Sern Lim¹; A Ranasinghe¹¹Queen Elizabeth Hospital, Birmingham, United Kingdom

A 44-year old man with dilated cardiomyopathy presented with 2 weeks of cough and breathlessness. He was hypoxemic with pulmonary oedema on X-ray. Echocardiogram showed LV ejection fraction of 10% but normal right ventricular (RV) function. Over the ensuing 2 days, he became hypotensive and worsening of oxygenation. Pulmonary artery (PA) catheter data: right atrial pressure (RAP) 8, PA systolic/diastolic/mean pressure 56/28/35, pulmonary artery wedge pressure (PAWP) 25mmHg, cardiac output (CO) 3.9L/min on inotropes. He underwent an uncomplicated left ventricular assist device (LVAD) implant in view of the deterioration. The patient was extubated 12 hours later but remained hypoxemic, albeit hemodynamically stable on enoximone. However, his gas exchange worsened (FIO₂ 0.6, PO₂ 8.4kPa, PCO₂ 7.8kPa) on post-operative day 6 and was re-intubated. Chest X-ray showed bilateral infiltrates and low tidal volume ventilation was adopted (tidal volume 380ml, peak airway and end-expiratory pressure 27 and 8cmH₂O). He deteriorated further on post-operative day 7: heart rate 148/min, mean BP 56mmHg (non-pulsatile), LVAD flows 3.3L/min with recurrent 'suction' events and oliguria. Pulmonary hemodynamics were: RAP 18, PAP 52/25, mean 32, PAWP 14mmHg and CO 3.6L/min. Echocardiogram showed RV dilatation, small LV cavity, no aortic valve opening and normal cannula Doppler flow. He failed to respond to escalating noradrenaline, adrenaline and enoximone, nitric oxide and pump speed adjustments. With progressive RV failure and acute respiratory distress syndrome (ARDS), a dual lumen cannula was inserted percutaneously via the right internal jugular vein and positioned in the PA [FIGURE], connected to a centrifugal pump for right ventricular support. He improved and vasopressors were weaned off within 24 hours. As oxygenation improved, the percutaneous right ventricular assist device was removed after 7 days without complications.

Problems: 1) Assessment/management of RV failure and selecting the modality of RV support in RV failure post-LVAD implant. 2) Differentiating cardiogenic and non-cardiogenic pulmonary oedema

Discussion: 1) Percutaneous RV support (which obviates the need for re-sternotomy) may be delivered via a microaxial catheter-mounted pump, a dual cannula system or dual-lumen single cannula system. The latter was chosen to minimise vascular access and allows extracorporeal oxygenation if required. 2) PA catheter may differentiate cardiogenic from non-cardiogenic pulmonary oedema; and aid in the assessment of RV failure post-LVAD. In this case, increased RV afterload from ARDS (evidenced by low pulmonary capacitance and high pulmonary vascular resistance) as the likely cause.

Conclusion: ARDS-related RV failure post-LVAD can be effectively supported by a dual-lumen single cannula extracorporeal right ventricular assist device. PA catheters can differentiate the aetiology of pulmonary oedema and define nature of RV failure post-LVAD.

Percutaneous RVAD (dual lumen cannula)

Transseptal implantation of a balloon-expandable transcatheter heart valve in a native mitral annulus for treatment of radiation-induced valvulopathyF Praz¹; T Suter¹; A Moschovitis¹; D Reineke²; S Windecker²¹Bern University Hospital, Department of Cardiology, Bern, Switzerland; ²Bern University Hospital, Cardiovascular Surgery, Bern, Switzerland

A 49-year old patient was admitted because of recurrent episodes of left heart decompensation (New York Heart Association class IV) and paroxysmal nocturnal dyspnea requiring home oxygen therapy. He was previously followed in our cardio-oncology clinic for radiation-induced coronary and valvular heart disease, consecutive to treatment of Hodgkin's lymphoma in 1983 (cumulative mediastinal dosis 46 Gray). In 2002 endocarditis of the aortic valve was diagnosed and the patient underwent mechanical aortic valve replacement combined with coronary artery bypass grafting. Twelve years later, mitral stenosis due to progressive thickening of the mildly calcified leaflets was diagnosed and a percutaneous balloon mitral valvuloplasty was attempted. Despite technical success, the transvalvular gradient remained elevated and the patient experienced progressive heart failure. A consecutive transesophageal echocardiography showed severe mitral stenosis with a mean transvalvular gradient of 13mmHg and an effective orifice area ranging between 0.9cm² and 1.1cm². In addition, moderate mitral regurgitation was observed. After discussion in the Heart Team, the patient was rejected for open-heart surgery or transapical valve implantation due to "hostile chest" and numerous comorbidities including severe vascular calcification, post-radiation pneumopathy, chronic renal disease (GFR 32ml/min) and hepatitis C with subsequent cirrhosis (Child-Pugh A) contracted because of intravenous drug abuse. A detailed anatomic evaluation showed mild calcification of both leaflets. The mitral annulus dimensions were deemed amenable to the implantation of a 29mm balloon-expandable bioprosthesis with the mechanical aortic valve serving as additional anchoring structure (Figure 1 E). The delivery catheter could successfully be advanced through the previously dilated interatrial septum (Figure 1 A-B) and the valve correctly positioned into the native mitral annulus under echocardiographic guidance (Figure 1 C-D). After deployment, minimal para- or transvalvular regurgitation was observed (Figure 1 E-F) and the mean gradient was acutely reduced to 5mmHg. A transthoracic echocardiography one day after the intervention confirmed normal valve function and excluded a relevant LVOT obstruction or valve migration. The patient was discharged after 5 days and was alive at 30 days reporting symptomatic improvement with complete resolution of the nocturnal dyspnea, but persistent dyspnea on exertion (NYHA II-III). This case report shows the feasibility of the transseptal implantation of a balloon-expandable transcatheter heart valve in a minimally calcified mitral annulus for treatment of radiation-induced mitral stenosis. This technique represents a promising minimal-invasive treatment option for selected inoperable patients.

Constrictive pericarditis with large multiloculated pericardial effusion as a tuberculosis and HIV co-infection presentation: the role of multimodality imaging

Al Ana Isabel Azevedo¹; J Goncalves Almeida¹; N Ferreira¹; M Ponte¹; R Fontes-Carvalho¹; J Ribeiro¹; A Dias¹; M Mota¹; V Gama Ribeiro¹

¹Hospital Center Vila Nova Gaia, Porto, Portugal

Introduction Pericardial tuberculosis (TB) is common among TB and HIV co-infected patients and is associated with high morbidity and mortality. Large pericardial effusion can develop, leading to heart failure. Accurate diagnosis is crucial and different imaging techniques have an important role in the evaluation and management of these patients.

Case report: A 28-year-old man, natural from Guinea-Bissau, presented with cough, low grade fever, increasing dyspnoea and a weight loss of 15Kg over the previous 3 months. On initial assessment he was diaphoretic, hypotensive (109/62mmHg), tachycardic (122bpm) and tachypneic. Pulmonary auscultation revealed severely diminished breathing sounds at the lower third of the left hemithorax. Chest X-ray showed left pleural effusion and an enlarged cardiac silhouette. The patient was admitted for further evaluation. He was diagnosed with HIV infection (CD4 cell count=202cells/uL). Sputum smear was positive for acid-fast-bacilli and a positive culture for *M. tuberculosis* complex confirmed the diagnosis of TB. Transthoracic echocardiography (TTE) showed pericardial thickening and a large multiloculated pericardial effusion, with no signs of hemodynamic compromise (panel A). Chest computed tomography (CT) showed a large pericardial effusion, with pericardial thickening and a large left pleural effusion. Cardiac magnetic resonance (CMR) confirmed signs of constrictive acute pericarditis with large, multiseptated pericardial effusion (panels B and C). The patient was started on standard treatment regimen for tuberculosis and referred to initiate antiretroviral therapy.

Discussion: Clinical manifestations of pericardial TB may overlap with other diseases in HIV-patients and a high index of suspicion for pericardial disease is required. TTE, the first-line imaging modality, may reveal signs of pericardial effusion of tuberculous etiology (thickened pericardium with echogenic coating and fibrin strands) and of hemodynamic compromise. On contrast-CT imaging, enhancement of a thickened pericardium points to an inflamed pericardium and density measurements can characterize pericardial fluid accurately. CMR with high-resolution gradient-echo cine-images allows accurate measurement of pericardial thickening and effusion. Real-time cine imaging enables assessment of ventricular interdependence, and late gadolinium enhancement is seen in inflammatory pericarditis. Antituberculous therapy should be started as soon as the diagnosis is made, with the same treatment regimens recommended for pulmonary TB. Antiretroviral therapy is indicated regardless of CD4 count.

Conclusion: Pericardial TB is a common manifestation of HIV and tuberculosis co-infection. Imaging techniques are essential for the diagnosis and patients' management. An analysis of their strengths and limitations is required in order to select their appropriateness in each clinical scenario.

Aorta right atrial tunnel : do always need surgical correction?

SK Sunki Lee¹; HS Yong²; CW Choi¹; HE Lim¹; JO Na¹; EJ Kim¹

¹Korea University Guro Hospital, Cardiovascular Center, Korea University Guro Hospital, Seoul, Korea Republic of; ²Korea University Guro Hospital, Department of Radiology, Seoul, Korea Republic of

An asymptomatic 31-year-old was referred to our hospital for evaluation of a heart murmur. The patient had no family history of congenital heart disease or collagen vascular disease. Cardiac auscultation revealed a grade 3/6 continuous murmur at the right parasternal border. Transthoracic echocardiography (TTE) revealed a round, tunnel-like structure from the left aortic sinus to the right atrium (RA) (Figure A, arrows) without any evidence of right atrial or ventricular enlargement. Cardiac catheterization showed a normal pulmonary artery pressure (systolic/diastolic: 24/7 mmHg), normal mean RA pressure (4 mmHg) and the Qp/Qs ratio was 1.3:1. Aortography confirmed a large tunnel beginning in the left aortic sinus and ending into the RA (Figure B, asterisk) with normal looking left coronary arteries arising independently from different proximal portions of the tunnel. For better visualization of shunt anatomy, computed tomographic (CT) angiography was performed. CT angiography (Figure C) and 3D reconstructed images (Figure D) delineated the extracardiac structure, showing a large, tortuous, tunnel-like structure originating from the left sinus of Valsalva, running through the posterior side of the aortic root, and terminating in the RA. Based on multiple imaging studies, we could confirm the diagnosis of aorta-right atrial tunnel (ARAT). The patient was asymptomatic, the Qp/Qs ratio was less than 1.5:1, and he showed no evidence of right heart overload; therefore, we decided to observe the patient closely without surgical treatment. At 12 and 24-months follow up of TTE, the size of ARAT diameter was still unchanged without any hemodynamic alterations. During 36-months of follow up period, the patient is still asymptomatic and shows a good performance state without any complications.

Twenty five years of acute heart failure in 1800 consecutive patients: no short- and long-term survival improvement.JC Van Den Berge¹; KM Akkerhuis¹; AA Constantinescu¹; JA Kors¹; RT Van Domburg¹; JW Deckers¹¹Erasmus Medical Center, Rotterdam, Netherlands

Introduction: Acute heart failure has a poor prognosis. However, limited data is available regarding the long-term mortality of such patients. Purpose – We investigated the trends in short- and long-term mortality of patients with acute heart failure in the period 1985 thru 2008. We also determined the influence of major prognostic factors.

Methods: In this prospective consecutive registry, we included patients admitted for acute heart failure at the Intensive Coronary Care Unit of our tertiary referral hospital in the period of 1985 until 2008. Patients were classified into four aetiology categories: ischemic cardiomyopathy, other cardiomyopathy, valvular heart disease, and other/unknown. The time window was split up in periods of 1985-1989, 1990-1999 and 2000-2008.

Results We identified 1810 patients (age 64 years, 64% male). In the last decade, the number of patients with a history of myocardial infarction, revascularization therapy and diabetes mellitus increased significantly. The overall cumulative mortality at one and ten years was respectively 31% and 71%. Over time, no overall change in mortality rate was found (Figure). After adjustment, compared to valvular heart disease, ischemic cardiomyopathy was associated with a higher mortality (HR 1.25; 95% CI 1.08-1.47). Other parameters associated with poor outcome were advanced age (HR 1.027; 95% CI 1.022-1.031), male sex (HR 1.27; 95% CI 1.13-1.43), previous heart failure (HR 1.58; 95% CI 1.41-1.76), and diabetes (HR 1.20; 95% CI 1.05-1.36).

Conclusions: Patients admitted with acute heart failure continue to have very high short- as long-term mortality, identical between the different decades. The prognosis of patients with heart failure due to ischemic cause was worst.

Noradrenaline combined with either dobutamine or levosimendan - similar outcome and cardiac biomarker evolution in cardiogenic shockT Tuukka Tarvasmaki¹; J Lassus²; A Sionis³; M Banaszewski⁴; J Silva Cardoso⁵; V Carubelli⁶; J Spinar⁷; J Parissis⁸; A Mebazaa⁹; V-P Harjola¹⁰¹Helsinki University Central Hospital, Department of Medicine, Helsinki, Finland;²Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland;³Hospital de la Santa Creu i Sant Pau, Cardiology Department, Barcelona, Spain;⁴Institute of Cardiology, Intensive Cardiac Therapy Clinic, Warsaw, Poland; ⁵Sao Joao Hospital, Department of Cardiology, Porto, Portugal; ⁶Civil Hospital of Brescia, Department of Medical and Surgical Specialties, Brescia, Italy; ⁷University Hospital Brno, Department of Internal Medicine and Cardiology, Brno, Czech Republic;⁸Attikon University Hospital, Heart Failure Clinic and Secondary CardiologyDepartment, Athens, Greece; ⁹Hospital Lariboisiere, INSERM U942, Paris, France;¹⁰Helsinki University Central Hospital, Emergency Care, Helsinki, Finland

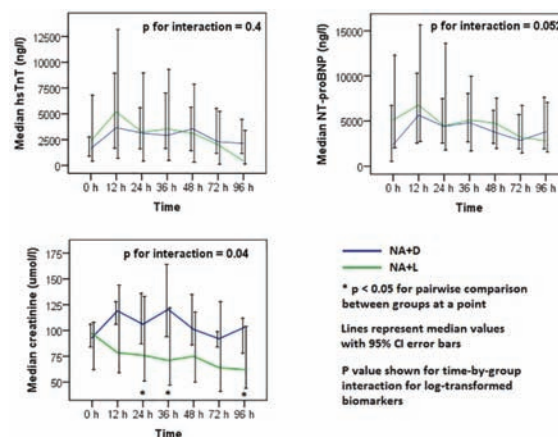

Background: In cardiogenic shock (CS), an inopressor-inodilator combination has been proposed to be a more beneficial, or less harmful, alternative than using inopressors alone. However, little data exists to guide clinicians in the choice of specific agents.

Purpose: To assess whether there are differences in outcome, or evolution of cardiac and renal biomarkers between two commonly used inopressor-inodilator combinations in CS: noradrenaline either with dobutamine (NA+D) or levosimendan (NA+L).

Methods: The CardShock study is a prospective European multicenter study including 219 patients with CS. Serial plasma samples were collected in 178 patients, of which 95 had samples taken until 96 hours from the study baseline. The samples were immediately frozen at -80°C. Creatinine, high-sensitivity troponin T (hsTnT) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) were analysed centrally. Use of vasoactive medications was registered until 96 hours from baseline. Patients who received adrenaline were excluded. Association with mortality was analysed with propensity score adjustment. Biomarker differences at each time point between groups were analyzed with Mann-Whitney U test. Linear mixed modeling was used to analyse differences in changes of biomarkers between groups over time.

Results: Of the patients with baseline plasma samples collected, NA+D and NA+L were administered to 38 and 28 patients, respectively. In this cohort of 56 patients, mean age was 66 (SD 13) years, 79% were men and 82% had acute coronary syndrome as CS etiology. Overall 90-day mortality was 38%. No difference between the two treatment groups appeared in mortality after propensity score adjustment. Levels of cardiac biomarkers were similar in the two groups during the initial 96 hours, but there was a trend towards higher creatinine levels in NA+D group (figure).

Conclusions: No significant differences between NA+D and NA+L appeared in mortality or in evolution of cardiac biomarkers during the initial 96 hours of CS. There was a trend toward higher creatinine levels in NA+D group.

Prognostic significance of multi-organ dysfunction/damage in acute heart failure

R Zymliński¹; M Sokolski²; J Biegus²; P Siwolowski¹; S Nawrocka¹; J Krzysztofik²; EA Jankowska³; W Banasiak¹; P Ponikowski²

¹Centre for Heart Disease - Clinical Military Hospital, Wrocław, Poland; ²Wrocław Medical University, Department of Heart Diseases, Centre for Heart Disease - Clinical Military Hospital, Wrocław, Poland; ³Wrocław Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wrocław, Poland

Background: Presence of end-organ dysfunction/damage during early phase of acute heart failure (AHF) is associated with poor outcome. In this context, however, clinical relevance of the inter-organ crosstalk has not been evaluated. This study was designed to assess prognostic consequences of the interplay between impaired function/damage of different organs in AHF.

Methods: Consecutive patients hospitalized for AHF between September 2010 and July 2012 were studied (those with clinical diagnosis of concomitant acute coronary syndrome were excluded). The organ dysfunction/damage on admission was diagnosed with the following criteria: a. cardiac damage – as troponinI (TnI) increase above the upper normal limit (>0.056 ng/ml); b. renal dysfunction – as the estimated glomerular filtration rate below 60 mL/minute/1.73 m²; c. liver dysfunction – as at least one of the following abnormal liver function tests: AST/ALT above the 3 times of the upper normal limit (114 IU/L, 105 IU/L, respectively), bilirubin above the upper normal limit (>1.3 mg/dl), albumin below the lower normal limit (<3.8 mg/dl). The primary endpoint was all-cause mortality during 12-month follow-up.

Results: We recruited 316 patients with AHF (mean age 66 ± 12 years, 73% men). At baseline, renal dysfunction, myocardial damage and liver dysfunction were present in 54%, 41% and 61% of patients, respectively. Only 39 (12%) patients did not show any evidence of organ dysfunction/damage. Patients were classified into 2 subgroups: those with 2 or 3 organs dysfunction/damage (159 [50%]) vs those without or with only single organ dysfunction/damage (157 [50%] patients). The former group comprised older patients (68 ± 11 vs 65 ± 12 years), with lower systolic blood pressure (125 ± 31 vs 134 ± 34, mmHg), higher level of urea (40 [27–67] vs 30 [19–44], mg/dL), NT-proBNP (7309 [4169–13104] vs 4302 [2305–6947], pg/mL), CRP (11 [5–30] vs 8 [4–21], mg/L) and lower level of sodium (138 ± 5 vs 139 ± 4, mmol/L), who more often required inotropic support during in-hospital stay (14% vs 4%) (P < 0.05 in all comparisons). The 1-year mortality rates were 43% in former vs 17% in the latter group, respectively (P < 0.0001). Importantly there was no statistically significant difference in 1-year mortality between patients without vs with only single organ dysfunction/damage (10% vs 19%). The multivariable analysis revealed that dysfunction/damage of 2–3 organs predicted higher mortality after adjustment for the other prognosticators.

Conclusion: In patients with AHF, presence of multi-organ dysfunction/damage on admission carries relevant prognostic information. Interestingly, the number of affected organs (rather than the organ itself) seems to be crucial to identify those at high risk of poor outcomes (similarly to the multi-organ dysfunction syndrome).

130

Clinical characteristics and prognosis of patients hospitalized for heart failure depending on ejection fraction: analysis of administrative data of a nationwide population

RBF Bover Freire¹; C Fernandez²; J Elola³; A Esteban⁴; I Vilacosta¹; JL Bernal⁵; JV Segura⁶; V Bertomeu⁷; C Macaya¹

¹Hospital Clinic San Carlos, Department of Cardiology, Madrid, Spain; ²Hospital Clinic San Carlos, Preventive Medicine, Madrid, Spain; ³Hospital Clinic San Carlos, Foundation Institute for Healthcare Improvement, Madrid, Spain; ⁴Hospital Clinic San Carlos, Instituto de Investigación Sanitaria San Carlos, Madrid, Spain; ⁵University Hospital 12 de Octubre, Control Management Service, Madrid, Spain; ⁶IUI Operative Research Center, Miguel Hernández University, This author is partially supported by Ministerio de Economía y Competitividad of Spain (Grant N°. MT, Alicante, Spain; ⁷University Hospital San Juan de Alicante, Cardiology, Alicante, Spain

Introduction: Multiple studies have evaluated the different profile and prognosis of heart failure (HF) patients with reduced (HF-ref) or preserved (HF-pef) ejection fraction, with heterogeneous results. We present, for the first time, the clinical characteristics and prognosis of HF-ref and HF-pef patients in a whole country (Spain, 46.77 millions population).

Methods: All the discharges from Spanish hospitals corresponding to 2012–2013 with a primary diagnosis of HF, according to the ICD-9-CM classification, were analyzed. Codification as HF-ref or HF-pef was taken into account, discarding those with other codifications. In-hospital mortality and readmissions rate at 1 year were analyzed.

Results: 400,861 hospital admissions were recorded. 77,652 of them had HF as primary diagnosis (4,241 HF-ref and 1,752 HF-pef). HF-ref were mainly hospitalized in Cardiology (45.4%) or Internal Medicine (47.3%), with different proportions in HF-pef (65.4% Internal Medicine, 22.9% Cardiology). In the index episode, the

average stay was 9.7 ± 8.3 days vs. 9.2 ± 7.2 (p < 0.01) and in-hospital mortality 6.1% vs. 4.5% (p < 0.001) in HF-ref and HF-pef, respectively. At 1 year, readmissions rate was 37.9% vs. 32.9% (p < 0.001) and in-hospital mortality 12% vs. 10% (p < 0.01) also in HF-ref and HF-pef, respectively. In the multivariate analysis, at 1 year the odds ratio of HF-ref (considering as reference HF-pef) was 1.52 (95% CI, 1.27–1.84) for in-hospital mortality and 1.09 for readmissions (95% CI, 0.97–1.23).

Conclusions: In our nationwide study, patients hospitalized for HF showed different medical department of admission depending on ejection fraction. At follow-up, patients with HF-ref had higher annual mortality than HF-pef, without differences in readmissions rate.

131

Combined measurement of sST2 and NT-proBNP is a very early marker of severity in cardiogenic shock complicating acute coronary syndromes

HEV Heli Tolppanen¹; M Rivas-Lasarte²; M Sadouane³; J Lassus⁴; E Gayat³; J Spinar⁵; A Sionis²; V-P Harjola⁶; A Mebazaa³

¹Helsinki University Central Hospital, Helsinki, Finland; ²Hospital de la Santa Creu i Sant Pau, Intensive Cardiac Care Unit, Cardiology Department, Barcelona, Spain; ³Inserm UMR-S 942, Paris, France; ⁴Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland; ⁵International Clinical Research Center, Department of Cardiovascular Disease, Brno, Czech Republic; ⁶Helsinki University Central Hospital, Division of Emergency Care, Department of Medicine, Helsinki, Finland

Background: The short-term mortality in cardiogenic shock (CS) complicating acute coronary syndromes (ACS) is high, and risk stratification is needed for rational use of advanced therapies. To date, in the absence of prognosticators of poor outcome, risk assessment is based on clinical findings. In patients with myocardial infarction and acute heart failure, soluble ST2 (sST2), a marker of adverse cardiac remodeling and fibrosis, has been shown to have strong prognostic value, which is additive to natriuretic peptides.

Purpose: The aim of this study was to evaluate the added value of sST2 and NT-proBNP to clinical variables for risk stratification in patients with CS complicating ACS.

Methods: CardShock study was a prospective, observational, European multinational study of CS. The main study introduced CardShock risk score including 7 clinical variables available at baseline, which showed good discrimination for short-term mortality. In this sub-study serial plasma samples at 8 time-points from baseline to the last day of intensive care were analyzed from 145 patients with CS caused by ACS. The cut-off values for sST2 (470 ug/mL) and for NT-proBNP (4800 ng/L) were evaluated with receiver operating characteristic curves for 30-day mortality at 24 hours.

Results: Patients' mean age was 68 years, 78% were men, and all-cause 30-day mortality was 44%. The levels of both sST2 and NT-proBNP were higher in non-survivors compared to survivors at each time point measured (all p-values < 0.01). The combination of sST2 and NT-proBNP showed excellent discrimination for 30-day mortality when measured at 24 hours or later (AUC from 0.83 at 24 hours to 0.93 at last sample). Patients with both biomarkers above the cut-off level (470 ug/mL for sST2 and 4800 ng/L for NT-proBNP) had markedly higher mortality compared to those with either or both biomarkers below the cut-off level when measured at any time point (figure; all p-values < 0.05). The combination of sST2 and NT-proBNP measured at 24 hours was independent of and gave added value to CardShock risk score and peak value of troponin T (likelihood ratio 45.5 vs. 27.0, p < 0.001).

Conclusions: The combination of sST2 and NT-proBNP is an early, accurate, and independent marker of severity in patients with CS complicating ACS. The combined measurement may help the risk stratification of these patients and support clinical decision for advanced therapies.

30-day mortality

132

Short and long-term prognostic value of hyponatremia in heart failure with preserved ejection fraction versus reduced ejection fraction: An analysis of the Korean Acute Heart Failure (KorAHF) Registry

J J Jin Joo Park¹; DG Park²; GY Cho¹; IH Chae¹; DJ Choi¹; ES Jeon³
¹Seoul National University Bundang Hospital, Division of Cardiology, Seongnam, Korea Republic of; ²Hangang Sacred Hospital, Division of Cardiology, Seoul, Korea Republic of; ³Samsung Medical Center, Division of Cardiology, Seoul, Korea Republic of

Purpose: Hyponatremia is a well-known risk factor for worse outcomes in acute heart failure (HF) patients. The impact of hyponatremia on short and long-term clinical outcomes according to the ejection fraction is unknown.

Methods: From March 2011 through December 2013, a total of 5,620 acute HF patients have been consecutively enrolled in ten regionally-representative tertiary university hospitals. Serum sodium level was measured at the hospital admission. Hyponatremia was defined as serum sodium level <135 mmol/L, and heart failure with preserved ejection fraction (HFpEF) and reduction ejection fraction (HFrEF) as EF ≤40% and ≥50%, respectively. The primary endpoint was in-hospital and 1-year all-cause mortality stratified by the serum sodium level.

Results: The mean age was 69 ± 15 years and 46% were female. Three thousand two-hundred fourteen patients had HFpEF and 1,359 patients HFrEF. There was no difference in serum sodium level (HFrEF: 134.5 ± 47 mmol/L vs. HFpEF: 137.5 ± 5.0 mmol/L, $P = 0.966$), nor in the prevalence of hyponatremia (HFrEF: 21.6% vs. HFpEF: 21.2%, $P = 0.782$) between both groups. As for short-term outcomes, hyponatremic patients had higher in-hospital mortality in all (11.3% vs. 4.5%, $P < 0.001$), in HFrEF (13.3% vs. 5.3%, $P < 0.001$), and in HFpEF (6.9% vs. 2.1%, $P < 0.001$). After adjustment for significant clinical variables, hyponatremia was independently associated with an increased risk for in-hospital mortality (all: HR, 2.46; 95% CI, 1.78-3.43; HFrEF: HR, 2.51; 95% CI, 1.71-3.68; HFpEF: HR, 2.42; 95% CI, 1.07-5.47). Regarding long-term outcomes, hyponatremic patients had higher 1-year all-cause in HFrEF group (log-rank $P < 0.001$), but not in HFpEF patients (Log-rank $P = 0.074$). After adjustment, hyponatremia was associated with increased mortality in patients with HFrEF (HR, 1.85; 95% CI, 1.26-2.01), but not in those with HFpEF (HR, 1.04; 95% CI, 0.60-1.82).

Conclusions: Hyponatremia is a significant risk factor for in-hospital outcomes in all AHF patients regardless of EF. But its prognostic value on long-term outcomes is only valid in patients with HFrEF, not in those with HFpEF.

133

Monitoring of pulmonary congestion in chronic heart failure patients with multiple re-hospitalizations for acute decompensation - randomized controlled (IMPEDANCE-HF) trial.

M Michael Shochat¹; A Shotan¹; I Dahan¹; I Kleiner²; J Weinstein²; M Kazatsker¹; D Blondheim¹; A Asif¹; S Meisel¹
¹Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; ²Saroka Medical Center, Cardiology, Beer Sheva, Israel

Prediction and prevention of re-hospitalizations for heart failure (HF) in patients with congestive heart failure is an unmet need. In this study we used a new type of impedance technique based on calculated lung impedance (LI) rather than on the traditionally measured transthoracic impedance for monitoring and prediction of re-hospitalization for HF. Aim To determine the dynamics of pulmonary congestion at admission for AHF during long-term follow-up in HF patients.

Method and Results: In "Non-invasive Lung IMPEDANCE-Guided Preemptive Treatment in Chronic Heart Failure Patients: a Randomized Controlled Trial (IMPEDANCE-HF trial)" 256 CHF patients with LVEF <35% were randomized (1:1) to a control group treated by clinical assessment and a monitored group whose therapy was also assisted by Lung Impedance (LI). Was found that LI-guided treatment reduced HF hospitalizations by 45% and HF associated death by 58% during 48 months of treatment. Decreasing LI reflects increasing lung fluid. Signs, LI and ratio of the instantaneous LI to the calculated baseline LI (Δ LIR) were monitored monthly. Initial NT-proBNP level was 3594 ± 5114 pg/ml. Of 256 study patients, 190 were admitted for HF, 31 for non-HF causes only and 35 were not hospitalized at all during the follow up period. Of the 190 HF patients who were admitted for HF, 156 were followed for more than 4 years, with at least one admission each year of follow up. Mean Δ LIR values at admission for HF during the first to fourth year of follow up were -32.74 ± 5.7%, -38.3 ± 6.2%, -43.6 ± 5.8% and -48.1 ± 6.3%, respectively ($p < 0.001$).

Conclusion: Our findings support the notion that as heart failure persists and follow up increases, patients adapt better to higher degrees of pulmonary congestion and only a pronounced exacerbation of lung fluid accumulation and congestion will prompt hospitalization for HF.

134

Characterisation of a hypercoagulable phenotype with increased thrombin generation in acute heart failure

B Popovic¹; H Louis²; R Fay³; F Zannad¹; P Lacombe²; V Regnault²
¹CHU Brabois, Département de cardiologie, Vandoeuvre les Nancy, France; ²INSERM 1116, Université de Lorraine, Vandoeuvre les Nancy, France; ³CHU Brabois, Centre d'Investigations Cliniques Plurithématique 1433, Vandoeuvre les Nancy, France

Aims: Subjects with heart failure (HF) are at higher risk of developing thrombosis. We determined the thrombin generating capacity in patients with acute decompensated heart failure (ADHF).

Methods and Results: Our prospective study included 34 ADHF patients and 19 control inpatients without HF. In vitro thrombin generation and its downregulation by activated protein C (APC) was monitored by calibrated automated thrombography at hospital admission, at the day of discharge and after at least six weeks of clinical stability. Concentrations of circulating microparticles (MPs) were determined by flow cytometry. Compared to controls, endogenous thrombin potential (ETP) was higher in ADHF patients at admission using platelet-rich plasma. Thrombin generation remained increased during the hospital course. After six weeks of clinical stability, ETP values were lowered to values of controls. The APC concentration inhibiting thrombin generation by 50% was higher at admission compared with the post-discharge period. ADHF patients had higher von Willebrand factor and endothelial protein C receptor plasma levels at admission. Significantly higher concentrations (3 to 5-fold increase) of annexin-V and tissue factor (TF)-positive MPs whatever their cellular origin were also found in ADHF patients at admission but not at the post-discharge point compared to controls. The concentration of TF-positive endothelial or platelet MPs were positively correlated with ETP.

Conclusion: The hypercoagulable state at the acute phase of decompensated HF results from increased procoagulant circulating MPs and dampened dynamic anticoagulant APC activity. Our findings demonstrate that thrombin generation assays and MP signatures are sensitive to the temporal evolution of this disease.

135

Relationship of ventricular conduction defects, angiographic findings and mortality in cardiogenic shock

T Javanainen¹; H Tolppanen¹; MS Nieminen²; J Lassus²; A Sionis³; J Spinar⁴; M Banaszewski⁵; V-P Harjola⁶; R Jurkko²
¹Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland; ²Helsinki University Central Hospital, Heart and Lung Center, Division of Cardiology, Helsinki, Finland; ³Hospital de la Santa Creu i Sant Pau, Intensive Cardiac Care Unit, Cardiology Department, Barcelona, Spain; ⁴University Hospital Brno, Department of Internal Medicine and Cardiology, Brno, Czech Republic; ⁵Institute of Cardiology, Intensive Cardiac Therapy Clinic, Warsaw, Poland; ⁶Helsinki University Central Hospital, Division of Emergency Care, Department of Medicine, Helsinki, Finland

Background: Ventricular conduction defects, such as bundle branch blocks, hemiblocks and non-specific intraventricular conduction defects (IVCD), are frequently present in cardiogenic shock (CS), but their relationship with angiographic findings and mortality is not clear.

Purpose: The aim of this study was to investigate whether ventricular conduction abnormalities are associated with specific angiographic findings and increased mortality.

Methods: We analysed the baseline electrocardiogram (ECG) of patients who underwent angiography in a multinational prospective cohort study of CS (n = 219) conducted in 2010-2012 with one-year follow-up. In total 182 (83.1%) patients underwent angiography. The baseline ECG was available for 164 (74.8%) of these patients. The patients with ventricular conduction defects (n = 80; 48.8%) were compared with those who had other ECG pattern (n = 84; 51.2%). The multivariate models were calculated with logistic regression adjusted for age, previous myocardial infarction and the CardShock risk score. The risk score takes into account age, confusion at presentation, previous myocardial infarction or coronary artery bypass graft, acute coronary artery syndrome aetiology, left ventricle ejection fraction, serum lactate and estimated glomerular filtration rate.

Results: Nearly half of the patients had a ventricular conduction defect (LBBB 2.4%, RBBB 12.2%, LAHB 14.6%, LPHB 3.7% or non-specific IVCD 15.9%). Most of the patients had significant coronary artery stenosis (n = 152; 92.7%) and the prevalence did not differ between the groups (95.0% vs 90.5%; $p = 0.27$). In the patients with conduction defects the culprit lesion was more often in the left main (LM) coronary artery (25.0% vs. 9.5%; $p = 0.008$). There was no difference between the groups in three vessel disease (25.0% vs. 32.1%; $p = 0.31$) or in the finding of TIMI flow grade 0 (64.9% vs 71.6%; $p = 0.38$). One-year mortality was higher in patients with ventricular conduction defects (Figure). In the multivariate model ventricular conduction defects independently predicted mortality (OR 1.79; 95% CI 1.07-3.01; $p = 0.027$). When we further adjusted mortality rates for the prevalence of the LM coronary artery disease, ventricular conduction defects

were still an independent predictor of mortality (OR 1.73; 95% CI 1.02-2.93; $p=0.043$).

Conclusions: In CS ventricular conduction defects in baseline ECG are associated with increased mortality and higher incidence of the LM coronary artery disease. However conduction abnormalities do not associate with three vessel disease or TIMI flow grade 0. Conduction defects are an independent risk factor also after eliminating the effect of LM disease. This study suggests that in CS ventricular conduction abnormalities predict mortality regardless of the severity of the coronary artery disease.

Figure: One-year mortality

136

Application of a simplified risk score derived from cardshock score for prognostic stratification in patients with cardiogenic shock

I Ilaria Battistoni¹; M Marini¹; L Angelini¹; M Francioni¹; A Gili¹; S Moretti¹; GP Perna¹

¹University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy

Background: Cardiogenic shock (CS) is a severe state of systemic hypoperfusion due to cardiac failure, often resulting in multiorgan dysfunction with rate of death ranging from 50 to 90% of cases. Recently a Cardshock score (CSS) was developed to improve early decision-making and prognostic stratification in CS patients.

Purpose: to evaluate the feasibility of the CSS for risk stratification of patients with CS.

Methods: we retrospectively evaluated 66 patients admitted for CS in our cardiac intensive care unit over 3 years (2012-2015). At first evaluation, CSS was calculated for each patient. We also evaluated which of the Cardshock variables best predicted mortality.

Results: Our population (72.8 ± 12.7 years, 61% men) presented a mean MAP of 61.9 ± 14.4 mmHg, severe LV dysfunction (LVEF 31.1 ± 9.9 %) and moderate to severe renal failure (eGFR/CKD-EPI): 43.7 ± 24.2 ml/min/1.73m²). Lactates were 6.64 ± 4.5 mmol/l. 98% of patients received IABP. The mean CardShock risk Score was 5.0 ± 2 with an in-hospital mortality of 55%. Among Cardshock variables, at Cox multivariate analysis (table 1), age and lactates best correlated outcomes and when considering a simplified score, with age and arterial lactates evaluation, it predicted in-hospital mortality well (area under the curve 0.79) as the CSS (area under the curve 0.71).

Conclusions: The CSS well stratified the risk and short-term mortality in CS patients. We developed a simplified risk score that equally well stratifies the risk and short-term mortality of our patients as the CSS.

Variable	HR	95%CI	P
Age	1.05	1.02-1.09	0.005
Age score	2.22	1.07-4.60	0.032
Previous PTCA-CABG	0.79	0.32-1.95	0.618
LVEF	0.97	0.94-1.01	0.180

Sleep-disordered breathing is associated with impaired left ventricular function and heart failure after acute myocardial infarction

HF Fox¹; T Bitter¹; D Horstkotte¹; O Oldenburg¹

¹Department of Cardiology, Heart and Diabetes Center North Rhine-Westphalia, Ruhr University Bochum, Bad Oeynhausen, Germany

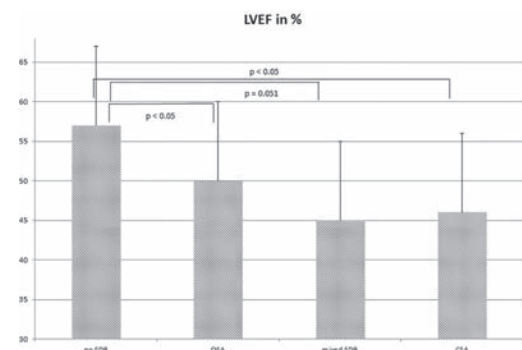

Background: Heart failure after acute myocardial infarction (AMI) remains a denotative topic today and routes to identify factors increasing myocardial salvage after infarction are of great interest. Recent literature has indicated an association between sleep-disordered breathing (SDB) and the degree of myocardial salvage after AMI, but only few data is available yet.

Purpose: This study investigated the relationship between left ventricular ejection fraction (LVEF) and SDB in patients with AMI.

Methods: 223 patients (age 63.3 ± 11.2 years, 81.6% male, BNP 296.7 ± 547.8 pg/ml, CK max 2376.5 ± 2646.6 U/l) were enrolled and underwent multichannel cardiorespiratory polygraphy (PG) after revascularization of myocardial infarction (ST elevation myocardial infarction and non-ST elevation myocardial infarction). None of the patients was treated with ventilation therapy and all patients were naïve to ventilation therapy. The prevalence of SDB (apnea-hypopnea index [AHI] ≥ 5 /h) was 86 % (40.8 % had central sleep apnea and 42.2 % had obstructive sleep apnea, rest mixed SDB). Mean AHI was 25.7 ± 19.7 /h and mean LVEF after AMI was 49.4 ± 12.5 %.

Results: The presence of SDB worsened LVEF after AMI, an association which showed statistical significance, for both presence of OSA or CSA versus no SDB ($p < 0.05$, graph 1). There was also a trend for worsened LVEF and resulting heart failure for mixed SDB versus no SDB ($p = 0.051$), as depicted in graph 1.

Conclusions: In conclusion, SDB (CSA and OSA) is associated with worsened LVEF after AMI and SDB seems to impair myocardial salvage after AMI. Further studies to investigate this relationship are needed and ongoing.

138

Comparison of treatment response by cardiac and lung ultrasound with symptomatic status - impact on prognosis in patients hospitalized for acute heart failureJ Jonas Oehman¹; V-P Harjola²; P Karjalainen¹; J Lassus³¹Satakunta Central Hospital, Cardiology, Pori, Finland; ²Helsinki University Central Hospital, Emergency care, Helsinki, Finland; ³Helsinki University Central Hospital, Helsinki, Finland**Introduction:** Poor treatment results remain a major concern in patients hospitalized for acute heart failure (AHF) and has been associated with poor prognosis**Objectives:** To evaluate the impact of treatment response defined by residual congestion on lung ultrasound (LUS) and symptomatic status on mortality in hospitalized AHF patients -To evaluate the correlation between residual congestion and symptomatic status to cardiac filling pressures (E/e')**Methods:** We included 101 dyspneic hospitalized AHF patients who were to receive standard in-hospital AHF treatment -We followed these patients daily using a focused thoracic ultrasound protocol combining E/e' and LUS with simultaneous symptom assessment using visual analog scale (VAS) for dyspnea -Patients who were asymptomatic (VAS 0) and non-bedridden at the day of discharge were defined as symptomatic responders -Patients who had no residual congestion on LUS at the day of discharge were defined as sonographic responders -LUS was considered congestive if presenting bilateral B-lines and/or right sided- or bilateral pleural fluid -Patients with both a sonographic- and symptomatic treatment response were considered complete responders, whereas patients with neither treatment response were considered non-responders and patients with either sonographic- or symptomatic treatment response were considered partial responders Results -Only 44.6 % of the patients were complete responders, 27.7 % partial responders and 27.7 % non-responders -Only 54.5 % of the patients had a sonographic treatment response, with 46.5 % having residual congestion at the day of discharge -Sonographic treatment response significantly predicted symptomatic treatment response (PPV 70.3 %, NPV 75.7 %, $p < 0.001$) -6 month mortality was 53.6 % in non-responders (group 1), 21.4 % in partial responders (group 2) and 11.1 % in complete responders (group 3) ($p < 0.001$ for comparison of group 1 to group 2 or 3, $p = NS$ for comparison of group 2 to 3) -Mean E/e' at the day of discharge was 21.1 (SD 6.1) in non-responders (group 1), 18.90 (SD 5.7) in partial responders (group 2) and 15.6 (SD 4.0) in complete responders (group 3), ($p < 0.001$ between group 1 and 3, $p = 0.005$ between group 2 and 3, $p = NS$ between group 1 and 2) with no significant difference in E/e' on admission -Mean decrease (Δ) E/e' during treatment was 0.8 (SD 4.5) in group 1, 1.5 (SD 4.2) in group 2 and 4.5 (SD 4.4) in group 3, ($p = 0.001$ for group 1 vs. group 3, $p = 0.006$ for group 2 vs. group 3, $p = NS$ for group 1 vs. group 2) -Mean final E/e' or $\Delta E/e'$ during treatment did however not have a statistically significant impact on prognosis ($p = NS$ for both) Conclusions -Poor treatment response was common and associated with an increased short-term mortality -Sonographic- and symptomatic treatment responses correlated well with each other -Responsive patients had a greater $\Delta E/e'$ during treatment and a lower E/e' at discharge -E/e' per se did not have prognostic significance

Survival according to treatment response

Management of heart failure in the real-world: does gender make the difference? Findings from the ARNO administrative database.F Orso¹; S Calabria²; E Rossi³; E Cinconze³; S Baldasseroni¹; N Martini⁵; A P Aldo Pietro Maggioni⁶¹Azienda Ospedaliero-Universitaria Careggi, Department of Geriatrics, Section of Geriatric Medicine and Cardiology, Firenze, Italy; ²CORE, Collaborative Outcome Research, Bologna, Italy; ³CINECA Interuniversity Consortium, Casalecchio diReno, Italy; ⁴Azienda Ospedaliero-Universitaria Careggi, Department of Heart and Vessel, Section Internal Medicine and Cardiology, Firenze, Italy; ⁵Accademia Nazionale di Medicina, Roma, Italy; ⁶ANMCO Research Center, Florence, Italy**Background:** Among patients with heart failure (HF), female gender has generally been shown to be associated with more favourable outcomes. Females are frequently excluded from randomized clinical trial and to some extent from cardiology registries. Purpose. The purpose of this study is to describe gender differences in terms of clinical characteristics, treatments, one-year outcomes and management costs in a real world setting of acute heart failure analysing a large administrative database.**Methods:** Data came from the ARNO Observatory that includes nearly 3,000,00 in-habitants of 7 Local Health Authorities of the Italian National Health Service (NHS). Patients with HF were selected when discharged for HF (from January 1, 2008 to December 31 2012) and prescribed on at least one HF treatment. We compared patients according to gender. Results. The total study population was composed by 41,413 patients discharged alive and prescribed on HF treatments. Female gender accounted for 51.4%. Mean age was higher among female patients (80.4 vs 75.5%), with increasing number of females particularly among the "very elderly" (> 85 yrs: 66.3% vs 33.7%). Comparing co-morbidities we found a lower prevalence of COPD (27.4 vs 33.7%) and diabetes (29.5 vs 31.9%) in females and a higher prevalence of depression (26.1 vs 15.5%). Females were less frequently managed in a cardiology setting (20.6 vs 32.9%) and more frequently in internal medicine (54.6 vs 44.6%) and geriatric (15.2 vs 12.0%) wards. During the 1-year follow-up, prescription rate of ACE-inhibitors/Angiotensin Receptor Blockers and Beta-Blockers was lower in females (63.5 vs 68.3 % and 45.9 vs 53.6% respectively), as well as for Mineralocorticoid antagonists (41.9 vs 42.3%) and higher for digoxin (29.3 vs 24.2). During the 1-year follow-up, males had a higher re-hospitalisation rate (at least one re-hospitalisation during follow-up) 60% vs 53.3% and less frequently due to non-cardiovascular causes (47.9% vs 50.4%). NHS's total direct cost per year were higher in males than in females, 13,273 vs 10,451 €. p values for all above differences < 0.01.**Conclusions:** Real world evidence show a gender-related high variability in both clinical epidemiology and management of patients with HF. Females are older, have a different co-morbidity pattern, are less frequently treated in cardiology setting and with HF guidelines recommended drugs.

140

Bioactive adrenomedullin: a novel prognostic marker in cardiogenic shockM Mercedes Rivas Lasarte¹; H Tolppanen²; J Lassus²; A Sionis Green¹; V-P Harjola²; A Mebazaa³¹Hospital de la Santa Creu i Sant Pau, Cardiology Department, Barcelona, Spain;²Helsinki University Central Hospital, Cardiology department, Helsinki, Finland;³Inserm UMR-S 942, Paris, France**Background:** The short-term mortality in cardiogenic shock (CS) is high, and risk stratification is needed for rational use of advanced therapies.**Purpose:** The aim was to evaluate the prognostic value of bioactive adrenomedullin (bio-ADM) and lactate in CS.**Methods:** CardShock study was a prospective, observational, European multinational cohort of CS. This is a sub-study of 178 patients with serial plasma samples.**Results:** Both lactate and bio-ADM levels were higher in non-survivors compared to survivors at all time points ($p < 0.05$). Lactate levels fell to normal ($\leq 2 \text{ mmol/L}$) within the first 24 hours in most patients regardless of outcome. Lactate had good prognostic value during the first 24 hours, whereas bio-ADM showed incremental prognostic value starting at 48 hours (Figure). The addition of bio-ADM at 48 hours to the baseline lactate levels re-stratified the patients in 3 risk groups with 90-day mortality of 8.1%, 35.4%, and 61.1% ($p < 0.001$). Prognostic value of serial measurement of lactate and bio-ADM were independent of conventional risk factors. High bio-ADM levels were associated with persistently impaired hemodynamics (cardiac index, mean arterial, central venous, and pulmonary arterial pressures) and end-organ dysfunction.**Conclusions:** Bio-ADM is a valuable prognostic marker after the initial phase of management in CS. Combining bio-ADM with early lactate measures may help the recognition of high-risk patients and support clinical decision for the use of advanced therapies in CS.

Evolution of AUC of lactate and bioADM

Management of heart failure following primary PCI after st-elevation myocardial infarction: a large UK tertiary centre experience

A Ghosh Dastidar¹; S Wood-Gismera¹; S Boles¹; M Townsend¹; Y Ismail¹; C Bucciarelli-Ducci¹; A Nightingale¹

¹Bristol Heart Institute, NIHR Bristol Cardiovascular Biomedical Research Unit, Bristol, United Kingdom

Patients presenting with ST-segment elevation myocardial infarction (STEMI) represent 30% of all acute coronary syndromes (ACS). Even with successful and timely primary percutaneous coronary intervention (PPCI) development of heart failure is a frequent adverse consequence. Local follow up of these patients is often challenging due to the centralisation of acute PPCI services.

Purpose: To evaluate the: i) Prevalence of left ventricular systolic dysfunction (LVSD) following PPCI, ii) Predictors for development of heart failure, iii) Prescription of Mineralocorticoid Receptor Antagonist (MRA) as per ESC guideline iv) Number qualifying for primary prevention ICD.

Methods: This retrospective observational study was performed at a large tertiary centre in the South-West of England. Data were collected on consecutive patients who underwent PPCI (Jan 2013 -Dec 2013). Echocardiography was used to assess of LV function. Ejection fraction <40% was defined as significant LVSD. Fisher's exact test and student-t test were used to establish statistical significance. P-value of <0.05 was considered significant.

Results: Of the 573 patients who underwent PPCI, 73.8% were male and the median age was 64 years. 9 patients died prior to formal assessment of LV function and were excluded. 42% (n=231) of patients with a recorded EF had LVSD. Such patients had a significantly greater median length of hospital stay (4 vs 3, P<0.0001) and 30-day mortality rate (17 vs 9, P=0.01). Patients with LVSD also had a significantly higher peak troponin level (5981 vs 2816, P<0.0001) and were more likely to have the LAD as their culprit artery (138 vs 104, P<0.0001) than patients without LVSD. 83.5% (n=193) of patients with LVSD qualified for an MRA; however, only 47% (91/193) of these patients received this medication. 214 patients had LVSD on initial assessment and were alive after 40days. 29.0% (62/214) patients were lost to follow up and hence excluded from further analysis. 76% (115/152) had a repeat assessment of their EF. 29% (33/115) patients qualified for an ICD under ESC guidelines. On the contrary, only 3% (3/115) qualified under the NICE guidelines, as only 3 patients had a QRS >120ms with or without LBBB.

Conclusion: Significant heart failure following STEMI is still a major health problem even after timely and successful PPCI. It is associated with a significantly higher mortality and increased length of hospital stay. Higher troponin level and LAD culprit artery are predictors of severity of LV impairment. Use of MRA is moderate. Heart Attack Centres and local heart failure teams need to coordinate follow up echo and clinical care. This remains challenging. Moreover, adoption of ESC guideline leads to a significantly higher number qualifying for an ICD when compared to NICE guidelines. Further research into the impact of adoption of NICE vs ESC guideline on primary prevention ICD post STEMI is urgently required.

Transvenous stimulation of cardiac autonomic nerves improves hemodynamics

MPC Michael Cuchiara¹; CM Marin Y Kall²; MP Penn³; AE Ebner⁴

¹NeuroTronik, Clinical Research, Durham, United States of America; ²University of Miami, International Medicine Institute, Miami, United States of America; ³Summa Cardiovascular Institute, Akron, United States of America; ⁴Facultad de Ciencias Medicas UNA Paraguay, Asuncion, Paraguay

Despite advances in therapies for the management of heart failure, Acute Heart Failure Syndrome (AHFS) is a leading cause of mortality and morbidity. An electrically

active, catheter-based technology is being investigated to transvenously stimulate cardiac autonomic nerves to control left-ventricular contractility and heart rate in order to improve hemodynamics. The purpose of this study was to investigate cardiac autonomic nerve stimulation effects on acute hemodynamics. The present study was a single center feasibility study performed in patients undergoing cardiac catheterization. The study protocol was approved by the Republic of Paraguay, National Council of Health, Bioethics Committee and was conducted in our institute. All subjects signed a written informed consent in order to participate in the study. Purpose built electrical stimulation catheters were percutaneously inserted into an upper venous structure near the heart via either right femoral vein and or left subclavian vein access using standard introducers. All subjects were instrumented with solid state pressure catheters in the left-ventricle and the femoral artery to measure left ventricular and femoral artery pressure respectively. Cardiac output was estimated using an average of three methods: modified Starr Pulse Pressure Cardiac Output, direct pulse pressure method and continuous thermal dilution method. Sixteen (16) subjects were stimulated for one hour and hemodynamics were continuously measured during stimulation. Changes in hemodynamics during stimulation were determined by comparison to a pre-stimulation, reference period when stimulation was off. Statistics were calculated using a single tail paired t-test of the means compared to the reference period. After only 10 minutes of stimulation, left ventricular contractility (maximum first derivative of left ventricular pressure) and mean arterial pressure were increased by +9.8% and +12.7% respectively. After 1 hour of stimulation, left ventricular contractility and mean arterial pressure continued to increase to 16.2% (p=0.005) and +15.9% (p=0.0003) respectively. During this time, heart rate increased by 0.8% (p=0.346) while average cardiac output increased by 10.7%. Increases in left ventricular contractility, mean arterial pressure and cardiac output coupled with small changes in heart rate suggests stimulation preferentially increases cardiac contractility over heart rate. Furthermore, increases in cardiac output that exceed increases in heart rate suggest that left ventricular contractility and subsequently stroke volume drove increased cardiac output. Further potential likely exists to develop the therapy such that increased cardiac output is achieved in the presence of lowered heart rate. In conclusion, we believe this study demonstrates the promise of transvenous cardiac autonomic nerve stimulation therapy to improve hemodynamics.

Stimulation Effects on Hemodynamics

DIRECTIONS IN HFpEF RESEARCH

Saturday 21 May 2016 14:15–15:45

Na⁺/Ca²⁺ Exchanger (NCX) inhibition with ORM 11035 improves cardiac function and remodeling without lowering blood pressure in a model of heart failure with preserved ejection fractionU Primessnig¹; T Bracic²; P Pollesello³; B Pieske¹; FR Heinzel¹¹Charité - Universitätsmedizin Berlin, Campus Virchow-Klinikum, Department of Cardiology, Berlin, Germany; ²Medical University of Graz, Department of Cardiology, Graz, Austria; ³Orion Pharma, Critical Care, P.O. Box 65, Espoo, Finland, Espoo, Finland**Background:** Heart failure with preserved ejection fraction (HFpEF) is increasingly common but there is currently no established pharmacological therapy. We could demonstrate that in a rat model of HFpEF cardiomyocyte dysfunction is associated with impaired cardiomyocyte Ca²⁺ handling and altered Na⁺/Ca²⁺ exchanger (NCX) function. Therefore we investigated the effects of chronic inhibition of the NCX with ORM 11035, a new NCX inhibitor, on cardiac function and remodeling in HFpEF.**Methods:** Young male Wistar rats were subjected to subtotal nephrectomy (NXT, n = 24) or sham operation (SOP, n = 24). 8 weeks after intervention chronic treatment for 16 weeks with the novel NCX inhibitor ORM 11035 (1mg/kg body weight) or vehicle was started. At 24 weeks non-invasive blood pressure measurements, echocardiography, pressure-volume loops (PV) and LV morphometry were performed. LV cardiomyocytes were isolated and contractile function and Ca²⁺ transients were measured. NCX-mediated Ca²⁺ extrusion was quantified from the caffeine-induced Ca²⁺ transient. Results NXT rats (untreated) showed signs and symptoms of HFpEF (hypertrophied LV, left- and upward shift of end diastolic pressure (EDP) volume relationship (EDPVR), increased lung weight/body weight ratio (LW/BW) indicating pulmonary congestion and preserved LV systolic function (EF, dP/dt). In LV cardiomyocytes from untreated NXT early relaxation was prolonged and NCX-mediated Ca²⁺ extrusion was decreased. ORM 11035 treatment reduced heart weight/BW ratio and LW/BW significantly as well as LV mass without effects on systolic blood pressure (157 ± 1 vs. 158 ± 1, mmHG in NXT, p=ns). LVEDP (13 ± 1 vs. 8 ± 1, mmHG in NXT, p < 0.05) and EDPVR were reduced after chronic treatment with ORM 11035 in NXT. LV cardiomyocytes from ORM-treated rats showed improved diastolic cytosolic Ca²⁺ decay as well as restored NCX-mediated Ca²⁺ removal indicating specific NCX inhibition as a promising target in the treatment of HFpEF patients.**Conclusion:** Chronic inhibition of the Na⁺/Ca²⁺ exchanger with ORM 11035 significantly attenuated cardiac remodeling and diastolic dysfunction without lowering systemic blood pressure in this model of HFpEF.

164

A restrictive pattern of LV filling is only present in one third of cardiac AL amyloidosis patientsS Perlini¹; F Musca²; F Salinaro¹; R Mussinelli¹; T Perrone¹; E Binot¹; M Boldrini¹; G Gioia¹; G Palladini³; G Merlini³¹Dept. Internal Medicine, University of Pavia, Amyloidosis Research and Treatment Center, IRCCS S.Matteo, Pavia, Italy; ²IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Cardiology, Milan, Italy; ³Amyloidosis Research and Treatment Center, Dept. Molecular Medicine, IRCCS S.Matteo, University of Pavia, Pavia, Italy**Background:** Cardiac amyloidosis represents an archetypal form of restrictive heart disease, characterized by profound diastolic dysfunction, associated with a "normal" ejection fraction (EF) that is preserved until the late stage of the disease in the vast majority of patients. Therefore cardiac amyloidosis patients typically fulfil the definition of heart failure with preserved ejection fraction (HFpEF). A restrictive pattern of transmitral left ventricular (LV) filling is often reported as a typical hallmark of diastolic dysfunction in these patients.**Objective and Methods.** In order to evaluate the extent of diastolic dysfunction in cardiac light-chain (AL) amyloidosis, we enrolled 221 consecutive never-treated subjects, in whom a first diagnosis of cardiac AL amyloidosis was concluded

between 2007 and 2010, according to the International Society of Amyloidosis criteria. Further inclusion criteria were EF>50%, and the absence of significant valve disease, previous myocardial infarction, atrial fibrillation, or chronic obstructive lung disease. The extent of diastolic dysfunction was graded according to the ESC guidelines. To this aim, transmitral Doppler early (E) and atrial (A) velocities, E deceleration time, pulmonary venous flow velocity, early diastolic tissue Doppler peak velocity (E') and E/E' ratio were recorded at diagnosis. Survival was assessed over a median follow-up of 35.8 months (range, 19-60 months).

Results: Quite surprisingly, grade III diastolic dysfunction was only present in 37.1% of the whole cardiac AL population (82/221), grade II and grade I diastolic dysfunction being evident in 84 (38.0%) and 55 (24.9%) patients, respectively. The extent of amyloid deposit, as assessed by interventricular septal thickness, was slightly lower in grade I than in grade III diastolic dysfunction groups (14.2 ± 2.0 vs. 14.7 ± 2.1 mm; p < 0.05). Both left atrial dimensions and estimated systolic pulmonary pressure progressively increased from grade I to grade III diastolic dysfunction (p < 0.01 for both). At variance with EF, the grade of diastolic dysfunction was a significant predictor of survival after a 3-year median follow-up (p < 0.001).**Conclusions:** A clear-cut restrictive LV filling is only present in one third of patients with overt cardiac AL amyloidosis, grade I diastolic dysfunction being present in almost one fourth of patients. Despite being an important prognostic factor, the presence of a restrictive pattern of transmitral LV filling cannot be viewed as a "red flag" diagnostic marker in cardiac AL amyloidosis.

165

Dipeptidyl peptidase 4 inhibitor sitagliptin reduces oxidative stress, endothelial dysfunction and preserves diastolic function in a rat model of heart failure with preserved ejection fractionK Urbanek¹; D Donato Cappetta¹; E Piegari¹; G Esposito¹; R Russo¹; LP Ciuffreda¹; A Rivellino¹; L Berrino¹; F Rossi¹; A De Angelis¹¹Second University of Naples, Department of Experimental Medicine - Section of Pharmacology, Naples, Italy**Background:** Heart failure with preserved ejection fraction (HFpEF) appears to be a systemic syndrome driven by risk factors and co-morbidities and its pathophysiology is poorly understood. Interstitial fibrosis, myocyte hypertrophy and altered intracellular calcium homeostasis trigger diastolic dysfunction by impairing relaxation and increasing ventricular stiffness. HFpEF associates with diabetes when systemic proinflammatory state and endothelial dysfunction influence patient's cardiovascular profile. Several studies suggesting that dipeptidyl peptidase 4 (DPP4) might be involved in the pathophysiology of HF prompted investigations of DPP4 inhibitors (DPP4i) cardiovascular safety and potential benefits. DPP4i may have effects on cardiovascular system as DPP4 reduces the biological activity of peptides with cardio-, vaso- and reno-protective actions. In addition, DPP4 may exert pro-fibrotic and inflammatory effects, but the possible underlying mechanisms are not clear.**Objective:** To determine whether inhibition of DPP4 affects the progression of HFpEF independently from the effects on a glycemic control and to identify mechanisms involved in the potential cardioprotection.**Methods:** Non-diabetic seven-weeks old Dahl salt-sensitive rats were fed a high salt diet (8% NaCl) for 5 weeks to induce hypertension. Afterwards, rats continued with a high salt diet and were administered either with vehicle or sitagliptin (SITA, 10 mg/kg/die, oral) for the following 8 weeks. Control rats were maintained on a low salt diet (0.3% NaCl).**Results:** Treatment with SITA significantly attenuated diastolic dysfunction ameliorating hemodynamic indices (decreased dP/dt min, increased LVEDP, longer time constant and steeper slope of the end-diastolic pressure-volume relationship). SITA significantly reduced mortality, arterial blood pressure and improved general conditions. Myocardial levels of pro-inflammatory tumor necrosis factor-α and monocyte chemoattractant protein-1 were reduced. It was associated with decreased markers of oxidative stress, nitrotyrosine and oxidized dihydroethidium. Moreover, SITA

reduced the levels of eNOS monomer, responsible for ROS generation, and elevated the amount of NO-producing dimeric form. Finally, increase of collagen deposition and activation of pro-fibrotic TGF- β /SMAD3 signaling that leads to elevated myocardial stiffness and diastolic compliance were attenuated by SITA.

Conclusions: SITA positively modulates active relaxation and passive diastolic compliance interfering with inflammatory-related endothelial dysfunction and fibrosis associated with HFpEF.

166

HFpEF and HFrEF display different anabolic phenotypes as assessed by IGF-1 and IGFBP-1

U Ljung Faxen¹; C Hage¹; L Benson²; S Zabarovskaja¹; A Andreasson³; E Donal⁴; JC Daubert⁴; C Linde¹; K Brismar¹; L H Lund¹

¹Karolinska Institutet, Department of Medicine, Stockholm, Sweden; ²Karolinska Institutet, Department of Clinical Science and Education, Stockholm, Sweden;

³Karolinska Institutet, Division of Family Medicine, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden; ⁴University Hospital of Rennes, Département de Cardiologie & CIC-IT U 804, Rennes, France

Background: Anabolic drive is impaired in heart failure with reduced ejection fraction (HFrEF) but has been insufficiently studied in HF with preserved EF (HFpEF). Insulin-like growth factor 1 (IGF-1) mediates growth hormone effects and IGF-1 binding protein 1 (IGFBP-1) regulates IGF-1. Both can be used as markers of anabolism.

Purpose: We tested the hypothesis that HFpEF and HFrEF are similar syndromes with regard to IGF-1 and IGFBP-1 by assessing concentrations, correlations with natriuretic peptides, and prognostic impact.

Methods: Concentrations of IGF-1 and IGFBP-1 were measured in patients with HFpEF (n=79), HFrEF (n=85), and controls without cardiovascular disease (n=136); and analysed, logarithmically transformed (ln) with ANOVA, Pearson's r and Cox regression. In HFpEF the composite endpoint was hospitalisation due

to HF and death and in HFrEF, implantation of left ventricular assist device, heart transplantation, or death. Results Age standardized scores of IGF-1 (SD score IGF-1) were increased in HFpEF; median arbitrary units (interquartile range) 1.21 (0.57-1.96), vs controls, 0.22 (-0.47-0.96); p=0.013 and reduced in HFrEF, 0.09 (-1.40-1.62) vs controls; p=0.001. IGFBP-1 was increased in HFpEF, 48 (28-79) and HFrEF, 65 (29-101) vs. controls, 27 (14-35) μ g/L, p overall <0.001. These patterns persisted after adjusting for metabolic and severity confounders. High levels of IGFBP-1, but not IGF-1, were associated with high levels of NT-pro-BNP in both HFpEF, r=0.458, p<0.001; and HFrEF, r=0.533, p<0.001. IGF-1 was protective in HFrEF; adjusted hazard ratio per ln increase in IGF-1 SD score, 0.31 (95% confidence interval 0.13-0.77, p 0.011) but not in HFpEF. IGFBP-1 neither predicted outcomes in HFpEF nor HFrEF.

Conclusion: HFpEF and HFrEF were similar with regard to IGFBP-1 elevations but differed regarding IGF-1 levels and prognostic impact. HFrEF may be associated with a syndrome-specific impairment in anabolic drive, whereas IGFBP-1 activation in HFpEF may be less specific and related to comorbidities.

Levels of SD score IGF-1 and IGFBP-1

RAPID FIRE 2 – IMAGING IN CHRONIC HEART FAILURE

Extracellular volume fraction for characterization of patients with heart failure and preserved ejection fractionKP Rommel¹; M Von Roeder¹; S Blazek¹; K Fengler¹; C Besler¹; M Sandri¹; C Luecke²; M Gutberlet²; G Schieler¹; P Lurz¹¹Heart Center of Leipzig, Internal Medicine / Cardiology, Leipzig, Germany; ²Heart Center of Leipzig, Radiology, Leipzig, Germany

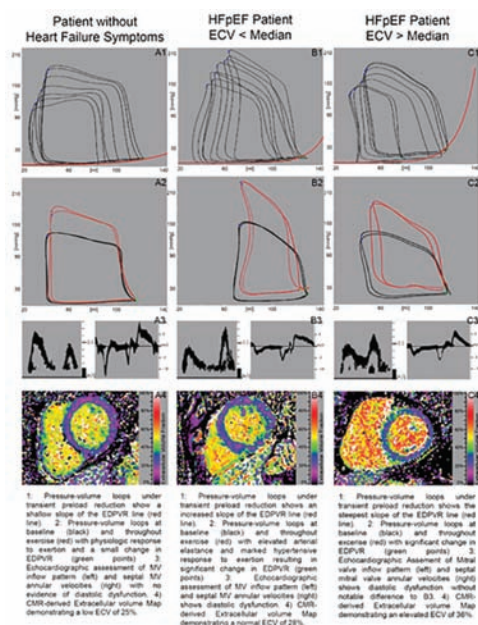

Background: Optimal patients characterization in Heart Failure with Preserved Ejection Fraction (HFpEF) is essential to tailor successful treatment strategies. Cardiac magnetic resonance derived T1-Mapping allows for non-invasive quantification of diffuse myocardial fibrosis as extracellular volume fraction (ECV).

Objectives: We aimed to elucidate the diagnostic performance of T1-Mapping in HFpEF by examining the relationship between ECV and invasively measured parameters of diastolic function and investigated the potential of ECV to differentiate between different pathomechanisms in HFpEF.

Methods: We performed T1-Mapping in 21 patients with HFpEF and 11 patients without heart failure symptoms. Pressure-volume-loops were obtained with a conductance catheter during basal conditions and handgrip exercise. Transient preload reduction was used to extrapolate the diastolic stiffness constant.

Results: Patients with HFpEF showed a higher ECV ($p=0.001$), an elevated load-independent passive left ventricular (LV)-stiffness-constant Beta ($p<0.001$), and a longer time constant of active LV-relaxation τ ($p=0.04$). ECV correlated highly with Beta ($r=0.75$, $p<0.001$). Within the HFpEF cohort, patients with ECV $>$ median showed a higher LV-stiffness-constant ($p=0.05$) whereas ECV $<$ median identified patients with a prolonged active LV-relaxation ($p=0.01$) and a marked hypertensive reaction to exercise due to a pathologic arterial elastance ($p=0.05$). On multiple linear regression analyses, ECV independently predicted intrinsic LV stiffness ($\beta=0.75$; $p<0.01$).

Conclusion: Diffuse myocardial fibrosis, assessed by CMR derived T1-Mapping, independently predicts invasively measured LV stiffness in HFpEF. In addition, ECV helps to non-invasively distinguish the role of passive stiffness and hypertensive exercise response with impaired active relaxation. Thus, ECV facilitates refinement of patients characterization, which is a prerequisite for any successful therapy in the future.

Results for ECV groups and controls

168

Exercise-induced B-lines identify worse functional and prognostic stage in heart failure patients with depressed left ventricular ejection fractionMC Scali¹; L Cortigiani²; A Simioniu¹; M Marzilli¹; E Picano³¹University Hospital of Pisa, Cardio-Thoracic Department, Pisa, Italy; ²San Luca Hospital, Cardiology Division, Lucca, Italy; ³Institute of Clinical Physiology, CNR, Biomedicine Department, National Research Council, Pisa, Italy

Background: Exercise stress echo (ESE) is recommended by latest European Society of Cardiology guidelines for evaluation of heart failure (HF) patients. Recently, lung ultrasound (LUS) has been proposed for dynamic assessment of extravascular lung water through B-lines.

Aim: To assess B-lines during ESE in HF.

Methods: We performed standard transthoracic and LUS evaluation during semi-supine ESE in 103 NYHA class I-III HF patients (76 males; age 64 ± 12 years) with depressed left ventricular ejection fraction ($35 \pm 8\%$). B-lines were measured by scanning 28 intercostal spaces on anterior chest, both at rest and peak stress. Resting plasma BNP levels and exercise capacity during cardiopulmonary testing with peak oxygen uptake (VO_2 max) were assessed in all patients. All patients were followed-up for a median of 8 months (first quartile, 6; third quartile, 11).

Results: LUS was feasible and interpretable in all subjects, with additional scanning time <3 minutes. The overall B-lines number increased from 7 ± 9 (mean \pm SD) at rest to 24 ± 24 at peak stress ($p<0.0001$). The number of stress B-lines was more closely correlated with resting BNP ($r=0.79$, $p<0.0001$) than resting B-lines ($r=0.69$, $p<0.0001$). Stress B-lines were also significantly correlated with stress E/e' ($r=0.22$, $p=0.03$), stress pulmonary artery systolic pressure ($r=0.42$, $p<0.0001$), stress left ventricular ejection fraction ($r=0.86$, $p<0.0001$) and VO_2 max ($r=0.87$, $p<0.0001$). During follow-up, 37 events occurred: 10 cardiac deaths, 22 re-hospitalizations for acute heart failure, 1 sustained ventricular tachycardia, 4 nonfatal myocardial infarctions. Twelve-month event-free survival was 95% in the 36 patients with stress B-lines <30 (best cut-off identified by Receiver Operating Curve analysis) vs. 7% in patients with ≥ 30 B-lines ($p<0.0001$). When only death was considered, survival was 100% vs. 72%, respectively ($p<0.0001$). At multivariable analysis for all spontaneous events, only resting BNP values and stress B-lines (HR 1.04, 95% CI 1.01-1.06, $p=0.004$) were independent prognostic indicators.

Conclusion: B-lines are easy to obtain, frequent in HF patients and often increase during ESE. Exercise-induced B-lines are associated more closely than resting B-lines to higher natriuretic peptides plasma levels. Spontaneous events were more frequent in patients with more B-lines during ESE. LUS expands the information provided by standard transthoracic echocardiography, and might be easily incorporated in ESE for direct imaging of functionally and prognostically meaningful extra-vascular lung water accumulation.

4D flow cardiovascular magnetic resonance parameters represent novel imaging biomarkers in heart failure and correlate with conventional prognostic remodelling parameters and myocardial energetics

Dr V. Stoll was funded by the British Heart Foundation (Ref FS/12/14/29354).

V. Stoll¹; A. Hess¹; J. Eriksson²; C. Rodgers¹; W. Clarke¹; P. Dwyerfeldt²;T. Ebbers²; S. Myerson¹; C. J. Carlhall²; S. Neubauer¹

¹University of Oxford, OCMR, Oxford, United Kingdom; ²Linköping University, Division of Cardiovascular Medicine, Linköping, Sweden

Introduction: Cardiac remodelling is initiated by a myocardial insult and causes progression to heart failure. Insights into multidimensional flow patterns and kinetic energy within the left ventricle (LV) are now afforded by the use of 4D flow MRI.

Purpose: We hypothesised that in heart failure derangements in 4D flow measures would relate to decreased mechanical function, increased biochemical remodelling markers, worsening symptoms, including reduced exercise capacity and impaired myocardial energetics.

Methods: 34 dilated cardiomyopathy (DCM) patients, 30 ischaemic cardiomyopathy (IHD) patients and 36 controls underwent cardiovascular 4D flow MRI. The LV volume was analysed as functional flow components including the direct flow (LV inflow that passes directly to ejection), and the residual volume (resides within the LV for >2 cardiac cycles). The kinetic energy (KE) was measured throughout the cardiac cycle. Assessment of functional capacity (6 minute walk test), biochemical remodelling (B-Type Natriuretic peptide) and patient symptoms was additionally performed. A subgroup of 25 DCM patients and 10 controls underwent phosphorus spectroscopy for quantification of myocardial energetics.

Results: DCM and IHD patients demonstrated adverse cardiac remodelling with ventricular dilatation, and impaired systolic function (DCM LVEF $36 \pm 11\%$, IHD LVEF 39 ± 12 , control LVEF $67 \pm 4\%$). Both patient groups had reduced direct flow proportion (DCM $11 \pm 6\%$, IHD $14 \pm 9\%$, control $38 \pm 4\%$, $P < 0.0001$) and KE (DCM and IHD 59% decrease in average kinetic power compared to controls, $P < 0.0001$); whilst residual volume proportion (DCM $51 \pm 11\%$, IHD $49 \pm 10\%$ and controls $30 \pm 4\%$) and KE values were increased (DCM by fivefold, IHD by fourfold compared to controls, $P < 0.0001$). Both direct flow KE and residual volume KE correlated, though in opposite directions, with left ventricular end diastolic and systolic volumes, systolic function, BNP, functional capacity and symptoms (All P values < 0.0001). In a multiple linear regression model the average kinetic power of the direct flow was predictive of the patient's 6 minute walk test result ($\beta = 0.279$, $P = 0.039$, overall model $R^2 = 0.464$, $P = 0.003$), whereas LV EF was not. DCM patients had impaired myocardial energetics compared to controls (PCr/ATP 1.54 ± 0.38 DCM vs 1.95 ± 0.25 control, $P = 0.004$). The PCr/ATP ratio correlated with the proportion of the direct flow ($r = 0.415$, $P = 0.013$) and the KE of the residual volume ($r = -0.52$, $P = 0.001$).

Conclusions: Heart failure patients demonstrated less efficient blood flow patterns with deranged kinetic energy profiles compared to controls. The greater the derangement of 4D flow parameters the worse the conventional markers of cardiac remodelling, patient symptoms and myocardial energetics. 4D flow parameters represent a novel biomarker of disease severity and may provide additive value in monitoring novel heart failure therapies and predicting prognosis.

Relative prognostic importance of longitudinal strain of right ventricle and tricuspid annular plane systolic excursion in systolic heart failure

C Riccini¹; E Erberto Carluccio¹; P Biagioli¹; G Bardelli¹; R Laucello¹; A D'antonio¹; MF Cerasa¹; A Mengoni¹; G Alunni¹; G Ambrosio¹

¹Division of Cardiology, University of Perugia, Perugia, Italy

Background: Right ventricular (RV) systolic dysfunction, either assessed by tricuspid annular plane systolic excursion (TAPSE) or longitudinal 2D-strain of the RV free wall (RVFWS), is a strong prognostic predictor in chronic heart failure (HF). However, the relative prognostic importance of these two parameters is not known. In particular, it is not clear whether assessment of RVFWS could provide additive prognostic informations over TAPSE.

Methods and Results: We prospectively enrolled 150 stable HF patients (age 65 ± 11 months; mean EF $29 \pm 7\%$). RV function was assessed using standard and Speckle Tracking echocardiography to measure both TAPSE and 2D longitudinal strain of the RV free wall. Patients were followed-up for a median time of 13 months (IQR 5-30). Cox regression hazard model was used to assess association of clinical and echocardiographic parameters with the composite end-point of all-cause death/HF re-hospitalization. In the whole population, mean value of TAPSE was 19.7 ± 4.5 mm, and mean value of RVFWS was $-18.4 \pm 6.2\%$. During the follow-up, 42 patients experienced the primary outcome. By Cox analysis, both TAPSE < 16 mm, and RVFWS $> -15\%$ were independently associated with outcome. Figure A and B respectively show the adjusted prediction and the event-rate (per 100 pts/year) when patients were grouped by TAPSE and RVFWS. As shown, the relative contribution of RVFWS in predicting prognosis increases in the presence of progressively low values of TAPSE. Patients with normal TAPSE but impaired RVFW had worse outcome than patients with normal RVFWS ($p < 0.05$).

Conclusions: Right ventricular longitudinal 2D-strain of the RV free wall seems to have additive prognostic value over TAPSE, mainly in patients in whom TAPSE is impaired.

171

Extracellular volume is an independent predictor of outcome in heart failure with preserved ejection fraction

F Franz Duca¹; A Kammerlander¹; C Zotter-Tufaro¹; S Aschauer¹; D Bonderman¹; J Mascherbauer¹

¹Medical University of Vienna, Cardiology, Vienna, Austria

Background: Cardiac magnetic resonance (CMR) T1 mapping allows accurate non-invasive quantification of extracellular matrix volume (ECV). Accumulation of extracellular matrix (ECM) is a key pathophysiological mechanism in heart failure with preserved ejection fraction (HFpEF). However, the prognostic relevance and hemodynamic consequences of CMR-ECV in HFpEF are unknown.

Purpose: We aimed to elucidate the influence of ECV on the outcome in HFpEF and hemodynamic parameters.

Methods: Between January 2011 and August 2015 we prospectively enrolled 108 HFpEF patients. All patients underwent CMR T1 mapping for ECV measurement, using the Modified Look-Locker Inversion recovery (MOLLI) sequence. Furthermore, we investigated the influence of ECV on invasively assessed hemodynamic parameters.

Results: The study cohort was prospectively followed for up to three years, during which 33 (30.6%) had a cardiac event (hospitalization and/or death for cardiac reason). Patients in the event group had higher NT-proBNP levels ($p = 0.001$), shorter 6 minute walking distance ($p = 0.014$), were more often in NYHA class III or IV and smoked more frequently ($p = 0.010$). With regards to CMR data, ECV ($p = 0.006$) and right ventricular end-diastolic volume (RVEDV) were higher in the event group. Among clinical parameters NT-proBNP ($p = 0.001$), 6 minute walking distance ($p = 0.004$), NYHA class III or IV ($p = 0.005$) and smoking ($p = 0.015$) were associated with adverse outcome by univariable Cox analysis. CMR parameters predictive of adverse outcome in univariable analysis were ECV ($p = 0.003$), RVEDV ($p = 0.017$) and left ventricular end-diastolic volume ($p = 0.044$). By multivariable Cox analysis only NYHA class III or IV ($p = 0.015$) and NT-proBNP ($p = 0.026$) remained as predictors of outcome among clinical parameters. ECV ($p = 0.039$) and RVEDV ($p = 0.041$) were independent predictors of cardiac events among CMR parameters. ECV significantly correlated with clinical, CMR and hemodynamic parameters: 6MWD ($R = -0.272$, $p = 0.006$), NYHA class ($R = 0.220$, $p = 0.023$), NT-proBNP ($R = 0.362$, $p < 0.001$), right atrial volume ($P = 0.299$, $p = 0.002$), mean right atrial pressure ($P = 0.246$, $p = 0.020$), SvO₂ ($P = -0.241$, $p = 0.023$) and stroke index ($P = -0.234$, $p = 0.030$).

Conclusions: CMR-ECV independently predicts outcome in HFpEF and is correlated with severity of symptoms as well as exercise capacity. Reduction of ECV may therefore be a promising therapeutic target.

Kaplan Meier Curves for ECV

172

Comparison between global strain of right ventricle by 2-D speckle tracking (RVGS) and longitudinal strain of free lateral wall (RV-fwLS) in predicting prognosis in chronic heart failure patients.

F Monitillo¹; G Citarelli²; MS Lattarulo¹; M Leone¹; V Antoncicchi²; C Rizzo¹; P Terlizze¹; D Grande¹; R Romito³; M Iacoviello⁴

¹University of Bari, School of Cardiology, Bari, Italy; ²San Paolo Hospital, Cardiovascular Department, Bari, Italy; ³Polyclinic Hospital of Bari, Emergency Cardiology Unit, Bari, Italy; ⁴Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

Background: The assessment of right ventricular (RV) function still remains a challenge. Two-dimensional (2-D) speckle tracking has recently been proposed in order to evaluate right ventricular systolic function by analysing myocardial deformation. However, it is not clear if the analysis of RV systolic strain should be limited to RV lateral wall or if it should include septum. The aim of this study was to evaluate the role of two different RV strain measures obtained by 2-D speckle tracking analysis in predicting mortality in a group of patients affected by chronic heart failure (CHF).

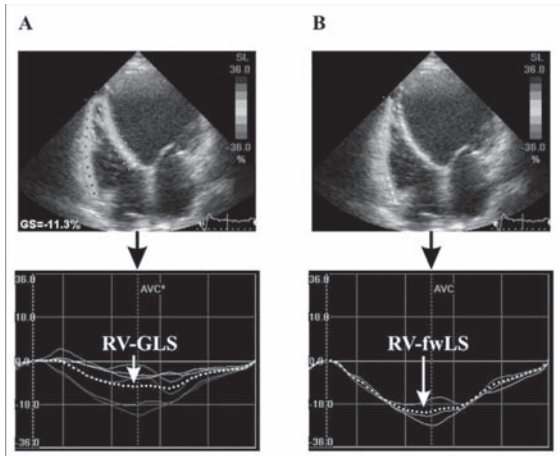

Methods: We enrolled 332 outpatients (76% males, 64 ± 14 years, NYHA class 2.2 ± 0.7 , left ventricular ejection fraction, LVEF, $33 \pm 9\%$) with CHF (ESC criteria), in stable clinical conditions (> 1 month) and in conventional therapy (86% ACE-inhibitors and/or ARBs, 94% betablockers). By echocardiogram (Echo-PAC, GE) a 4-chamber view (frame rate 50-70/sec) was obtained in order to evaluate by 2-D speckle tracking global strain of right ventricle by 2-D speckle tracking (RVGS) and the longitudinal strain of free lateral wall (RV-fwLS). Figure shows in panel "a" the assessment of RV-GLS; in panel "b" the assessment of RV free wall longitudinal strain (RV-fwLS).

Results: During follow-up (36 ± 26 months), 72 patients died (62 for cardiovascular causes and 10 for non cardiovascular causes). Thirteen patients underwent heart transplantation. As shown in the table, at univariate analysis both RV-GLS and RV-fwLS were associated with all cause mortality, but RV-GLS showed a slight greater value of C-index. At multivariate Cox regression analysis, both RV-GLS and RV-fwLS remained associated with events in a model including age, NYHA class, LVEF. AUC of ROC curve for the 12 months occurrence of death of RV-GLS (0.81; 95%CI: 0.72-0.91) was greater than that of RV-fwLS (0.75; 95%CI: 0.65-0.85), but the difference was not statistically significant ($p: 0.088$).

Conclusions: Our findings demonstrate that RV-fwLS and RV-GLS can be similarly used in order to stratify patients' prognosis, although RV-GLS seems to have a slight greater prognostic power. These data strengthen the clinical usefulness of this echocardiographic approach in daily management of CHF outpatients.

Variable	Univariate analysis		Multivariate analysis*		
	HR(95%CI)	p	C-index	HR (95%CI)	p C-index
RV-GLS	1.20 (1.14-1.27)	<0.001	0.73	1.10 (1.03-1.19)	0.005 0.86
RV-fwLS	1.12 (1.07-1.16)	<0.001	0.70	1.06 (1.02-1.11)	0.005 0.86

*Multivariate models included separately right ventricular systolic function parameters due to collinearity.

Tissue doppler indexes of diastolic function predict outcome in primary care outpatients

No sources of financial support

C Mazzone¹; S Nistri²; A Di Lenarda¹; G Barbati¹; P Gentile¹; P Ballo³; E Casanova Borca¹; G Cioffi⁴; G Faganelli¹; A Cherubini¹

¹Cardiovascular Center A.A.S. 1 of Trieste, Trieste, Italy; ²CMSR Veneto Medica, Altavilla Vicentina, Italy; ³Santa Maria Annunziata Hospital, Cardiology Unit, Florence, Italy; ⁴Villa Bianca Hospital, Department of Cardiology, Trento, Italy

Background: Diastolic dysfunction (DD) provides prognostic information in the general population and has been associated with development of heart failure (HF), increased all-cause and cardiovascular mortality and reduced quality of life. The prognostic relevance of DD detected by Doppler echocardiography in asymptomatic individuals with normal left ventricular (LV) ejection fraction in primary care is unresolved.

Purpose: To explore if DD portends independent prognostic information in asymptomatic patients (pt) without normal LV function, in an outpatient clinic.

Methods: We performed a retrospective study of clinical and echocardiographic records of pt referred to the Cardiovascular Center of Trieste, between November 2009 and October 2014. Inclusion criteria were age > 50 years, sinus rhythm, absence of previous HF, LV ejection fraction $\geq 50\%$, no atrial fibrillation or pacemaker, no significant valvular heart disease or prosthesis. The endpoint (EP) was a composite of all-cause mortality and hospital admission for cardiovascular (CV) causes. Diastolic function was assessed by analyzing DTI-derived indices, namely E/e' and e', divided in tertiles estimated in our population. Multivariable Cox regression was applied to evaluate predictors of outcome and Kaplan Meier survival curves were estimated; the Net Reclassification Index (NRI) and the median improvement in risk score for censored data were also computed when adding e' tertiles to standard predictors.

Results: 2628pt were included. 52.8% were male, median age 71 years (IQR 63-77), 71% with hypertension, 27% with diabetes, 33% with coronary artery disease and 16% with stroke/TIA. E/e' was ≤ 8.33 in 35%, 8.34-11.33 in 32%, > 11.33 in 33%; e' was ≤ 6 cm/s in 40%, 6.01-8 cm/s in 33%, > 8 cm/s in 27%. During 26 ± 17 months the EP occurred in 392pt: 114(4.3%) deaths and 304(12%) CV hospitalizations. E/e' showed a correlation with EP, from 11.6% in E/e' ≤ 8.33 to 15.3% in 8.34-11.33 and 18% in E/e' > 11.33 (Log rank $p < 0.02$ vs E/e' ≤ 8.33). The event free survival at 36 months in the E/e' tertiles were 87% vs 82% vs 78%. E' was related to an increased risk of the EP, ranging from 9.7% in e' ≥ 8 cm/s, 14% in 6.01-8 cm/s and 19.1% in e' ≤ 6 cm/s (Log rank $p < 0.01$ for all contrasts). The event free survival in the e' tertiles were 88% vs 84% vs 77%. After adjustment for clinical and echocardiographic confounders, only e' remained an independent predictor of EP (HR 0.68, 95% CI 0.49-0.94, $p = 0.02$), while E/e' was no longer significant. A borderline significant value of NRI was found, taking into account the events within 36 months from the visit ('average' NRI = 0.10, 95% CI 0.002-0.203, $p = 0.053$) and a significant median improvement in the risk score was also observed (0.007, 95% CI 0.001-0.014, $p = 0.013$).

Conclusions: In a large outpatient population without HF, different e' tertiles significantly predict the EP, adjunctively to clinical, therapeutic and echocardiographic variables.

Atrial strain analysis and quality of life of heart failure patients

M Cameli¹; F Loiacono¹; E Iardino¹; S Sparla¹; GE Mandoli¹; E Incampo¹; FM Righini¹; S Mondillo¹

¹University of Siena, Department of Cardiovascular Diseases, Siena, Italy

Background: One of the most important keypoint in the analysis of the patients with heart failure is the relationship between instrumental data and quality of life. The Minnesota Living with Heart Failure Questionnaire (MLHFQ) is a disease-specific measure of health-related quality of life. The aim of this study was to evaluate the relationship between noninvasive LV and LA analysis and MLHFQ score in patients with HF and reduced ejection fraction.

Methods: 235 consecutive ambulatory heart failure patients with reduced LV ejection fraction ($< 50\%$) were studied. Patients underwent clinical and echocardiographic examination, both standard transthoracic echocardiography (TTE) and speckle tracking echocardiography (STE) and were asked to perform the MLHFQ. Results Patients were in NYHA Class I (24%), NYHA class II (45%) and NYHA class III (31%). The mean LV ejection fraction was $(41.5 \pm 9.8\%)$. Strong correlations were obtained between global LA strain and MLHFQ Score ($r = -0.83$ $p < 0.0001$) and NYHA Class ($r = -0.74$ $p < 0.0001$). Poorer correlations were found between MLHFQ Score and LV ejection fraction ($r = -0.31$; $p = 0.05$), LV global longitudinal strain ($r = -0.28$; $P = ns$). Not significant correlation with MLHFQ score was found for LA indexed volume ($r = 0.19$; $P = ns$) and E/E' ratio ($r = 0.09$ $P = ns$). In multivariate analysis, global LA strain emerged as a determinant of MLHFQ Score, independent on other confounding factors.

Conclusions: LA function analysis by STE appears to be a mirror of patients symptoms and quality of life in patients with heart failure and reduced LV ejection fraction.

175

Prognostic value of left atrial structure and function in patients with heart failure. A report from SICA-HF study (FP7/2007-2013/ 241558)

L Luca Monzo¹; P Pellicori²; A Bennet²; P Putzu²; C Gaudio¹; AL Clark²; JGF Cleland³

¹Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrological, Anesthesiological, and Geriatric Sciences, Rome, Italy; ²Castle Hill Hospital, Department of Academic Cardiology, Hull, United Kingdom; ³Imperial College London, National Heart and Lung Institute, London, United Kingdom

Background: Left atrial (LA) dilatation is an established marker of adverse outcome in patients with heart failure (HF), but the prognostic utility of left atrial function assessed by transthoracic echocardiography is still unclear.

Methods: Ambulatory patients with HF and control subjects enrolled in the SICA-HF study were assessed if they were in sinus rhythm. Left atrial emptying function (LAEF) was measured as [(maximal LA volume-minimum LA volume)/maximal LA volume] *100.

Results: Of 500 patients, 341 fulfilled the criteria for HF; 49% had left ventricular ejection fraction (LVEF) <40% and 51% had LVEF >40%. Compared to controls, patients with HF were younger (69 ± 11 vs 71 ± 9 years, $p=0.04$) and had lower LAEF ($50 \pm 14\%$ vs $62 \pm 11\%$, $p<0.01$). Compared to patients in the higher tertiles of LAEF, those in the lowest tertile (worst LAEF) had more severe symptoms, higher jugular venous pressure, higher plasma NTproBNP (1100 (410-2838) vs 452 (214-1192) and 444 (211-907)ng/L, respectively, $p<0.001$) and lower LVEF (39 ± 14 vs 43 ± 11 vs $44 \pm 12\%$ respectively, $p=0.02$). Log[LAEF] and log[NTproBNP] were inversely correlated ($r -0.33$, $p<0.001$). During a median follow-up of 943 (IQR 604-1229) days, 84 patients (25%) with HF died or were hospitalised for HF. LA structure and function were associated with this outcome in univariable analysis. However, only worse symptoms and increasing age, NTproBNP and inferior vena cava diameter independently predicted adverse prognosis.

Conclusions: In ambulatory patients with HF and in sinus rhythm, LAEF measured by echocardiography is associated with an adverse outcome but in multivariable analyses adds little prognostic information to biochemical or other echocardiographic measures of congestion.

Kaplan-Meier curves for primary EP

Diffuse myocardial fibrosis of non-infarcted myocardium correlate with biomarkers of cardiac stretch and remodeling in patients with heart failure

WC Meijers¹; TM Gorter¹; AR Van Der Velde¹; MHL Van Der Wal¹; A Koops¹; J Warink - Riemersma¹; KS Van Dijk¹; TP Willems¹; DJ Van Veldhuisen¹; RA De Boer¹

¹University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands

Purpose: Biomarkers are commonly used in heart failure (HF) for risk stratification but it has been debated if they reflect cardiac remodeling. Myocardial fibrosis plays a role in (pathological) cardiac remodeling, and can be assessed by cardiac magnetic resonance imaging (MRI). We examined whether circulating biomarkers are associated with MRI-assessed myocardial fibrosis, i.e either to myocardial scarring (measured by late gadolinium enhancement, LGE) and/or diffuse myocardial fibrosis (measured by T1 time).

Methods: In a tertiary referral academic hospital, we routinely measured galectin-3 (whenever NT-proBNP was assessed) and included patients in this study if they also underwent a cardiac MRI with administration of gadolinium ($n=129$). All MRI studies were performed on a 1.5-T scanner. Focal myocardial scar, usually a myocardial infarction, was assessed by LGE. Subsequently, diffuse ("interstitial") myocardial fibrosis of the non-infarcted myocardium was quantified by the myocardial post-contrast T1 time, using a cine Look-Locker sequence. Patients were categorized based upon the presence or absence of LGE, and by the median of the post-contrast T1 time (shorter T1 times reflect increased interstitial fibrosis).

Results: Mean age of the 129 patients was $58 (\pm 14)$ years, 55% of the patients were male, and mean LVEF was $37\% (\pm 14)$. NT-proBNP levels were higher in the LGE positive patients compared to the LGE negative patients (1155pg/mL vs. 484pg/mL , $p=0.007$), whereas LVEF was not (34% vs. 37% , $p=0.62$). In the LGE positive patients ($n=52$) both NT-proBNP and galectin-3 were significantly higher in subjects with short T1-time, when compared to patients with long T1-time, reflecting the presence of diffuse myocardial fibrosis (NT-proBNP: 1186pg/mL vs. 469pg/mL , $p=0.026$; galectin-3: 20ng/mL vs. 15ng/mL , $p=0.004$). On the other hand, in the LGE negative patients ($n=77$), no relations between NT-proBNP, galectin-3 and T1 time were observed, which could implicate that these biomarkers reflect active remodeling of the non-infarcted tissue of patients with a scar.

Conclusion: In HF patients with an old myocardial infarction and a scar on MRI, significantly elevated NT-proBNP and galectin-3, markers of cardiac stretch and remodeling, are observed in those who have diffuse myocardial fibrosis of the non-infarcted myocardium, suggesting ongoing adverse pathological remodeling.

Utility of cardiovascular magnetic resonance imaging in heart failure with preserved ejection fraction for diagnostic and prognostic evaluation

NIHR Comprehensive Local Research Network and the NIHR Leicester Cardiovascular Biomedical Research Unit.

P Prathap Kanagala¹; ASH Cheng²; J McAdam¹; AM Marsh¹; IB Squire¹; LL Ng¹; GP Mccann¹

¹NIHR Biomedical Research Unit in Cardiovascular Disease, Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom;

²Kettering General Hospital, Kettering, United Kingdom

Background: Heart failure with preserved ejection fraction (HFPEF) is poorly characterised, confers poor prognosis and definitive therapies are lacking. Transthoracic echocardiography (TTE) currently remains the primary imaging choice in HFPEF. Purpose We aimed to evaluate the diagnostic and prognostic utility of cardiovascular magnetic resonance imaging (CMR) in HFPEF.

Methods: Patients were recruited as part of Developing Imaging And plasma biomarkers in Describing-HFPEF (DIAMOND-HFPEF): a prospective, single-centre study. Inclusion criteria were: clinical or radiographic evidence of heart failure (HF)

characteristics of patients

	No definite evidence of HF (159)	Evidence of HF (341)	p value	LAEF4C tertile 1 (114)	LAEF4C tertile 2 (114)	LAEF4C tertile 3 (113)	p value

Abbreviations: HF: Heart Failure; LAEF: Left Atrial Ejection Fraction; LAV - Left Atrial Volume; LVEF - Left Ventricular Ejection Fraction; NT-proBNP - N-terminal B-type natriuretic peptide; IHD - Ischemic Heart Disease.

and ejection fraction >50% on TTE. Exclusion criteria were: myocardial infarction (MI) in the preceding 6 months, suspected or confirmed cardiomyopathy, constrictive pericarditis, non-cardiovascular life expectancy <6 months and severe valve/ lung/ renal disease. The CMR protocol comprised cine, adenosine stress/rest perfusion and late gadolinium enhancement imaging on a 3-Tesla scanner. Both TTE & CMR were performed during the index study visit and reported independently. Follow-up outcome data was collected at a minimum of 6 months post-enrollment for the composite endpoint (death and/or re-hospitalisation with HF). Results 154 patients (mean age 72.4 ± 10.0 years, 51% Male) underwent both CMR and TTE. The following previously unknown diagnoses were identified by CMR: significant coronary artery disease ($n=20$, including 14 with 'silent' MI), hypertrophic cardiomyopathy ($n=10$) and constrictive pericarditis ($n=5$). During follow-up (median = 623 days, interquartile range 455 – 753), there were 53 primary outcome events. Kaplan-Meier survival analysis (see Figure 1) revealed worse outcomes in the 'new diagnoses group' (Log Rank test $p=0.046$). In a multivariate Cox Regression model comprising significant independent predictors during univariate analysis (diastolic blood pressure, NYHA class, urea and log BNP), only the 'new diagnoses group' (hazard ratio [HR]: 1.999; 95% confidence interval [CI]: 1.078 to 3.709; $p=0.028$) and urea (HR: 1.068; CI: 1.000 to 1.141; $p=0.049$) were significant predictors of outcomes.

Conclusions: In HFrEF, CMR identifies previously unknown pathologies in a significant proportion. This group of 'new diagnoses' is associated with worse outcomes and is an independent predictor of death and/or re-hospitalisation with HF.

Singapore; ³National University Heart Centre, Singapore, Singapore; ⁴Tan Tock

Seng Hospital, Singapore, Singapore; ⁵Singapore General Hospital, Singapore,

Singapore; ⁶Changi General Hospital, Singapore, Singapore; ⁷National University

Health System, Singapore, Singapore

Background: Right ventricular (RV) dysfunction is recognized as a major pathophysiological factor in heart failure (HF). However, the relative contribution of RV dysfunction in preserved versus reduced ejection fraction HF (HFpEF vs HFrEF) is unclear.

Methods: Echocardiographic speckle tracking was used to determine global longitudinal RV strain, along with tricuspid annular plane systolic excursion (TAPSE) in HFpEF (EF ≥ 50%; $n=219$), HFrEF (EF < 50%; $n=219$) and controls without HF ($n=219$), all recruited in a prospective longitudinal population-based study and followed for the composite outcome all-cause death and HF hospitalization (174 events over a median of 2 years).

Results: Across groups from controls to HFpEF to HFrEF, both RV strain and TAPSE decreased (figure; all $p < 0.001$). LV strain similarly decreased across groups. These differences remained significant after adjusting for clinical covariates, E/e' ratio, LVEF, pulmonary artery systolic pressure (PASP) and NT-proBNP ($p < 0.001$). With increasing PASP, TAPSE, and to a lesser extent RV strain, increased in controls and HFpEF, but decreased in HFrEF. In patients with HF, TAPSE, but not RV strain, was related to outcomes ($p=0.018$), regardless of HF group (Pinteraction = 0.488), and even after multivariable adjustment (adjusted $p=0.035$).

Conclusion: RV dysfunction parallels LV dysfunction in HFpEF and HFrEF, suggesting a concomitant myocardial process involving both ventricles. Right-sided arterioventricular coupling is preserved in HFpEF but reduced in HFrEF. The potent impact of TAPSE on outcomes, independent of LV dysfunction, suggests that RV dysfunction may be a pathophysiologic target in HF regardless of EF.

TAPSE, RV strain and LV strain

179

Congenitally Unguarded Tricuspid Orifice Presenting as Heart Failure in Adults

JC Jagdish Mohan¹; V Agrawal²

¹Fortis Hospital, New Delhi, India, Cardiology, New Delhi, India; ²Medanta Heart Institute, The Mediciti, Cardiology, Gurgaon, India

Background: Congenitally unguarded tricuspid orifice (CUTO) with patent right ventricular outflow, a rare form of extreme tricuspid valve dysplasia, is reported in fetuses and in neonates. Very few survive to adulthood. However CUTO is not so rare in adult life and several patients survive to middle age and present with right heart failure, atrial fibrillation or portal hypertension secondary to cardiac cirrhosis. Such cases need to be differentiated from unguarded tricuspid orifice caused by carcinoid disease, infective endocarditis and traumatic tricuspid regurgitation. Purpose. The purpose of this study is to report demographics of CUTO in adult life, their clinical and echocardiographic features, management and follow-up.

Methods: Echocardiography enables accurate evaluation of the morphology and function of valve leaflets, chordae tendineae, and papillary muscle. CUTO has been defined as severe low-pressure tricuspid regurgitation due to a large regurgitant orifice secondary to absent or rudimentary tricuspid valve leaflets and subvalvar apparatus. This report describes 18 adult patients of CUTO observed over year 2000-2015, their clinical and echocardiographic features, management and follow-up.

Results: Over a period of 15 years, 18 adult patients (age 18-57 years, 6 females) met the criteria of an unguarded tricuspid valve. All presented with right heart failure of variable duration with massively dilated right ventricular outflow tract, dilated and severely hypokinetic right ventricle and right atrium without evidence of infective endocarditis, carcinoid disease or trauma. Atrial fibrillation was present in five and two patients had right atrial thrombi. Two patients underwent tricuspid valve replacement and three underwent Fontan operation. None showed any improvement in symptoms.

Conclusion: Dysplasia of the tricuspid valve is probably the most common cause of isolated tricuspid regurgitation and the unguarded tricuspid orifice is its most extreme form. Because of the poor right ventricular contractile function, the pulmonary circulation is maintained by the pumping action of the right atrium or the outflow tract. Some such patients survive into adulthood, present with refractory right heart failure and present therapeutic dilemma.

180

Clinical predictors and prognostic significance of right ventricular dysfunction in systolic heart failure

G Gianluca Mirizzi¹; A Giannoni²; V Chubuchny²; C Taddei²; E Pasanisi²; R Poletti²; A Barison²; C Passino²; M Emdin²

¹Sant'Anna School of Advanced Studies, Pisa, Italy; ²Gabriele Monasterio Foundation, Department of Cardiovascular Medicine, Pisa, Italy

Background: Right ventricular (RV) dysfunction is an acknowledged determinant of clinical deterioration and worse prognosis in systolic heart failure (HF). Little is known about clinical and neurohormonal features of this subgroup of patients. Aim of this study was then the clinical, neurohormonal and prognostic evaluation of HF patients with RV dysfunction.

Methods: the study evaluated patients with systolic HF (left ventricular ejection fraction [LVEF] < 50%) on guideline directed medical therapy. All patients received a comprehensive clinical evaluation, including assessment of plasma renin activity (PRA), aldosterone, N-terminal pro-brain natriuretic peptides (NT-proBNP) and norepinephrine. All patients underwent transthoracic echocardiography; only patients with a comprehensive RV morphology and function (with evaluation of tricuspid annular plane systolic excursion [TAPSE], Doppler tissue imaging [DTI] of tricuspid

lateral annular systolic velocity [S']) were included. RV dysfunction was defined as TAPSE <17 mm or S' <9.5 cm/sec. Follow-up evaluated cardiac mortality as endpoint.

Results: three-hundred and fifty patients met inclusion criteria (LVEF $34 \pm 9\%$, mean \pm SD, age 66 ± 13 years, NYHA class III-IV 29%, beta-blockers 96%, angiotensin converting enzyme inhibitors [ACEI] or angiotensin receptor blockers [ARB] 92%, mineralocorticoid receptor antagonists 71%; 7% implantable cardioverter defibrillator [ICD], 18% resynchronization therapy with ICD). RV dimension was 28 ± 4 mm (parasternal long axis view); mean TAPSE was 19 ± 5 mm, S' 11 ± 3 cm/sec, pulmonary artery systolic pressure (PAPs) 40 ± 11 mmHg. RV dysfunction was present in 95 patients (27%; TAPSE 11 ± 3 mm, S' 7.6 ± 1.1 cm/sec, RV diameter 29 ± 5 , PAPs 41 ± 12 mmHg). They were older (69 ± 12 vs 66 ± 13 years, $p < 0.05$) and less frequently in ACEI/ARB therapy (96% vs 86%, $p < 0.05$); they had worse LV dysfunction (LVEF 31 ± 9 vs 35 ± 9 , $p < 0.05$), increased LV end-diastolic pressure (E-wave/e' wave ratio at DTI 16 ± 7 vs. 13 ± 6 , $p < 0.05$) and left atrial volumes (43 ± 12 ml vs. 38 ± 12 ml, $p < 0.05$), increased neurohormonal activation: NT-proBNP: median 2202 ng/L, interquartile range 1082-5362 vs. 956 ng/L, 347-2341, $p < 0.01$, PRA: 0.8 ng/ml/h, 0.2-2.3 vs. 0.5 ng/ml/h, 0.2-1.7, $p < 0.05$; aldosterone: 134 ng/L, 69-200 vs. 99 ng/L, 52-175, $p < 0.05$. At follow-up (28 months, 13-41), 32 cardiac events (23 HF progression, 6 sudden cardiac deaths, 3 myocardial infarction) were recorder. At Kaplan-Meier analysis, RV dysfunction was associated with worse prognosis (log-Rank 6.5, $p = 0.01$). At Cox regression analysis, PRA, NT-proBNP, E/e' and RV dysfunction were predictors of cardiac events. At paired multivariate analysis, RV dysfunction resulted independent predictor of cardiac events.

Conclusions: RV dysfunction occurs in a significant proportion of patients with systolic HF and is associated with neurohormonal activation (renin-angiotensin system and natriuretic peptides); its occurrence is also independently associated with worse prognosis.

181

Prognostic value of myocardial fibrosis assessed by cardiac magnetic resonance in patients with idiopathic dilated cardiomyopathy with left ventricular systolic dysfunction

L Lupi¹; D Farina¹; E Gavazzi¹; M Bonavita¹; E Rocco¹; N Berlinghieri¹; R Maroldi¹; S Nodari¹

¹ University of Brescia, Brescia, Italy

Background: The prognosis of patients (pts) suffering from idiopathic dilated cardiomyopathy (DCM) has improved significantly through the use of the current guidelines for the treatment of heart failure (HF); however in a high proportion of cases, mortality and morbidity remain high. The role of multiple prognostic indicators since the early stage of disease remains limited. The assessment of myocardial fibrosis by cardiac magnetic resonance (CMR) might allow the identification of patients with poor prognosis but its role is still debated.

Purpose: to evaluate the prognostic role of myocardial fibrosis assessed by CMR in patients with DCM and left ventricular systolic dysfunction.

Methods: We enrolled retrospectively pts suffering from DCM with left ventricular ejection fraction (LVEF) $\leq 45\%$ underwent CMR with administration of paramagnetic contrast agent followed at our HF Department from January 2012 to December 2014. We evaluated demographic, laboratoristic, therapeutic and imaging parameters (presence of late gadolinium enhancement (LGE), as indicator of fibrosis, LVEF, right ventricular ejection fraction, ventricular volumes and myocardial mass). The composite endpoint was death from any cause and hospitalization for cardiovascular (CV) causes or HF.

Results: We enrolled 109 pts (68% male, mean age 52 ± 3 years). 54 pts (49%) showed left ventricular LGE. The parameters that were predictive for the composite endpoint at univariate and multivariate analysis were evidenced in Table 1. At multivariate analysis, only the presence of LGE confirmed its prognostic value (HR 8,009; IC 95% 2,504–25,621; $p = 0.0001$).

Conclusions: Myocardial fibrosis is an independent predictor of death and CV and HF hospitalization in pts affected by DCM and may allow early detection of pts at high risk of poor prognosis, needing more aggressive treatment and closer follow-up visits.

Table 1

Univariate	Multivariate		p value	p value
	EVENTS (38, 34%)	NO EVENTS (71, 66%)

Relationship between left ventricular myocardial longitudinal mechanics and in-hospital heart failure in patients with acute myocardial infarction: a two-dimensional speckle-tracking study

KH Batmyagmar¹; CH Surenjav²; B Amarjargal³; Z Lkhagvasuren⁴

¹ The State Third Central Hospital, Coronary Care Unit, Ulaanbaatar, Mongolia;

² Institute of Medical Sciences, Department of Cardiology, Ulaanbaatar, Mongolia;

³ Pharmaceutical Science University of Mongolia, Ulaanbaatar, Mongolia; ⁴ The

State Third Central Hospital, Department of Angiography, Ulaanbaatar, Mongolia

Background: In-hospital heart failure during acute myocardial infarction is associated with adverse outcome. However, data about relationship between left ventricular longitudinal myocardial mechanics and in-hospital heart failure with normal left ventricular ejection fraction in patients with acute myocardial infarction is limited.

Aim of study In this study, we hypothesized that speckle-tracking derived global longitudinal strain parameter is independent associated with in-hospital heart failure.

Material and methods: We prospectively included patients who presented acute myocardial infarction and treated by primary PCI. In-hospital heart failure is defined by Killip class during admission. Multiple logistic regression analysis was used to reveal relationship between left ventricular global longitudinal strain and in-hospital heart failure. Separate multiple logistic regression model constructed for patients with preserved left ventricular ejection fraction (LVEF $\geq 55\%$). The incremental value of global longitudinal strain was tested by assessment of model c-statistics.

Results: A total of 414 patients (mean age 60 ± 13 , 84% male) were included and 93 patients (22.5%) presented in-hospital heart failure. Left ventricular global longitudinal strain (GLS) was significantly impaired in patients with in-hospital heart failure compared patients without in-hospital heart failure (-16.1 ± 3.7 vs. -11.6 ± 3.1 , $p < 0.001$). After adjustment of possible predictor of in-hospital heart failure such as age, clinical, biochemical and echocardiographic parameters, global longitudinal strain was independently associated with in-hospital heart failure (odds ratio 1.32, 95% CI 1.16-1.50, $p < 0.001$). In-hospital heart failure presented in 21 patients with LVEF $\geq 55\%$ and GLS is also significantly impaired in this group (-17.7 ± 3.2 vs. -12.7 ± 2.2 , $p < 0.001$). Separate multiple logistic regression model constructed for this group of patients and global longitudinal strain was still independently associated with in-hospital heart failure. Every 1 unit change of global longitudinal strain is associated with 1.4 fold increased probability of in-hospital heart failure (odds ratio 1.43, 95% CI, 1.31-1.55, $p < 0.001$). Adding global longitudinal strain into model consisting age, clinical, biochemical and echocardiographic parameters associated with increased c-statistics (c-statistic 0.864, 95% CI 0.823-0.905 vs. c-statistic 0.839, 95% CI 0.793-0.885, $p < 0.001$).

Conclusion: Left ventricular global longitudinal strain is independently associated with in-hospital heart failure during acute myocardial infarction. This relationship is still evident for group of patients who had preserved LVEF.

POSTER SESSION 1

Saturday 21 May 2016 8:30–17:30

Location: Poster Area

ACUTE HEART FAILURE

P183

Systolic time intervals (STI) in acute heart failure(AHF) : comparaison between patients with reduced and preserved left ventricular ejection fraction(LVEF)

INES Elidi¹; HBIB Grissa¹; KAOOUTH Beltaief¹; MARIAM Ben Marzouk¹; NOUSSA Azaiez¹; ZIED Ezzina¹; HAMD I Boubaker¹; WAHID Bouida¹; SEMIR Nouria¹
¹fattouma bourguiba hospital, emergency department, monastir, Tunisia

Introduction: The distinction between AHF with reduced or preserved LVEF is essential to the early management of patients in the emergency department (ED).

Objective: To assess the discriminative value of STI measured by horacioimpedance (TBI) in patients admitted for AHF with and without reduced LVEF.

Patients and methods: Prospective study conducted from January 2012 to September 2015 including patients aged more than 18 years old and admitted to the ED for AHF. Reduced LVEF is defined as a LVEF <50 % measured by echocardiography. STI including pre-ejection period (PEP), LV ejection time (LVET) and PEP / LVET ratio are determined by TBI at admission in all included patients (n=398). **Results:** Mean age 68 ± 14 years, sex ratio (M / F) 1.2 ; 62% of patients have a reduced LVEF. Comparison of patients with reduced and preserved LVEF is mentioned in the table. Area under the ROC curve for: PEP, LVET, PEP/LVET ratio were respectively: 0.66, 0.62, 0.7. **Conclusion:** Only PEP/LVET ratio could be considered as a meaningful non invasive method to help differentiating AHF patients with and without reduced LVEF in ED setting.

Mean (SD)	LVEF<50 n=248	LVEF≥50% n=150	p
PEP (seconds)	0.12 (0.01)	0.11 (0.02)	< 0.01
LVET(seconds)	0.27 (0.09)	0.28 (0.07)	< 0.01
PEP/LVET ratio	0.45 (0.1)	0.39 (0.14)	< 0.01

P184

Diagnostic performance of lung ultrasound in the emergency department in the management of acute dyspnea

NIZAR Fredj¹; KAOOUTH Beltaief¹; HBIB Grissa¹; INES Elidi¹; LASSAA Bouraoui¹; ADEL Sekma¹; HAMD I Boubaker¹; WAHID Bouida¹; SEMIR Nouria¹
¹fattouma bourguiba hospital, emergency department, monastir, Tunisia

Objective: To evaluate the performance of lung ultrasound (LUS) in the diagnosis of heart failure (HF) in patients with acute dyspnea.

Methods: Prospective observational study performed in the emergency department including all patients aged over 18 years admitted to the emergency department for acute non-traumatic dyspnea. The diagnosis of acute dyspnea of cardiac origin was based on clinical, laboratory (BNP), cardiac ultrasound and expert opinion. LUS was performed at admission and pulmonary congestion score (PC score) is calculated according to B-lines number (range 0 -80). A PC score > 15 defined the presence of HF.

Results: 78 patients were included in this study. Mean age 69 ± 11 years and sex ratio (M / F) 1.17; HF was demonstrated in 36 (46%) patients. The area under ROC curve of the PC score was 0.81 with sensitivity 91%, specificity 62%, positive predictive value 68% and negative predictive value 89%. **Conclusion:** In patients admitted to the emergency department for acute dyspnea, LUS was a valuable aid in ruling out HF.

P185

Atrial fibrillation stroke and bleeding risk scores can also predict admissions for acute decompensated heart failure

J B Augusto¹; M Borges Santos¹; D Roque¹; M Silva¹; J Castro²; J Sala¹; A Faustino¹; M Branco¹; F Frade¹; C Morais¹

¹Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; ²Hospital de Cascais, Cascais, Portugal

Background: Atrial fibrillation (AF) is a frequent comorbidity in patients with heart failure (HF). There are many tools for prediction of hospital readmission for acute decompensated heart failure (ADHF).

Purpose: We aimed to evaluate the diagnostic value of well-known AF stroke and bleeding risk scores in the prediction of hospital admissions due to ADHF.

Methods: 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period were included retrospectively in our study. Among them, 423 patients were admitted for in-hospital management. All patients underwent routine clinical and laboratory exams. We evaluated medical charts in order to identify patients with ADHF and to calculate each score: AF stroke (CHADS2, CHA2DS2-VASc, ATRIA Stroke) and bleeding (HEMORR(2)HAGES, HAS-BLED, ATRIA Bleeding) risk scores.

Results: 101 patients were admitted with both AF and ADHF (mean age of 77.2 ± 9.6 years, 40.6% males). In receiver-operating characteristic (ROC) analyses (figure) CHADS2 score performed better than other scores in predicting ADHF (CHADS2 – c-index 0.688, p < 0.001; CHA2DS2-VASc – c-index 0.682, p < 0.001; ATRIA Stroke – c-index 0.624, p < 0.001; HEMORR(2)HAGES – c-index 0.617, p < 0.001; ATRIA Bleeding – c-index 0.591, p = 0.006; HAS-BLED – c-index 0.560, p = 0.067). A CHADS2 > 2 has a sensitivity of 71.3% and specificity of 62.3% (negative predictive value = 68.9%, positive predictive value = 65.7%) in prediction of ADHF.

Conclusion: CHADS2 proves an easy and simple tool with modest performance which can predict the risk of admission due to ADHF in patients with AF.

P186

Acute heart failure in the course of a suicide attempt by intoxication with *Taxus baccata* leaves.

M Kobusiak-Prokopowicz¹; A Marciniak¹; S Slusarczyk²; K Sciborski¹; A Stachurska¹; A Matkowski³; A Mysiak¹

¹Wrocław Medical University, Department of Cardiology, Wrocław, Poland;

²Institute of Plant Cultivation and Soil Science, Department of Biochemistry, Pulawy, Poland; ³Wrocław Medical University, 2Department of Pharmaceutical Biology and Botany, Wrocław, Poland

Background: *Taxus* (yew) is one of the most frequently reported plants causing potentially fatal outcome when taken incidentally or for suicidal reasons. A fast and reliable method of detection of poisonous compounds or their metabolites is critical in life-saving procedures in cases of yew ingestion. Previously, several chromatographic analytical procedures have been described usually taking longer than one hour of total analysis time.

Case presentation: In this report we describe a suicide case study and an ad hoc developed fast method of detection and quantitation of 3,5-dimethoxyphenol – the main taxane metabolite in the blood plasma from the patient as well as the determination of major taxane components in the plant material (*Taxus baccata*). At present, there is no reasonable alternative for mass spectrometry that could match its high sensitivity and accuracy, and Multiple Reaction Monitoring could be adequate and useful mass spectrometry technique in analyzing and identification of plants material compounds that cause severe poisoning in humans. In the reported case, intensive cardiac care together with the astuteness of the treating physicians not only saved the patient's life, but also allowed for his complete recovery and return to work.

Conclusion: The developed of ultra fast liquid chromatography tandem mass spectrometry UFLC-MS/MS method provides a fast means to confirm yew alkaloids and their metabolite in various material. The applied analytical procedure allows early detection of main metabolite in patient material as well as comparing to those extracted from the plant. In our study, the taxanes remained undetected, probably due to the time elapsing from the patient admittance and collection of plasma. In cases like reported in this study, retaining the gastric material should be obligatory to confirm the ingestion of yew. The possibility of using this approach in detection of native taxane compounds in human plasma remains to be verified.

P187

Advanced peripheral endothelial dysfunction predicts future cardiovascular events in patients with acute decompensated heart failure

E Eiichi Akiyama¹; H Suzuki¹; Y Matsuzawa¹; C Kawashima¹; M Konishi¹; M Endo¹; K Hibi¹; T Ebina¹; S Umemura²; K Kimura²

¹Yokohama City University, Division of cardiology, Yokohama, Japan; ²Yokohama City University, Department of Medical Science and Cardioresenal Medicine, Yokohama, Japan

Introduction: Early post-discharge rehospitalization and mortality rates in patients with acute decompensated heart failure (ADHF) continue to be high. To achieve the better postdischarge outcomes in patients hospitalized for ADHF, optimizing treatments in the early post-discharge period will require the improvement of risk stratification and patient triage during the compensated condition of HF symptoms. Endothelial dysfunction plays an important role in the pathogenesis of HF. We previously reported that endothelial dysfunction could predict future cardiovascular events in patients with chronic HF with reduced or preserved ejection fraction. However, clinical significance of peripheral endothelial dysfunction in ADHF has not been determined.

Purpose: The purpose of this study was to investigate whether peripheral endothelial dysfunction could predict occurrence of future cardiovascular events in patients with ADHF.

Methods: We conducted a prospective cohort study of 95 patients with ADHF who were referred in a University Medical Center between July 2011 and November 2013 (age: 71 ± 11 years, male: 60%, left ventricular ejection fraction (LVEF): 38 ± 16%). We non-invasively assessed peripheral endothelial function by reactive hyperemia peripheral arterial tonometry (RH-PAT) as RH-PAT index (RHI) in patients with ADHF. ADHF patients were followed until January 2015 or an endpoint occurred. The endpoint was a composite of cardiovascular death, nonfatal myocardial infarction, or HF re-hospitalization)

Results: A total of 40 patients had a cardiovascular event (median follow-up period: 16 months). Kaplan-Meier analysis demonstrated a significantly higher probability of cardiovascular events in the low-RHI group than in the high-RHI group (a cut-off value 0.46, median, log-rank test, $P = 0.05$). Multivariate Cox hazard analysis including LVEF and B-type natriuretic peptide levels on admission identified RHI (hazard ratio 0.40, 95%-confidence interval 0.18-0.89, $P = 0.03$) and serum creatinine levels (hazard ratio 2.46, 95%-confidence interval 1.64-3.68, $P < 0.001$) as independent predictors of the future cardiovascular events.

Conclusions: Peripheral endothelial dysfunction independently correlated with the future cardiovascular events, adding incremental clinical significance for risk stratification in patients with ADHF.

P188

In acute heart failure admissions should a plasma NT-proBNP of 300ng/litre or 400ng/litre be the threshold for ruling out the diagnosis of heart failure

J Draper¹; J Jessica Webb¹; Y Yiu¹; S Piper²; S Kapetanakis¹; R Rajani¹; T McDonagh²; G Carr-White¹

¹St Thomas' Hospital, Cardiology Department, London, United Kingdom; ²King's College Hospital, Cardiology Department, London, United Kingdom

Background: The recently published National Institute of Clinical Excellence (NICE) guidelines on the management of acute heart failure recommended using a plasma NT-proBNP threshold of 300ng/litre to assist in ruling out the diagnosis of heart failure, updating previous guidelines recommending using a threshold of 400ng/litre.

Purpose: We reviewed all the plasma NT-proBNP results in our institution over one year to see how many additional patients with heart failure presented with plasma NT-proBNP 300-399ng/litre. In our hospital all patients presenting with possible heart failure undergo NT –proBNP testing. Those with results above 400ng/l automatically receive an echocardiogram with a dedicated heart failure sonographer, if no study has been done within 6 months, and a heart failure consultant review.

Methods: All consecutive patients who had plasma NTpro-BNP requested between 10/09/2014 and 09/09/2015 were included. Hospital databases and records were used to identify diagnoses, length of stay and inpatient mortality. Outpatient mortality was confirmed using Summary Care Records (follow up range 4 to 16 months). Data was collected as part of our Institution's approved Clinical Audit.

Results: In total, 2135 patients had plasma NTpro-BNP tested between 10/09/2014 and 09/09/2015. 1791 patients had NT-proBNP over 400ng/litre compared to 344 patients with plasma NTpro-BNP under 400 ng/litre, of which 71 patients had results 300-399 ng/litre (3.3%). Two patients represented during the year, and so 69 patients were identified with NT-proBNP 300-399ng/litre.

Of these 69 patients, 4 patients had Heart Failure with preserved ejection fraction (HFpEF), two patients had left ventricular systolic dysfunction (LVSD) and one patient had Right Heart Failure (RHF). Three of these patients had previously been seen in cardiology outpatients and one of the patients with HFpEF had presented 6 months previously with known HFpEF. The average length of stay for the HFpEF patients was 5.5 days (SD 4.7), for the LVSD 13 days (SD 5) and right heart failure 6 days.

None of the patients with HFpEF, LVSD or RHF died. The overall inpatient mortality for patients with plasma NTpro-BNP 300-399ng/litre was 2.9% with outpatient mortality was 12.9%. This is compared to patients with plasma NTpro-BNP >400ng/litre, the inpatient mortality was 8.1% and the outpatient mortality was 25.3%

Conclusions: In our institution, lowering the plasma NTpro-BNP level from 400 to 300ng/litre would have identified 71 new patients compared to 2135 with levels of over 400. In these 71 patients we only identified three new patients with heart failure over the year (4 patients were already known to cardiology). This real world experience would suggest that the recent updated NICE guidelines to lower the plasma NT-proBNP threshold of 300ng/litre to rule out the diagnosis of heart failure will be relatively inefficient if applied on a large scale.

P189

Efficacy of levosimendan after PCI in patients with acute decompensated heart failure and low ejection fraction

I Imad Meray¹; MA Teterina¹; LA Babaeva¹; VV Maiskov¹; VS Moiseev¹

¹Peoples Friendship University of Russia (RPFU), Moscow, Russian Federation

Background: Treatment of patients with acute decompensated heart failure (ADHF) and low ejection fraction is still a field of research. In-hospital death is very high in this group of patients.

Purpose: To examine the efficacy PCI followed by 24 hour infusion of inotropic drug levosimendan in patients with very low left ventricle ejection fraction.

Methods: In our study 12 patients with ADHF and very low left ventricle ejection fraction (< 25%) were included. All patients were with documented coronary artery disease and myocardial infarction in the past. Coronary angiography with PCI was done for all patients and followed by 24 hour infusion of levosimendan. On admission and after 48 hours echocardiography and levels of NT-proBNP were examined.

Results: After 48 hours of treatment in 9 patients ejection fraction improved from 21+/-3.4 to 32+/-4.1% and level of NTproBNP decreased in 8 of these patients from 7643+/-1321 to 5265+/-1018 pg/ml, in one patient NT-proBNP was not changed. In the other 3 patients no any changes in ejection fraction or NT-proBNP were noticed, 2 of these patients died during hospital course. The other patients were discharged from hospital.

Conclusion: PCI followed by 24 hour infusion can be considered as effective strategy in patients with ADHF and very low ejection fraction. More studies are needed in this group of patients.

P190

Effectiveness and safety of ivabradin use in patients with acute ischemic heart failure (AIHF) requiring inotropic supportO Koval¹; A Skoromna²¹Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine; ²Regional Clinical Center of Cardiology and Cardiac Surgery, Dnipropetrovsk, Ukraine

Background: Dobutamine (D) is the most used for inotropic support in AIHF, causes tachycardia that in turn results in decrease of its inotropic effect. Ivabradin (I) in addition to suppression of tachycardia ameliorates calcium metabolism in sarcoplasmic reticulum. Albeit such combination therapy seems to be pathophysiologically relevant, the data are very scarce, and in majority of cases include concomitant therapy with beta-blockers (BB). Aim was to assess the effectiveness and safety of simultaneous use of D and I in patients with AIHF requiring inotropic support.

Material and methods: 20 pts admitted at Dnipropetrovsk regional emergency centre with acute myocardial infarction (MI) and experienced AIHF with sinus rhythm, arterial hypotension (Killip II-III, mean 2.7 ± 0.1) requiring inotropic support during first 24 hrs after admission, despite previous therapy by BB in anamnesis (interrupted at admission in 35%). Pts having cardiogenic shock, ventricular tachycardia/fibrillation (VT/VF), atrial fibrillation (AF), and known severe concomitant pathology were excluded. Investigation was approved by local ethic committee. All patients received standard therapy without reperfusion because of late admission (after 12 hrs, no access to primary PCI) and were subdivided into 2 subgroups: standard therapy with inotropic support (S) – 11 pts and additional ivabradin (I) use: 5 mg/bid with increase dose to 7.5 mg/bid if required (4 pts). Both groups were comparable for gender, age, anterior MI, arterial hypertension, diabetes, prior MI, HF and smoking, initial hemodynamic indexes (APs 114.0 ± 12.8 (S); 98.9 ± 11.8 (I) mmHg); heart rate: 95.6 ± 12.7 (S) 98.9 ± 11.8 b/min (I) and EF $34.5 \pm 5.7\%$ (S) $35.6 \pm 6.2\%$ (I). BB therapy renovated/prescribed after 48 hrs after stabilization and up titrated if required without decrease of I dose.

Results: Heart rate reliably was lower in I group after D infusion despite dose regimen: $5\mu\text{g/kg/min}$ (106.8 ± 15.6 (S) 89.8 ± 10.8 b/min (I); $p=0.05$); $10\mu\text{g/kg/min}$: 108.7 ± 16.7 (S) 84.5 ± 12.6 b/min (I); $p=0.024$); $15\mu\text{g/kg/min}$: 115 ± 14.5 (S) 85.5 ± 10.7 b/min (I); $p=0.0047$). There were no bradycardia episodes in I group, less VT/VF (3, one fatal in S group; 1 – nonfatal in I group with $15\mu\text{g/kg/min}$ D dose). The difference in heart rate frequency remain significant at 7 days despite latter BB inclusion (78.1 ± 7.5 (S) 66.4 ± 8.2 b/min (I); $p=0.05$) and disappeared at discharge (65.4 ± 8.1 (S) 63.5 ± 6.7 b/min (I) group). In both groups there was death, 3 subacute LV aneurysm formation and 7 huge hypokinetic zones in S group, and no aneurysm formation and 5 hypokinetic zones in I group.

Conclusions: In patients with MI and AIHF with sinus rhythm requiring inotropic support with D simultaneous therapy with Ivabradin is safe and effective as for suppression of unwanted tachycardia and for trend of better clinical outcome. In pts, who received I therapy in AIHF period its further constant preservation is recommended.

P191

Ivabradine use in acute heart failure: safety and efficacyI Ilaria Battistoni¹; M Marini¹; L Angelini¹; MV Matassini¹; M Francioni¹; A Gili¹; S Moretti¹; GP Perna¹¹University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy

Background: Despite novel therapies, acute heart failure syndromes (AHFS) with cardiogenic shock (CS) are characterized by poor prognosis. Tachycardia, early compensatory mechanism, in long term increase myocardial oxygen demand, reduce diastolic coronary perfusion, further impairing cardiac performance.

Purpose: to assess clinical and hemodynamic effects of ivabradine in AHFS/CS patients on top of therapy.

Methods: 19 patients (14 M, 61 ± 12 years) with AHFS (53%) and CS (47%), severe LV dysfunction (LVEF $25 \pm 6\%$), requiring inotropic and vasopressor drugs, were treated with Ivabradine 5 mg bid and monitored through clinical and non-invasive echocardiographic hemodynamic evaluation at 24, 48, 72, 120 hours.

Results: Ivabradine administration was associated with reduction in HR (from baseline 103 ± 14 to 77 ± 11 bpm at 120h, $p=0.04$) without negative effects on mean blood pressure (from 68 ± 13 to 70 ± 7 mmHg at 120h, $p=ns$). Cardiac index increased (from 1.8 ± 0.2 to 2.2 ± 0.5 l/min/mq at 120h, $p<0.001$) as stroke volume index (from 20 ± 4 to 30 ± 9 ml $p<0.001$), cardiac stroke index (from 18 ± 9 to 28 ± 14 g/m/m2 at 120h, $p=0.002$) and LVEF (from 25 ± 6 to $30 \pm 9\%$ at 120h, $p<0.001$). No serious side effects ivabradine-related occurred.

Conclusions: Ivabradine administration in AHFS/CS patients is safe and effective leading to assume a future promising use in acute ill patients.

P192

High incidence of anxiety and depression in in-hospital acute heart failure patientsL Surdi¹; MC Murru¹; O Bettinardi²; U Corvi¹; A Verde¹; S Binno¹; GQ Villani¹; M F Massimo Francesco Piepoli¹¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy;²Guglielmo Da Saliceto Hospital, Piacenza, Italy

Introduction: After acute heart failure event, depression has been estimated to have an incidence of around 20%, to increase significantly the risk of cardiac death, hospitalisation and recurrences and poor compliance to treatments. Therefore recent position papers recommend early screening of symptoms of depression to optimise medical therapy and improve secondary prevention. Aim of the study was to investigate the incidence of markers of anxiety and depression in in-hospital patients after acute heart failure events by an appropriate psychometric screening.

Materials and method: All consecutive patients admitted for acute cardiac events during the time interval of June-July 2012 were requested to fill in Questionnaire AD-R (2) for the evaluation of anxiety and depression. The study population included 254 consecutive patients (mean age 62 ± 12 years, 77% male), hospitalised for heart failure secondary to acute coronary syndrome (60%), valve disease (11%), arrhythmic event (19%).

Results: The percentages of patients with score above the clinical cut-off were 41% for anxiety (STAI-X3) and 25% for depression (QD-R). The percentages of critical answers to questions "Life is worth living" and "Sometime I wish I were dead" were 2.5% e 8.5% respectively. The presence of anxiety and depression was associated with prolonged hospitalisation (11 ± 3 days vs 9 ± 3 days), and early (1 month) hospital readmission (19% vs 15%) ($P < 0.05$).

Conclusions: The results confirm the importance of the screening for anxiety and depression among heart failure patients and the need to develop adequate strategies of intervention and therapy.

P193

Nursing management of acute heart failure: applying the GRADE system to adapting heart failure guidelines for nursing care

China Medical Board (no. 04-797)

X Xiaofeng Kang¹; Z Li¹; C Hummelfard²; J Zhang³; Q Li³; R Lv³; F Zhang¹¹Peking Union Medical College, Beijing, China People's Republic of; ²Johns Hopkins University of Baltimore, Baltimore, United States of America; ³Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China People's Republic of

Background: Nurses are key healthcare professionals to provide immediate care of someone who is acutely unwell as a result of heart failure. There has been an increase in the development of clinical practice guidelines (CPGs) to improve standards of care, and yet there are no evidence-based practice guidelines developed for nurses in managing acute heart failure (HF).

Objective: The purpose of this study was to rate the quality of evidence based on the GRADE system for adapting generally available HF clinical practice guidelines to nursing.

Methods: The databases of Cochrane Library, PubMed, EMBase, SinoMed, CNKI, WanFang and the websites of SIGN, NICE, NGC and so on, were retrieved for systematic review of existing evidence. The quality of all guidelines was critically appraised using the Appraisal of Guidelines for Research and Evaluation II instrument (AGREE II). Clinical Recommendations were analyzed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach. All relevant recommendations for management of acute heart failure that nurses can undertake were synthesized.

Results: Ten pertinent clinical questions were articulated by panel of experts. Eight evidence-based guidelines with recommendations concerning acute heart failure were included. They were AHA/ACCF 2013, ESC 2012, NICE 2014, SIGN 2007, NHFA 2011, CCS 2013, HFSA 2010, China 2014. Twenty-five recommendations were identified, which were divided into 5 groups (assessment, intervention, medication, education, and document).

Conclusions: The format and methodology of the Clinical Guidelines have changed over time. This critical appraisal can assist Chinese nurses to adapt evidence-based clinical practice guidelines to improve outcomes in managing acute heart failure.

Nutritional intervention in malnourished hospitalized patients with heart failure and hypoalbuminemia: subanalysis of PICNIC studyJL Bonilla Palomas¹; AL Gamez Lopez²; MC Moreno Conde¹; MC Lopez Ibanez¹; E Ramiro Ortega¹; P Castellano Garcia¹; Y Pimentel Quezada¹; AL Villar Raéz¹¹Hospital San Juan de la Cruz, Úbeda, Spain

Introduction: Hypoalbuminemia is common in acute heart failure (HF) patients and has been associated with increased hospital mortality and long-term mortality. In this clinical setting, malnutrition is a factor causing hypoalbuminemia. The PICNIC study results show that a nutritional intervention in malnourished hospitalized patients with HF reduces the risks of all-cause death and of readmission for HF.

Purpose: We aimed to investigate whether the efficacy of a nutritional intervention is consistent among the subgroups of patients with and without hypoalbuminemia.

Methods: In PICNIC study, a total of 120 malnourished hospitalized patients due to acute HF were randomised to conventional HF treatment or conventional HF

treatment combined with an individualised nutritional intervention. The primary endpoint was a composite of all-cause death or readmission for worsening of HF, with a maximum follow-up of 12 months. In this substudy we assessed the interaction of the effects of a nutritional intervention among patients with and without hypoalbuminemia. Analysis was by intention to treat.

Results: 59 (49,2%) patients demonstrated hypoalbuminemia and 61 (50,8%) had no hypoalbuminemia. At 12 months, the number of events for the primary endpoint in the intervention group compared with the control group was consistent among patients with hypoalbuminemia (25,8% intervention vs 60% control, hazard ratio 0,35, 95% CI 0,15-0,81, $p=0,014$) and those without (28,6% intervention vs 61,3% control HR 0,34, 95%CI 0,15-0,79, $p=0,012$).

Conclusions: There was no evidence that the relative efficacy of a nutritional intervention in malnourished acute HF patients was different between patients who had hypoalbuminemia and those who had no hypoalbuminemia.

Effectiveness of rotating tourniquets for acute heart failure: a systematic review based on GRADE system

FY Fang-Yuan Zhang¹; Z Li¹; XF Kang¹

¹Peking Union Medical College, School of Nursing, Beijing, China People's Republic of

Background: Rotating tourniquets is common traditional treatment for managing people with acute heart failure. Yet this intervention has not been systematically evaluated using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) system.

Objective: To evaluate the effectiveness and safety of rotating tourniquets for people with acute heart failure.

Methods: Evidence-based methodology was performed to form a PICO model. Systematic reviews, RCTs and observational studies concerning rotating tourniquets for the treatment of acute heart failure were searched in Cochrane Library, EMBASE, PubMed, SCI, CINAHL, Chinese Biomedicine Literature Database (CBM), WanFang Database, China National Knowledge Internet Database (CNKI). Studies meeting the inclusion criteria were selected and data were then extracted. The evidence level of outcomes was appraised through the GRADE system. All these procedures were conducted by two researchers.

Results: Four observational studies and one RCT were included. Because of bias among the studies, descriptive analysis was chosen. The evidence level of outcomes, including dyspnoea, PaO₂, right atrial pressure, cardiac output and so on, was rated as low to very low quality according to the GRADE system. There was no improvement in both dyspnoea and PaO₂ with the intervention of rotating tourniquets.

Conclusions: This review suggests no effectiveness of rotating tourniquets for the management of acute heart failure, thus don't recommend offering rotating tourniquets for people with acute heart failure routinely, though the evidence level is of very low quality. Besides, studies with large sample and high quality are needed in the future.

Multi-vessel stenting versus staged revascularization for STEMI with multi-vessel coronary artery disease in cardiogenic shock

JO Jin-Ok Jeong¹; KT Ahn¹; SA Jin¹; JK Oh¹; MJ Kim¹; UL Choi¹; SW Seong¹; SW Choi¹; IW Seong¹

¹Chungnam National University Hospital, Daejeon, Korea Republic of

Introduction: There are several treatment strategies for non-infarct related artery in ST-elevation myocardial infarction (STEMI) patients with multivessel coronary artery disease (MVCD): multivessel stenting in the primary PCI setting and staged revascularization. We aimed to compare the staged PCI versus multivessel stenting reducing mortality.

Methods: From the Korea Acute Myocardial Infarction Registry, 1078 patients with STEMI with MVCD (63.2 ± 12.1 years, 21.8% women) were enrolled between November 2011 and July 2015. The patients were divided into two groups. group I: staged PCI after primary PCI group (n = 600) and group II: multi-vessel PCI group in the primary PCI setting (n = 478). Major cardiovascular events and cardiovascular deaths were compared between two groups.

Results: Cardiovascular death (HR, 0.173; 95% CI, 0.092-0.327, $p < 0.001$), major adverse cardiac event (MACE) were significantly lower in staged PCI group (HR, 0.499, 95% CI, 0.345-0.723, $p < 0.001$). After adjusted for clinical variables, although the risk of MACEs were not significantly different between staged PCI group and multi-vessel PCI group ($p = 0.810$), the risk of cardiovascular death were significantly lower in staged PCI group (HR, 0.4335, 95% CI, 0.20-0.94, $p = 0.035$). The beneficial effect of stage PCI is much higher in patients with cardiogenic shock. Cox regression analysis confirmed staged PCI as a negative predictor for cardiovascular death in patient with STEMI undergone primary PCI.

Conclusions: This study demonstrates that staged PCI after primary PCI is associated with reduced cardiac death compared to multi-vessel PCI in the primary PCI setting with STEMI.

Intravenous furosemide in a heart failure unit: effectiveness and security in a three days protocol.

A Esteban Fernandez¹; M Perez Serrano¹; M Gonzalez Barja¹; S Ortega Gonzalez¹; J Higuera Nafria²; C Olmos Blanco²; I Vilacosta²; M Mendez Bailon³; C Macaya Miguel²; R Bover Freire¹

¹Hospital Clinic San Carlos, Heart Failure Unit, Madrid, Spain; ²Hospital Clinic San Carlos, Cardiology Service, Madrid, Spain; ³Hospital Clinic San Carlos, Internal Medicine Service, Madrid, Spain

Introduction: Intravenous (iv) treatment of congestion in heart failure (HF) is a common issue in clinical practice, but there is not a strong evidence of the most suitable and safe protocol for running it.

Purpose: Present our experience in the effectiveness and safety of a three days protocol for intravenous diuretic administration in a HF Unit.

Methods: We selected patients with moderate or severe HF decompensation, not requiring urgent admission. Clinical evaluation (weight, abdominal perimeter, signs of congestion...) and also analytic determinations were performed before starting treatment. Two days iv furosemide was administered according to diuretic ambulatory dose and renal function, continuing their habitual oral diuretic dose at home. 24 h after the last administration, clinical and analytic evaluation were repeated. Also, 24 hour diuresis, was registered.

Results: We included 29 iv furosemide administrations (63.2% in men). Mean age was 76 ± 8.7 years old and causes of cardiomyopathy were: ischaemic 78.9%, dilated 15.8% and hypertensive 5.3% (mean LVEF 0.51 ± 0.19). All of them had optimal HF treatment, including diuretics. Basal characteristics before administration were recorded in table 1. The mean dose of iv administered furosemide was 56.84 ± 15.29 mg. The 24 h diuresis after first infusion was 1985.3 ± 560.1 mL and after the second one 2125.0 ± 577.6 mL. No adverse effects were reported. The characteristics of the patients 24 h after iv treatment were recorded in table 2.

Conclusions: Three days iv furosemide administration in a HF unit, with doctor and nurse supervision, improves clinical status and reduces congestion, without significant renal deterioration or electrolyte disturbances. Because of that, it could be a good option to reduce readmission and improve patient's quality of life.

Table 1. Characteristics of the patients

Usefulness of combining admission BNP plus hospital discharge Bioelectrical Impedance Vector Analysis (BIVA) in predicting 90 days cardiovascular mortality in patients with Acute Heart Failure.

S Simona Santarelli¹; B De Berardinis¹; S Navarin¹; L Magrini¹; A Piccoli²; G Avanzi³; H Villacorta⁴; P Barreto De Araujo Porto⁴; A Villacorta⁴; S Di Somma⁴
¹Sant' Andrea Hospital, Emergency Medicine, Rome, Italy; ²University of Padova, Department of Medicine, Padova, Italy; ³University of Eastern Piedmont, Traslational Medicine, Novara, Italy; ⁴Federal University of Rio de Janeiro, departamento de ciencias cardiovasculares, Rio de Janeiro, Brazil

Background: Heart Failure is a disease with high prevalence, mortality, and frequent relapses episodes. Indeed, despite all available therapies and drugs, its incidence remains unacceptably high worldwide.

Purpose: Aim of this study was to investigate the prognostic power for death of combining Brain Natriuretic Peptide (BNP) and peripheral congestion detected by Bioelectrical Impedance Vector Analysis (BIVA).

Methods: This was an observational, prospective, multicentre study. We performed BNP at arrival and BIVA at discharge. Cardiovascular deaths were evaluated by a 90 days follow up phone call.

Results: We enrolled 292 patients. BNP was higher in non survivors (mean value 838 pg/ml vs 515 pg/ml, $p < 0.001$). BIVA at discharge showed statistically significant difference in patients who died than in survivors (respectively: HI 85 vs 74, $p < 0.001$; Xc 26.7 vs 37, $p < 0.001$; R 445 vs 503, $p < 0.01$). Discharge BIVA showed prognostic value in predicting cardiac death (HI: AUC 0.715, 95% CI 0.65-0.76; $p < 0.004$; Xc: AUC 0.712, 95% CI 0.655-0.76, $p < 0.007$; R: AUC 0.65, 95% CI 0.29-0.706, $p < 0.0247$), and when combined with BNP a greater prognostic power was obtained (combined ROC: AUC 0.74; 95% CI 0.68-0.79; $p < 0.001$). **Conclusion:** In AHF, high BNP levels at arrival, and a discharge BIVA assessments showing congestion both have a significant predictive value for 90 days cardiovascular mortality. The combined use of BNP and BIVA increases prognostic power of cardiovascular death.

P199

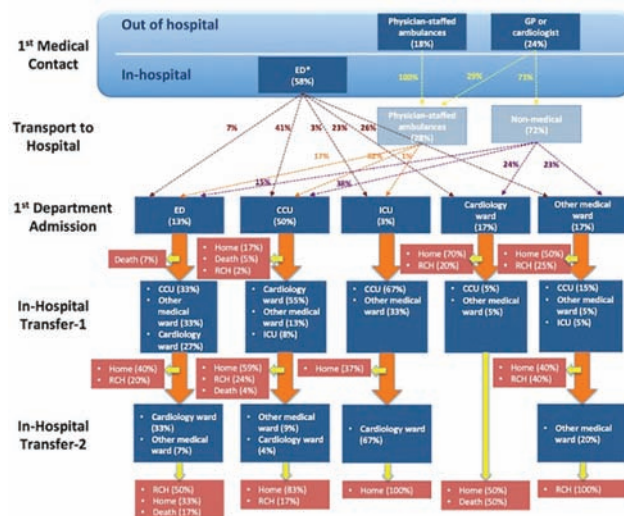

Pre- and in-hospital course of care for patients with acute heart failure: features and impact on prognosis in the real life

L Laura Cluzol¹; J Cautela²; P Michelet¹; A Roch³; J Mancini⁴; M Laine²; M Peyrol²; F Paganelli²; L Bonello²; F Thuny²
¹Hospital La Timone of Marseille, Emergency Department, Marseille, France; ²Hospital Nord of Marseille, Unit of Heart Failure and Valvular Heart Diseases, Department of Cardiology, Marseille, France; ³Hospital Nord of Marseille, Emergency Department, Marseille, France; ⁴Hospital La Timone of Marseille, Public Health Department (BIOSTIC), and UMR 912 SESSTIM, INSERM, IRD, Marseille, France

Background: Acute heart failure (AHF) is a life-threatening medical emergency for which no new effective therapies have emerged during recent decades. No previous studies have exhaustively described the entire course of care of AHF patients from first medical contact to hospital discharge nor assessed its impact on prognosis.

Methods and Results: One hundred and nineteen adults with AHF were consecutively enrolled in a multicenter prospective observational cohort study. All of the emergency departments, intensive care units, coronary care units, cardiology wards, and other medical wards participated to the study. The composite primary outcome, including 6-month rate of cardiovascular death, readmission for acute heart failure, acute coronary syndrome or stroke, occurred in 59% of patients. This rate was high and similar regardless the first medical contact, the type of transport, the first medical department of admission, and the number of medical departments involved in the course of care. A cardiologist was involved in the management in 80% of cases and the global median hospital stay was then shorter (7 days [IQR 4-11]) versus 10 days [IQR 7-18], $P = 0.003$. History of hypertension ($P = 0.004$), need for non-invasive ventilation ($P = 0.023$), and Lee prognostic score ($P = 0.028$) were independently associated with the primary outcome.

Conclusions: Morbi-mortality and readmissions were high regardless of the course of care for patients admitted for AHF in the real life. The reduction of hospital stay when cardiologists were involved in the management encourages the creation of "mobile acute heart failure cardiology teams".

Course of Care for patients with AHF

¹University of Würzburg, Department of Internal Medicine I / Comprehensive Heart Failure Center, Würzburg, Germany; ²Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany

Background: Elevated natriuretic peptides are well-established indicators of fluid overload in heart failure, but their utility after cardiac decompensation is limited since the individual baseline level in a single patient is often unknown. Measurement of procalcitonin (PCT) is well established for the management of septicemia. However, elevated PCT levels have also been reported in patients with congestive heart failure and were related to elevated plasma endotoxin concentrations. Increased gut permeability and pulmonary congestion may elicit such PCT response following bacterial challenge under these circumstances. We hypothesized that PCT indicates residual fluid overload at discharge from hospitalisation for cardiac decompensation and thus predicts the risk of re-hospitalisation for worsening heart failure or cardiovascular (CV) death.

Methods: PCT was measured prior to discharge in patients hospitalized for decompensated systolic heart failure (left ventricular ejection fraction [LVEF] $\leq 40\%$). According to manufacturer's instruction, cut-off level for normal healthy individuals was < 0.05 ng/ml, and the detection limit of relevant bacterial infection was 0.5 ng/ml. After 6 months, rates of re-hospitalisation and death (all-cause and cause-specific) were evaluated.

Results: In 910 patients (68 ± 13 years; 72% male; LVEF $29 \pm 6\%$), PCT was measured. In the total cohort, levels ranged from 0.00 to 9.77 ng/ml with a median of 0.061 ng/ml (quartiles: 0.039, 0.099). PCT levels were < 0.05 ng/ml and < 0.5 ng/ml in 39% ($n = 355$) and 97% ($n = 889$) of the total cohort, respectively. Within 6 months after discharge, 41% ($n = 374$) of all patients had experienced re-hospitalization or death, and 16% ($n = 146$) had been re-hospitalized for worsening heart failure or had died from CV death. Univariable Cox regression revealed that in patients with PCT < 0.05 ng/ml both, the risk of all-cause re-hospitalisation or death and the risk of re-admission for worsening heart failure or CV death were significantly lower compared to subjects with PCT ≥ 0.05 ng/ml: hazard ratio (HR) 0.60 (95% confidence interval (CI) 0.48-0.75) and HR 0.39 (95% CI 0.26-0.57), respectively (all $p < 0.001$). The association of low PCT with low risk of re-admission for worsening heart failure or CV death was not attenuated by adjustment for age, sex, C-reactive protein, white blood cell count, NYHA functional class, N-terminal pro-brain natriuretic peptide, renal dysfunction and diabetes: HR 0.60 (95% CI 0.38-0.93; $p = 0.024$).

Conclusion: In systolic heart failure, PCT may be a surrogate marker of residual congestion. After an episode of cardiac decompensation, a PCT level below 0.05 ng/ml indicates a fluid-balanced and therefore stable condition, i.e. at low risk for rehospitalisation for worsening heart failure or CV death. The clinical utility of such biomarker information deserves to be tested in a controlled trial.

P201

Prognosticators of heart failure in patients after treatment because of acute coronary syndrome

I Kotlar¹; M Vavlukis¹; B Pocesta¹; G Krstevski¹; H Taravari¹; E Shehu¹;D Kitanoski¹; I Bojovski¹; F Taneski¹; S Kedev¹¹University Clinic of Cardiology, Skopje, Macedonia The Former Yugoslav Republic of**Aim:** of the study was to identify frequency and predictors of heart failure in patients treated for acute coronary syndrome (ACS).**Patients and methods:** Patients with ACS treated medically or with PCI, were extracted from the hospital registry. Analyzed variables: age, gender, risk factors, SBP and HR at hospital admission, type of MI, location, CAD severity, LV function, type of treatment, in-hospital morbidity, pharmacologic treatment post discharge, time to event. Statistical analysis: descriptive and comparative analysis, uni and multivariate regression analysis, Kaplan-Meier event free survival analysis.**Results:** 437 patients treated for ACS, at mean age 63.2 ± 11.1 years, 294(67.3%) males and 143(32.7%) females, were followed up for mean 17.3 ± 10.3 months. A total of 128(29.3%) patients had 136 cardiac events (CE), 32(25%) of whom heart failure (HF). Mean time to HF was 5.9 ± 7.4 (SE), CI(3,3-8,6) (Figure 1). As univariate predictors of HF in ACS treated patients we identified: length of hospitalization (for ACS treatment) 3.9 ± 2.2 vs 5 ± 2.5 days ($\beta=1.169$, $p=0.009$); diuretic utilization during ACS hospitalization ($\beta=1.992$, $p=0.001$); EF (%) ($\beta=-0.092$, $p=0.001$); reduced EF ($<40\%$) had OR for HF 3.282 (CI 1,129-9,542, $p=0.011$); receiving PPCI ($\beta=-1.584$, $p=0.011$, exp(B) 0.205); known DM ($\beta=0.741$, $p=0.007$, exp(B) 2,098); previous MI ($\beta=0.832$, $p=0.068$, exp(B) 2,297); statin therapy prior ACS ($\beta=0.955$, $p=0.028$, exp(B) 0,385); PCI performed ($\beta=0.990$, $p=0.043$, exp(B) 0,372); in-hospital morbidity ($\beta=0.868$, $p=0.028$, exp(B) 2.382). In multivariate analysis (binary logistic regression) four independent predictors were identified: known diabetes ($p=0.004$), PCI treatment for ACS ($p=0.006$), diuretic therapy during ACS hospitalization ($p=0.004$) and LV function ($p=0.024$).**Conclusion:** Predictors of HF development in pts. after ACS, seems to be pre-existing DM, need for diuretic therapy during ACS event, and reduced LV systolic function as negative ones, but, receiving PCI (myocardial revascularization) is the most important positive predictor.

Kaplan-Meier cumulative hazard ratio-HF

P202

Impact of acute heart failure: precipitating factors, one-year outcome and risk factors.

R Rita Pocinho¹; R N Leao¹; S Faustino¹; J Ribeiro¹; J Almeida¹¹Hospital de São José, Internal Medicine Department, Lisbon, Portugal**Introduction:** Acute heart failure is a frequent condition associated with high morbidity and mortality. Despite advances in its care, the prognosis of patients hospitalized for acute heart failure remains poor and rates of readmissions continue to rise. In order to effectively prevent readmissions and improve overall outcomes, it is important to have a complete characterization of the hospitalized patients and identify prognostic factors.**Purpose:** This study was performed to analyze patient characteristics, precipitating factors and outcomes of acute heart failure in our population and to determine prognostic factors.**Methods:** A retrospective observational study was conducted with data prospectively collected in an internal medicine department. All consecutive patients hospitalized with acute heart failure during the year 2014 were included. Demographic, clinical, laboratorial data and parameters from transthoracic echocardiograms were collected. Patients were followed for a period of one year in order to determine the outcomes (rehospitalizations, emergency admissions and death).**Results:** 255 patients were included, with 81 ± 8 years, 146 women. Hypertension, atrial fibrillation and coronary heart disease were the most common underlying conditions, present in 88.6%, 60.8% and 47.5% of the patients, respectively. Infectious diseases, therapeutic failure/disease progression and arrhythmias were the precipitating factor in 45.5%, 32.9% and 10.6% of the cases, respectively. Preserved left ventricular ejection fraction was observed in 61.5%; valvular disorders were common, especially mitral regurgitation, which was reported on echocardiography in 49.5% of patients. Median length of stay was 11 ± 8 days and the 12-month all-cause mortality was 27.5%. During the one-year follow up period 61.2% of patients needed to be readmitted and 34.1% required treatment in the emergency department due to decompensated heart failure. Univariate statistical analysis determined that coronary heart disease ($p=0.04$), diabetes ($p=0.05$), pulmonary hypertension ($p=0.03$), valvular disorder ($p=0.04$) and hypertension ($p=0.05$) were associated with the need of rehospitalization and mortality.**Conclusion:** Characteristics and prognosis of an unselected population of acute heart failure patients are presented. Preserved systolic function was found in a substantial proportion of the patients. One-year readmissions and mortality were high. In this population, coronary heart disease, diabetes, pulmonary hypertension, valvular disorder and hypertension were identified as independent risk factors for rehospitalization and mortality.

P203

Acute heart failure secondary to cardiac amyloidosis: a case series

S Steven Back¹; F Raza²; R Alvarez²¹Temple University Hospital, Internal Medicine, Philadelphia, United States ofAmerica; ²Temple University Hospital, Cardiology, Philadelphia, United States of America**Introduction:** Amyloidosis is a disease characterized by the abnormal deposition of protein in visceral organs and soft tissue. Affected organs include the heart, kidney, liver and nervous system. Deposition of amyloid in the heart characterizes advanced stages of the disease and cardiomyopathy due to amyloidosis is the leading cause of morbidity and mortality in patients affected by the disease. Patients can present with signs of right-sided heart failure, including elevated jugular venous pressures and lower extremity edema. While there have been as many subtypes of amyloid proteins identified, the most common subtypes to deposit in the heart are immunoglobulin light chain (AL) amyloid as well as wild-type (wt) and mutant transthyretin amyloid (ATTR). Cardiac involvement occurs in about 50% of patient with AL amyloidosis. Some reports indicate that 4% of African Americans possess a mutant variant of ATTR and 23% of African Americans with cardiac amyloidosis have the Val122Ile mutant variant of ATTR.**Purpose:** The purpose of this study is to analyze three cases of acute decompensated heart failure due to amyloidosis and compare and contrast each patient's presentation, diagnosis and acute and long-term management of the disease.**Methods:** Three cases of cardiac amyloidosis were identified in our hospital's advanced heart-failure clinic and analyzed as a part of a case-series.**Results:** The cases of cardiac amyloidosis in our case study included one patient each diagnosed with AL, wt ATTR and Val122Ile mutant ATTR amyloid. The age of our patients at presentation was 53, 71 and 72 years old. One patient was African American, two were Caucasian and all were male. Each patient presented to our clinic with either symptoms of shortness of breath or volume overload. In each case, diagnosis was made by endomyocardial biopsy and immunohistochemistry. Each patient was treated, when appropriate, for heart failure with a beta-blocker and an ACE-inhibitor or angiotensin receptor blocker as well as a diuretic for volume control. Definitive treatment strategy varied with respect to the patient's subtype of cardiac amyloidosis.**Conclusions:** The management strategy of acute decompensated heart failure secondary to amyloid deposition in the heart is two-fold: treatment of the symptoms of heart failure as well as the source of the abnormal protein production. Heart failure management is similar regardless of the amyloid subtype. Patients require heart rate and after-load control as well as volume regulation with diuretics. Long term treatment and potential cure is dependent upon the source of amyloid production. AL and ATTR subtypes are synthesized in the bone marrow and liver respectively. Therefore, patients with AL amyloid deposition require chemotherapy and stem cell transplantation while patients with ATTR amyloid are treated with liver transplantation. Novel therapeutic strategies focus on eliminating amyloid from the body.

P204

Sex-determined differences of short- and long-term prognosis of mortality in patients hospitalized with acute decompensated heart failureVA Kostenko¹; VV Kostenko²; M Sitnikova³; E Skorodumova¹; A Fedorov¹¹Institute for Emergency Medical Care, Saint Petersburg, Russian Federation;²Higher School of Economics, Laboratory for Comparative Social Research,Moscow, Russian Federation; ³Federal Almazov Centre of Heart, Blood and Endocrinology, Scientific Research Department "Heart Failure", Saint-Petersburg, Russian Federation**Purpose:** We evaluate sex-dependent features of acute decompensated heart failure (ADHF) in terms of in- and post-hospital prognoses.**Methods and materials:** We observed 450 patients, 235 males and 215 females (average age 69.4 ± 10.6 years) hospitalized to cardiological departments or intensive care units with ADHF of ischemic or hypertensive origin. 25 patients (5.6%) died in hospital, 425 (94.4%) were discharged. We obtained 2-years outcome concerning vital status about all of 425 patients discharged, 208 of them died within 2 years. We performed multivariate statistical analyses using t-test at first for independent cohorts, and then binomial logistic regressions were applied stepwise. The regression outcome was taken as in-hospital death (of any cause) for the first series of models, and as post-hospital death after initial discharge for the second series of models.**Results:** We obtained some significant risk factors for in- and post-hospital mortality for patients who were discharged after ADHF. For in-hospital death these factors were the following: High hs-CRP level (> 20 mg/l; ULN = 5 mg/l), high BNP-level (> 1000 pg/ml; ULN = 100 pg/ml), low LV EF (< 33%), age (≥ 75 years), and sex (male). We revealed certain interactive effects for each sex: higher CRP was more dangerous for males (p=0.0001). Higher BNP was a stronger predictor of death for females (p=0.003), as well as low EF (p=0.0003). All measured values were assessed at hospital admission. For post-hospital mortality patients' data at discharge were analyzed. Significant factors were the following: High hs-CRP level (> 20 mg/l; ULN = 5 mg/l), high BNP-level (> 600 pg/ml; ULN = 100 pg/ml), age (≥ 75 years), and sex (male) raise the probability of death within two-years after discharge. Interactive effects have shown that the higher CRP adds more to male mortality (p=0.001), as well as older age (p=0.009), and lower EF (p=0.02).**Conclusion:** There are clear sex-dependent differences in a range of significant factors for short-term and long-term prognosis of in-hospital and post-hospital mortality for males and females. Generally, females show better outcomes. Higher BNP levels, and lower LV EF have stronger worsening effect for females than for males. Higher CRP, and older age result in higher probability of death for males. Those differences to be considered when short- and long-term mortality prognoses for patients with ADHF are assessed.

P205

Primary valvular non-acute coronary syndrome pulmonary edema-clinical and paraclinical characteristics. Prognosis factors.I Iordache¹; V Enache¹; AC Nechita¹; SC Stamate¹¹St. Pantelimon Emergency Hospital, cardiology, Bucharest, Romania**Acute:** Pulmonary Edema (APE) represents a severe clinical form of acute heart failure, with high in-hospital (IH) and 1 year mortality. A few data describe APE regarding the etiology and prognosis factors.**Purpose:** Characterization of a group of patients with primary valvular (PV) non-acute coronary syndrome (non-ACS) APE, regarding demographic, clinical and paraclinical data, the analysis in relation to the other etiologies (hypertensive and ischemic). Identification of short and medium term prognosis parameters.**Material and methods:** 92pts with non-ACS APE, with polymorphic etiology (23.91% primary valvular, hemodynamic graded at least moderate, 28.26% non-ischemic hypertensive, 44.56% ischemic and 3.26% others), admitted in our clinic, between 01.01-31.12.2013. We analyzed demographic, clinical, biological and echo parameters in relation to etiology and IH and 1 year mortality.**Results:** In relation with the other two etiologies: equal gender distribution, differences with statistic value (p=0.03), similar mean age (75.3 years), same incidence for hypertension (80.56%) and type II diabetes mellitus (27.77%), higher for smoking (19.44%) and lower for dyslipidemia (38.89%). The main valvular diseases (VD) identified were mitral regurgitation (36.11%) and aortic stenosis (13.88%); these two were associated in 31.94% of cases. 19 (20.65%) of 92 pts have mixt etiology (valvular and ischemic). For the entire group, IH mortality (IHM)-23.91%, was not influenced by the etiology (p=0.6); 18.18% PV, 23.08% hypertensive and 52.27% ischemic; the results were different from 1 year mortality (28.25%), which was associated with ischemic etiology (ischemic-68.42% vs PV - 31.58%, p=0.01, RR=1.43). 50% of ischemic death associated a significant VD (p=0.001). The next parameters were associated with IHM for PV etiology: urea (p=0.004) and sodium (p=0.002) at admission, diastolic left ventricular diameter (p=0.003), right atrial-ventricular gradient (p=0.02), E/E' (p=0.06), and with 1 year mortality: pre-therapeutic heart rate (HR, p=0.02), LVEF (p=0.04), TAPSE (p=0.02), PAAT (p=0.04).**Conclusions:** Ischemic etiology is dominant in non-ACS APE. IH and 1 year mortality is not influenced by PV etiology, but the association of significant valvular disease with ischemic etiology rises the 1 year mortality risk (p=0.001). For PV etiology a lot of clinical, biological and echo parameters proved to have statistical value for short and medium term prognosis. Early identification of underlying pathology and prognosis factors in non-ACS APE is important for risk stratification.

P206

INTERMACS profile predicts in-hospital mortality in cardiogenic shockI Iago Sousa Casasnovas¹; X Li¹; A Ayesta-Lopez¹; C Devesa-Cordero¹;M Juarez-Fernandez¹; F Diez-Delhoyo¹; J Garcia-Carreno¹; A Alonso-Garcia¹;M Martinez-Selles¹; F Fernandez-Aviles¹¹University Hospital Gregorio Marañon, Madrid, Spain**Background:** Mortality in the setting of cardiogenic shock (CS) is high, but some patient characteristics can stratify this risk. INTERMACS profiles are useful in the characterization of advanced heart failure before ventricular assist device implantation. This classification could be useful as mortality predictor among the patients with CS due to medical conditions admitted to the Cardiovascular Intensive Care Unit (CICU).**Methods:** We performed a retrospective analysis of all the patients with CS due to medical conditions in our CICU from February 2012 to Sept 2015. We collected base-line characteristics and shock, treatment and mortality data. INTERMACS profile at 24 hours of CS diagnosis was assigned by two cardiologists independently, in case of discrepancy the case was discussed.**Results:** We collected 196 patients during the study period.**Etiology:** Acute coronary syndrome 57.7%; Acutely decompensated heart failure 23.4%; Arrhythmias 13.2%; other etiologies 5.6%. Men 70.4%. Age 67.8 (SD 14.3). After INTERMACS classification the groups resulted: INTERMACS1 19.9%; INTERMACS2 32.5%; INTERMACS≥3 56.6%. The overall in-hospital mortality rate was 32.1%. Regarding to INTERMACS profile, the mortality rate was resulted: INTERMACS1 89.7%; INTERMACS2 39.1%; INTERMACS≥3 9%. Comparison with univariate logistic regression showed significant differences among the groups (p<0.001). After analysis with multivariate logistic regression and adjusting with traditional predictors (blood pressure, LVEF, glycemia, diabetes, chronic renal insufficiency and age) the signification persisted with worse prognosis as INTERMACS profile decreased: INTERMACS2 vs INTERMACS≥3 (p<0.001; OR 6.5 [2.7-15.6]); INTERMACS1 vs INTERMACS≥3 (p<0.001; OR 88.4 [26.0-299.8]).**Conclusion:** INTERMACS profile at 24h of CS diagnosis was strongly associated with in-hospital mortality. We suggest that it can be a valuable tool in order to stratify the risk of the patient suffering from CS, and thus it can help to guide the need for more aggressive therapies.

P207

Acute heart failure and cardiogenic shock are predictors for in-hospital mortality in patient admitted with acute coronary syndromeB Bambang Widiantoro¹; DA Juzar¹; I Firdaus¹; SS Dany¹; S Dharma¹; DZamroni¹; I Irmalita¹; DPL Tobing¹¹Dept of Cardiology and Vascular Medicine, Universitas Indonesia-NCVC Harapan Kita Hospital, Jakarta, Indonesia

Despite aggressive intervention, morbidity and mortality of patients with acute coronary syndrome (ACS) remain high. Various clinical condition may contribute to

the outcomes during acute phase. The aim of this study was to analyze clinical parameters that predict in-hospital mortality of ACS patient. We examined 1315 consecutive patients admitted with ACS in CVCU of our National Cardiovascular Center in 2015. Multivariable logistic regression was used to analyze predictors for in-hospital mortality. Among 1315 patients, 786 (59.8%) were STEMI and 529 patients were UA/NSTEMI. Most of them are male (82.4%), below 65 years old and smoker (59.1%). Overall in-hospital mortality were 5.7% (76 of 1315), including 47 patients with STEMI and 29 with UA/NSTEMI. STEMI patients who failed to survive during hospitalization more likely have diabetes, suffered from acute heart failure (AHF) and cardiogenic shock (CS). However, after multivariable risk adjustment, only AHF and cardiogenic shock remain independent predictors for in-hospital mortality (odds ratio 7.64; 95%CI 3.41-17.13 and 11.45; 95%CI 5.61-23.36 respectively). Almost similar findings were observed in UA/NSTEMI population, with CS as strong predictor for in-hospital mortality (odds ratio 24.2; 95%CI 8.5-68.27), and those who underwent early revascularization were survive (odds ratio 0.361; 95%CI 0.131-0.994). We also observed no significant differences in mortality between cardiogenic shock patients who had IABP implantation and those without IABP. In conclusion, we observed AHF and cardiogenic shock as predictors for in-hospital mortality among STEMI patients, and cardiogenic shock in UA/NSTEMI population. Early revascularization but not IABP implantation predicted survival during hospitalization.

Predictors of left ventricular systolic dysfunction in patients with first acute ST-segment elevation myocardial infarction undergoing primary angioplasty

WSA Wael Mohamed¹; MAA Aljarallah¹; AST Mousa¹; ASEM Abdulla¹; AYMAN Gaballa¹

¹ Sabah Al Ahmed Cardiac Center, Kuwait City, Kuwait

Background: The degree of left ventricular systolic dysfunction (LVSD) determines the prognostic outcome of STEMI.

Purpose: To define different variables related to LVSD in patients with first STEMI referred for primary PCI.

Methods: The sample included 288 patients from January 2013 till December 2014. Demographic, clinical, laboratory and angiographic data were collected prospectively into a computerized registry. Patients were divided into four groups by degree of LV systolic function: normal (EF ≥ 50%), mild (EF = 40-49%), moderate (EF = 30-39%), and severe (EF < 30%) and compared for different variables.

Results: LVSD was associated more with females ($p = 0.029$), anterior STEMI ($p = 0.004$), longer symptom to door time, longer door to device time, more than Killip class II on presentation (0.001), extend of CAD ($p = 0.021$), and high peak creatine kinase. There were no significant correlations between LVSD and age, DM, hypertension, dyslipidemia, technique of PCI or use of aspiration device. On bivariate analysis, symptom to door time ($r = -0.312$, $P < 0.001$), door to device time ($r = -0.327$, $P < 0.001$) and peak creatine kinase ($r = -0.202$, $P = 0.003$) were the most significant independent predictors of LVSD. Patients with LVSD had higher in-hospital mortality ($p = 0.001$). **Conclusion:** LVSD after first STEMI can be predicted by female gender, anterior STEMI, Killip class on presentation, symptom to door time, door to device time and the size of infarction assessed by peak creatine kinase. Patients with LVSD had higher in-hospital mortality.

Hemographic indices are associated with mortality in acute heart failure

W M Wei Ming Huang¹; SH Sung¹; HM Cheng¹; DY Lu¹; CW Lee¹; PF Hsu¹; WC Yu¹; CH Chen¹

¹ Taipei Veterans General Hospital, Cardiology, Taipei, Taiwan ROC

Background: Hemographic indices have been associated with clinical outcomes in patients with chronic heart failure. We therefore investigated the prognostic values of hemographic indices in patients hospitalized for acute heart failure (AHF), regardless of left ventricular functions.

Methods: Patients hospitalized primarily for AHF were drawn from an intramural registry. Hemographic indices, including white blood cell counts, neutrophil counts, neutrophil-to-lymphocyte ratio, reciprocal of lymphocyte (RL) and platelet-to-lymphocyte ratio were recorded. National Death Registry was linked for the identifications of all-cause mortality, with a follow-up duration of up to 5 years.

Results: Among a total of 1923 participants (mean age 76 ± 12 years, 68% men), 875 patients died during a mean follow-up duration of 28.6 ± 20.7 months. All of the hemographic indices were related to mortality, independent of age, sex, mean blood pressure, left ventricular ejection fraction, sodium and hemoglobin level, estimated glomerular filtration rate, and medications. In a forward stepwise Cox regression analysis among hemographic indices, RL was the strongest predictor getting into the model [HR and 95% CI: 1.166 (1.097-1.240)] after accounting for

the confounding factors. RL was consistently correlated with mortality, irrespective of age, gender, diabetes, chronic kidney disease, coronary artery disease, and left ventricular systolic function. However, conditioned on the survivals, the hemographic indices were independently related to mortality within 3 years of follow-up, rather than beyond.

Conclusions: Hemographic indices were independent risk factors of mortality in patients hospitalized for AHF, especially in patients with impaired left ventricular systolic function. As an acute presentation of inflammation, hemographic indices might be useful to identify subjects at risk of mortality soon after the index hospitalization.

P210

The effects of continuous iv furosemide on arterial stiffness and ventricular-arterial coupling in AHF patients

E Edoardo Sciatti¹; E Vizzardi¹; I Bonadei¹; F Platto¹; V Carubelli¹; M Metra¹

¹ University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy

Background: Congestion and fluid overload are the hallmarks of heart failure (HF). Arterial stiffness and ventricular-arterial coupling (VAC) are independent prognostic factors in HF patients. No studies to date have investigated the role of decongestion with continuous iv furosemide regarding these parameters.

Purpose: we aimed at evaluating arterial stiffness and VAC at admission and discharge in patients hospitalized for acute HF (AHF) with reduced left ventricular ejection fraction (LVEF).

Methods: 26 patients hospitalized for AHF were enrolled. Before the administration of iv furosemide and at discharge they underwent radial artery applanation tonometry to evaluate central blood pressures and augmentation index (AIx@75), and transthoracic echocardiography to assess aortic elastance (Ea), end-systolic left ventricular elastance (Ees) and their ratio, namely VAC.

Results: mean age was 76 ± 10 years. 12 (46.2%) were male. LVEF at admission was $34 \pm 9\%$. Hemodynamic parameters are reported in Table 1. After iv furosemide there was a great improvement in central pressure. We found that AIx@75 significantly worsened in parallel with decongestion. On the other hand, no effects were seen on VAC and its components. These results are independent from LVEF increasing and weight loss.

Conclusion: In patients hospitalized for AHF iv furosemide is associated to an improvement in central pressure, with no effects on VAC. The surprising arterial stiffening in parallel with decongestion can be probably linked to a reduced shear stress due to fluid unloading. Considering the prognostic role of arterial stiffness in patients with HF, our results are contrasting and need further analysis.

Variable	Admission	Discharge	p
Aortic SBP (mmHg)	109 ± 19	105 ± 11	0.211
Aortic DBP (mmHg)	75 ± 5	71 ± 5	0.001

The impact of admission blood glucose level on clinical picture and prognosis in cardiogenic shock

AL Kataja¹; T Tarvasmäki¹; J Lassus²; VP Harjola¹

¹Helsinki University Central Hospital, Emergency Medicine, Helsinki, Finland;

²Helsinki University Central Hospital, Heart and lung center, Helsinki, Finland

Introduction: Critically ill patients often present with hyperglycaemia, regardless of previous history of diabetes mellitus (DM). Stress hyperglycaemia has been associated with adverse outcome in acute myocardial infarction and acute heart failure, but data regarding cardiogenic shock (CS) are sparse.

Purpose: To investigate the impact of admission plasma glucose level on clinical picture and short-term mortality in CS.

Methods: We enrolled 219 adult CS patients, that were divided into five categories according to admission plasma glucose level (hypoglycaemia (glucose <4mmol/L), normoglycaemia (4-7.9mmol/L) and mild (8-11.9mmol/L), moderate (12-15.9mmol/L) and severe (≥16mmol/L) hyperglycaemia). We compared the clinical picture, biochemical findings and short-term mortality between the groups.

Results: Glucose levels were distributed equally between normoglycaemia (26% of patients) and mild (27%), moderate (20%) and severe (25%) hyperglycaemia, while hypoglycaemia (2%) was rare. Severe hyperglycaemia was associated with higher blood leukocyte count (17.3 E9/L), higher plasma lactate level (4.4mmol/L) and lower arterial pH (7.23) compared with normoglycaemia or mild to moderate hyperglycaemia ($p < 0.001$ for all). The hypoglycaemic patients presented with hyperlactatemia (8.3mmol/L), acidosis (arterial pH 7.19) and high levels of NT-proBNP (26300 ng/L) and alanine aminotransferase (466 U/L). In contrast, the normoglycaemic patients had normal levels of arterial pH (7.35) and plasma lactate (1.8mmol/L). Acute coronary syndrome was the aetiology of CS particularly often in patients with severe hyperglycaemia (92%) in comparison with normoglycaemic (69%) and hypoglycaemic (60%) patients ($p = 0.029$). 90-day mortality was highest among hypoglycaemic and severely hyperglycaemic patients (60% for both) compared with 26% in normoglycaemic patients (Figure 1.). Severe hyperglycaemia was an independent predictor of in-hospital mortality (OR 3.72, 95% CI 1.18-11.7, $p = 0.025$), when adjusted for age, gender, LVEF, lactate and DM. Mean glucose level of survivors and non-survivors differed significantly among non-diabetic patients (10.1 vs. 12.9 mmol/L, $p = 0.009$), but not among patients with prior DM (16.3 vs. 17.4 mmol/L, $p = 0.59$).

Conclusions: Glucose level significantly affects the outcomes in CS, and prior DM status modifies the prognostic value of plasma glucose. Mortality rates are highest among hypoglycaemic and severely hyperglycaemic patients. Moreover, severe hyperglycaemia is an independent predictor of in-hospital mortality in CS and is associated with biochemical findings of hypoperfusion. In contrast, plasma lactate and pH remained within the normal range among normoglycaemic patients, suggesting that tissue perfusion and oxygenation were sufficient to meet the demands despite the clinical manifestation of shock.

Figure 1. Kaplan-Meier survival curves

P212

Prognostic value of changes in cardiotrophin-1 levels over time in patients with acute heart failure

L Malinova¹; T Povarova²; T Denisova³

¹Saratov State Medical University, Research Institute of Cardiology, Saratov, Russian Federation; ²Saratov Road Clinical Hospital, Cardiology, Saratov, Russian Federation; ³Saratov State Medical University, Saratov, Russian Federation

Background: Cardiotrophin-1 (CT-1) is a factor enhancing cardiomyocyte survival and protection in response to biomechanical stress. Data received from rodent and canine models suggest that CT-1 also behaves as a profibrotic cytokine. In rodent myocardial infarction model, CT-1 expression in the late phase of wound healing and the onset of heart failure may also contribute to ventricular dilation by inducing hypertrophy of myocytes. Nevertheless, the role of CT-1 expression at early stages of myocardial remodeling remains unclear. Clinical significance of serial measurements of CT-1 in acute heart failure has not yet been reported.

The purpose of the study was to assess the significance of repeated measurements of CT-1 in patients with acute heart failure.

Methods: 172 patients admitted for acute dyspnea aged 39...60 were included in ongoing prospective open local study. The plasma concentrations of CT-1 were determined using available commercial immunoassay kits at baseline and on 7th day since AHF manifestation. For the purpose of the study, results of 72 male patients with acute heart failure were analyzed by categorical and percentage changes in CT-1 level. Patients are followed-up for duration of hospital stay (in-patient), cardiovascular rehospitalization, cardiovascular death and heart failure signs and symptoms (shortness of breath, ankle swelling, weight gain>2 kg within 3 days).

Results: Baseline CT-1 was comparatively high: 236.3 (220.4; 263.8) pg/mL. Increasing CT-1 level over time from baseline to 7th day's level was associated with significant increase in baseline levels of RDW (15.3 (14.7; 15.7) vs 14.5 (13.9; 14.8), $p = 0.006$), left ventricular myocardial mass index (94 (90; 99) vs 82 (75; 95), $p = 0.023$) and lower baseline CT-1 level (227.0 (213.1; 249.3) vs 256.5 (222.1; 270.2) pg/mL, $p = 0.042$). In 25% of patients CT-1 increased by > 10%, while deceleration of CT-1 by >10% was in 29.2%. Both increase and decrease of CT-1 by 10% were associated with higher relative hazard of adverse cardiovascular event within one (HR 1.43 (CI 1.01; 2.84), HR 2.34 (CI 1.05; 3.01)) and six months (HR 2.53 (CI 1.71; 3.86), HR 2.14 (CI 1.65; 4.17)) since admittance due to acute heart failure. Categorized changes in CT-1 level correlated with the duration of hospital stay ($r = 0.651$, $p < 0.05$).

Conclusion: In male adult patients with acute heart failure repeated measurements of cardiotrophin-1 level provide important information on acute heart failure risk stratification.

CHRONIC HEART FAILURE

P213

The role and importance of interleukin investigation in chronic heart failure

MI Juraev¹; KHA Mamatkulov¹; MX Usarov¹; DM Tolipov¹

¹Tashkent Medical Academy, ?1 Republican Clinical Hospital, Tashkent, Uzbekistan

Background: The study of the content immunocytokines in patients with chronic heart failure (CHF) due to the fact that cytokines play a significant role in the formation of myocardial remodeling and progression of heart failure. Purpose of the study. Study of the level of cytokines and their relationship with the course of ischemic CHF.

Material and methods: The study included 45 patients with a confirmation of CHD and post myocardial infarction which complicated with heart failure, corresponding to stage II and III CHF. At echocardiography all of patients ejection fraction is below 50%. All participants underwent an electrocardiogram, chest X-ray, general clinical and biochemical studies. We have chosen for the determination of interleukin-6 (IL-6) and tissue necrosis factor-alpha (TNF- α). Thus, in stage II A the concentration of TNF- α and IL-6 was 20,6 ± 3,32 and 34.0 ± 12,3 pg / ml, stage II B stage - 72.1 ± 8.43 and 67.8 ± 11.1 pg / ml and increased to stage III to 172 ± 17,1 and 141 ± 21,2 pg / ml ($p = 0.001$).

Conclusions: Thus, definition of interleukin status in serum of patients with CHF can use as markers of the disease, in combination with a standard inspection. The level of interleukin status had a direct correlation with the stage of heart failure.

P214

Impaired gas diffusion and RV to pulmonary circulation uncoupling limit exercise performance in heart failure patients

V Valentina Labate¹; V Donghi¹; G Generati¹; PL Laforgia¹; F Bandera¹;

M Guazzi¹

¹IRCCS Policlinico San Donato, heart failure unit, San Donato Milanese, Italy

In heart failure (HF) patients, an altered gas diffusing capacity for carbon monoxide (DLCO) is a marker of lung capillary injury that bears relevant clinical and prognostic information. It is unknown whether right heart-pulmonary circulation (RH-PC)

uncoupling abnormalities and gas diffusion are linked and may become synergic in causing exercise limitation and ventilation inefficiency.

Methods: 17 HF patients (mean age 64 ± 11 ; male 75%; NYHA II-III; mean left ventricular (LV) ejection fraction $34 \pm 9\%$) underwent DLCO measurements with assessment of membrane component (DM) an capillary blood volume (Vc) and underwent to maximal cardiopulmonary exercise testing (CPET, tilt-ergometer, personalized ramp protocol) combined with Echo-Doppler assessment of right ventricular function by assessing tricuspid annular peak systolic excursion (TAPSE) and pulmonary systolic pressure (PASP).

Results: Patients exhibited an abnormal gas diffusion (mean DLCO 17 ± 3.9 ml/min/mmHg) with depressed alveolar-capillary membrane diffusing capacity (DM) component (mean 23.4 ± 6.8 ml/min/mmHg) and elevated capillary volume (mean 111.2 ± 64 ml) along with significant functional limitation (mean peak VO2 12.5 ± 3.7 ml/kg/min) and ventilatory inefficiency (mean VE/VO2 slope: 34.4 ± 6.9 and mean end-tidal of CO2 mean 32.1 ± 5.2 mmHg). Significant correlations were found between DM, TAPSE/PASP relationship, peak VO2 and VE/VO2 slope at peak exercise (figure).

Gas diffusion and CPET parameters

Study of the effect of lisinopril on the kidney functional state in the patients with chronic heart failure

Z D Zulfya Rasulova¹; UK Kamilova¹; HA Redgaboev¹; DR Masharipova¹; SHR Ibabekova¹

¹Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan

Purpose of research was study of the effect of lisinopril on the kidney functional state (KFS) in the patients with chronic heart failure (CHF).

Methods: This investigation included 86 males with ischemic heart disease associated with II - III FC CHF (mean age 59.4 ± 8.9 years). Control group - 10 healthy persons. The patients received additionally to the standard therapy (spironolactone, beta-blockers, antiagregants) the lisinopril (mean dose - 8.1 ± 3.6 mg/day). The KFS was evaluated by the level of glomerular filtration rate (GFR by MDRD) and the renal blood flow (RBF) assessment was performed by pulse-wave dopplerography. Peak blood flow systolic velocity (Vs), end-diastolic velocity (Vd), resistive and pulse index (RI, PI) were studied at the right and left renal artery.

Results: The results of investigation show that in the patients with FC II and III CHF - GFR was 65.3 ± 9.8 and 57.7 ± 9.4 ml/min/1.73 m², respectively. In the patients with CHF at the level of renal arteries there was noted additionally to the increase in parameters of RI and PI with reduction of velocity parameters during systole and diastole periods also increase in comparison with control parameters. During dynamics of treatment of the patients with CHF at the level of right and left renal arteries there was noted tendency to reduction of the parameters of RI by 10.1% and 7.3% and PI - by 12.5% and 11.7%, there was noted increase in velocity parameters during systole period by 9.8% and 11.0% and diastole by 10.5% and 11.5% in comparison with initial parameters.

Conclusions: In the patients with CHF the treatment during 6 months with inclusion of lisinopril resulted in improvement of the parameters of renal functional state and renal blood flow that characterizes nephroprotective effect of the therapy performed.

P216

Risk stratification of ambulatory patients with chronic heart failure by six-minute walking test and B-type natriuretic peptide: results from the nebula network study group

AB Scardovi¹; P Faggiano²; S Ghio³; PL Temporelli⁴; A Rossi⁵; GG Galeotti⁶; A Simioniu⁶; A Alessandro Ferrarioni¹; R Ricci¹; FL Dini⁶

¹santo spirito hospital, Rome, Italy; ²University of Brescia, Brescia, Italy; ³Policlinic Foundation San Matteo IRCCS, Pavia, Italy; ⁴Fondazione Maugeri, Veruno, Italy; ⁵University of Verona, Verona, Italy; ⁶University of Pisa, Pisa, Italy

Background: Reliable assessment of patients with chronic heart failure (HF) is sometimes difficult in an ambulatory setting. Although clinical evaluation still represents a cornerstone of daily practice, such an approach not always allows accurate prognostic stratification. In this scenario, a strategy based on the combination

of simple instrumental and laboratory parameters, such as 6-minute walking test (6-MWT) and B-type natriuretic peptide (BNP), could sharpen the simplistic clinical examination and guide patients' management during follow-up. Aim. This study was designed to assess the value of 6-MWT and BNP assessment in the prognostication of patients with chronic stable HF either with preserved (EF $\geq 45\%$) or reduced ejection fraction (EF $< 45\%$).

Methods: 641 ambulatory patients (mean age: 70 ± 12 yrs; 31% female) with chronic HF with preserved (HFpEF; n=341) or reduced EF (HFrEF; n=300) were enrolled. They underwent a complete echocardiographic examination. Effort tolerance by 6MWT and BNP plasma levels were evaluated at the time of the index echocardiogram. The end-point was all cause-mortality.

Results: During the follow-up (30 ± 18 months, median: 30 months), there were 86 deaths. The most powerful univariate predictors of all-cause mortality were BNP ($p < 0.0001$), estimated glomerular filtration rate (eGFR) ($p < 0.0001$), etiology ($p < 0.0001$), 6-minute walking distance ($p < 0.0001$), age ($p < 0.0001$), NYHA class ($p < 0.0001$), LV EF ($p < 0.0001$), left atrial diameter ($p = 0.0001$), and restrictive mitral flow ($p = 0.006$). In the multivariate model, etiology ($p = 0.002$), 6MWT ($p = 0.003$), eGFR ($p = 0.004$), gender ($p = 0.005$), age ($p = 0.022$) and BNP ($p = 0.041$) emerged as predictors of outcome. Receiver operating curve analyses showed that 6-minute walking distance of 322 m and BNP of 330 pg/ml were the best cut-off values for outcome prediction. Kaplan-Meier analyses showed a survival free from all-cause mortality at 48-months in 41% of patients with 6-minute walking distance ≤ 322 m and BNP > 330 pg/ml, in 66% of those with 6-minute walking distance > 322 m and BNP > 330 pg/ml, in 86% in those with 6-minute walking distance ≤ 322 m and BNP ≤ 330 pg/ml, and in 93% in those with 6-minute walking distance > 322 m and BNP ≤ 330 pg/ml (Log-rank: 118.7; $p < 0.0001$).

Conclusion: In patients with chronic stable HFpEF and HFrEF, 6-MWT and BNP had a strong predictive power for the end-point of all-cause mortality. Our results highlight that 6MWT and BNP may be a first line approach for ongoing monitoring risk stratification of a population of ambulatory patients with HF.

P217

17beta-estradiol reduces endothelin-1 release in women with ischaemic left ventricular dysfunction

G M C Giuseppe M C Rosano¹; O Gebara²; M Wajngarten²; JC Aldrighi²; JAF Ramires²

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy; ²Instituto do Coracao FMUSP, Sao Paulo, Brazil

Objectives: To assess whether acute administration of 17 β -estradiol influences pacing-induced cardiac release of endothelin-1 in female menopausal patients with ischaemic left ventricular dysfunction.

Background: Endothelin-1 is a potent vasoactive peptide, estrogens decrease plasma levels of endothelin-1 and improve stress-induced myocardial ischemia in menopausal women with coronary artery disease. Methods. Thirty-two postmenopausal women with angiographically proven coronary artery were screened to enter a double blinded, placebo-controlled study. Selected were those with left ventricular dysfunction (LVEF $< 40\%$). Patients were sampled into the coronary sinus and aorta for endothelin-1 at baseline and after incremental pacing. After baseline study patients were randomized to receive either sublingual 17 β -estradiol (1 mg) or placebo and underwent the sampling protocol 20 minutes thereafter.

Results: The time of onset of myocardial ischemia during pacing (AST > 1 mm) was significantly increased by 17 β -estradiol (223 ± 21 versus 296 ± 15 seconds; The coronary sinus plasma levels of endothelin-1 were significantly reduced by estradiol administration but not by placebo, at each step of pacing protocol. The maximum reduction of endothelin-1 levels after E2 administration was noted at peak pacing (-0.19 ; -0.08 ; -0.3 ; 95% CI) while no changes were noted in patients allocated to placebo (-0.002 ; -0.06 ; -0.01 ; 95% CI). Similarly, aorto-coronary sinus difference was also significantly influenced by estradiol administration but not by placebo.

Conclusion: Acute administration of 17 β -estradiol reduces pacing-induced cardiac release of endothelin-1 in postmenopausal women with ischaemic left ventricular dysfunction.

P218

Plasma volume is normal but heterogeneously distributed and true anemia is highly prevalent in patients with stable heart failure

P Petra Nijst¹; FH Verbrugge²; P Martens¹; PB Bertrand¹; M Dupont¹; W Mullens¹

¹Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium; ²University Hospitals (UZ) Leuven, Leuven, Belgium

Background: Both intravascular volume overload and depletion as well as anemia are associated with increased hospital admissions and mortality in patients with heart failure. The purpose of this study was to accurately measure plasma volume and red cell mass (RCM) in stable patients with chronic heart failure with reduced ejection fraction (HFrEF) and gain more insight into plasma volume regulation and anemia in stable conditions of HFrEF.

Methods and Results: Plasma volume and RCM measurement based on

99Tc-labeled red blood cells, venous blood samples and clinical parameters were obtained in 24 stable HFrEF patients under optimal medical therapy. Measured plasma volume values were compared with predicted values based on body surface area. Plasma volume was on average normal (99% of predicted) but heterogeneously distributed (variations of 81% up to 133%) (Figure 1). Neurohumoral activation and medication use were not associated with plasma volume status (Table 1). Furthermore, anemia based on measurement of RCM was more prevalent than anemia based on hemoglobin concentration and present in up to 75% of subjects. The origin of anemia was mostly a true anemia while hemodilution was very rare.

Conclusion: In stable chronic HFrEF patients under optimal medical therapy, plasma volume is overall normal but heterogeneously distributed. Anticipated factors such as neurohumoral activation and heart failure medication were not associated with plasma volume status. Furthermore, anemia is more common than assessed by hemoglobin in stable HFrEF, but seldom dilutional.

Table 1. Subjects with measured plasma v

		Plasma volume > 100% of predicted n = 11	Plasma volume < 100% of predicted n = 13	p
Hemoglobin (g/dl)	Creatinine (mg/dl)	13.1 ± 1.2	13.5 ± 1.3	0.35
aldosterone (ng/L)	PRA (ng/L/h)	1.38 ± 0.52	1.57 ± 0.77	0.189
BNP (ng/L)	NT-pro	260	129; 306	0.9, 0.54
		(117;438)	(4.6; 26.65)	
		11.9 (0.42;	1020 (374;1668)	
		34.2) 1025		
		(457;2590)		
Ratio measured vs predicted plasma volume		+11.2 ± 9.2	-9.6 ± 6.3	< 0.01*
Angiotensin converting enzyme inhibitor (None/≤50%/ > 50%)	Beta-blocker	2/6/3 1/5/5	2/6/5 0/7/6	11 0.82 0.60
(None/≤50%/ > 50%)	Mineralocorticoid receptor antagonist	8/4/1/6	5/4/4	0.35 0.47
Loop diuretic (None/<1 mg/1 -2 mg)				

Loop diuretic dose is expressed in bumetanide equivalent (mg B eq) e.g. furosemide 40 mg = bumetanide 1 mg. Other HF therapy is presented as the number of patients on none, ≤50% or >50% of the target dose.

Figure 1: Measured to predicted ratio of

P219 Integrated approach to the management of heart failure: cardio - nephrology ambulatory.

L Luana Sirugo¹; G Manca¹; L Quartarone¹; MT Giannone¹; C Dell'ali¹; S Randone²; G Daidone²

¹Ospedale G. Di Maria, Cardiologia, Avola, Italy; ²Ospedale G. Di Maria, Nephrology, Avola, Italy

Background: Advanced refractory cardiac failure is a chronic condition seriously compromising the patient's quality of life often associated with significant complication, most notably the kidney damage, with high costruzione to National Health

Service. Consequently an increased non hospital care is the focal point in the management of this complex pathology. In our medical center we focus on clinical examination of the patients with refractory cardiac failure and kidney failure, specifically hydration state and non invasive hemodynamic evaluation.

Purpose: The main aim of the our study is to assess whether early detection of worsening of the cardiac function improve patient's outcome (hospitalization for heart failure, slows the decrease of kidney function, improve the quality of life, improve diastolic function).

Methods: We use Blo impedance vector analysis (BIVA), non invasive technique to assess Hydration status and body mass, resistance and reactance measurements. Cardiac non invasive hemodynamic evaluation assess systolic function, ejection fraction, stroke volume and index cardiac output to evaluate diastolic function and semiquantitative estimation of left ventricular end diastolic pressure. The lung-ultrasound with the detection of lung comets is also used to evaluate the interstitial edema. The vena cava excursion during briefing is an indirect index to estimate the central venous pressure. Result: We have observed in over two years of practice activity, patients quality of life improvement and a reduction of 40% in rates of re-hospitalization in this very frail patient.

Conclusion: Integrated management model between cardiologists and nephrologists allow to clinically stabilize "frequent flyers" patients through responsible involvement in the disease management of patient and therapy improved.

P220

Tolvaptan is useful and safe for the treatment of very elderly patients with heart failure and chronic kidney disease

K Kei Yoshioka¹; T Yoshio¹; K Matsumura¹; T Noda¹; T Ueyama¹; T Sakuma¹; H Park¹; Y Iharada¹; Y Yamamoto¹; I Shiojima¹

¹Kansai Medical University, Moriguchi, Japan

Background: Very elderly patients hospitalized for the treatment of heart failure (HF) are increasing in number. Because of their older age, many of those patients also have chronic kidney disease (CKD). Treatment of very elderly patients with HF and CKD is relatively difficult since those patients tend to be resistant to conventional diuretics treatment and diuretics therapy is frequently associated with further reduction in kidney function. Tolvaptan (TVP) was approved in Japan for the treatment of congestive heart failure 5 years ago. However, the effect of TVP on these patients has not been evaluated.

Objective: To investigate whether TVP administration to the very elderly patients with HF and CKD improves HF and the other clinical parameters.

Methods: Among very elderly patients (aged 80 or older) with HF and CKD, those who were resistant to conventional treatment or who exhibited impaired kidney function following initial treatment were enrolled. Subjects were additionally given oral TVP (7.5–15mg/day).

Results: 45 patients were included in this study and TVP was clinically effective for 41 patients. In the TVP responders, urine volume was significantly increased, and body weight and plasma BNP levels were significantly decreased. There was no significant change in serum sodium and creatinine levels.

Conclusion: TVP is useful and safe for the treatment of very elderly patients with HF and CKD.

P221

Treatment with omega-3 PUFAs improves endothelial function and novel echocardiographic indices of left ventricle systolic function

E Economou¹; D Karlis¹; G Siasos¹; T Zografos¹; K Mourouzis¹; C Chrysoschoou¹; S Brilli¹; G Lazaros¹; E Dimitropoulos¹; D Tousoulis¹

¹University of Athens Medical School, 1st Cardiology Department, "Hippokraton" Hospital, Athens, Greece

Background: Omega-3 polyunsaturated fatty acids (PUFAs) improve endothelial function and arterial stiffness in several patient groups and prevent heart failure (HF) progression.

Purpose: To evaluate the effects of omega-3 PUFAs on cardiac function and remodeling in patients with HF.

Methods: The study was carried out on two separate arms (omega-3 PUFAs-2gr/day- or placebo for 8 weeks), in a cross-over double blind design with an 8-wash out period between the two arms. The study population consisted of 15 systolic stable HF patients of ischemic etiology. All subjects were under optimal medical therapy for a period of 6 months. All subjects were evaluated at baseline and after completion of each treatment arm. Endothelial function was assessed using flow-mediated dilation (FMD) of the brachial artery. Pulse wave velocity (PWV) and augmentation index (AIx) were assessed non-invasively to evaluate arterial stiffness. Left ventricular (LV) function before and after treatment was assessed using LV ejection fraction (LVEF), determined by the biplane modified Simpson method, and LV global longitudinal strain (GLS), using Philips QLAB software.

Results: Fifteen subjects (age 65.4 ± 5.9yr) were included in the study. FMD at the end of the treatment period was significantly improved in the PUFA group compared to baseline (4.8 ± 2.2% vs. 2.9 ± 2.3%; p=0.003) but not in the placebo group (3.0 ± 2.3 vs. 2.8 ± 2.2%, p=0.065). PWV and AIx were not significantly

different in either the PUFA or the placebo group ($p=NS$ for all). A significant improvement in LV function as assessed by LVEF and GLS was observed only after PUFA treatment ($35.2 \pm 7.7\%$ vs. $33.9 \pm 7.2\%$; $p=0.039$, and $-11.8 \pm 3.1\%$ vs. $-10.3 \pm 3.1\%$; $p=0.020$, respectively) as well as a marginal improvement in LV diastolic and systolic dimensions ($55.6 \pm 5.9\text{mm}$ vs. $57.0 \pm 6.1\text{mm}$; $p=0.245$, and $45.3 \pm 6.4\text{mm}$ vs. $47.6 \pm 5.5\text{mm}$; $p=0.101$, respectively).

Conclusions: In systolic HF patients, short term treatment with omega-3 PUFAs improves left ventricle function and global longitudinal strain in parallel with benefits on endothelial function. These findings may shed light to the favorable pathophysiologic mechanisms of omega-3 PUFAs in heart failure subjects.

P222

Profile of our patients with reduced left ventricular fraction (HFrEF) explored in a day care unit

NN Ali-Tatar Chentir¹; Y Tir¹; I Bouznada¹; MT Chentir¹

¹University Hospital Centre Mustapha, Algiers, Algeria

Introduction: Despite the major progress in the field of medical and interventional therapy, we have every day to challenge chronic heart failure patients therapy and hospitalization.

Purpose: To describe clinical, and echocardiographic characteristics of patients (pts) with heart failure and reduced left ventricular fraction (HFrEF).

Methods: From January 2005 to January 2015, 401 patients, 230 males and 171 females, sex ratio 1.3, mean age 62 ± 15 years with depressed left heart failure were analyzed. Epidemiological, anthropometric, chest radiography, EKG and echocardiographic data in the context of a prospective mono centric observational study were assessed.

Results: Association of hypertension and diabetes was found in 30% of the patients. Smoking is present in 40% of the male patients. Right heart failure in 325 (81%), left heart failure in 296 patients (73%). Cardiomegaly in 351 (87%) of the patients. Atrial fibrillation occurs in 99 pts (25%), complete left bundle branch block (LBBB) in 32 pts (8%) and electro stimulated rhythm in 13% of them. Average Left ventricular ejection fraction is present in $42 \pm 8\%$ and pulmonary arterial hypertension in 190 pts (47%). Regarding medical treatment : 301 pts (75%) were on ACE Inhibitors (Angiotensin Converting Enzyme Inhibitors inhibitors), 100 (24%) on Angiotensin II Receptor Blockers (ARBs), beta blockers: 355 (88%) and spironolactone: 155 (38%). Cardiac resynchronization therapy (CRT/P/D) occurs in 20 pts with LBBB (62%) and failed in 8 of them.

Conclusion: In our country, age and etiology for heart failure differs from the European ones: our patients are younger and etiologies are mainly valvulopathies followed by coronary diseases closely related to hypertension and diabetes.

Etiology of cardiovascular diseases

Valvulopathies (n, %)	98 (24)
Dilated cardiomyopathy	123 (30)
History of coronary disease (n, %)	88 (21)
Hypertensive cardiovascular disease (n, %)	11 (2.7)
Toxic cardiomyopathy (Anthracyclin) (n, %)	3 (0.7)
Arrhythmogenic right ventricular dysplasia (n, %)	3 (0.7)
Grown up congenital heart disease (n, %)	2 (0.4)
Myocarditis (n, %)	2 (0.4)
Left ventricular non compaction (n, %)	1 (0.02)
Hypertrophic cardiomyopathy (n, %)	1 (0.02)

CRT-P in patient with aortic prothesis

Who diagnoses and treats patients with chronic heart failure in Germany?

A retrospective study of the health risk institute healthcare claims database

This research was funded by Novartis Pharma AG, Basel, Switzerland
F Calado¹; S Stork²; S Hupfer³; D Souto¹; R Handrock³; J Jacob⁴; J Walker⁴; S Klebs³

¹Novartis Pharma AG, Basel, Switzerland; ²University of Wuerzburg, Department of Internal Medicine I, Cardiology, Wuerzburg, Germany; ³Novartis Pharma GmbH, Nuernberg, Germany; ⁴Elsevier, Berlin, Germany

Background: Little is known about the journey of patients with newly diagnosed chronic heart failure (CHF) in real-world settings in Germany. Therefore, a retrospective study of anonymized healthcare claims data from the Health Risk Institute (HRI) database was conducted.

Purpose: The objective was to describe the journey of patients with newly diagnosed CHF in Germany.

Methods: Data from patients with at least two recorded CHF-related diagnoses in 2011 (based on ICD-10 German Modification codes for CHF in a hospital or ambulatory setting) were analysed. Further, a subgroup of patients with newly diagnosed CHF was identified based on the absence of a CHF diagnosis in the year before first diagnosis in 2011. All patients were followed for 2 years.

Results: CHF was newly diagnosed in 26 368 patients; in 63.2% ($n=16\,653$) the diagnosis was made by an office-based physician, in 36.6% ($n=9\,653$) the diagnosis was made in a hospital inpatient setting. Among patients diagnosed by an office-based physician, 61.6% ($n=10\,254$) of diagnoses were made by family practitioners and 21.6% ($n=3\,595$) by specialists in internal medicine; of the latter, 68.5% ($n=2\,462$) of diagnoses were made by cardiologists. A small proportion (7.0%, $n=1\,171$) of first CHF diagnoses were made by an office-based physician outside of family and internal medicine. Among patients with a first CHF diagnosis made in a hospital inpatient setting, 70.7% ($n=6\,827$) of diagnoses were made by internal medicine specialists; 27.3% ($n=1\,864$) of these were made by cardiologists. There was no information available for CHF diagnosed in a hospital outpatient setting. Of patients surviving the first quarter after CHF diagnosis (95.4%, $n=25\,155$), almost all (98.0%, $n=24\,641$) were treated in primary care in the same quarter; this proportion remained virtually unchanged after 2 years. Of note, 26.0% ($n=6\,541$) of these patients received additional hospital inpatient care in the first quarter after CHF diagnosis; this decreased to 14.9% after 2 years. A much smaller proportion of patients (4.2%, $n=1\,058$) received hospital outpatient care; this fraction remained almost unchanged after 2 years.

Conclusions: These results demonstrate the pivotal role of family practitioners as the primary point of contact in the diagnosis and management of patients with CHF. Close collaboration and communication between all specialities and sectors is essential for providing optimal care for these patients. Further studies are needed to quantify the effectiveness of patient journeys in terms of costs and patient outcome.

P224

Implementation of device therapy in LVSD (HFREF) as per the new UK nice guidelines: real world experience in a UK district general hospital

M A Abdool¹; L E Cowie¹; L J Howarth¹; S Carruthers¹; M Wasfi¹; D Lai Chin Kon¹; A Dhawan¹

¹Royal Albert Edward Infirmary, Wigan, United Kingdom

Background/Introduction: New UK National Institute for Clinical Excellence (NICE) guidelines have been published in June 2014 with respect to device therapy for Heart Failure with Reduced Ejection Fraction (HFREF) and QRS durations of $>120\text{ms}$. The Institute has updated the recommendations in the use of Cardiac Resynchronisation Therapy (CRT) with or without an associated Implantable Cardiac Defibrillator (ICD) in Left Ventricular Ejection Fractions (LVEF) of $<35\%$.

Purpose: This retrospective, observational audit was conducted to evaluate the implementation of the NICE guidelines in real world terms in a UK District General Hospital. In this particular setting, cardiac devices are inserted off-site with the support of a local electrophysiologist.

Methods: Electronic patient records for admissions in patients labelled with heart failure over a period of 6 months (Aug 2014 – Feb 2015) were analysed. Patients with LVEF $<35\%$ on Transthoracic Echo with associated QRSD $>120\text{ms}$ on surface ECG were identified. Results 226 patients were found to have LVEF $<35\%$, out of which only 49 patients had QRSD $>120\text{ms}$. This constituted the study population ($n=49$). The ages ranged from 60 to 95 years old with 75% ($n=37$) being in the 70-89 age bracket. 65% ($n=32$) were male. 55% ($n=27$) had underlying AF. 63% ($n=31$) had LBBB with only 1 of these having a QRSD $>150\text{ms}$. 32% ($n=16$) mortality at 6 months with the overwhelming majority (81%, $n=13$) not having a device already in situ. 27% ($n=13$) of patients had a device (CRT/P/CRTd/ICD) in situ with a 23% ($n=3$) mortality at 6 months. 8% ($n=4$) of patients who were eligible for a device and did not have any other disqualifying reason (eg frailty, patient choice) were deemed to have been missed, and hence guidelines not been adhered to.

Conclusions: The population eligible to receive device therapy in HFREF is ageing, with over three quarters being in excess of 70 years old. Mortality at 6 months appears to be higher if a patient does not have a device. For this particular District

General Hospital, there appears to be good adherence of 92% to new UK guidelines pertaining to device therapy in HFREF.

P225

The use of digoxin and its association with mortality in heart failure patients

R Santillan-Sanchez R¹; J Pineda-Juarez J¹; A Arturo Orea-Tejeda²; B Santellano-Juarez B¹; D Gonzalez-Islas D¹; C Cintora-Martinez C¹; V Pelaez-Hernandez V¹; R Pablo-Santiago R¹; E Contreras-Ramirez E¹; R Herrera-Saucedo R¹

¹Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Clinic, Mexico City, Mexico; ²Instituto Nacional de Ciencias Médicas y Nutrición "SZ", Mexico, Mexico

Introduction: Digoxin is a drug use to treat heart failure especially in those with left ventricle ejection fraction (LVEF) reduced and/or atrial fibrillation. It has been reported the risk/benefit of the minimum concentration (0.5-0.9 ng/ml) reducing the mortality. Nevertheless, some studies have report that the mortality increased with concentration above of 1ng/ml.

Objective: Assess if the digoxin use in patients with heart failure increase the mortality risk.

Materials and methods: Retrospective cohort study carried out in the Heart Failure and Respiratory Clinic in 279 patients on digoxin therapy. The patients were divided in two groups according with the outcome (surviving=255 and death=24). Were analyzed, demographic (sex, gender), anthropometric (BMI, dynamometry, hip and waist circumference), body composition thorough bioelectrical impedance (phase angle) clinics (NYHA), echocardiography characteristics and co-morbidities.

Results: The 59.9% were male (167), mean age was 62.6 ± 15.3. The ejection fraction was: 40.1% (112 LVEF), 12.2% (34), and 36.9% (103) right heart failure. To compare the surviving/mortality groups we used a T student independent; significant difference were found between waist (94.7 ± 15.5 vs 87.8 ± 10.9, p=0.02), and hip (100.7 ± 12.4 vs 94.2 ± 6.9, p < 0.001) circumferences, ischemic heart disease (35.9% (80) vs 71.4% (15), p=0.001), NYHA 1: 32.1% (80) vs 25% (6), NYHA 2: 41.4 % (103) vs 29.2% (7), NYHA 3: 21.3% (53) vs 45.8% (11), NYHA 4: 5.2% (13), p=0.04. Respect to other drugs: nitrates 35.3% (90) vs 75% (18), p < 0.0001. A Cox regression model was made to value the risk of digoxin use on mortality adjusted by demographic, body composition, pharmacologic treatment and clinics variables, as well as co-morbidities. A risk of 4.23(IC95 1.12 – 15.8, p=0.03) were found

Conclusion: Patients with heart failure had 4 fold risk of die because the digoxin use compare with those with not use. Nevertheless those who died were chaquetic (69.1) and have a worst clinic status, indeed, it could be explain our these results.

P226

Effects of valsartan/sacubitril on parameters of ventricular-arterial coupling in patients with heart failure and reduced ejection fraction

Z Kobalava¹; S Villevalde¹; E Tyukhmenev¹; O Olga Lukina¹; L Babaeva¹; E Zharikova¹

¹Peoples Friendship University of Russia, Moscow, Russian Federation

Objective: Angiotensin receptor-neprilysin inhibition with LCZ696 is a novel approach for the treatment of heart failure with reduced ejection fraction (HFREF). The aim of the study was to assess the effects of valsartan/sacubitril on parameters of ventricular-arterial coupling and left ventricular (LV) work efficiency in patients with stable HFREF.

Methods: In the open-label follow-up to PARADIGM HF study 18 patients with stable HFREF (16 male, 69 ± 9 years (M ± SD), arterial hypertension 83%, previous myocardial infarction 89%, diabetes mellitus 39%, dyslipidemia 56%, LVEF 32 ± 4%, serum creatinine 118 ± 21 µmol/l, eGFR 56 ± 13 ml/min/1.73m2, potassium 4.45 ± 0.35 mmol/l) were enrolled. Patients received a stable background treatment for at least a month (ACEI 94%, beta-blockers 100%, aldosterone receptor antagonists 83.3%, loop diuretics 72.2%). ACEI treatment was interrupted for 36 h and replaced with LCZ696 100 or 200 mg (11 patients) BID according to baseline brachial BP (mean dose 185.7 ± 36.3 mg BID). 2-dimensional echocardiography was performed to assess arterial (Ea) and end-systolic LV elastance (Ees) baseline and after 6 month LCZ696 therapy. VAC was assessed as the ratio Ea/Ees. Wilcoxon test was considered significant if p < 0.05.

Results: Baseline brachial BP decreased from 137.1 ± 22.0/83.4 ± 11.8 to 120.5 ± 13.5/75.1 ± 9.3 mmHg (Δ -16.6 ± 14.2/-8.3 ± 10.3 mmHg, p < 0.05), heart rate did not change (78 ± 12 vs 75 ± 15 beats/min (Δ -2.7 ± 14.7 beats/min, p>0.05). LCZ696 therapy was associated with significant decrease of VAC (2.10 ± 0.55 vs 1.68 ± 0.32, p < 0.05), Ea (2.11 ± 1.04 vs 1.66 ± 0.6 mmHg/ml/m2 (Δ -0.70 (-0.26%)), p < 0.05), arterial peripheral resistance (0.029 ± 0.016 vs 0.027 ± 0.011 mmHg/ml/min, p < 0.05), increase of stroke volume (63 ± 24 vs 78 ± 26 ml, p < 0.05). Ees remained unchanged (1.11 ± 0.42 vs 1.01 ± 0.52 mmHg/ml/m2, p>0.05). LCZ696 therapy was associated with potential energy decrease (8049 ± 2846 vs 5037 ± 2492 mmHg*ml/m2, p < 0.05), stroke work/pressure-volume area index (LV work efficiency) increase (0.48 ± 0.09 vs 0.63 ± 0.05, p < 0.05). There was no statistically significant correlation between decrease of Ea and brachial BP decrease. LCZ696 was well tolerated and there were no BP-related adverse events.

Conclusion: In stable patients with HFREF LCZ696 therapy was associated with BP-independent improvement in VAC related with decrease of Ea rather than Ees changes. Treatment with LCZ696 was also associated with decrease of arterial peripheral resistance and improvement of LV work efficiency

P227

Value of right ventricular function measurements in cardiac CT for patients with severe heart failure

F Fabian Plank¹; P Burghard¹; A Mayr¹; G Poelzl¹; G Feuchtnner¹
¹Innsbruck University Hospital, Innsbruck, Austria

Purpose: Right ventricular (RV) function is a parameter of paramount importance to define and modify treatment in patients with severe heart failure. Since many patients carry non-MR compatible pacemakers or defibrillators, we compared RV function in cardiac CT with echocardiography and invasive catheter as gold standard.

Methods: Twenty-six patients with severe cardiomyopathy (EF <35%) underwent 128-dual source ECG-gated cardiac CT with a biphasic contrast agent injection protocol to define RV function (EF, end diastolic and systolic volume). Measurements were compared to transthoracic echocardiography (EF, TAPSE, RA diameters) and invasive catheter (right atrial pressure, right ventricular contractility).

Results: While RV-EF in CT showed no significant correlation with TAPSE (r = 0.366, p = 0.94), the correlation to right atrial pressure (RAP) was moderate (r = 0.595, p = 0.006). TAPSE correlated non-significantly with RAP (r = 0.317, p = 0.23). Increasing severity of tricuspid regurgitation in TTE was significantly, inversely correlated with RV-EV in CT (r = 0.44, p = 0.05) and stronger correlated with RAP (r = 0.58, p = 0.02), while TAPSE showed a weaker trend (r = 0.29, p = 0.2). **Conclusion:** RV-EF in cardiac CT may be a better surrogate for right atrial pressure than TAPSE in CMP patients with severe CMP and thus pose a useful alternative to MR in case of incompatibility.

P228

Evaluation of the effect of taurine supplementation in chronic heart failure patients; a new study on old amino acid.

S Refaat Azab¹; N Ali Sabri¹; H Khorshid²; V William²; M Ayman Saleh²

¹Faculty of Pharmacy, Ain Shams University, Clinical Pharmacy Department, Cairo, Egypt; ²Faculty of Medicine, Ain Shams University, Cardiology Department, Cairo, Egypt

Background/Introduction: Ample of preclinical studies pointed out a huge benefit of taurine on cardiac functions. There is no recommendation with or against taurine supplementation due to paucity of clinical studies.

Purpose: Our aim was to test the effect of taurine on NT-proBNP levels, NYHA class and echocardiographic parameters in chronic heart failure (CHF) patients.

Methods: 34 CHF patients admitted to cardiac rehabilitation program were randomized into two groups as follows: -taurine group received 1 gm taurine capsule twice daily and guideline based therapy (beta-blocker, ACE-I or ARB, MRA and diuretics) -control group received only guideline based therapy. Evaluation of patients were performed at baseline and after two months regarding: NT-proBNP, NYHA class and echocardiographic parameters.

Results: All variables were comparable at baseline in both groups except for LVESV which was lower in taurine group. There were a significant reduction in NT-proBNP levels in taurine group (median; from 216.4 to 120.1 pg/ml, p = 0.009) and in control group (median; from 352.7 to 208.8 pg/ml, p = 0.002). However, the percent change between groups was not significant. Regarding NYHA class, taurine group showed significant improvement (median; from 2 to 1, p = 0.002) while control group showed improvement but without statistical significance. Improvement of echocardiographic parameters occurred in both groups but without statistical significance.

Conclusion: Despite the early promising results of previous studies on taurine, this study did not show favorable effects of taurine on lab, NYHA class or echocardiographic parameters in CHF patients subjected to cardiac rehabilitation.

Role of echocardiography in identifying patient at risk of adverse events in a heart failure reduced ejection fraction (HFrEF) population: a single center experience

C Calogero Falletta¹; A Ruggieri²; G Caccamo²; G Di Gesaro¹; C Mina¹; E Tortorici²; G Romano¹; V Agnese¹; F Clemenza¹

¹Mediterranean Institute for Transplantation and High Specialization Therapies (IsMeTT), Palermo, Italy; ²University of Palermo, Palermo, Italy

Background: Heart failure (HF) is still the first cause of hospitalization and death in Western countries, with significant burden of costs for healthcare system. Several clinical parameters, laboratory and instrumental tools have been extensively studied and applied to predict outcome of HF patients. Echocardiography is the most useful tool to achieve this goal, based on its large availability and relative low cost, in the face of the numerosity of information obtained

Purpose: Aim of this study is to investigate any association between echocardiographic parameters and adverse events (death and/or hospitalization for HF) in a cohort of HF outpatients, referred to our center as heart transplant (HTX) candidate.

Methods: This is a prospective observational study of a single center HF patient population. Between November 2011 and September 2014, all patient with ejection fraction (EF) <35% referred to outpatient clinic of our Institution for evaluation for HTX candidacy have been enrolled in the study. Criteria of exclusion were congenital cardiomyopathy, recent hospitalization (<1 month) for HF, recent myocardial revascularization or cardiac resynchronization device implant (<6 months). At enrollment, clinical and demographics data, labworks, glomerular filtration rate with MDRD formula, 12-leads EKG and transthoracic echocardiogram were recorded. Such evaluation was repeated every six months and events (death and/or hospitalization for HF) registered. Association between clinical, laboratory, echocardiography data and events was analyzed.

Results: During the period of observation 217 patients (82% males) were enrolled in the study. Mean age was 59.4 ± 10.2 years, mean EF 27%. Median follow-up was 27 months (range 12-39). During the period of observation we recorded 16 death and 53 hospitalizations for cardiac causes, for a total of 47 patients reaching the end-point. At univariate analysis, a bigger left ventricle end-diastolic diameter (LVEDD, 67 ± 7 vs 62 ± 7 mm, p < 0.0001) and volume (LVEDV, 228 ± 69 ml vs 191 ± 64 ml, p = 0.003), a

lower EF (23 ± 6 vs 27 ± 6%, p < 0.0001), a bigger left atrium diameter (LAD, 51 ± 9 vs 4. ± 7 mm, p < 0.0001) and volume (LAV, 109 ± 46 vs 86 ± 41 ml, p = 0.007), an higher E/e' ratio (17.4 ± 9 vs 13.4 ± 6.5, p = 0.012), a bigger mitral regurgitation vena contracta (2.6 ± 1.2 vs 1.9 ± 1.3 mm, p = 0.002), a lower TAPSE (17 ± 5 vs 19 ± 4 mm, p < 0.04) and a higher estimated central venous pressure (8 ± 4.7 vs 6 ± 3.6 vs, p = 0.01) were associated with combined endpoint. At multiple logistic regression analysis, lower EF (HR 0.937, p = 0.036), higher LVEDD (HR 1.060, p = 0.008) and LAD (HR 1.048, p = 0.011) were associated with combined endpoint

Conclusion: Our experience confirms that in a cohort of HFrEF patients, most of the parameters currently used has been associated with adverse events (death and/or hospitalization for HF). Moreover, EF, LVEDD and LAD resulted associated with outcome, independently from other clinical and echocardiographic variables.

Exposure to heart failure treatments in newly diagnosed patients in Sweden

This research was funded by Novartis Pharma AG, Basel, Switzerland G Wikstrom¹; K Boman²; M Olofsson²; K Lindmark³; R Lahoz⁴; S Corda⁴; V Wintzell⁵; R Linder⁶; A Gondos⁶; J Stalhammar⁷

¹Uppsala University, Institute for Medical Sciences, Uppsala, Sweden; ²Umea University, Department of Public Health and Clinical Medicine, Umea, Sweden; ³Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden; ⁴Novartis Pharma AG, Basel, Switzerland; ⁵IMS Health Sweden, Stockholm, Sweden; ⁶IMS Health Germany, Berlin, Germany; ⁷Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden

Background: Exposure to heart failure (HF) therapies in newly diagnosed patients is unclear; a better understanding of therapy combinations used may improve treatment.

Purpose: To characterize HF therapies for patients with newly diagnosed HF (main ICD-10 code I50) in Sweden.

Methods: Primary and secondary care electronic medical records and the Swedish Prescribed Drug Register were used to identify patients and prescribed therapies. Patients (≥18 years) with a first HF diagnosis (index date) from 01/01/10–31/03/15 were included. A 9-year look-back period to exclude prevalent cases and a 2-year follow-up period per patient were applied. A therapy episode was assumed to last from first dispensation to 30 days after last dispensation (≤120 days between dispensations). Predefined therapy groups (including 'no therapy') were analyzed: angiotensin-converting-enzyme inhibitors (ACEi), angiotensin receptor blockers (ARB), beta-blockers (BB) and mineralocorticoid receptor antagonists (MRA) (alone or combined).

Results: Of 8777 records, 1885 patients were identified (45% women; mean age: 75 years); 357 (19%) had confirmed HF with reduced ejection fraction (HF-rEF; left ventricular EF ≤50%), 217 (12%) had confirmed HF with preserved EF (HF-pEF; left ventricular EF >50%) and 1311 (70%) had HF of unconfirmed phenotype (HF-unknown). One year after index, triple therapy (any combination) was used more often for HF-rEF than for HF-pEF or HF-unknown (Table 1). Dual therapy was consistently used more frequently than triple therapy. Proportions of patients in the following groups varied from 1 year before index to 1 year after index: ACEi+BB (1 year before index: 14%; at index: 22%; 1 year after index: 21%); ACEi+BB+MRA (1 year before index: 3%; at index: 10%; 1 year after index: 12%); and ARB+BB (1 year before index: 8%; at index: 11%; 1 year after index: 12%). Peak therapy exposure arose 2 months after index in all cases.

Conclusions: Patients with HF-rEF were more intensively treated with triple therapy than those with HF-pEF, as per ESC guidelines and evidence. Confirming HF phenotype may optimize HF therapies.

61058. Table 1

P231

Effect of ivabradine on functional status and cardiovascular disease risk of mortality, in patients with heart failure and left ventricular dysfunction. A PanHellenic prospective study

SERVIER HELLAS

I Kanonidis¹; V Grammatikou²; M S Kallistratos²; A Sideris³¹Hippocraton General Hospital of Thessaloniki, 2nd Department of Cardiology, Thessaloniki, Greece; ²Servier Hellas Pharmaceuticals, Ltd, Athens, Greece;³Evangelismos General Hospital of Athens, 2nd Department of Cardiology, Athens, Greece

Background/Introduction: Heart failure (HF) patients present increased cardiovascular (CV) morbidity and mortality and thus, are classified as high CV risk patients. Medical treatment represents the cornerstone to improve prognosis and reduce rehospitalizations in those patients.

Purpose: To record the effect of ivabradine on functional NYHA classification, as well as on the CV risk, in patients with HF and left ventricular systolic dysfunction (LVSD), recently hospitalized (in the last 6 months) for HF decompensation. To record patient's adherence with ivabradine treatment, co-administered medical treatments, as well as co-existing risk factors and comorbidities.

Methods: In this observational study, 1603 HF patients with LVSD were prospectively recorded from 140 public or private cardiology departments or practices. The estimation of the 10 year % risk of CV disease mortality was assessed through the FINRISK chart (including the following variables: age, gender, smoking, BMI and resting heart rate (HR)).

Results: From 1603 HF patients who participated in the study, 12 patients (0.7%) prematurely discontinued treatment. 67% of the sample were males aged 69.4 ± 10.8 years, while mean HR was 82.0 ± 10.9 bpm. After 4 months treatment, ivabradine addition resulted into an improvement of NYHA functional class; the percentage of patients NYHA I/II increased from 0%/48.5% to 32.7%/57.9%, while the percentage of patients NYHA III&IV decreased from 51.5% to 9.4% ($p < 0.001$). Heart rate was decreased from 82.0 ± 10.9 bpm to 66.7 ± 6.4 bpm ($p < 0.001$), leading to an improvement on 10 year % risk of CV disease mortality score. The percentage of patients with a 10 year % risk $\geq 10\%$ decreased from 47.6% to 24.4%, while the percentage of patients with a 10 year % risk $< 10\%$ increased from 52.4% to 75.7% ($p < 0.001$).

Conclusions: Ivabradine administration in patients with HF and LVSD improves not only NYHA classification, but also the 10 year % risk of CV disease mortality.

P232

Characterisation of circulating hepcidin levels in patients with heart failure

N Ebner¹; M Konishi¹; J Ishida¹; A Emami¹; M Rodrigues Dos Santos¹; A Sandek¹; J Springer¹; SD Anker¹; S Von Haehling¹¹University Medical center Göttingen, Cardiology and Pneumology, Göttingen, Germany

Background: Anaemia and iron deficiency (ID) are important factors for muscle function and exercise capacity in patients with chronic heart failure (HF). Their interaction in HF remains to be defined.

Methods: A total of 253 patients with stable chronic HF (mean age: 67 ± 11 y, 21% female, left ventricular ejection fraction [LVEF] $39 \pm 13\%$, body mass index [BMI] 29.5 ± 5.5 kg/m², New York Heart Association [NYHA] class 2.3 ± 0.6 , diabetes mellitus 30%, glomerular filtration rate 53.7 ± 15.6 mL/min) were enrolled from 2010 and followed until April 2014 or until they died. Anaemia was defined according to World Health Organization criteria [Hb < 13 g/dL in men, < 12 g/dL in women]. Iron deficiency (ID) was defined as serum ferritin < 100 µg/L or ferritin < 300 µg/L with transferrin saturation (TSAT) $< 20\%$. Exercise capacity was assessed by spiroergometry (peakVO₂) and 6-minute walk test (6MWT).

Results: A total of 72 patients (28%) presented with anaemia and ID was present in 122 patients (48%). Differentiating all patients according to iron status, patients with ID had lower peak VO₂ 15.5 ± 5.1 vs. patients without ID 17.9 ± 4.5 mL/kg/min ($p = 0.0002$). Likewise, hand grip strength was significantly reduced in patients with ID (34.3 ± 11.8 vs. patients without ID 39.1 ± 11.7 kg, $p = 0.002$) and 6MWT was reduced in patients with ID (400.8 ± 140.1 vs. patients without ID 456.2 ± 129.8 m, $p = 0.002$). Patients with ID showed significantly lower serum hepcidin (11.8 ± 11.6 vs. patients without ID 18.6 ± 12.4 ng/mL, $p = 0.002$), lower L-Kynurenin (3.6 ± 1.5 vs. patients without ID 3.3 ± 1.3 µmol/L, $p = 0.04$) and higher FGF-23 levels (216.8 ± 242.3 vs. patients without ID 117.9 ± 122.2 RU/mL, $p < 0.0001$), higher PTH (61.3 ± 36.3 vs. patients without ID 51.0 ± 30.2 pg/mL, $p = 0.02$). There were no differences in serum hepcidin between anaemic and non- anaemic patients. Patients with HFpEF showed significantly higher hepcidin levels (20.1 ± 16.2 ng/mL) than patients with HFrEF (14.2 ± 10.8 ng/mL, $p = 0.02$). Regardless of HFpEF or HFrEF patients in NYHA I-II had lower levels of hepcidin (14.0 ± 10.9 ng/mL) than patients in NYHA III&IV (18.8 ± 14.5 ng/mL, $p = 0.03$).

Conclusion: Increased level of hepcidin characterizes an early stage of HF, and is not accompanied by anaemia. The progression of HF is associated with the decline in circulating hepcidin and the development of ID.

P233

Systematic assessment of heart failure data sources across 120 countries: analysis of their suitability for real-world evidence research

This research was funded by Novartis Pharma AG, Basel, Switzerland
A Castelo-Branco¹; P Lecomte²; S Corda²; R Lahoz²; N Justo¹; F Calado²
¹Mapi Group, Stockholm, Sweden; ²Novartis Pharma AG, Basel, Switzerland

Background: There is a wealth of global real-world data relating to patients with heart failure (HF).

Purpose: This study aimed to identify real-world patient-level HF data sources in 120 countries across seven geographical regions that could be used in observational research designed to generate real-world evidence in HF. The study also aimed to critically evaluate data sources completeness to address pre-specified research questions in at least one data source from each country.

Methods: A systematic literature review for the period from 1 January 2010 to 7 December 2014 was conducted in Medline and EMBASE. A search of ISPOR databases, a focused Internet search and a survey of Novartis and Mapi colleagues were also conducted. A database abstraction tool was developed to record information on each data source. The value of each source for observational research was scored using 15 criteria relating to data on: patients with acute and chronic HF; five essential variables (including left ventricular ejection fraction); six pre-specified HF real-world evidence research questions (on epidemiology, treatment patterns, predictors of outcomes, safety, effectiveness and burden of illness); sample size of > 1000 ; ≥ 1 year of follow up; and accessibility to pharmaceutical companies.

Results: Overall, 1034 unique HF data sources were identified. Of these, 150 data sources (24 international and 126 national) covering 103 countries were selected for detailed evaluation. Coverage of variables related to the pre-specified HF real-world evidence research questions varied across sources, with the degree of completeness ranging from 0–97%; the largest number of sources ($n = 35$) had data which were 41–50% complete across variables. Of the variables related to the research questions, the most complete were age and sex (93%) and comorbidities (84%); the least complete were use of procedure codes (7%) and prescription codes (6%) and dates of procedures and prescriptions (6%). All geographical regions had at least one level-3 (high value) data source (44 level-3 sources in total). There were no level-4 (very high value) data sources.

Conclusion: There are many data sources containing real-world patient-level data on HF across the globe. However, the data available on real-world safety, effectiveness and burden of illness are limited. These limitations may be overcome by linking sources using patient identifiers. These evidence gaps need to be addressed so that existing data sources can be made suitable for observational studies in HF.

P234

Review in a specialist heart failure clinic is associated with reduced hospitalisation in patients with suspected heart failure and raised natriuretic peptides

L Philip Legate¹; P Kalra¹; G Morton¹¹Portsmouth Hospitals NHS Trust, Cardiology, Portsmouth, United Kingdom

Introduction: In the UK, national guidelines (NICE) recommend that patients with suspected heart failure (HF) and raised natriuretic peptides are seen at a specialist clinic for timely echocardiography and assessment. Limited data are available on whether this affects outcome. The aim of this study was to compare outcomes in patients with suspected HF and raised natriuretic peptides who were reviewed in a specialist clinic (HF clinic) to those who were managed in non-specialist primary care settings (No HF Clinic).

Methods: Data were collected retrospectively from hospital records. All outpatients with a raised NTproBNP (> 400 pg/ml) from February to September 2014 were included in the study. Outcomes assessed were hospital admissions, length of stay, reason for admission and mortality. Minimum follow up was 6 months from the raised NTproBNP result.

Results: 567 consecutive patients were identified: 161 (28%) in the HF Clinic group and 406 (72%) in the No HF Clinic group. All HF clinic patients were seen within 2 weeks (NTproBNP > 2000 pg/ml) or 6 weeks (NTproBNP 400–2000 pg/ml) of referral in line with NICE recommendations. Mean follow up was 8.9 ± 2.3 months. Results are shown in Table 1.

Conclusions: Hospitalisation rates were extremely high over a relatively short follow up period. Patients reviewed in HF clinic had much higher NTproBNP levels, suggesting they were at higher risk of adverse outcomes, yet also had significantly lower rates of all cause and cardiovascular hospitalisation. The data are observational so causation and association cannot be separated however the magnitude of difference between the two groups suggests referral to HF clinics may improve outcomes. Our findings support national guidelines that patients with suspected HF and raised natriuretic peptides should be seen at a specialist clinic.

Table 1

	HF clinic (n = 161)	No HF clinic (n = 406)	p value
Age	78 ± 9	80 ± 9	0.02
Males	84 (52%)	195 (48%)	0.42
Average NTproBNP	3352	2365	<0.0001
All-cause hospitalisation	37 (22.3%)	180 (44.3%)	<0.0001
CV hospitalisation	4 (2.5%)	57 (14.0%)	<0.0001
Deaths	9 (5.6%)	33 (8.1%)	0.3
Mean hospital stay	4.7 days	5.6 days	0.42

P235

Value of anti-HLA antibodies monitoring during the first year after cardiac transplantation

I Malek¹; T Gazdic²; M Hegarova¹; L Hoskova¹; A Slavcev¹; L Voska³; J Pirk²

¹Institute for Clinical and Experimental Medicine, Cardiology, Prague, Czech Republic;

²Institute for Clinical and Experimental Medicine, Cardiovascular surgery, Prague, Czech Republic;

³Institute for Clinical and Experimental Medicine (IKEM), Pathology, Prague, Czech Republic

Introduction: Examination of anti-HLA antibodies (HLAab) by solid base methods (Luminex) before cardiac transplantation (CTX) is useful for screening patients (pts) at risk of antibody-mediated rejection (AMR) after CTX. The value of de novo HLAab developed after CTX is less clear. Purpose Aim of the study was to estimate whether monitoring of HLAab during the 1st year after CTX can be useful for prediction of rejection and mortality of the pts.

Patients and methods: Between 1/2011 – 7/2013 CTX was performed in 119 pts. We prospectively studied the group of 97 pts with complete clinical and immunological data, who survived 1st 12 months after the operation. Follow-up was 27-57 months. Examination of HLAab was performed before CTX and in 1st, 3rd, 6th and 12th month after CTX. The results were correlated with clinical events (treated cellular rejection – ACR, AMR, graft dysfunction and death / retransplantation). ACR and AMR were assessed from endomyocardial biopsy (EMB) samples, decrease of left ventricular ejection fraction (LV EF) below 40 % was sign of graft dysfunction. HLAab were investigated by Luminex method. Results HLAab class I (I) were found in 33 % of pts (in 13 % only after CTX – de novo). HLAab class II (II) in 11.8 % (in 7, 5 % de novo). Donor specific ab (DSA) were found in 16 %. ACR occurred in 13 pts, AMR in 6, graft dysfunction in 13 pts. Nine pts died, 6 of them from cardiovascular (CV) cause. Pts with de novo HLAab II had higher rate of (1) ACR (26 % vs 9 %, p=0.042; OR 6.3 [1.2 – 32.5] PPV 43 %, NPV 89 %); (2) graft dysfunction (43 % vs 11 %, p=0.047; OR 6.2 [1.2 – 32.1]; PPV 43 %, NPV 89 %); (3) mortality from CV cause (28.6 % vs 3.6 %, p=0.046; OR 10.8 [1.5 – 80.1]; PPV 29 %, NPV 96 %). Patients with de novo DSA experienced higher rate of graft dysfunction (42.9 % vs 10.0 %, p=0.04; OR 6.8 [1.3 – 35.7]; PPV 43 %, NPV 90 %).

Conclusions: Absence of HLAab II during the 1st year after CTX predicted good clinical outcome in middle-term follow up, but positive predictive value was low. Developing de novo HLAab did not allow prediction of AMR in our group of pts.

P236

Cardiac resynchronisation in elderly patients: improvement in left ventricle ejection fraction in real world.

S Briongos Figuero¹; M Cortes²; J Benezet-Mazuecos²; A Romero²; A Garcia²;

JA Palfy²; A Estevez¹; A Sanchez¹; R Munoz-Aguilera¹; J Farre²

¹University Hospital Infantil Leonor, Cardiology, Madrid, Spain; ²Foundation

Jimenez Diaz, Cardiology, Madrid, Spain

Background: improvement in left ventricle ejection fraction (LVEF) after cardiac resynchronization therapy (CRT) appears in around 57%, when pooled data are analysed. Response in the elderly is poorly defined. We aimed to study echocardiographic response to CRT in a group of elderly patients (≥75 years old).

Methods: A total of 45 patients (mean age 79.2 ± 2.9 years; 79.6% men) undergoing CRT implantation between June 2006 and October 2014 were studied. Echocardiographic response was defined by an improvement in LVEF ≥15% (relative).

Results: average LVEF was 23.1 ± 6.7% at the time of the implant. The mean QRS duration was 155.4 ± 25 ms and mean left ventricle end diastolic diameter (LVEDD) was of 60.4 ± 6.6 mm. Left bundle branch block (LBBB) was present in two thirds and most of the patients included were in NYHA III-IV functional class (FC) (54.2%). Population was under optimal medical treatment (Beta blockers: 87.5%; ACEI (angiotensin-converting enzyme inhibitors)/ARB (angiotensin II receptor blockers): 64.6/27.1% respectively). After a mean follow up of 37.2 months, a significant improvement in LVEF (mean value: 30.8 ± 13.7%) and FC (NYHA I-II in 60.5% of population) was observed and the mean LVEDD also decreased (57.3 ± 9.3 mm). Response estimated by LVEF improvement of ≥5% was observed in 55.6% of

the sample (25 patients). Responders not only showed significant improvement in LVEF (baseline LVEF 23.3 ± 6.6 and final LVEF 30.7 ± 13.8; p=0.001) compared with non responders (baseline LVEF 22.9 ± 6.7 and final LVEF 24.7 ± 9.6; p=0.297) but also greater reductions in LVEDD (baseline 59.3 ± 7.7 mm and final 53.3 ± 10.1; p=0.014 in responders Vs baseline 61.4 ± 4.6 mm and final 61.9 ± 5.9; p=0.655 in non responders). None of the predictors of response to CRT in general population (gender, non-ischemic etiology, LBBB, QRS duration, sinus rhythm) were useful in our population of elderly patients.

Conclusion: echocardiographic response to CRT in old patients was similar than in younger population. Up to 55.6% of elderly patients under optimal medical treatment showed a significant improvement in LVEF after long-term follow up. Indications used for CRT in general population must be also followed in patients ≥ 75 years.

P237

Use and benefit of angiotensin-converting enzyme inhibitors/ angiotensin receptor blockers in senior patients with left ventricular systolic dysfunction

M Lopez Castillo¹; M Cortes Garcia¹; M Martin Mariscal¹; A Garcia Ropero¹;

A Romero Daza¹; JA Palfy¹; S Briongos Figuero¹; J Farre Muncharaz¹

¹Foundation Jimenez Diaz, Cardiology, Madrid, Spain

Background: ACE inhibitors and ARBs have been demonstrated to enhance survival in patients with HF and reduced ejection fraction (EF), therefore its use has a class I indication in this patient population according to current guidelines.

Purpose: We aim to assess the use and benefit of ACEi/ARB's in the daily clinical practice in elderly patients.

Methods: Between 2008 and 2013 we prospectively collected and analysed clinical and technical data of patients over 75 years diagnosed with left ventricular EF < 35% by transthoracic echocardiography in our laboratory. At the end of the follow-up, medical history and test results were completed by a detailed medical report review. We evaluated the rates of mortality and cardiac events, defined as death from cardiovascular cause or hospitalization for Heart Failure.

Results: A total of 802 patients were included with a mean age of 82 ± 4.9 years, 33.8% were female and the mean LVEF was 28 ± 6.5% at inclusion. The rate of high BP was 79.2%. Thirty-three percent of the population was diabetic and 35.7% had chronic renal disease. During the follow-up (32.7 ± 22.7 months), 381 patients (47.5%) died and there were 496 cardiac events (61.8%). Regarding anti-remodelling therapy, 73.9% of the study population was on ACEi/ARBs, 69.3% on beta blockers and 45.1% of the patients received aldosterone antagonists. Although the use of ACEi resulted to be associated to a significantly lower mortality (OR:0.66;0.53-0.82) and cardiac event rate (OR: 0.65;0.54-0.79), 26.1% of our patients did not receive this therapy during the follow-up. Chronic renal disease (32.8%), dizziness or hypotension (16.9%), and hyperkalaemia (2.2%) resulted to be the most common causes of not taking ACEi/ARBs. Nevertheless in 28.4% of the patients no formal contraindication was found.

Conclusions: In our study population, ACEi/ARBs therapy was associated to a lower mortality and cardiac event rate. However, a significant number of patients did not receive these drugs without having a formal contraindication. Becoming aware of its beneficial effect, and with a more strict adjustment to the current guideline recommendations, ACEi/ARB therapy could improve the prognosis of a particular patient population: the elderly.

P238

Prescription of recommended therapy decreases with the severity of heart failure

J Jindrich Spinar¹; J Parenica¹; O Ludka¹; L Spinarova²; M Spinarova²; K Labr²;

F Malek³; P Ostadal³; D Vondrakova³

¹University hospital, Brno, Czech Republic; ²Masaryk University, Brno, Czech

Republic; ³University Hospital, Prague, Czech Republic

Aim: To describe pharmacotherapy of heart failure in stable patients with chronic heart failure treated in specialized cardiology outpatient departments.

Methods: Anamnestic data were collected from November 2014 till November 2015 in 7 cardiology outpatient departments in 3 university hospitals in 2 cities. The patients had to be treated for systolic heart failure (EF < 50%) and stable for at least one month.

Results: 1121 patients were included mean age 65 years, 80.5% were male. The etiology of heart failure was ischemic heart disease in 49.1%, dilated cardiomyopathy in 41.0% and 9.9% were classified as other. The median of blood pressure was 120/80 mmHg, median of heart rate 72. 149 (13.3%) were classified as NYHA I, 673 (60.0%) NYHA II and 299 (26.6%) as NYHA III and IV. Patients with higher NYHA class had more frequently leg oedema (p<0.001), atrial fibrillation (p<0.001), lower ejection fraction (38% resp. 30% resp 25%) and more frequently co morbidities. They had lower BPs (131 resp. 129 resp. 125 mmHg), but the same BpD 80 mmHg (ns) and more frequently co morbidities. The prescription of ACE-I/AIIA decreased with the severity of the disease (95.3% resp. 88.4% resp. 82.9%, p<0.001), the prescription of betablockers remained stable + 92% and the prescription of furosemide increased (52.3% resp 81.5% resp. 93.6% p<0.001) as well as the prescription of digoxin (16.1% resp. 29.0% resp. 49.8%, p<0.001). Increased prescription with increased

NYHA class was also observed in aldosterone blockers ($p < 0.001$), anticoagulants ($P < 0.001$) on the opposite there was a decrease in the prescription of antiaggregation ($p = 0.003$) or statins ($p = 0.05$).

Summary: the trends in pharmacological prescription probably reflex not only the Severity of heart failure, but also co morbidities and complications like renal failure or atrial fibrillation. The data will be further analysed, complete biochemistry (including Nt-proBNP) is available in all patients.

P239

Effect of long term treatment with trimetazidine on left ventricular systolic function, on quality of life and exercise capacity in patients with chronic heart failure

G Giuseppe Marazzi¹; F Pelliccia²; G Campolongo¹; L Cacciotti³; M Sbarigia¹; C Bevilacqua¹; M Volterrani¹; G Rosano¹

¹IRCCS San Raffaele Pisana Hospital, Rome, Italy; ²Sapienza University of Rome, Department of Cardiovascular Diseases, Rome, Italy; ³Madre Giuseppina Vannini Hospital, Rome, Italy

Background: Metabolic treatment involves the use of drugs that improve cardiomyocyte function. Trimetazidine is one of the most investigated drug in this group with a well-established role in the treatment of chronic angina. The available data suggest that therapy combining trimetazidine and hemodynamic drugs is effective in patients with chronic heart failure.

Methods: Patients were randomized to receive either trimetazidine (twice daily) or placebo (twice daily) in addition to optimal standard therapy, and were evaluated at baseline and after 12 months left ventricular function, exercise tolerance and quality of life.

Results: we have enrolled fifty patients (30 male, mean $[+/-SD]$ age 63 ± 5.9 years). NYHA class and left ventricular ejection fraction were comparable between the two groups. At 12 months there was a significant improvement in the number of dyspnea episodes per month in the trimetazidine group (-4.1 ± 2 , $p < 0.05$), also the left ventricular ejection fraction increased only in the trimetazidine group from 32.1% to 34.6% , $p < 0.05$ while in the placebo group there are not significant difference (from 31.7 to 32.1% , $p > 0.05$). For the distance at 6 minutes walking test the patients in the trimetazidine group increased more than the placebo group (respectively from 274 m to 388 m ($p < 0.05$) and 283 m to 301 m ($p > 0.05$). The overall assessment of QoL showed an improvement in patients randomized to trimetazidine at 12 months (from 5.4 to 7.1 , $P < 0.01$) and no changes in patients randomized to placebo (from 4.8 to 4.9 , $P > 0.05$).

Conclusions: In patients with chronic heart failure, trimetazidine improves clinical condition, left ventricular systolic function, quality of life and exercise capacity.

P240

Pharmaco-invasive approach aimed at preservation of the left ventricular function in patients with stable coronary artery disease on the top of carbohydrate metabolism disorders

E Elena Vershinina¹; TR Ryabova¹; AN Repin¹

¹State Research Institute of Cardiology of Tomsk, department of rehabilitation, Tomsk, Russian Federation

Introduction: the coronary artery disease (CAD) treatment in type 2 DM patients remains a major issue for cardiologists. Despite significant advances in medical and invasive treatment, including implantation of drug-eluting stents, the patients still have high morbidity and mortality due to progression of atherosclerosis and HF even after percutaneous or surgical revascularization.

Purpose: the aim of our study was to investigate the effect of the metabolic agent trimetazidine (TMZ) on the left ventricular function in patients with CAD on the top of carbohydrate metabolism disorders, who underwent elective percutaneous coronary intervention (PCI).

Methods: an open label, prospective, randomized clinical trial was conducted in 63 patients stable CAD on the top of carbohydrate metabolism disorders. All patients underwent elective coronary stenting. The patients of the main group ($n = 32$) received TMZ 35 mg bid in addition to standard therapy for 2 weeks before and 1 year after the procedure. In control group patients ($n = 31$), PCI and the following follow-up were performed on the top of standard therapy only, without the use of metabolic agents. At baseline, two groups did not differ significantly in terms of the severity of myocardial ischemia, clinical and medical history data, degree of carbohydrate metabolism disorder, as well as concomitant treatments, characteristics of coronary artery lesions and performed PCI. The echocardiography was performed twice: at baseline and at 12 months of follow-up.

Results: despite the performed PCI, the carbohydrate metabolism disorders in CAD are associated with a significant deterioration in the regional contractility of myocardium and reduction in the LV pump function at the follow-up (WMSI increase by 8.3% and LV SVI decrease by 7.25% at 12 months after the intervention, compared with baseline). Long-term treatment with myocardial cytoprotector in this patients results in a significant improvement in the contractile function of the LV myocardium in the long-term, according to the EchoCG data (LV EDI decrease by 5.5% , LV ESI decrease by 4.4% , LVEF increase by 2.5% at 12 months after the

intervention, compared with baseline). The improvement in the myocardial function during the long-term treatment with TMZ is evidenced clinically by a longer distance walked during the 6MWT ($+18.4\%$ vs. the standard treatment group).

Conclusion: the pharmaco-invasive approach, namely the addition of a metabolic agent trimetazidine to the standard therapy in patients with carbohydrate metabolism, undergoing the elective PCI, contributes to the preservation of myocardial function.

Ethnic differences in quality of life and its association with survival in patients with heart failure

National Medical Research Council, Singapore (grant no. R-172-003-219-511); Clinician Scientist Award (C.S.P.L)

THK Tiew-Hwa Katherine Teng¹; WT Tay²; G Stein³; AM Richards L-H Ling⁴; RN Doughty⁵; DKL Sim⁶; PSD Yeo G-K-T Leong⁶; FR Jauferally⁷; HY Ong⁸; CSP Lam⁹

¹National Heart Centre Singapore; School of Population Health, University of Western Australia, Singapore, Singapore; ²National Heart Centre Singapore, Singapore, Singapore; ³Montefiore Medical Center (Bronx), Dept of Psychiatry and Behavioural Sciences, New York, United States of America; ⁴National University of Singapore, Cardiovascular Research Institute; Yong Loo Lin School of Medicine, Singapore, Singapore; ⁵The University of Auckland, Cardiovascular Research Group, Auckland, New Zealand; ⁶Tan Tock Seng Hospital, Department of Cardiology, Changi General Hospital, Department of Cardiology, Singapore, Singapore; ⁷Duke-NUS Graduate Medical School Singapore, Internal Medicine, Singapore General Hospital, Singapore, Singapore; ⁸Khoo Teck Puat Hospital, Department of Cardiology, Singapore, Singapore; ⁹National Heart Centre Singapore, Duke-National University of Singapore, Cardiovascular Research Group, National University, Singapore, Singapore

Background: Optimizing quality of life (QoL), as a patient-centred outcome, is a key priority in the management of heart failure (HF). Aims: To investigate ethnic differences in QoL and its association with 1-year survival among Asian HF patients.

Methods: In a prospective nationwide cohort ($n = 1070$, mean age 62 years, 24.5% women) of Chinese (61.6%), Malay (27.2%) and Indian (11.1%) ethnicities from Singapore, QoL was assessed using the Minnesota Living with HF Questionnaire (MLHFQ) at baseline presentation and 6 months, and patients were followed for all-cause mortality.

Results: At baseline, mean MLHFQ scores for total, physical, and emotional components were 32.9 ± 23.1 , 15.4 ± 11.0 and 5.9 ± 6.0 , respectively in the entire cohort. Chinese had a lower (better) MLHFQ total score (29.1 ± 21.6) compared with Malays (38.5 ± 23.9) and Indians (41.7 ± 24.5); $p < 0.001$. Of the 21 MLWHF questions, patients reported the greatest burden in response to "Costing you money for medical care?" (median score: 3). NYHA class was the strongest independent predictor of MLHFQ scores (17.3 additional units for class III/IV vs I/II; $p < 0.001$). After adjusting for NYHA class, demographics, BNP levels, comorbidities and medications, ethnicity remained an independent predictor of QoL ($p < 0.001$). At six months, all ethnicities showed improvement in QoL, with the greatest improvement in Indians (41.7 to 21.2). Crude 1-year mortality was 16.5%. A significant interaction between MLHFQ and ethnicity was found ($p = 0.019$), where poor MLHFQ score predicted higher adjusted mortality only in Chinese (HR 1.2 for total score and 1.4 for physical and emotional score per 10 unit increase). Per 10 unit increment of the physical component (of MLHFQ) was associated with an increased hazard (HR 1.2) of 1-year mortality ($p = 0.018$) in the overall cohort.

Conclusions: Ethnicity is an independent determinant of QoL in HF. In spite of better baseline QoL in Chinese, QoL was more strongly related to survival in Chinese compared to Malays and Indians. These findings support an ethnicity-specific approach in the assessment of QoL in HF.

P242

Heart failure: predictors of mortality in elderly patients

H Hugo Antunes¹; G Pereira¹; L Abreu¹; B Marmelo¹; E Correia¹; M Correia¹; C Cabral¹; O Santos¹

¹Hospital Sao Teotónio, Cardiology, Viseu, Portugal

Background: Heart failure (HF) has a high prevalence in the elderly population and with the expected aging of the population will increase its incidence. This group of patients still needs further characterization.

Purpose: To investigate which clinical, biochemical and echocardiographic parameters routinely assessed may affect in-hospital mortality in elderly patients.

Methods: We identified all patients admitted for HF in a single center between 01/01/2009 and 31/12/2014. Only the first episode of each patient was included. We selected all patients with 85 years or older. It was evaluated clinical, laboratory and echocardiographic parameters and were compared with in-hospital mortality.

Results: During the reporting period, there were 262 patients who met the inclusion criteria. Predominance of females (58.8%), 88.20 ± 2.80 years old and in-hospital mortality was 10.3%. The results obtained are in the table. Conclusion: This study showed that urea is superior to creatinine in predicting in-hospital mortality in

60631. Table 1

	Hemoglobin	Urea	Creatinine	C-reactive protein	BNP	PSAP	Ejection Fraction
No Deaths	12,18 ± 1,92	74,67 ± 36,00	1,36 ± 0,74	2,21 ± 2,77	904,00 ± 1076,62	47,80 ± 14,68	53,77 ± 15,27
Deaths	11,42 ± 1,67	114,38 ± 61,11	2,52 ± 3,69	3,35 ± 2,97	1770 ± 1514,00	59,56 ± 14,14	50,42 ± 15,79
T-test	p=0,760	p=0,000	p=0,124	p=0,058	p=0,013	p=0,038	p=0,461

Biochemical and echocardiographic results

this age group. The value of the BNP is also a good predictor of mortality. The hemoglobin and c-reactive protein do not appear to correlate with mortality in patients with HF. In the echocardiographic parameters, the PSAP proved to be a good predictor of mortality; however, ejection fraction did not get a statistically significant result as predictor of mortality in elderly patients with HF.

P243

Acute effects of positive airway pressure on mitral regurgitation in heart failure patients with reduced ejection fraction

T Kato¹; T Kasai²; S Yatsu¹; H Matsumoto²; A Murata¹; S Suda²; M Hiki¹; H Daida¹

¹Juntendo university, department of cardiology, Tokyo, Japan; ²Juntendo University, Cardio-Respiratory Sleep Medicine, Tokyo, Japan

Background: Acute effects of positive airway pressure (PAP) on mitral regurgitation (MR) in heart failure patients with reduced ejection fraction (HFrEF) remain controversial. Purpose: We evaluate whether PAP therapy reduce Mitral Regurgitation in patient with heart failure.

Methods: Seven HFrEF patients (5 men; EF, 35.5%; BNP, 641pg/ml) with moderate-to-severe MR underwent echocardiogram during 10-min continuous PAP (4, 8 and 12 cmH₂O) and adaptive servo-ventilation (ASV). MR area defined as a ratio of MR-to-left atrial area. Stroke volume (SV) was calculated from the time-velocity integral and cross-sectional area of aortic annulus.

Results: MR area was reduced significantly by the increase in continuous PAP level, and reduced further on ASV (0.38 ± 0.10, 0.38 ± 0.11, 0.37 ± 0.10, 0.34 ± 0.13, and 0.33 ± 0.10, P < 0.05) (Figure) in association with the stepwise increase in SV (P < 0.05). **Conclusion:** In HFrEF with moderate-to-severe MR, PAP, especially ASV, reduced MR in association with the increase in forward SV.

baseline CPAP of 4cmH₂O CPAP of 8cmH₂O CPAP of 12cmH₂O ASV

Comparison of MR during PAP therapy

P244

What kind of information does patients with heart failure find interesting - a substudy from paceman-hf?

EH Hagglund¹; M Michael Melin¹; BU Ullman²; HP Persson³; IH Hagerman¹

¹Karolinska Institute, Cardiology Department, Stockholm, Sweden; ²South Hospital Stockholm, Cardiology Department, Stockholm, Sweden; ³Danderyd University Hospital, Cardiology Department, Stockholm, Sweden

Background: OPTILOGG is a home based tool for heart failure (HF) patients, which monitors symptoms, titrates diuretics and educates the patient about HF. Patient Centred Management of Heart Failure (PACEMAN-HF) was a prospective, multi-centre, randomized controlled trial (RCT) that showed significantly improved self-care behaviour and increased knowledge in HF. HF patients currently receive information from various sources but there is a lack of knowledge about what type of information that the patient finds useful.

Methods: 32 patients using OPTILOGG were analyzed in the sub study. Mean age was 75 ± 8, 66 % were male, 62 % in NYHA class III, 38 % in NYHA class II. The information is presented in two ways. Either as a short "tip of the day" that is presented automatically every day, and if the patient wants to can select "Read More", or as a "Know More" tab that the patient actively selects. The "Know More" tab has four main categories, with associated sub categories.

Results: 100% of patients chose the "Learn More" at least once, and on average the patients chose to immerse one time every 2 weeks. 53% of the tips that often

triggered further need of information belonged to the main category of "What is heart failure?". Under the "Know More" tab "Food and beverages" was most popular with 31% of the elections, the least popular category was "Help, I feel bad!" that accounted for 17 % of the elections.

Conclusion: The study shows that patients tend to focus their active choices on subjects that are perceived as positive. The study provides insight into how patients seek information, and can provide guidance on how we should formulate individualized patient information. The challenge for health professionals is to create information based on the patient's needs and circumstances.

Validity of Zarit Burden Inventory in a sample of caregivers of heart failure patients

R Pablo-Santiago¹; V Pelaez¹; A Orea-Tejeda¹; E Perez-Cabanas¹; G Leija-Alva²; DG Gonzalez-Islas¹; JA Pineda-Juarez¹; EW Contreras-Ramirez¹; RN Sanchez-Santillan¹

¹Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", México City, Mexico; ²Instituto Politécnico Nacional, Centro Interdisciplinario de Ciencias de la Salud Santo Tomás, México City, Mexico

Background: The burden is one of the negative consequences that most reported among caregivers. The Zarit Burden Inventory is the instrument used for measuring the burden, composed of 22 items with Likert scale of 0-4, where 0 is never and 4 is always. It has been proved that caregivers with higher burden, measured by this instrument, show worse health perception and more likely to have emotional disorders.

Purpose: Evaluate the psychometric properties of Zarit Burden Scale in a sample of caregivers of heart failure patients.

Methods: This study includes a validation sample of 125 caregivers (75.2% females, age 54.8 ± 13.8) of patients with heart failure of Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas". Reliability analysis and factor was performed using Cronbach's alpha and the variability was calculated using t-student.

Results: Six items was eliminated. The final inventory was brief composed of 16 items, on a single factor: burden, with a Cronbach's alpha of 0.907. The variability was statistically significant (p < 0.05).

Conclusion: The scale demonstrated adequate psychometric properties comparable to the original. The results support the use of the inventory in caregivers of patients with heart failure in Mexico.

P246

Danger differences of biomarkers and damage myocardial mass in patients with a history of myocardial infarction: parallels with post myocardial infarction remodeling

G Kukharchik¹; A Morozova¹; N Nesterova¹; N Mitrophanov²; L Gaykovaya¹; L Sorokin³; I Yubrina¹

¹North-West State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation; ²Leningrad Regional Hospital, Saint-Petersburg, Russian Federation; ³Hospital St. Elizabeth, Saint-Petersburg, Russian Federation

Aim: To evaluate the risk factors, levels of the blood biomarkers, damage myocardial mass according to magnetic resonance imaging (MRI), their influence on the course of post infarction remodeling in female and male patients. **Methods:** 182 patients (42 women and 140 men) with myocardial infarction (MI) were entered into the study. A part of common standard tests (echo-cardiogram on the 5-7th day, and then again 3 and 12 months later) on the 3-4th day patients were tested for blood serum levels of the following: high sensitivity C-reactive protein (hs-CRP), N-terminal pro B-type natriuretic peptide (NT-proBNP), interleukin-6, metalloproteinases-1 and -9 (MMP-1, MMP-9), tissue inhibitor of matrix metalloproteinases-1 (TIMP-1). On the 9-11th day and after 3 months 66 patients were tested for MRI with contrasting.

Results: Women enrolled into study were 10 years men's senior (<0.05). Female patients more often presented diabetes mellitus (DM) (23.8 %) and hypertension (AH) (92.0 %), male patients presented smoking (28.5 %) and chronic obstructive pulmonary disease (26.4%). Mostly women have presented the multivessel coronary artery disease (30.9 % vs 15.7 %; <0.05) and the non-Q MI (54.8 % vs 23.5 %; <0.05). An acute left ventricular failure over the 2nd Killip Class more often

complicated MI in women (21.4 %), than in men (6.4 %). In the multivessel coronary artery disease the odds ratio of unfavorable course of remodeling 8.57 (95 % CI 1.31-70.59, $p=0.02$). The gender differences of concentration of hs-CRP, MMP-1, MMP-9, NT-proBNP, interleukin-6, TIMP-1 on the 3-4th day of MI and over the 3 months were not revealed. The unfavorable course of post myocardial infarction remodeling in men was associated with higher concentration of MMP-1 (10.6 (6.5; 15.4) vs 7.1 (4.4; 12.0) ng/ml; <0.05). In women the MMP-9/TIMP-1 was lower in unfavorable course of remodeling. Increase of the left ventricular systolic and diastolic volume indexes, damage myocardial mass, percent of damage myocardial mass, as well low ejection fraction were associated with unfavorable course of remodeling both in men and women. The early revascularization supported to protection of the viable myocardium in the peri-infarction zone. According to the MRI the scar myocardial zone's borders have not differences as women as men, however the dimension of the microcirculation obstruction (MVO) was less in female patients.

Summary: Women have mostly presented the risk factors as age, AH, DM, as well as multivessel coronary artery disease. Extended volume and size of LV, low EF were as predictors of the unfavorable remodeling and were not depended on the gender. Characteristics of the scar zone were not depended on the gender however the dimension of MVO in women was less than in men. In unfavorable course of post myocardial infarction remodeling as men as women have revealed in blood the high content of interleukin-6, MMP-9, NT-proBNP, and hs-CRP.

P247

Electrical dyssynchrony in LBBB and factors related to its severity

D Dmitry Duplyakov¹; Z Vozhdaeva²; V Glukhova²; E Sysuenkova²; G Golovina²; S Khokhlov¹

¹Samara Regional Cardiology Dispensary, Samara, Russian Federation; ²VAZ Medical Center, Togliatti, Russian Federation

Significant impact of left bundle branch block (LBBB) on heart failure (HF) development and progression has been demonstrated in many clinical studies. However, the true incidence of LBBB in a population, and factors related to its severity are not well established.

Aim: To evaluate the incidence of LBBB among patients <70 years of age, and to identify factors associated with the severity of electrical dyssynchrony.

Methods: 65.397 patients (35.585 male (59%) and 26.812 female (41%)), mean age 52.7 ± 12.5 yrs) underwent annual check-up with ECG screening between February 2008 and December 2012, followed by thorough examination. Congenital heart diseases, valvular diseases, cardiac tumors, and cardiomyopathies were exclusion criteria.

Results: During this period 104 (0,16%) patients with LBBB (51 male and 53 female, mean age 57.5 ± 8.6 yrs) have been identified, and 11 of them met exclusion criteria. Among the remaining 93 patients: 35 (37,6%) had a history of coronary artery disease with 34 of them suffered from MI. All of them underwent coronary angiography. Arterial hypertension (AH) has been diagnosed in 67 (72,0%) patients, and left ventricle hypertrophy was revealed in 32 (47,7%) of them. Signs of previous myocarditis have been demonstrated by cardiac MRI with gadolinium in 22 patients (23,7%). Only 4 (4,3%) patients with LBBB had no features of CVD after thorough examination including invasive and noninvasive tests. CHF was observed in 52 (55,9%) patients: NYHA I - 17 pts, NYHA II - 27 pts, and NYHA III - 8 pts. The remaining 41 (44,1%) patient was asymptomatic. The mean duration of the QRS complex was 148.2 ± 14.5 ms, and ≥ 150 ms in 52 (55,9%) patients. It was noted that 87 of 93 patients (93,5%) had criteria of LBBB proposed recently by Strauss (2011): duration of complex QRS > 140 ms in men and > 130 ms in women, QS or RS pattern in leads V1 and V2 and QRS notch at least in two of these leads (V1, V2, V5, V6, I, aVL). ST-segment depression was observed in 86 patients (92,5%), negative T waves were detected in 37 patients (39,8%), and 16 (17,2%) patients had left axis deviation $> 30^\circ$. Multiple linear regression analysis was used to identify factors associated with the severity of electrical dyssynchrony. Twenty six parameters were analyzed altogether. The severity of electrical dyssynchrony was related to male gender ($=0,004$), CAD ($=0,011$), End Systolic Volume (ESV; $<0,001$), and E wave - early peak LV filling velocity ($=0,02$).

Conclusions: The incidence of LBBB among patients <70 years of age was 0,16%. Male gender, CAD, ESV and E wave have the maximal impact on the severity of electrical dyssynchrony.

P248

Improvement of cognitive function in patients with heart failure by cognitive training: first results of the cognitive training in heart failure study (cogtrain-HF)

Supported by the German Heart Foundation/German Foundation of Heart Research

S Wedegaertner¹; J Karbach²; B Bernhard¹; J Ukena¹; M Boehm¹; I Kindermann¹

¹Saarland University Hospital, Department of Internal Medicine III, Cardiology, Angiology and Intensive Care Medicine, Homburg, Germany; ²JW Goethe University, Department of Psychology, Frankfurt am Main, Germany

Background/Introduction: Patients with heart failure show cognitive impairments which are associated with adverse effects. There is an association with higher mortality rates, worse quality of life, poor drug adherence and hospitalization. Cognitive impairment pertains to executive functioning (e.g., initiation and inhibition of actions), episodic and working memory, attention and processing speed. There is evidence for improvement in these areas under computer-based cognitive training in healthy subjects. Training enhances performance both in trained tasks and untrained tasks (transfer effects). However, there are only few studies dealing with cognitive training in cognitively impaired adults and it is unclear whether findings of studies with healthy subjects can be transferred to patient samples.

Purpose: The purpose of this study is to investigate the impact of an adaptive computer-based cognitive training on cognitive functioning in patients with heart failure. We assess improvements in three trained cognitive tasks as well as transfer effects on untrained tasks and cognitive abilities, changes in quality of life and drug adherence.

Methods: In a pretest-training-posttest design we compared three groups of heart failure patients ($n=39$; left ventricular ejection fraction ≤ 45 %, NYHA classification II-III): an experimental group, which performed a cognitive training over six sessions ($n=13$; mean age=63.76 years, SD=11.07, 7.1% females), an active control-group, which performed a training of general knowledge over six sessions ($n=12$; mean age=65.33 years, SD=9.19, 0% females) and a passive control group ($n=14$; mean age=65.96 years, SD=7.84, 14.3% females). During pretest and posttest all groups completed cognitive tests with untrained tasks to measure transfer effects.

Results: Results show a significant improvement in each of the training tasks when comparing the last to the first training session: verbal working memory ($F(1,9)=14.814$, $p=.004$, $\eta^2=0.622$), visual-spatial working memory ($F(1,9)=18.155$, $p=.002$, $\eta^2=0.669$) and cognitive flexibility ($F(1,12)=5.457$; $p=.038$, $\eta^2=0.313$).

Results: show no transfer effects.

Conclusion: Patients with heart failure can benefit from similar cognitive training tasks as healthy subjects. Results show improvements in cognitive functioning in patients with heart failure after cognitive training. These findings encourage further research to examine whether cognitive training could also lead to improvements in other fields, e.g. drug adherence or quality of life.

P249

Congestive heart failure has differential perioperative risk for myocardial infarction/cardiac arrest (MICA) in geriatrics vs. non-geriatrics patients

R Rami Alrezk¹; M Al Rezk²

¹University of California Los Angeles, Geriatrics Medicine/Biomathematics, Los Angeles, United States of America; ²Greater Los Angeles VA Hospital, Geriatrics, Los Angeles, United States of America

Background/Introduction: Geriatrics Patients have characteristic, progressive constriction of homeostatic reserve that occurs with aging in every organ system. The unique characteristics of this population make them respond differently to known risk factors. CHF is a known risk factor for MICA, however it not known whether geriatrics patients risk is different from the general population and by what extent.

Purpose: We aim in this study to examine if CHF has differential risk (ORs) for MICA in Geriatrics vs. Non-Geriatrics Patients. If this theory proves to be valid, then identifying risk factors becomes insufficient and weighting risk factors according to age groups becomes essential.

Methods: For testing our theory we utilized the American College of Surgeons National Surgical Quality Improvement Program NSQIP 2012 database, which is a multicenter prospective dataset collected systematically by trained professionals. It contains ($n=543,885$) cases submitted by 374 participating hospitals. After conducting descriptive analysis, we performed multivariate logistic regression analysis on all the variables believed to be risk factor for MICA. The model variables selection was theory driven. We applied the model on all the patients, patients <65 and patients ≥ 65 . We compared the odds ratio for these 3 groups.

Results: See table 1

Conclusions: CHF has differential OR for MICA in geriatrics vs. non-Geriatrics patients. This does not imply increased risk, rather a different risk weight. It proves our theory that risk factor identification should be followed by age group analysis to appropriately weight the risk factor in geriatrics patients.

Table 1

Age group	Overall	Age <65	Age ≥ 65
Sample N	489,133	314,001	175,132
Adjusted Odds Ratio	1.713	2.039	1.653
P-Value	<0.001	<0.001	<0.001

P250

The analysis of efficiency of physical rehabilitation of patients with chronic heart failureVL Galenko¹; TA Lelyavina¹; M Y Sitnikova¹¹North-west state medical university, Saint-Petersburg, Russian Federation

Introduction: In world practice, the selection intensity physical training of patients with CHF on the basis of achievement of anaerobic threshold when you perform cardiorespiratory test (CPET). The majority of patients with severe HF do not reach anaerobic threshold during the CPET that requires the use of certain indicators in the appointment of physical training. This alternative indicator can be lactate threshold, which achieved first during the execution of the CPET.

Purpose: To evaluate the effectiveness of aerobic physical exercise in HF patients, selected on the basis of determining the lactate threshold during CPET. Methods. 56 patients, CHF NYHA III (under the supervision of cardiologists-experts in heart failure) were randomized into two groups - primary (aerobic training) and control (standard treatment of heart failure). Main group - 43 patients, mean age 54 ± 12.5 years, body mass index (BMI) 26.46 ± 6.4 kg/m². The control group - 13 patients, age 53 ± 17 years, BMI was 25.4 ± 6.8 kg/m². The original estimated results of physical examination, laboratory parameters. CPET, quality of life (QOL), exercise tolerance (ET) was assessed at baseline and after 1,3,6 months of follow-up. The CPET served on treadmill using hardware "Oxycon ro". Echocardiography (EchoCG) were performed at baseline and after 6 months. The data were statistically processed using software package "Statistika, 6.0".

Results: In the main group after 6 months of training EF increased by $7.5 \pm 0.5\%$ from baseline, QOL was changed by 17.5 ± 8 points (significant regression of symptoms). ET increased by 9 ± 1 points. After 1 month of observation VO2 peak increased by 2.6 ± 0.1 ml/min/kg after 6 months - 4.4 ml/min/kg. In the control group showed an increase EF $4 \pm 1.1\%$, the change of QOL 14 ± 7.22 points, the increase in ET at 1.5 points. Decreased VO2 peak in a month 1.05 ± 1.2 ml/min/kg, after 6 months - 1.7 ml/min/kg. Revealed a strong positive correlation between the initial values of VO2 peak and EF ($r_{EF}=0.4$, p), and between baseline levels of sodium, hemoglobin and the effectiveness of physical rehabilitation ($r_{Na}=0.41$, $p=0.05$; $r_{Hb}=0.45$, $p<0.05$).

Conclusion: Aerobic physical exercise in CHF patients, selected on the basis of achieving lactate threshold during the CPET effective in improving values of CPET, EchoCG, QOL and increasing ET.

P251

The influence of ventilatory disorders and clinical status on the early and late prognosis in patients with recent chronic heart failure exacerbation

The research was financed by the Ministry of Higher Education allocated to the development of young scientists and doctoral students

A M Anna Maryla Kowalczyk¹; K Kuziemski²; M Wirtwein³; R Galaska¹; J Wdowczyk¹; E Jassem²; M Gruchala¹¹Medical University of Gdansk, 1st Department of Cardiology, Gdansk, Poland;²Medical University of Gdansk, Department of Pneumology and Allergology, Gdansk, Poland; ³Medical University of Gdansk, Department of Pharmacology, Gdansk, Poland

Purpose: The aims of the study were to assess: the prevalence of ventilatory disorders in patients with chronic heart failure (CHF) exacerbation, the correlation with clinical status and impact on prognosis.

Methods: There were 25 patients-22 (88%) men and 3 (12%) women (60 ± 13 years) with decompensated CHF recruited for the study. All patients underwent following examinations: medical history, physical examination, laboratory tests (repeated on the lung function tests day), 12-leads electrocardiogram, X-ray, echocardiogram. The spirometry and body plethysmography were performed after patient's clinical haemodynamic stabilization. The following lung function tests parameters were taken into analysis: forced expiratory volume in one second (FEV1), Tiffeneau ratio -FEV1 %VCmax (Maximal Vital Capacity), total lung capacity (TLC), vital capacity (VC), total airway resistance (Rtot). All examinations were repeated 3 months after the discharge. The median follow-up was 61 months. The Student's t-test or Mann-Whitney-U test, χ^2 test and Pearson correlation were used for the initial statistical analysis.

Results: The ejection fraction (EF) $\leq 35\%$ ($21.1\% \pm 7.42$) was confirmed in all patients on admission and 3 months after the discharge ($23.3 \pm 8\%$, $p=0.05$). The elevated BNP level (2131.3 ± 1096.8 pg/ml) was revealed in all patients on admission. Both BNP levels after stabilization (1192.4 ± 1070.8 pg/ml) and 3 months after the discharge (745.7 ± 635 pg/ml) were lower than initial ($p<0.0001$). The spirometry revealed obstructive disorders in 20 patients (80%) at the discharge and 3 months later. The body plethysmography confirmed restrictive disorders in 2 patients (8%) at the discharge. We revealed the significant correlations between FEV1 %VCmax and the highest BNP level ($r=-0.45$, $p=0.027$) and BNP level on lung function tests day ($r=-0.44$, $p=0.03$). We also found negative relationships between: EF and FEV1 ($r=-0.41$, $p=0.04$), EF and TLC ($r=-0.59$, $p=0.007$), EF and FEV1 measured 3 months after the discharge ($r=-0.45$, $p=0.04$). The mortality rate achieved 44% in 3 and 52%

in 5 year follow-up. There was a significant correlation between BNP level at the discharge ($p<0.01$), EF measured 3 months later ($p=0.02$) and death in 3 year follow-up period.

Conclusions: Ventilatory disorders appeared in the majority of patients with CHF exacerbation and 3 months after this episode. There is a significant correlation between maximal BNP level, BNP after the stabilization and FEV1 %VCmax. There were no correlations between lung function tests parameters and mortality in early and late follow-up in this group of patients.

P252

Revascularization type and outcome in patients with multivessel coronary disease and reduced ejection fractionT Tanja Popov¹; D Kovacevic¹; S Susak¹; A Vulin¹¹Institute of Cardiovascular Diseases Vojvodina, Novi Sad, Serbia

Background: Several studies have compared outcome of coronary artery bypass grafting (CABG) and percutaneous coronary intervention (PCI) in the treatment of multivessel coronary disease, but a few were focused on patients with reduced left ventricular function.

Purpose: To compare effectiveness of PCI and CABG in patients with ischemic cardiomyopathy and multivessel coronary disease.

Methods: This single-center study, included 178 patients, admitted because of symptomatic multivessel coronary disease, ejection fraction of left ventricle (EF) $\leq 50\%$, who underwent PCI or CABG, with two-years follow up of adverse cardiac and cerebrovascular events (MACCE), which included mortality, myocardial infarction (MI), target lesion/vessel revascularisation (TLR/TVR) and stroke.

Results: There was higher incidence of MACCE in PCI group (18.1% vs. 9.5%, $p=0.145$). That was mainly because of higher incidence of MI (6% vs. 0%, $p=0.021$) and TLR/TVR (6% vs. 0%, $p=0.021$) in PCI group. There was no difference in mortality rate (9.6% in PCI group vs. 9.5% in CABG group, $p>0.05$). Age, fibrinogen, C-reactive protein were predictors of stent thrombosis, while left ventricular dilatation, EuroSCORE and SYNTAXscore were predictors of mortality in our study.

Conclusion: There was no difference in mortality rate during 2-year follow-up after PCI and CABG in studied patients. Incidence of MI and TLR/TVR was higher after PCI comparing with CABG.

P253

Recent trends in diagnostic work-up among unselected patients newly diagnosed with heart failure: a Swedish population-based study

This research was funded by Novartis Pharma AG, Basel, Switzerland
J Stalhammar¹; K Boman²; M Olofsson²; K Lindmark³; R Lahoz⁴; S Corda⁴; V Wintzell⁵; R Linder⁶; A Gondos⁶; G Wikstrom⁷

¹Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden;²Umea University, Research Unit, Medicine and Geriatric, SkellefteåCounty Hospital, Department of Public Health, Umea, Sweden; ³Umea University,

Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden;

⁴Novartis Pharma AG, Basel, Switzerland; ⁵IMS Health Sweden, Stockholm,Sweden; ⁶IMS Health Germany, Berlin, Germany; ⁷Uppsala University, Institute for

Medical Sciences, Uppsala, Sweden

Background: Echocardiography, electrocardiogram (ECG) and natriuretic peptide (NP) testing are recommended by the European Society of Cardiology for the diagnostic work-up of heart failure (HF).

Purpose: To describe population-based trends in the use of diagnostic tests in patients newly diagnosed with HF (main ICD-10 code I50) in Sweden.

Methods: Patients were identified via primary and secondary care electronic medical records. All patients aged ≥ 18 years with a first HF diagnosis from 1 January 2010 to 31 October 2014 were included. A 9-year look-back period to 1 January 2001 was applied for each patient to exclude prevalent HF cases. The use of echocardiography, ECG and NP testing (for brain NP or the N-terminal of the prohormone brain NP [NTproBNP]) in the 6 months before and 6 months after a first HF diagnosis were determined. ECG was captured predominantly during secondary care.

Results: Of 8777 records, 3744 patients were identified (46.8% women; mean age: 78 years; mean Charlson comorbidity index: 2.2). Echocardiography had been used in 1605 patients (42.9%), ECG in 1736 patients (46.4%) and NP testing in 3436 patients (91.8%). Of 3071 patients who were tested for NTproBNP within 6 months after first diagnosis, the mean (standard deviation [SD]) NTproBNP level was 5155 (8736) ng/L. The mean (SD) number of days from first diagnosis to receiving NTproBNP results was 15.6 (36.1). First use of echocardiography, ECG and NP testing was stable from 2010–2014. Echocardiography and ECG were much more commonly used in younger patients (echocardiography, <75 years: 61.1%; ≥ 75 years: 33.2%. ECG, <75 years: 65.1%; ≥ 75 years: 36.5%). The use of NP testing was similar regardless of age (<75 years: 92.0%; ≥ 75 years: 91.7%). Men were more likely than women to undergo echocardiography (men: 47.9%; women: 37.2%) and ECG (men: 51.0%; women: 41.2%). The use of NP testing was similar regardless of sex (men: 92.0%; women: 91.6%). The waiting time between patient referral and the patient receiving their first echocardiography varied over time. The mean (SD)

number of days per year from referral to examination was as follows: 2010, 19.5 (41.4); 2011, 22.1 (60.9); 2012, 11.8 (25.7); 2013, 22.5 (49.4); 2014, 36.9 (101.2).

Conclusions: In this population, in contrast to NP testing, the use of echocardiography for the diagnosis of HF is low, particularly in patients aged ≥ 75 years and in women. Echocardiography is mandatory for the diagnosis of HF phenotype, which influences patient treatment; its use should be increased in clinical practice, especially among women and elderly patients.

P254

Assessment of patient selection bias in prospective studies for heart failure

JJGdV, IS, GG, SCP, JMR and AT are employed by Philips Research. ACG, KMG, JGC and ALC have received departmental research support from Philips. JJG Gert-Jan De Vries¹; I Sokoreli¹; G Geleijnse¹; SC Pauws¹; JM Riistama¹; A Tesanovic¹; A Crundall-Goode²; KM Goode²; JG Cleland³; AL Clark²
¹Philips Research, Healthcare, Eindhoven, Netherlands; ²University of Hull, Hull, United Kingdom; ³Imperial College London, National Heart & Lung Institute, London, United Kingdom

Purpose: Various types of recruitment bias can occur in clinical studies. These may occur deliberately through the use of pre-specified trial inclusion/exclusion criteria, or indirectly as a consequence of the place and method of enrolment; due to a patient's perception of the value, risk and inconvenience of being involved; or pre-selection bias by the clinicians approaching the patient. We set out to explore these biases.

Methods: OPERA-HF is a prospective, observational study enrolling patients hospitalized for or with heart failure. Other inclusion criteria are: age >18 years, treatment with loop diuretics and at least one of the following: left ventricular ejection fraction $\leq 40\%$, left atrial dimension >4.0 cm or NT-ProBNP >400 pg/mL (if sinus rhythm) or >1200 pg/mL (if atrial fibrillation). Three different study participation levels were possible: full, partial and routine care (via audit). All patients were eligible for the study, but might not be approached if the clinician thought it inappropriate; patients could choose which group to join if they declined to take part in the full study. Relative risk, for binary variables, and Wilcoxon rank-sum tests, for continuous variables, were estimated to compare data at different study participation levels.

Conclusion: Patients recruited into the full study had fewer comorbidities and used less medication than those recruited into the partial and routine care arms. They also had a lower risk of readmission and mortality. Trials should be interpreted in the light of possible selection bias for less ill patients. Whether the selection bias was due to clinicians/nurses or patient choice needs further study.

Results

	Full Participation (n = 428)	Partial Participation (n = 110)	Routine Care (n = 243)
Age	74 [66 - 81]	77 [68 - 84]*	77 [69 - 83]*
NT-proBNP	4924 [2010 - 10085]	3942 [1962 - 9803]	5288 [2476 - 10912]
Myocardial infarction	45 (10.6%)	21 (19.6%)*	43 (18.4%)*
Cerebrovascular accident	33 (9.1%)	11 (11.0%)	28 (20.9%)*
Ace inhibitor	217 (50.6%)	53 (48.2%)	170 (70.0%)*
Beta blocker	259 (60.4%)	75 (68.2%)	192 (79.0%)*
30 day readmission	8 (3.0%)	3 (2.9%)	15 (7.8%)
1 year death	41 (20.4%)	22 (23.4%)	65 (33.3%)*

Results of key characteristics by study participation level, represented as median [IQR] or # (%). Missing data were excluded. * Indicates significant ($p < 0.05$) difference compared with Full Participation.

Spinal cord stimulation in heart failure: effect on disease-associated biomarkers

J Naar¹; D Jaye²; C Linde³; P Neuzil¹; P Doskar¹; F Malek¹; F Braunschweig³; M Back³; B Linderroth⁴; M Stahlberg³

¹Na Homolce Hospital, Department of Cardiology, Prague, Czech Republic;
²Medtronic Inc, Cardiac Rhythm and Heart Failure, Minneapolis, United States of America; ³Karolinska University Hospital, Department of Cardiology, Stockholm, Sweden; ⁴Karolinska Institute, Department of Clinical Neuroscience, Stockholm, Sweden

Background: Experimental studies suggest that spinal cord stimulation (SCS) can reduce neurohormonal activation and reverse remodeling in animal models of heart failure (HF). The mechanism of SCS benefit in experimental HF remains ill defined and human data is limited. Purpose To test the hypothesis that SCS favorably affects disease-associated biomarkers in patients with systolic HF.

Methods: Thirteen patients with systolic HF and narrow QRS, previously participating in the larger DEFEAT-HF clinical trial with SCS treatment for ≥ 6 months were included in this cross-over study. Patients were randomly assigned to 6 weeks of SCS-ON followed by 6 weeks of SCS-OFF, or vice versa. Stimulation (aiming at the T2-T4 segments of the spinal cord) was delivered for 12 hours per day (amplitude: 90% of maximally tolerated paresthesia). Following the "ON" and "OFF" periods, peripheral blood samples were drawn for subsequent analysis of circulating biomarkers of neurohormonal activation (norepinephrine - NE, adrenaline ADR, aldosterone - ALDO and renin), inflammation (high-sensitivity C-reactive protein - hs-CRP), cytokine activation (Interleukin 1 and 6 - IL-1 α /IL-6) as well as myocardial stress (NT-proBNP) and injury (high-sensitivity cardiac troponin T-hs-cTnT). In addition, renal function was assessed using plasma cystatin C.

Results: Thirteen patients (mean age: 65.3 ± 8.0 yrs, 69% males, 46% ischemic cardiomyopathy) completed the study. The results of SCS on HF-associated biomarkers are shown in table 1.

Conclusion: In this small study, SCS was associated with a modest but significant increase in troponin T, which may reflect cardiac injury. The small magnitude of increase is not likely to be clinically relevant, but may offer a novel mechanistic insight into SCS in HF. Furthermore, a trend toward elevated levels of circulating cytokines was found. Whether cytokine activation contributes to SCS-associated cardiac injury warrants further studies.

Biomarker	SCS-ON	SCS-OFF	p-value
P-NE (nmol/L)	3.8 ± 1.8	4.1 ± 2.0	0.72

PACEMAN-HF - pooled analysis from two randomized controlled trials.

AHT Hovland-Tanneryd¹; EH Hagglund²; BU Ullman³; HP Persson⁴; IH Hagerman²; M Michael Melin²

¹Karolinska Institute, Stockholm, Sweden; ²Karolinska Institute, Cardiology Department, Stockholm, Sweden; ³South Hospital Stockholm, Cardiology Department, Stockholm, Sweden; ⁴Danderyd University Hospital, Cardiology Department, Stockholm, Sweden

Background: OPTILOGG is a home based tool for heart failure (HF) patients, which monitors symptoms, titrates diuretics and educates the patient. Patient Centred Management of Heart Failure (PACEMAN-HF) was a prospective, multi-centre, randomized controlled trial (RCT) that showed significant reduction in-hospital days by 28% and a system compliance of 85% after 6 months. There is a growing need for real-life data. Pragmatic trials are designed to evaluate the effectiveness of interventions in real-life routine practice conditions. Such a trial has been conducted within primary care in Sweden.

Methods: 100 patients were enrolled. The mean age was 78 ± 9 , 65% were male, 43% NYHA class III, 48% NYHA class II and 9% NYHA class I. All patients were listed at a HF clinic in primary care, with a confirmed HF diagnosis and recently performed echocardiography. Patients were randomized 1:1 to either receive OPTILOGG (intervention group, IG) or not (control group, CG). The 2 groups were well balanced at randomization. Aside from prescribing OPTILOGG, routine practise remained unchanged. All hospitalizations for the patients were recorded for 6 months. All HF related hospitalizations were adjudicated by a HF specialist.

Results: After 6 months, there was a 33% reduction of in-hospital days due to HF [RR: 0.67; 95% CI: 0.45-0.99; $p < 0.05$] in the IG, and the compliance was 97% [IQR: 91% - 99%]. A multiple regression analysis, adjusted for differences in health status, was performed on pooled data from both studies, based on 610 in-hospital days and 172 patients. The adjusted risk ratio with a 95% confidence interval was 29.2% [RR: 0.708; 0.607-0.825], and the median system compliance for the pooled cohort was 94% [IQR: 84% - 98%].

Conclusion: Results from pooled analysis are consistent with previously published results, showing a reduction of in-hospital days, indicating that the results are generalizable and reliable.

Mortality and mode of death in chronic heart failure patients

A R Ana Rita Marinheiro¹; P Amador¹; C Sa¹; T Duarte¹; R Rodrigues¹; M Fonseca¹; R Caria¹

¹Hospital Center of Setubal, Setubal, Portugal

Introduction: Heart failure (HF) remains a pertinent problem across Europe and it is responsible for high levels of mortality. The heterogeneity of the heart failure population is reflected in the different ways in which these patients die. Mode of death analysis provides an understanding of the clinical course of the disease.

Purpose: to evaluate the mode of death in outpatients with chronic HF of different etiologies and to define predictor variables for all-cause mortality.

Methods: We evaluate consecutive HF outpatients treated in a HF clinic. Mode of death was classified as cardiovascular (CV), non-CV, or unknown. Non-CV death was defined as a death due to a specific non-CV event; unknown death was defined as a death for which no information surrounding the event was available. CV death comprised pump failure, sudden cardiac death (SCD), acute myocardial infarction (AMI) and stroke. Twenty-one prespecified potential predictor variables were used in a stepwise Cox proportional hazards model for all-cause mortality.

Results: Of the 224 patients evaluated, death occurred in 59 (26%) during a median of 51 months. Mean age was 64.5 ± 11.4 ; 74 % were male; mean ejection fraction was 32%; 49% had an ischemic etiology and 50 % were in New York Heart Association (NYHA) functional class II. Of all deaths, 31.0% were due to pump failure, 13.8% due to SCD, 3.4% due to AMI, 5.2 % due to stroke, and 31.0% due to non-CV causes (figure). Age and use of diuretics were associated with significantly increased mortality (table).

Conclusion: In our study, cardiac mortality was the leading cause of death. However almost one third of HF patients died from non-cardiovascular causes.

Multivariate analysis of mortality

	p-value	Cox HR (95% CI)
Variables that remain in the equation		
Age (years)	0,0210	1,0316 (1,0048 - 1,0591)
Use of diuretics	0,0060	1,0098 (1,0028 - 1,0168)

Variables removed from the equation: gender, weight, systolic blood pressure, NYHA functional class, left ventricular ejection fraction, ischemic etiology, total cholesterol, plasma hemoglobin, plasma sodium, lymphocyte's percentage, uric acid, use of angiotensin converting enzyme inhibitors, angiotensin II receptor blockers, betablockers, aldosterone antagonists and allopurinol; implantable cardioresuscitator and cardiac resynchronization therapy. HR, hazard ratio; CI, confidence interval

Mode of death in heart failure patients

P258

Heart failure with reduced ejection fraction is associated with the highest visit-to-visit blood pressure variability in complicated arterial hypertension

E Elena Troitskaya¹; N Kotovskaya¹; Y Kotovskaya¹; Z Kobalava¹

¹ Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Background: Visit-to-visit blood pressure variability (BPV) is associated with adverse cardiovascular outcomes in different patients' populations. Mechanisms of visit-to-visit BPV in different groups of patients have not been determined yet. The aim of our study was to assess visit-to-visit systolic BPV in patients with uncomplicated controlled arterial hypertension (AH) and patients with controlled AH and

stable coronary heart disease (CHD) or heart failure (HF) with reduced ejection fraction.

Methods: In retrospective study we assessed 3 groups of patients with controlled AH. Group 1 included 52 patients with uncomplicated AH (20 men, age 58.9 ± 9.0 yrs) who achieved target BP on RAAS-inhibitor/amlodipine combination. Group 2 included 40 pts with stable CHD (28 men, age 69.2 ± 5.9 yrs). Group 3 included 100 pts with HF with reduced EF (80 men, age 64.4 ± 9.3 yrs, mean EF $32.3 \pm 4.3\%$). Pts in groups 2 and 3 received stable therapy for CHD and HF. BP was measured with a validated oscillometric device. Visit-to-visit BPV was calculated as SD for 5-7 visits during 8-18 months of stable therapy. $p < 0.05$ was considered significant.

Results: First evaluated BP in group 1 was $126.4 \pm 7.6/76.7 \pm 7.2$ mmHg, in group 2 - $125.5 \pm 7.5/75.2 \pm 8.8$ mmHg, in group 3 - $127.6 \pm 15.1/77.9 \pm 8.3$ mmHg. At final evaluated visit BP was $123.7 \pm 9.7/76.8 \pm 6.7$ mmHg, $124.2 \pm 13.4/72 \pm 8.5$ mmHg and $123.6 \pm 13.6/74.8 \pm 8.9$ mmHg, respectively. Despite stable levels of BP, BPV on stable therapy varied in wide range in all groups: 1.8-16.8 mmHg, 0.7-23.3 mmHg, 2.3-20.0 mmHg for systolic BPV, respectively and 1.0-11.4 mmHg, 0-17.9 mmHg and 1.5-13.1 mmHg for diastolic BPV, respectively. Despite similar levels of final BP, there were significant differences in mean BPV between groups: systolic BPV in group 1 was 7.2 ± 3.6 mmHg vs 7.8 ± 6.6 mmHg in group 2 and 10.2 ± 3.8 mmHg in group 3; diastolic BPV - 4.8 ± 2.7 mmHg vs 7.0 ± 4.4 mmHg and 7.3 ± 2.2 mmHg, respectively ($p < 0.01$ for trend). No predictors of BPV were found in all groups.

Conclusion: Despite similar BP levels HF with reduced EF is associated with the highest visit-to-visit BPV compared to uncomplicated AH and stable CHD. Thus high visit-to-visit BPV may be a marker of the severity of cardiovascular disease.

P259

Early remodeling of left ventricle after heart valve surgery in patients with chronic heart failure (REVERSE-HF study)

G Gabriella Locorotondo¹; E Fedele¹; C Pierandrei¹; V Melita¹; A Masi²; M Massetti¹; F Crea¹; L Galiuto¹

¹ Catholic University of the Sacred Heart, Department of Cardiovascular Medicine, Rome, Italy; ² University of Sassari, Department of Clinical and Experimental Medicine, section of Cardiology, Sassari, Italy

Background: In heart failure (HF) due to chronic volume overload, heart valve surgery determines LV reverse remodeling (LV-R). In aortic regurgitation (AR), LV-R mainly occurs in the early postoperative stage. Entity of early LV-R usually vary among patients with AR or mitral regurgitation (MR). Its pathophysiology and prognostic significance are actually unknown.

Purpose: To verify entity, determinants, gender-related differences and impact on long-term outcome of LV-R, occurring early (discharge) after surgery for AR and/or MR.

Methods: 52 pts (median age 70 yrs [interquartile range 54-76], 75% male) with HF due to AR and/or MR, underwent echocardiography prior to (baseline) and at 7 ± 4 days after surgery (discharge). LV end-diastolic volume (EDV) and its variation at discharge vs baseline value (Δ EDV,%) were analyzed. Δ EDV $\geq -20\%$ indicated LV-R, while Δ EDV $< -20\%$ was considered as No-LV-R. Outcome data were collected in 43 pts at 13 ± 6 month follow-up for an unpowered survival analysis.

Results: In the total study population (63% pts with MR, 17% with AR, 19% with MR+AR) median Δ EDV was -28.71% ($p < .001$ for discharge vs baseline EDV), without significant differences among valvular diseases (-26.32% , -36.81% , -33.13% , respectively). Replacement caused greater Δ EDV in MR+AR and AR than MR pts ($p=.01$ and $p=.027$, respectively). Δ EDV in MR pts was greater after repair than replacement ($p=.017$). No-LV-R was associated to smaller EDV and LV mass at baseline and more MR than LV-R (115 vs 165 mL, $p=.025$; 241 vs 331 g, $p=.005$; 86.66% vs 54.05% , $p=.031$, respectively). Baseline EDV ≥ 152.5 mL independently predicted LV-R ($p=.017$) with 60% sensitivity and 73% specificity (AUC 0.70, $p=.025$). No gender-related differences were found in Δ EDV. EDV (indexed for body surface area) was smaller in women than men, both at baseline and at discharge ($p=.001$ and $p=.031$, respectively). Mortality was 19% in LV-R and 23% in No-LV-R pts, despite absence of statistical significance. Rehospitalization for HF similarly occurred in LV-R and No-LV-R pts, but seemed more frequent in MR than AR and MR+AR (24% vs 6.66%, $p=ns$) pts. Women apparently had better prognosis than men if remodeled (100% vs 81% survival rate, respectively, $p=ns$) and worse prognosis than men if did not remodeled (50% vs 11.11% mortality, respectively, $p=ns$).

Conclusions: In HF due to AR and/or MR, early LV-R is greater in pts with higher baseline EDV. It is not gender-related, but might predict long-term outcome. Pts with MR display smaller EDV at baseline, less LV-R at discharge and might have worse prognosis than pts with AR and MR+AR.

P260

High red cell distribution width is able to predict hospitalisation for heart failure in patients with coronary artery disease

A Pratesi¹; F Orso¹; E Carrassi²; R Barucci¹; ML Di Meo¹; C Ghiara²; S Parlapiano²; A Herbst²; N Marchionni¹; S Baldasseroni¹

¹Careggi University Hospital (AOUC), Geriatric Cardiology and Medicine, Florence, Italy; ²University of Florence, Florence, Italy

Background: Red Cell Distribution Width (RDW) is the measure of the range of variation of red blood cell volume and it is found to be a very strong independent predictor of morbidity and mortality in patients with chronic heart failure.

Purpose: We aimed to analyse whether RDW was a predictor of hospitalization for heart failure in patients with CAD, with or without systolic dysfunction. Method: we prospectively enrolled patients with stable Coronary Artery Disease (CAD) from our Outpatient Clinic from 2009 to 2013. We enrolled patients with or without left ventricular dysfunction. Each patient underwent clinical evaluation and biomolecular measurements and a telephone follow-up was planned to register the long term outcomes. Sensitivity/specificity ratio for RDW was analysed with ROC analysis and the independent role of RDW was evaluated with Cox regression model of analysis. The survival rate was represented by Kaplan Meier curves.

Results: 152 patients were enrolled with mean age 69.1 ± 10.8 ; the mean left ventricular systolic function was $43.9 \pm 14.9\%$. Mean time follow up was 1340.9 ± 803.7 days, mortality rate was 20.9% (32 deaths) and hospitalization for heart failure rate was 27.5% (42 events). Mean value of RDW was $14.8 \pm 3.0\%$; the analysis of the ROC curve identified a RDW cut-off level of 13.2% (AUC 0.767; $p < 0.0001$). Patients with RDW $> 13.2\%$ had significant independent (adjusted for age, sex, NYHA class, NT-proBNP, Ejection Fraction and eGFR) higher risk of hospitalization for heart failure (HR=6.50; 95% CI: 2.40-17.70) and of composite outcome (hospitalization and mortality) (HR=0.87; 95% CI: 0.31-2.44). Its predictivity remained significant either in patients with left ventricular systolic dysfunction and in those without.

Conclusions: in patients with CAD with or without heart failure, RDW value of $> 13.2\%$ independently predicts increased risk of hospitalization for heart failure and composite outcome.

P261

Need for support for patients with chronic heart failure, the development and implementation of self management strategies at home- A qualitative research study in Switzerland

C Blaeuer¹; R Spirig²; W Schnepf³

¹University Hospital Basel, Basel, Switzerland; ²University Hospital, Zurich, Switzerland; ³Universität Witten/ Herdecke, Witten, Germany

Introduction: Chronic heart failure (CHF) is characterized by a wide range of symptoms, high prevalence in the elderly, poor (quality of life QoL) and frequent hospitalisations. Managing one's condition at home is important to successful treatment. Multiprofessional patient education programs have shown positive effects on self management strategies (SMS), QoL, mortality and costs although a lack of congruency exists in methods, quantity and duration of programs. It is unclear what support these patients need to integrate and maintain SMS at home. This survey explored the support needed to maintain SMS at home for CHF patients who have completed a self-management (SM) course during hospitalisation. Additionally, it evaluated which available social networks support SMS at home.

Methods: A qualitative study was utilized to explore the subjective perspective of patients. Grounded theory was chosen to examine patients' perspectives in SM at home. Twenty two interviews were conducted at the participants' homes after hospital discharge. Various methods of coding, open, axial and selective were used. The process was completed after the main phenomenon has been identified.

Results: The results show intrinsic motivation as the main phenomenon. This motivation gives patients strength and energy to develop SMS for achieving a good QoL. SM is influenced by the patient's relationship with the health care providers, and their personal experiences shape their behaviour. Confidence is the key factor for cooperation between patients and health care providers. It results from behaviours such as reliability, feeling encouraged to ask questions, listening, attentiveness and friendliness, being able to talk to each other and taken seriously, knowing each other and more. In the critical event of transitions from inpatient to outpatient, the social network and the collaboration between the patient and the health care provider may be the key element for successful SMS at home.

Conclusion: Results show a wide range of factors influence intrinsic motivation for effective SMS at home with the aim of a high QoL and preventing hospitalisation. Professionals need to be aware of influencing factors and should build networks to provide patient support. Each patient situation requires a comprehensive assessment to provide individualised help with SMS at home and to establish a supportive social network.

The Impact of optimized care on heart transplant outcome in high-risk patients at Germanys First advanced Heart Failure Unit

PW Raake¹; R Ramon Tschierschke¹; M Kreusser¹; J Beckendorf¹; L Frankenstein¹; E Giannitsis¹; A Ruhparwar²; M Karck²; HA Katus¹

¹University Hospital of Heidelberg, Internal Medicine III, Heidelberg, Germany;

²University Hospital of Heidelberg, Department of Cardiac Surgery, Heidelberg, Germany

Hospitalizations for acute and advanced heart failure are increasing, with patients presenting in complex conditions affecting multiple organs. Optimized medical and interventional therapies have led to a better survival even in severe heart failure. Consequently more patients with very advanced disease have to be treated in cardiology units by sophisticated medical and interventional strategies. To our knowledge there is so far no ward that will meet these high expectations in the European hospital system. Here we report our 3-year experience with a dedicated advanced heart failure unit (AHFU) in Germany, with special focus on its impact on outcome in high-risk heart transplant candidates. The AHFU is an intermediate care facility with 8 treatment units established as an extension of our intensive care unit (14 beds) and our coronary care unit (10 beds). The eight beds unit was established as an extension of the cardiologic intensive care (14 beds) and coronary care (10 beds) units in an intermediate care setting. Each bed was equipped with 24 hours hemodynamic, respiratory and arrhythmia monitoring. The unit is served 24 hours/7 days a week by 5 residents in cardiology, one staff cardiologist specialized in medical and interventional heart failure care and 10 intensive care nurses. The cardiology team is supported by colleagues from cardiac surgery, sports medicine, psychosomatics and the internal medicine departments with routine interdisciplinary conferences and rounds. Due to this unique interdisciplinary therapeutic approach under the leadership of the cardiologic department special tailor-made treatment plans are elaborated for each patient. The cohorts of patients undergoing high risk heart transplantation from HU status before (pre AHFU 2008-2011) and after establishment of the AHFU (AHFU 2012-2014) were studied and compared to test intensified advanced heart failure care on the AHFU. Interestingly, post-heart transplant survival was comparable in both cohorts, despite significant increase in morbidity and comorbidity as assessed by the Index for Mortality Prediction After Cardiac Transplantation (IMPACT) model in the AHFU group. AHFU being the first in Germany is improving the care of patients with advanced HF. The evaluation of the AHFU in Heidelberg shows that patients with advanced heart failure benefit from the high degree of expertise, the experienced team and the outstanding interdisciplinary cooperation at the AHFU. From our perspective, the AHFU represents a milestone in the treatment of these critically ill patients.

Figure 2: INTERMACS score, IMPACT score. Means±SEM or absolute numbers and %, Mann-Whitney-test.

Cardiac resynchronisation therapy in the treatment of end-stage inotrope-dependent class IV heart failure

S Sana Ouali¹; Y Massoudi¹; S Kacem¹; E Boughzela¹

¹Sahloul Hospital, Sousse, Tunisia

Background: Currently, cardiac resynchronisation therapy (CRT) is recommended only for New York Heart Association (NYHA) class IV ambulatory patients. However, some recent reports have suggested that CRT could also be beneficial for end-stage inotrope-dependent heart failure (HF) NYHA class IV patients. In this report, we summarise the results of CRT implantation in a group of 11 HF inotrope-dependent patients. Orthotopic heart transplantation (OHT) and Left ventricular assist devices were not available in many developing countries.

Methods and results: Between March 2005 and December 2014, 11 end-stage inotrope-dependent HF patients with wide QRS complex, ineligible for urgent OHT, were implanted with CRT. Dependence on inotropic therapy was defined as an inability to stop the infusion of the drug without the occurrence of hypotension, oligo or anuria and/or hypoxemia. All patients were successfully implanted with CRT P. Rapid haemodynamic amelioration allowed the withdrawal of inotrope support gradually within the median time of two (1,17) days. Mean QRS duration shortened from $143, 6 \pm 17$ ms at baseline to $102, 7 \pm 15$ ms ($p < 0.001$) after the procedure. All patients were discharged from hospital. Median hospital stay after the procedure was ten (5,3) days. During the median follow-up of 534 (range : 180 - 1500) days, LV volumes decreased (end-diastolic from $334, 3 \pm 48$ to 222 ± 53 ml; $p = 0.07$; end-systolic from 251 ± 25 to 135 ± 98 ml; $p < 0.01$). LV ejection fraction increased ($21.72 \pm 6\%$ to $29.9 \pm 12\%$; $p < 0.05$). Three patients died (one because of arrhythmic

storm, one because of infective endocarditis and another because of progressive pump failure).

Conclusion: CRT can be safe and effective and can be an alternative for end-stage inotrope-dependent HF patients with wide QRS where heart transplantation is not available. CRT should be considered relatively early in the course of sustained inotropic therapy.

P264

Percutaneous valve-in-valve implantation in tricuspid position as an alternative for very high surgical risk patients with refractory heart failure symptoms.

FJ Francisco Javier Irazusta Cordoba¹; O Gonzalez Fernandez¹; SO Rosillo Rodriguez¹; A Sanchez-Recalde¹; AM Iniesta Manjavacas¹; P Meras Colunga¹; V Rial Baston¹; D Gemma¹; F Gutierrez-Laraya¹; JL Lopez-Sendon¹

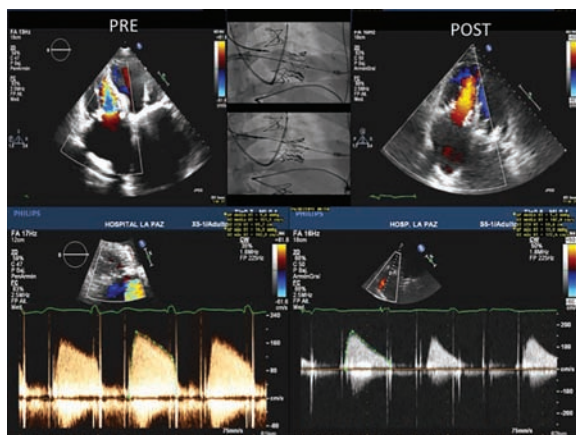

¹University Hospital La Paz, Cardiology, Madrid, Spain

Background: Redo valve surgery for failure of a tricuspid bioprosthesis is recommended in symptomatic patients when optimal medical therapy becomes unsuccessful, but still represents a challenge. Transcatheter valve-in-valve implantation has emerged as a new valid technique for these patients, yet experience is very limited. Previously reported cases have described the use of valves designed for pulmonary position, although their maximum available size of 22mm results in a significant limitation. Transcatheter aortic valves (TAVI) may then be a useful alternative.

Methods: We present a series of percutaneous valve-in-valve implantation of TAVI in tricuspid position performed at our center in patients with refractory heart failure symptoms due to stenotic tricuspid bioprosthesis and high risk for surgical intervention.

Results: A total of three cases were performed and described as follows: 14-year-old female with a 25 mm tricuspid bioprosthesis due to repaired complex congenital heart disease; 38-year-old male with Ebstein's anomaly corrected with a 31 mm bioprosthesis, and a 73-year-old male with rheumatic valve disease and a 31 mm bioprosthesis. In all cases implantation was performed under general anesthesia in the catheterization laboratory; two through a transfemoral approach and one transjugular. Only one procedure required pre-stenting. Two TAVI of 29 mm and one of 23 mm were implanted in opposite direction of the aortic valve. Transoesophageal echocardiographic assessment after implantation revealed normal valvular function and ruled out further complications. Mean transvalvular gradient decreased from 11.1 to 6.7 mmHg at discharge. Improving of heart failure symptoms at mid-term follow-up (2,4 and 12 months), was confirmed in all patients with a mean reduction of one level of their baseline NYHA class.

Conclusions: Percutaneous TAVI implantation in failing bioprosthetic tricuspid valve seems to be a valid alternative in very high risk surgical patients with refractory heart failure symptoms. More cases and longer follow-up are required to confirm our results.

P265

Feasibility of the first year post-heart-transplantation follow-up in a cardiology day hospital

I Iago Sousa Casasnovas¹; A Ayesta-Lopez¹; E Gomez-Gomez¹; P Diez-Villanueva¹; A Alonso-Garcia¹; M Martinez-Selles¹; A Villa Arranz¹; J Fernandez-Yanez¹; E Zatarain-Nicolas¹; F Fernandez-Aviles¹

¹University Hospital Gregorio Marañon, Madrid, Spain

Introducción: First year post-heart transplantation (HTx) follow-up consists of a close monitoring of the graft function, immunosuppression and related complications. It requires multiple tests, some of them invasive like endomyocardial biopsy, right heart catheterization or coronariography, so classically the patient was admitted in the cardiology ward. In the last decades the experience in ambulatory procedures has offered the possibility of a fully outpatient follow-up. The feasibility and security of this strategy is not well known.

Methods: From 2007 we transitioned from an inpatient to an outpatient follow-up in the first year post-HTx through a cardiology hospital day. We have retrospectively reviewed the clinical course during the first year post-HTx of the outpatient group (2007 to 2014) and an immediately prior inpatient group (2000-2006). Patients with postoperative death or mixed follow-up were excluded. Data collected were: basal characteristics, hospital stay, infections, rejection episodes and invasive tests performed during the first year.

Results: During the period of study 87 patients had an Inpatient Follow-up (IF) and 99 patients had an Outpatient Follow-up (OF). Basal characteristics were similar in both groups: Male sex 79.3% in IF, 67.7% in OF (ns); Hypertension 39.1% vs 35.7% (ns); Diabetes 65% vs 71.7%; IgG-CMV negative 18.4% vs 12.2%. We found significant differences in immunosuppression and age due to historical comparison: tacrolimus 44.8% vs 90.8% ($p < 0.001$); mycophenolate 86.2% vs 100% ($p < 0.001$); 52 ± 11.5 vs 56.1 ± 11 ($p = 0.014$).

More clinical visits were performed in the OF group (10.4 ± 2 vs 13.1 ± 3.7 , $p < 0.001$). Hospital stay (postoperative stay excluded) was lower in the OF group (27.8 ± 14.8 vs 12.4 ± 18.2 , $p < 0.001$). A similar percentage of patients presented infection, rejection or vascular complications. No difference was either in mortality in the first year: 2 patients IF and 1 patient in OF (2.3% vs 1%, ns).

Conclusion: The first year post-HTx follow-up seems to be feasible and safe in terms of infection, rejection, vascular complications and mortality. It offers the benefit of more frequent clinical visits and lower hospital stay.

P266

Clinical aspects of continuous intravenous morphine for palliative care in patients with advanced heart failure from experience with 55 cases

S Oishi¹; W Fujimoto¹; T Miyata¹; Y Taniguchi¹; Y Yoshinori¹; H Kawai¹

¹Himeji Cardiovascular Center, Himeji, Japan

Background: Heart failure is epidemic in developed countries and approximately 5% of patients with heart failure are refractory to medical therapy. Palliative care for those patients is recommended for relief of symptom and patient satisfaction. However, we could not intervene enough because of insufficient evidence and experience including pharmacotherapeutic intervention.

Methods: We experienced continuous intravenous infusion of morphine for palliative care in 55 patients with advanced heart failure from March 2011 to December 2015. We reviewed our experience and evaluate safety and efficacy of morphine administration. Intensity of symptoms was evaluated by Visual Analogue Scale (VAS).

Results: Morphine hydrochloride was administered for 55 patients among 2042 patients (male 51%, aged 79 ± 12 yrs) for palliation of dyspnea (85%) and pain (15%) during 6.5 ± 6.0 days. LVEF was $35.8 \pm 14.4\%$, estimated glomerular filtration rate (eGFR) was 32.7 ± 36.0 ml/min/1.73m², BNP level was 1855 ± 1546 pg/ml. Inotropic agents, diuretics, and sedative medication were administered in combination with morphine in 75%, 92%, 35%, respectively. Systolic blood pressure, heart rate, respiratory rate were 101.0 ± 23.7 vs 97.9 ± 24.6 mmHg ($p = 0.51$), 95.0 ± 22.7 vs 92.3 ± 19.9 beats per minute ($p = 0.52$), 26.8 ± 7.2 vs 18.2 ± 4.3 breaths per minute ($p < 0.001$) at baseline and 24 hours after administration respectively. Mean dosage of drug was 7.2 at initiation and 10.5 mg/day at maintenance. Dyspnea was significantly improved after morphine administration (VAS 6.0 ± 1.8 vs 2.7 ± 1.9 , $p = 0.0008$).

For patients discharged after discontinuation of morphine due to amelioration of symptoms. No patients discontinued morphine due to adverse events. ICD was deactivated in 7 among 11 implanted patients (64%).

Conclusion: Low dose morphine hydrochloride was relatively safe and effective even though for the patients with advanced heart failure.

	Baseline	24 hours after administration	p value
Dosage amount (mg/day)	7.0 ± 5.0	11.0 ± 7.4	0.0008
Systolic blood pressure (mmHg)	101.0 ± 23.7	97.9 ± 24.6	0.51
Heart rate (bpm)	95.0 ± 22.7	92.3 ± 19.9	0.52
Respiratory rate (bpm)	26.8 ± 7.2	18.2 ± 4.3	0.0001
SpO2 (%)	95.7 ± 4.1	95.9 ± 4.7	0.84
Intensity of symptoms (Visual Analogue Scale)	6.0 ± 1.8	2.7 ± 1.9	0.0008

Effect of intravenous morphine for palliative care in patients with advanced heart failure

P267

Tricuspid valve regurgitation after heart transplantation: does it really have a poor prognosis?

IM Iris Maria Esteve Ruiz¹; A Grande-Trillo¹; D Rangel-Sousa¹; E Jimenez-Baena¹; A Gonzalez-Garcia¹; E Lage-Galle¹; M Sobrino-Marquez¹

¹Hospital Universitario Virgen del Rocío, Área del corazón, Sevilla, Spain

Introduction: Tricuspid regurgitation (TR) is the most common valvular abnormality after orthotopic heart transplantation (OHT). Although endomyocardial biopsy is responsible for the majority of cases (chordal damage), there are others causes: Shumway technique, pulmonary hypertension, cardiac allograft rejection ...

Some studies show that TR is a significant clinical finding and has an important impact on the long-term clinical progress of the OHT patients.

Purpose: Analyse the patients with severe TR after OHT in our Advanced Heart Failure and Heart Transplant Unit.

Methods: A retrospective single-centre study. Patients with severe TR after OHT from January 1992 to December 2015 were enrolled. Clinical and echocardiographic variables were collected.

Results: 25 patients (92% male) were analysed. The etiology of cardiomyopathy before OHT was 48% ischemic, 32% idiopathic dilated, 12% valvular and 8% congenital. 84% were performed by Shumway technique and 16% by bicaval technique. 56% of the cohort remained asymptomatic despite the severe TR, although 28% developed left ventricle failure symptoms, 8% showed systemic congestive symptoms and only 8% had global heart failure symptoms. The 40% of our population were diagnosed with allograft vascular disease.

About TR etiology, a flail leaflet was found in 18 cases (72%); functional TR with right ventricle dilatation in 6 cases (24%) and infective endocarditis was described in one case (4%). None of the patients underwent tricuspid valve surgery. Freedom from severe TR is described in the figure 1a.

For a follow-up of 13.3 ± 6.8 years, the cumulative survival is described in the figure 1b. 33% died of sudden death, 25% of advanced heart failure and 42% of non-cardiac causes.

Conclusion: Although many studies in the literature correlate severe TR with a poorer prognosis, our series showed a high survival rate, which suggests that TR is not related with a worst prognosis. The 5 years survival rate in our serie (88%) is higher than the XXV Spanish Registry of Heart Transplant (65%), published in December 2015. This may be caused by the small size of our series and by missed cases (early deaths after the OHT).

None of our patients underwent tricuspid valve surgery. Recipients with significant TR are more symptomatic in the reviewed literature but in our series more than a half remained asymptomatic.

Many patients died of non-cardiac causes, as infection or cancer.

A larger comparative study in our population is needed to obtain further information.

Figure 1

P268

The criterion of unfavorable postoperative period in patients with ischemic cardiomyopathy

VM Shipulin¹; MO Gulya¹; SL Andreev¹; KF Zavadovsky¹; EA Alexandrova¹; BN Kozlov¹

¹Federal State Budgetary Scientific Institution "Research Institute for Cardiology", Tomsk, Russian Federation

Objective: to study preoperative perfusion and metabolism of left ventricular (LV) myocardium in patients with ischemic cardiomyopathy (ICMP) for the further prognosis and evaluation of possible postoperative repeated heart remodeling.

Methods: The study included patients with ICMP (n=32) of 56 ± 7 years old, subjected to Triple V type surgical treatment (CABG, SVR, MVR). Inclusion criteria: obliterating atherosclerosis of coronary arteries (CA) (stenosis of the left main CA $\geq 75\%$ or proximal stenosis of the anterior descending CA, and/or more than 75% stenosis of two and more CAs); previous myocardial infarction; chronic HF NYHA II-IV; LVEF $< 40\%$; LV ESVI over 60 ml/m²; presence of akinetic and dyskinetic areas of LV by echocardiography. SVR was performed by L. Menicanti technique. Exclusion criteria: organic heart diseases; acute myocardial infarction; right ventricular

failure; acute cerebrovascular disease; absolute contraindications to surgical treatment. Prior to the surgery myocardial scintigraphy with 99mTc-MIBI at rest was performed to evaluate perfusion and with 123I-MIBG to evaluate metabolism of fatty acids in the myocardium. Scintigraphy results were presented as a median of lower/higher quartiles (Me (IQ/hQ)). Clinical status of LV and EchoCG data were evaluated before the surgery, 1 month after the surgery and 1 year after the surgery.

Results: One year after the intervention the patients were allocated into two groups: (Group 1) patients (n=18) with a positive effect from the surgery, in which LV repeated postoperative remodeling process was not noticed: ESVI decreased, remained at the same postoperative level or increased $< 15\%$ if compared with that in the early postoperative period; (Group 2) patients (n=14) in which, despite successful surgery, repeated LV remodeling took place: ESVI increased $\geq 15\%$ in comparison with that in the early postoperative period. The groups were comparable by their LV volumes and clinical status prior to the surgery and in the immediate postoperative period. Significant preoperative differences were revealed by the following baseline scintigraphy data: defect of metabolism in the delayed images (26.5% (20.6%; 32.4%) and 38.2% (16.2%; 44.1%), $p=0.02$, respectively), perfusion-metabolic mismatch in the early (5.9% (-5.9% 7.4%) and -1.5% (-7.4% 1.5%), $p=0.02$, respectively) and delayed (14.7% (5.9%; 27.9%) and 4.4% (2.9% 7.4%), $p<0.0001$) images. The largest area under the ROC curve was found to be for the method of identification of perfusion-metabolic mismatch in the delayed scans (AUC=0.778, $p<0.0001$).

Conclusion: The size of the perfusion-metabolic mismatch $\geq 12\%$ predicts positive effect of surgical treatment with sensitivity and specificity of 100% and 56%, respectively.

P269

Application of the new classification of primary graft failure in a contemporary heart transplantation series

I Iago Sousa Casasnovas¹; A Ayesta-Lopez¹; E Gomez-Gomez¹; A Alonso-Garcia¹; F Diez-Delhoyo¹; P Diez-Villanueva¹; M Martinez-Selles¹; A Villa Arranz¹; J Fernandez-Yanez¹; F Fernandez-Aviles¹

¹University Hospital Gregorio Marañon, Madrid, Spain

Introduction: Primary graft failure (PGF) is a severe complication in the initial post-transplantation period. There is significant discrepancy in the definitions used by the different studies. In 2014 the International Society of Heart and Lung Transplant (ISHLT) established new criteria for the diagnosis of PGF and proposed a severity scale in the left ventricle (LV) PGF. The utility of this classification to predict postoperative mortality is not fully evaluated.

Methods: We analysed retrospectively all heart-transplantation patients in our department between January 2005 and December 2014. We collected basal characteristics and data of the initial postoperative period (echocardiogram, hemodynamics, cardioactive drugs). The application of the ISHLT classification was determined independently by two cardiologists, discussing the data in case of disagreement. Finally, the combined event postoperative death and graft loss was analyzed.

Results: During the study period 165 heart-transplantations were performed. We excluded from analysis 14 patients, not fulfilling the PFG criteria (due to pulmonary hypertension with PSAP > 50 mmHg, GTP > 15 mmHg and RVP > 4.5 UW, or technical complications). The basal characteristics of the remaining 151 patients were: Age 55.1 ± 11.8 y; Male 66.9%; diabetes 41.7%; hypertension 37.7%; positive CMV-IgG 88.1%; urgent status listing 31.1%. The global incidence of PGF was 60.3%, with the following distribution: Isolated right ventricle (RV) PGF 30.5%; Isolated LV-PGF 1.3%; Biventricular PGF 28.5%. The severity in the LV-PGF group resulted: mild 17.7%; moderate LV-FPG 53.3%; severe LV-PGF 40%.

The analysis of the combined event resulted: non-PGF 3.3%; Isolated RV-PGF 10.9%; mild LV-PGF 0%; moderate LV-PGF 8.3%; severe LV-PGF 94.1%. Logistic regression analysis showed statistically significant difference only in the severe LV-PGF in comparison with the non-PGF group ($p<0.001$; OR 464 [IC95 39.5-5449.7]).

Conclusion: With the application of the new ISHLT classification to a contemporary heart-transplantation series we found that any kind of PFG was frequent (60.3%). There was similar proportion of isolated RV-PGF and biventricular-PGF (30.5 and 28.5%), with a very low proportion of isolated LV-PGF (1.3%), so LV-PGF was mostly combined with RV dysfunction. In terms of mortality or graft loss, the only group with a significant higher risk was the severe LV-PGF.

P270

LVAD bridge to recovery

Ministry of Health Saudia Arabia
M Mustafa Alrefai¹; MUSTAF Refae¹

¹SAUD ALBABBAIN CARDIAC CENTER, cardiology, dammam, Saudi Arabia

We reported three cases with non ischemic cardiomyopathy with chronic heart failure symptoms recovered their lv systolic function after LVAD implantation and lv recovered to have LVAD explanted case 1-20year female presented with severe left ventricular failure with lvef 10% with failure of medical therapy case discussed

in our cardiac meeting then decision for LVAD implantation. LVAD implanted without complication with regular follow up with 2dehcardiography lvef improve from 10% to 55% LVAD explanted after one year of implantation. Case 2- 40y male patient with chronic heart failure secondary to non ischemic dilated cardiomyopathy with lvef 15% with narrow qrs complex with failure of medical therapy LVAD implanted at our center with regular fu with transthoracic echo cardiography lvef improve from 15% to 50% over 1 year period with recovery of lv function so LVAD explanted case-3 36y male patient diagnosed with dilated cadiomyopathy lvef 20% with repeated hospitalisation with left ventricular failure so LVAD implanted at our center with regular follow up with transthoracic echo cardiography lvef improve from 20% to 60% so improvement in clinical and surgical expertise in LVAD has improved the quality of life in well selected patient and to be as bridge to recovery.

ATRIAL FIBRILLATION

P271

Atrial fibrillation does not impair functional performance in patients with chronic stable heart failure.

RB Pharithi¹; EE Egom²; A A Jago³; SM Fay³; AM Maher¹; S Fall¹; C Murphy¹; V Maher¹

¹The Adelaide and Meath Hospital, Tallaght, Heart Efficiency Unit, Cardiology Department, Dublin, Ireland; ²Trinity College Dublin, Department of Clinical medicine, Dublin, Ireland; ³Institute of Technology, Tallaght, Department of Science, Dublin, Ireland

Background: Atrial fibrillation(AF) is commonly observed in patients with Heart failure and may impair their functional capacity. We evaluated this by comparing functional performance in patients with chronic stable heart who were in AF with those in Sinus rhythm (SR).

Objective: To assess if there is a significant differences in measured functional capacity between patients with chronic heart failure whether they were in AF or SR.

Methods 95 consecutive patients with chronic Heart failure were enrolled. 33 with AF and 62 in SR (controls). Functional performance was assessed using New York Heart Association (NYHA) class, 6 minute Walk Test and 3 Day FitBit Activity tracker.

Results: AF patients were older (73.15 ± 2.10) compared to patients in sinus rhythm (63.20 ± 1.54) and their mean heart rate was higher; 78.09 ± 2.34 vs 66.85 ± 1.68 . Results are summarized in the table below. **Conclusion:** Our results highlight that in patients with chronic stable heart failure, the presence of atrial fibrillation and higher heart rates did not significantly impair their objectively measured functional capacity compared to those in sinus rhythm. These observations cast doubt on strategies to revert these patient to sinus rhythm.

	Atrial fibrillation	Sinus rhythm	p-value
No. pts (n)	33	62	<0.0001
Male (%)	72.73	64.52	0.416
Age (Yrs \pm SD)	73.2 ± 2.1	63.2 ± 1.6	0.0002
Mean heart rate(beat/min)	78.1 ± 2.3	66.9 ± 1.7	0.0002
Body Mass index(kg/m ²)	29.0 ± 1.0	28.8 ± 0.7	0.480

P272

Ivabradine improves heart rate control and exercise tolerance in patients with heart failure with preserved ejection fraction and atrial fibrillation.

G Giuseppe Caminiti¹; C Fossati¹; D Battaglia¹; G Rosano¹; M Volterrani¹

¹IRCCS San Raffaele Pisana Hospital, Rome, Italy

Purpose: to evaluated the impact of Ivabradine administration on heart rate control and exercise tolerance of patients with heart failure with preserved ejection fraction (HFpEF) and permanent atrial fibrillation (PAF).

Methods: 11 subjects with of HFpEF and PAF, age 74.5 ± 21 years, M/F = 9/2, ejection fraction 56.5 ± 8.3 , resting heart rate > 100 bpm were included. all subjects performed 24/h ambulatory ECG monitoring (AEM), six minute walking test (6MWT) and cardiopulmonary test, at baseline and after two months of treatment with ivabradine. The dose of ivabradine was 5 mg/bid. We defined patients as responders to ivabradine if their mean heart rate at 24/h AEM decreased at least of 15% at two

months. According to the observed response, patients were divided in two groups as responders (group 1) or not responders (group 2).

Results: After two months seven out of 11 patients (63.6%) were responders. Group 1 had a significant reduction of mean heart rate at 24/h AEM compared to group 2 ($-37.5 \pm 11\%$ bpm vs -8.6 ± 3.1 bpm, p 0.003) After two months 6MWT distance (group1 = 97 ± 28 m; group 2 = 41 ± 19 m; p0.0002) and VO2 peak(group1 = $19.8 \pm 5.3\%$; group 2 = $-2.3 \pm 1.4\%$; p0.004) increased significantly in group 1 compared to group 2.

Conclusions: Ivabradine improved heart rate control in more than half patients with HFpEF and PAF. The decrease of heart rate was associated with an improvement of exercise tolerance.

P273

Left atrial longitudinal strain for discrimination of thromboembolic risk in patients with atrial fibrillation

AA Andrey Shavarov¹; GK Kiyakbaev¹; AA Yusupov¹; VS Moiseev¹

¹Peoples' Friendship University of Russia, Moscow, Russian Federation

Background: According to the results of a retrospective study patients (pts) with atrial fibrillation (AF) and CHA2DS2-VASc score of 1 may be at lower risk for thromboembolic events than previously reported. Consideration of additional factors can provide a more comprehensive assessment of an individual's suitability for anticoagulation treatment.

Purpose: To evaluate whether left atrial (LA) speckle tracking measurements improve risk discrimination in pts with AF and CHA2DS2-VASc score of 1 in whom it is unclear if treatment with anticoagulants is beneficial.

Methods: Sixty pts [mean age 65 (60; 72) yrs, 45% men] with AF were divided into three groups based on CHA2DS2-VASc score: the score of 1, the score of 2, the score of ≥ 3 . All pts underwent conventional and speckle tracking echocardiography. Apical four- and two-chamber views images of 6 myocardial segments in the filling phase were obtained to assess global peak left atrial longitudinal strain (PALS) in the reservoir (r) and contractile (c) phase.

Results: In nonlinear logistic regression analyses, only higher PALSr was significantly associated with lower CHA2DS2-VASc score (OR 0.61; 95% CI 0.38-0.97; p=0.03). The ROC curve showed the optimal PALSr cut-off point for prediction of CHA2DS2-VASc score of 1 was 16.7%. This had a sensitivity of 62.5% and a specificity of 39.0% and an area under the curve of 0.85 (95% CI 0.72-0.98; p=0.002).

Conclusions: PALSr was independently associated with CHA2DS2-VASc score in pts with AF. Use of a PALSr threshold may be clinically available instrument for decision making to initiate anticoagulation treatment based on the risk versus benefit of therapy in pts with AF and CHA2DS2-VASc score of 1.

P274

Relationship between central blood pressure and left atrial remodeling in patients with diastolic heart failure

IM Irina Balabanenko¹; AA Shavarov¹; GK Kiyakbaev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Left atrial (LA) remodeling is associated with left ventricular (LV) diastolic dysfunction that could cause diastolic heart failure (DHF). Arterial stiffness is elevated in patients with arterial hypertension, atherosclerosis, diabetes mellitus, but it's relations with HF and atrial fibrillation (AF) is not well known.

Aim: to compare central blood pressure in patients with recurrent AF and DHF in dependence of structural and functional changes of LA.

Methods: The study included 55 hypertensive patients (40% men) aged 66 (62; 73) years with recurrent AF and DHF (EF<50%). Standard echocardiography with Doppler technique and applanation tonometry were performed. LA structural abnormalities were defined as LA volume index (LAVI) ≥ 34 mL/m². LA emptying fraction (LAEF) $\leq 45\%$ and LA expansion index (LA exp inx) $\leq 90\%$ were categorized as LA phasic dysfunction. All patients were divided into 3 groups: G1 had both structural and functional abnormalities, G2 – had normal structure but phasic dysfunction and G3 – had normal LA parameters.

Results: The groups were similar in terms of age, body mass index, brachial blood pressure (BP) and antihypertensive therapy. The highest HR was in G1 patients [75 vs 71 and 70 bpm in G2 and G3 respectively, p=0,03]. Significant changes observed in timing to reflected wave (Tr), that was shortest in G1 group (p=0,02). Alx-HR75 had the highest range in G1 group [33 vs 25 and 22% in G2 and G3 respectively, p=0,02]. There was no difference in central BP and PWVcf between three groups. LAVI had significant (p < 0,05) inverse correlations with Tr (r=-0,22) and direct correlations with Alx-HR75 (r=0,16). Both LAEF and LA exp inx had equal negative relations with HR (r=-0,31), brachial and central DBP (r=-0,25 and r=-0,23 respectively) and PTIsystole (r=-0,22). Significant positive relations were observed between phasic function parameters and ejection duration, subendocardial viability ratio (SEVR) and Alx-HR75 (r=0,24 for all cases).

Conclusion: LA remodeling is associated with higher HR and Alx-HR75 and shorter Tr in AF patients with DHF. LAVI correlated with Alx-HR75 and Tr, while LA function had a relation with HR, brachial and central DBP, ejection duration, SEVR and PTIsystole.

P275

Conservative approach for patient in acute heart failure with cor triatriatum dexter and atrial fibrillation : a rare case reportS M Satyadharma Michael Winata¹¹Budhi Asih General Hospital, Cardiovascular Medicine, Jakarta, Indonesia

Introduction: Cor triatriatum dexter (CTD) is an very rare congenital cardiac anomaly in which right atrium (RA) is divided into 2 chambers by a membrane. This congenital abnormality is commonly associated with other right-sided cardiac abnormalities. In this report, we describe a patient presenting with acute heart failure precipitated by atrial fibrillation (AF) which was caused by CTD.

Clinical summary: A 33-year-old man was admitted to emergency room with acute-onset dyspnea and chest pain. He was presented with jugular vein distension with respiratory rate 36 / minute and 96% percutaneous oxygen saturation in air. Auscultation of the chest revealed bilateral fine crepitations on lung bases. Other physical examination results were between normal limit. A 12-lead electrocardiogram (ECG) showed irregular rhythm consistent with atrial fibrillation with a ventricular rate of 80, no ST segment or T wave changes. Chest X-ray showed cardiomegaly. An initial transthoracic echocardiogram showed a membrane partitioned the right atrium into two chambers consisted with CTD. The left ventricular function was normal and no abnormalities detected on the cardiac valve with no turbulent flow detected using the Doppler method. Medical treatment using intravenous diuretics, anticoagulation treatment and beta-blocker showed a significant improvement in patient's condition. The patient was discharged with beta-blocker and anticoagulation treatment. Outpatient clinic follow-up showed a good result with no complications detected, even though the ECG still showed atrial fibrillation. The patient refused to have further evaluation and management of his heart rhythm.

Discussion: Clinical manifestation in patients with CTD are variable from asymptomatic and often detected incidentally during echocardiography or surgery to correct other cardiac abnormalities. This condition can lead to trapped catheters, supraventricular arrhythmias (such as AF), or embolisms. CTD can be diagnosed by echocardiography and magnetic resonance imaging (MRI). Symptomatic patient with significant obstruction should have a surgical resection. In this patient, beta blocker and anticoagulant given with short course of parenteral diuretic eliminated the symptoms and shared a good results of the follow-up without any complication detected. Although we found that the AF associated with CTD had a tendency to be persistent or permanent, our further evaluation and treatment could not be done because of patient preferences.

Conclusion: Although CTD is extremely rare, it can be presented in a young patient with right-sided heart failure. It can be easily corrected by surgical excision of the membrane if indicated. Eventhough excision of an abnormal membranous septum could eliminate AF, our patient outcome for months was still good with beta blocker and anticoagulation treatment.

Transthoracic echocardiogram showing CTD

P276

Impact of atrial fibrillation patterns in patients with acute decompensated heart failureJ B Augusto¹; M Borges Santos¹; D Roque¹; M Silva¹; J Castro²; J Sala¹; A Faustino¹; M Branco¹; F Frade¹; C Morais¹¹Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; ²Hospital de Cascais, Cascais, Portugal

Background: Atrial fibrillation (AF) is a frequent comorbidity in patients with heart failure (HF) with an associated increase in mortality.

Purpose: We aimed to evaluate the prognostic value of different patterns of AF (paroxysmal vs non-paroxysmal) in patients with acute decompensated heart failure (ADHF).

Methods: 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period were included retrospectively in our study. Among them, 423 patients were admitted for in-hospital management. All patients underwent routine clinical and laboratory exams. We evaluated medical charts in order to identify patients with ADHF. Non-paroxysmal AF included both persistent and permanent AF (defined according to the European Heart Rhythm Association). Patients were evaluated 30 days after discharge to assess the incidence of stroke.

Results: 101 patients were admitted with both AF and ADHF (mean age of 77.2 ± 9.6 years, 40.6% males). There were no differences in age ($p = 0.664$), admission heart rate ($p = 0.318$), nor in left ventricle ejection fraction ($p = 0.229$) between paroxysmal and non-paroxysmal AF. A non-paroxysmal pattern was associated with higher hospital admissions for ADHF (28.9% vs 19.7%; odds ratio, OR=1.65, 95% confidence interval, 95% CI 1.05-2.59, $p = 0.03$). In patients with ADHF, non-paroxysmal AF was more frequently associated with longer length of hospital stay (mean \pm standard deviation, 2.4 ± 0.1 vs. 1.9 ± 0.1 days, $p = 0.046$) and higher HAS-BLED score (3.6 ± 1.1 vs. 2.8 ± 1.1 $p < 0.001$). Urgent pharmacological cardioversion was also less successful in patients with non-paroxysmal AF (7.1% vs 24.4%, OR=4.21, 95% CI 1.24-14.29, $p = 0.023$). There was no difference in CHA2DS2-VASc score between paroxysmal AF and non-paroxysmal AF ($p = 0.961$), nor in stroke rates 30 days after discharge ($p = 0.782$), despite patients with non-paroxysmal AF being more frequently under oral anticoagulation (55.4% vs 31.1%, $p = 0.017$). In-hospital death rates were also similar between both subgroups ($p = 0.533$).

Conclusion: In patients with AF, the risk of admission due to ADHF was higher among non-paroxysmal AF. These results suggest that maintenance of sinus rhythm may decrease the rate of admissions and the length of hospital stay for ADHF.

P277

CHA2DS2-VASc scores and HAS-BLED score in patients with paroxysmal atrial fibrillation treated in the intensive internal care unitD Danijela Vranes¹; B Dzudovic¹; L Torbica¹; N Ratkovic¹; A Ristic¹; V Milic¹; S Obradovic¹¹Military Medical Academy of Belgrade, Clinic of Emergency Medicine, Belgrade, Serbia

Background: Atrial fibrillation (AF) is the most common heart rhythm disorder that can be found associated with many acute diseases and carries an increased risk of ischemic stroke and systemic thromboembolic complications. Incidence of paroxysmal AF in patients admitted in the intensive care unit because of non cardiac reasons and risk of thromboembolic and bleeding complications in these patients is not studied well. Method. This is prospective study which included 1700 consecutive patients treated in the Clinic for Emergency and Internal Medicine of Military Medical Academy during 12 months (June 2014 – June 2015) and 200 (34%) patients had electrocardiographic evidence of AF. Thromboembolic and bleeding risk stratification was evaluated with CHA2DS2-VASc and HAS-BLED scores respectively.

Results: Among 200 patients with electrocardiographic evidence of AF 87 (43.1%) had paroxysmal AF, and the remaining 113 patients (56.9%) had permanent or persistent AF [92 (45.5%) or 21(10.4%), respectively]. CHA2DS2-VASc score 0 or-1 was found in 13 patients (14.8%), and CHA2DS2-VASc score ≥ 2 was detected in 74 (85.2%) patients. HAS-BLED skor 0-2 had 33 (37,9%) patients, and HAS-BLED ≥ 3 had 54 (62,1%) patients. In our group of patients with paroxysmal AF, 54 (62.1%) had an increased risk for thromboembolic complications and bleeding (CHA2DS2-VASc ≥ 2 and HAS-BLED ≥ 3 , respectively), 25 (28.7%) patients had an increased risk for thromboembolic complications and low bleeding risk and 8 (9.2%) patients had a low risk for thromboembolic complications and low bleeding risk.

Conclusion: In patients with paroxysmal AF treated in the intensive care unit high proportion of patients have both high thromboembolic and bleeding risk.

P278

Prevalence and incidence of atrial fibrillation in heart failure patients with either reduced or normal left ventricular ejection fraction

P Pierpaolo Pellicori¹; K Kaur¹; A Urbinati¹; P Shah¹; T Nikolaidou¹; JFG Cleland¹; AL Clark¹

¹University of Hull, Department of Academic Cardiology, Hull, United Kingdom

Background: Heart failure (HF) and atrial fibrillation (AF) are both associated with increased morbidity and mortality. We aimed to determinate the prevalence and incidence of AF in patients with HF.

Methods: HF was defined by the presence of symptoms or signs of HF supported by objective evidence of cardiac dysfunction: either a left ventricular ejection fraction (LVEF) $\leq 40\%$ (or worse than, or equal to, mild to moderate left ventricular systolic dysfunction (LVSD)) on echocardiography (HFrEF); or LVEF $> 40\%$ and raised plasma concentration of amino-terminal pro-B type natriuretic peptide (NT-proBNP > 220 pg/ml; HFnef).

Results: Of 3570 patients with HF, 1164 were in AF at baseline (33%), with a greater prevalence among patients with HFnef compared to HFrEF (40% vs 26%, respectively, $p < 0.001$). Compared to patients with HF in sinus rhythm (SR), those in AF were older, had more severe symptoms, and higher NT-proBNP, worse kidney function and more often received loop diuretics, despite their higher LVEF. Of those in SR, 1372 patients had HFrEF and 1034 had HFnef, the incidence of AF at one year was 2.8% in each group ($p = 0.73$). Increasing age, male sex, history of paroxysmal AF and increasing NT-proBNP were independent predictors of incident AF during a median follow-up of 1574 (IQR: 749-2821) days; the predictors were similar for each cardiac phenotype.

Conclusions: The prevalence of AF is high, especially in patients with HFnef but its incidence is modest. This may be explained by a high concurrent onset of HF and AF. Greater age, a prior history of AF and increasing NT-proBNP, a marker of congestion, but not LVEF predict the risk of developing AF in patients with HF.

Giovanni XXIII, Cardiology Unit, Bergamo, Italy; ⁶San Martino Hospital, Heart

Failure Clinic, Belluno, Italy; ⁷Villa Bianca Hospital, Division of Cardiology, Trento,

Italy

Background: Aim of the study was to prospectively assess the relation between atrial fibrillation (AF), cognitive impairment (CI), frailty and disability in older patients with chronic heart failure (HF).

Methods: 331 patients aged > 70 years (mean 78 ± 6 ; range 70-93; 43% women) in stable conditions and optimized therapy were enrolled in 7 HF cardiology clinics. CI was defined by a corrected Mini Mental State Examination score < 24 . Gait speed was used as marker of frailty and measured on a 4 meters distance at usual pace (figure 1).

Results: 98 patients (30%) were on AF at enrolment and 20 (6%) had a history of paroxysmal/persistent AF. At multivariable analyses, AF emerged as independently related to CI (OR 1.909 [1.072-3.397]; $p = 0.028$), as well as to reduced gait speed (OR 4.366 [2.104-9.060]; $p < 0.001$). Furthermore, AF was significantly associated to disability in either basic or instrumental activities of daily living. During a 1-year follow-up, 80 patients died (24.2%), 125 (37.8%) had at least one hospital readmission due to HF and 147 (44.4%) had a non HF-related admission. There was no significant association between baseline AF and 1-year mortality (19.4% vs 18.4%, $p = 0.188$) as well as between AF and HF readmissions (36.7% vs 38.2%; $p = 0.451$) and non-HF related admissions (43.8% vs 46.8% $p = 0.649$).

Conclusions: Among patients with chronic HF, those with AF present a high prevalence of frailty, CI and disability. The hypothetical mechanisms by which AF and HF may affect these conditions are multiple and further studies are warranted. However, screening for these variables in clinical practice is simple and inexpensive and may allow better strategies for intervention in this high risk population.

Major bleeding among rivaroxaban users with nonvalvular atrial fibrillation and heart failure

This study is funded by Janssen Scientific Affairs, LLC, and Bayer Healthcare. WF Peacock¹; S Sally Tamayo²; Z Yuan³; NM Sicignano⁴; K Hopf⁴; M Patel⁵
¹Baylor College of Medicine, Houston, United States of America; ²Naval Medical Center Portsmouth, Cardiology, Portsmouth, United States of America; ³Janssen Research and Development, LLC, Titusville, United States of America; ⁴Health ResearchTx LLC, Trevose, United States of America; ⁵Duke University Health System and Duke Clinical Research Institute, Durham, United States of America

Background: Predictors and outcomes of major bleeding (MB) in heart failure (HF) patients treated with anticoagulants for nonvalvular atrial fibrillation (NVAf) are poorly described.

Purpose: Our purpose was to describe the incidence of MB and evaluate outcomes in HF patients receiving rivaroxaban for NVAf.

Methods: As part of an FDA post-marketing safety requirement, we queried nearly 10 million electronic medical records (EMRs) from the United States Department of Defense healthcare system, from January 1, 2013 to June 30, 2015, to identify MB-related hospitalizations among rivaroxaban users with NVAf. A validated case-finding algorithm was used for detection of MB, and the presence of HF was determined by evaluation of diagnosis codes in the EMRs. Incidence, outcomes, demographics and comorbidities associated with MB were stratified by HF status.

Results: Of 44,793 NVAf patients on rivaroxaban, 20.7% had HF. Major bleeding rates were higher with HF than without, 5.33 (95% CI 4.88-5.82) versus 2.21 (95% CI 2.06-2.37) per 100 person-years. Of MB patients, mean (SD) age was similar for those with and without HF, 78.8 (7.4) versus 78.7(8.1) years, respectively. Of MB patients, those with HF had more hypertension (90.0 versus 85.8%), coronary artery disease (62.5 versus 44.7%), diabetes (45.3 versus 31.2%), prior ischemic stroke (9.2 versus 6.5%) and higher mean (SD) CHA2DS2-VASc scores [5.4 (1.4) versus 4.1(1.4)], than those without HF. Fatal outcomes associated with MB were higher with HF versus no HF, 0.12 (95% CI 0.07-0.22) versus 0.08 (95% CI 0.06-0.12) per 100 person-years, respectively.

Conclusion: In a post-marketing study of 44,793 rivaroxaban users with nonvalvular AF, those with HF had more comorbidities and experienced higher rates of MB and fatal outcomes.

Myocardial gene expression and cardiac remodeling in patients with myocarditis

O Moiseeva¹; A Runov²; M Vonsky²; D Khaschevskaya¹; L Mitrofanova¹
¹Federal Almazov North-West Medical Research Centre, Non-coronary disease, St.Petersburg, Russian Federation; ²Institute of Cytology RAS, St.Petersburg, Russian Federation

Introduction: Myocardial gene expression analysis has attracted attention as potential diagnostic tool for a differential diagnosis of heart failure.

Purpose: The aim of the study was to estimate the possible association between myocardial gene expression profile and the clinical data in patients with biopsy-proven lymphocytic myocarditis.

Methods: We analyzed 11 endomyocardial biopsies (EMBs) from patients with myocarditis and 6 heart transplantation autopsy samples. Individual normalized levels of heart-specific IgG autoantibodies (AAB) were quantified by ELISA. Circulating CD4+CD25bright+FOXP3+ cells were studied by flow cytometry. Thirty candidate genes were selected for the study. mRNA content was examined by quantitative PCR after reverse transcription (RT-qPCR).

Results: Expression of 10 candidate genes (NF- κ B, IL2, NOTCH3, GLIPR, TMOD3, SEC24A, FCER1G, ITGB2, SIGLEC1, ADCY7) out of 30 studied was altered in EMBs from patients with myocarditis. Left heart dilatation was associated with down-regulated ITGB2 and SIGLEC1 gene expression. HLA expression was also associated with down-regulated NOTCH3 TMOD3 gene expression. Circulating FoxP3+ T-reg cells were correlated with up-regulated NF- κ B and down-regulated IL2 gene expression. We identify the relationship between the gene expression and AAB profile.

Conclusion: Preliminary results suggest that the gene expression profile can predict the cardiac remodeling and outcome for patients with myocarditis.

Clinical and Morphologic Characteristics

	Patients of myocarditis
Age, yrs	39,2 \pm 13,5
Male, n (%)	7 (64)
HF onset, n (%)	8 (73)

Endomyocardial miR-133a levels correlate with immunohistological markers of inflammation, improved LV function and clinical outcome in patients with inflammatory cardiomyopathy

C Besler¹; D Urban¹; S Watzka¹; R Kandolf²; K Klingel²; H Thiele³; A Linke¹; G Schuler¹; V Adams¹; P Lurz¹

¹Heart Center of Leipzig, Cardiology, Leipzig, Germany; ²University Hospital of Tübingen, Department of Molecular Pathology, Tübingen, Germany; ³University Hospital of Schleswig-Holstein, Medical Clinic II (Department of Cardiology, Angiology and Intensive Care Medicine), Lubeck, Germany

Aims: Inflammatory heart disease represents an important cause of chronic dilated cardiomyopathy. Predicting the clinical course of patients with inflammatory cardiomyopathy (ICMP) is difficult and the prognostic value of current biological markers remains controversial. We tested whether expression of selected microRNAs (miRNAs) in endomyocardial biopsies (EMB) is related to left ventricular (LV) functional recovery and clinical events during follow-up in patients with ICMP.

Methods and Results: EMB were obtained from patients with histologically proven ICMP (n = 76) and non-inflammatory dilated cardiomyopathy (n = 22). Based on literature search, we predefined a set of 6 miRNAs implicated in inflammation (miR-155, miR146b), heart failure (miR-21, miR-133a), endothelial cell (miR-126) and skeletal muscle function (miR-206). miRNA expression in EMB was quantified by RT-PCR. Expression of miR-155 and miR-133a was markedly upregulated in EMB from patients with ICMP as compared to patients with non-inflammatory dilated cardiomyopathy, irrespective of viral or non-viral etiology. Levels of miR-133a (R = 0.73, P < 0.01) and miR-155 (R = 0.63, P < 0.01) significantly correlated with the inflammatory cell count on EMB from patients with ICMP. Patients with ICMP and preserved LV function at study entry demonstrated higher endomyocardial expression of miR-133a than patients with reduced LV function. Also, higher expression levels of miR-133a were associated with recovery of LV function during a mean follow-up of 3.1 years. Importantly, in a Kaplan-Meier estimate, patients with ICMP and miR-133a levels in the upper tertile showed longer survival free of death, malignant arrhythmias and hospitalizations for heart failure.

Conclusion: The present study demonstrates that in a predefined set of miRNAs, relevant to cardiovascular pathology, endomyocardial miR-133a levels correlate with macrophage infiltration, improved LV function and clinical outcome in a comparatively large cohort of patients with histologically proven ICMP. miR-133a may serve as a potential novel biomarker and therapeutic target in human ICMP.

P283

Takotsubo cardiomyopathy with spontaneous left ventricular wall thickening

H Hideyuki Hayashi¹

¹Kitano Hospital, Cardiology, Osaka, Japan

Purpose: It is well known the functional disruption after takotsubo cardiomyopathy (TC) recovers within 1 or 2 weeks. Recently, we reported a case of TC with spontaneous left ventricular wall thickening (LVWT) after recovery of cardiac function. Therefore, we tried to elucidate the frequency and clinical characteristics of LVWT in TC patients.

Methods: We retrospectively investigated 65 patients with TC who were admitted to our hospital between 2004 and 2014.

Results: Six patients emerged LVWT, which were detected by echocardiography during 2 to 4 weeks after the onset of TC. In total, 31 patients underwent echocardiography during this period. Interestingly, all cases of LVWT occurred after the impaired contraction improved, and they persisted for several months. Comparing LVWT group (6 patients, 19.4%) with non-LVWT group (25 patients, 80.6%), the number of leads showing negative T wave in 12-lead electrocardiogram (9.3 ± 1.2 vs 6.0 ± 3.7 , p = 0.01) and E/E' ratio on echocardiography (15.5 ± 4.5 vs 10.1 ± 3.0 , p = 0.013) at the onset of TC significantly correlate to following LVWT.

Conclusion: The prevalence of LVWT is higher than previously reported. It is possible 12-lead electrocardiogram and echocardiography help to foresee LVWT. Although the mechanism of LVWT is still unknown, sequential cardiac magnetic resonance imaging obtained from two patients suggests edematous change.

P284

The relation between subclinical left ventricular systolic dysfunction in type II Egyptian diabetic patients and grade of diabetic retinopathy by 2D Global longitudinal strain.

S Soheir Bostan¹

¹Ministry of Scientific Research, Cardiovascular Ultrasound Unit at Research Institute of Ophthalmology, Cardiovascular Ultrasound Unit, Giza, Egypt

Background: Alterations in cardiac structure and function occur in type 2 diabetes independently of coronary artery disease or hypertension, so it might be important to diagnose diabetic cardiomyopathy in the early stages to prevent development of heart failure in the future. Retinopathy is one of the micro vascular complications of

diabetic mellitus (DM). In some studies, it has been proposed that diabetic retinopathy might be associated with LV diastolic dysfunction and development of heart failure.

Aim of study: To evaluate left ventricular (LV) systolic function in Egyptian type II diabetic patients using two-dimensional (2D) global longitudinal strain and to study its relation to the grade of diabetic retinopathy.

Patients and methods: A total of 30 patients with type II (DM) enrolled after exclusion of ischemic heart disease by (negative Dobutamine stress echo), valvular heart disease, congenital and other related co-morbidities were included. In our study, Patients were classified according to diabetic retinopathy grade in to Group A: 22 patients with non proliferative diabetic retinopathy and Group B: 8 patients with proliferative diabetic retinopathy. All patients underwent conventional 2D echocardiography and longitudinal peak strain was calculated in apical long-axis, Apical four-chamber, and Apical two-chamber views, and values of the three views were averaged (global longitudinal peak strain (GLPS)). Results for both groups were statistically analysed by SPSS).

Results:- All patients had preserved LV ejection fraction (LV-EF ≥ 50) by Conventional 2D Echo parameters. Both groups non proliferative and proliferative diabetic retinopathy had lower average GLPS mean = -17.7 ± 2.4 . There was no statistically significant difference on comparing the GLPS average (18.1 ± 2.1 vs. 16.6 ± 2.6 , $p = 0.06$) in two groups.

Conclusion: The global longitudinal strain can be a useful novel technique in the determination of subclinical LV systolic dysfunction in egyptian diabetic patients. Diabetic patients have lower longitudinal myocardial mechanics. In our study, There was no significant association between diabetic retinopathy grade and sub clinical LV systolic dysfunction.

Average Global longitudinal peak strain

	Group A n(22)	Group B n(8)	p value		
mean	SD	Mean	SD		
GLPS Average	-18.1	2.1	-16.6	2.9	0.06

there is non significant difference in average GLPS between the 2 groups.

P285

Is there a Marfan cardiomyopathy?

M Tavares Da Silva¹; M Vasconcelos¹; A Lebreiro¹; G Pestana¹; R Pinto¹;

T Pinho¹; AJ Madureira²; J Almeida³; MJ Maciel¹

¹Sao Joao Hospital, Cardiology, Porto, Portugal; ²Sao Joao Hospital, Radiology, Porto, Portugal; ³Sao Joao Hospital, Cardiothoracic Surgery, Porto, Portugal

Purpose: Marfan syndrome (MFS) is the commonest inherited connective tissue disease, with an estimated prevalence of 1 in 5000 individuals. It occurs due to a mutation encoding fibrillin-1, essential to the structure of the extracellular matrix. The main system affected is the cardiovascular, namely the aorta. It has recently been proposed the existence of a primary cardiomyopathy in MFS patients (pts) with biventricular enlargement and dysfunction. The aim of this work was to evaluate the existence of a cardiomyopathy related to MFS in our population of MFS pts using echocardiography and cardiovascular magnetic resonance (CMR).

Methods: We enrolled 19 consecutive MFS pts, according to 2010 Ghent criteria, from 2011 to 2015, who underwent CMR for evaluation of the aorta and the heart. Echocardiography was also performed. Aorta was measured at different levels and left and right ventricular (LV and RV) volumes, ejection fraction (EF) and LV mass were evaluated as well as was the presence of late gadolinium enhancement. Echocardiographic parameters included dimensions of aorta segments accessible through this exam, left atrial (LA) dimensions, valvular evaluation and also LVEF. Data is presented as percentages and the relationship between variables is expressed by Pearson correlation test. A p value less than 0.05 was considered statistically significant.

Results: The majority of pts were male ($n = 14$, 73.7%) and all were on ARB II therapy. Four pts have already been submitted to aortic root replacement but as there were no differences in population characteristics, global results are presented. Aortic regurgitation was present in 26.3% of pts. Mitral valve prolapse was found in 42.1% and mitral regurgitation in 36.5%. LA dilation was observed in 36.5%, mainly graded as mild (26.3%). Concerning CMR evaluation, 21.1% of pts had reduced LVEF, 42.1% of pts had increased LV end-diastolic (LVED) and 68.4% had increased end-systolic (LVES) volumes. RVEF was normal in all pts, with increased RVED volume in 31.6% and increased RVES volume in 57.9%. Hypertrabeculation matching criteria for myocardial non-compaction was found in 10.5%. Late gadolinium enhancement was present in 26.3% of pts, being the subepicardial pattern the most common form. Even though all pts had normal LV indexed mass values, a significant correlation was found between LV indexed mass and LVED volume ($r = 0.713$, $p = 0.001$) and also between LV indexed mass and LA dimensions ($r = 0.528$, $p = 0.036$).

Conclusion: These results support the existence of a primary cardiomyopathy at least in a subgroup of MFS pts. Biventricular enlargement and LV dysfunction found are usually mild. However, the impact of these changes in outcome of these pts is not fully understood. Indeed, further studies are needed to assess potential causes and

the natural history of this condition and also to help to support potential treatment decisions in these pts.

P286

Markers of takotsubo cardiomyopathy in clinical practice

M Monika Budnik¹; J Kochanowski¹; R Piatkowski¹; K Wojtera¹; M Gaska¹; P Glowacka¹; P Karolczak¹; D Ochijewicz¹; M Peller¹; G Opolski¹

¹Medical University of Warsaw, 1st Department of Cardiology, Warsaw, Poland

Background: Takotsubo cardiomyopathy (TTC) mimics acute coronary syndrome and is most often characterized by chest pain, ST segment elevation, cardiac enzymes increase and left ventricular dysfunction. It is important to distinguish ST elevation myocardial infarction (STEMI) and TTC at early stage. The symptoms are similar but the treatment and prognosis are completely different. The aim of the analysis was to find a simple marker that can differentiate patients (pts) with TTC from STEMI.

Methods: The analysis included 66 consecutive female pts diagnosed with TTC and 66 consecutive female pts with STEMI. In all pts we performed Echo examination during the first 24h of hospitalization. We measured level of biomarkers of heart failure and myocardial necrosis in order to correlate with the results of echocardiography. All pts had coronary angiography performed.

Results: The ejection fraction (EF) was lower in pts with TTC. Pts with TTC had higher NT-proBNP concentration. Pts with STEMI had higher concentration of TnI and CKMB mass. The greatest differences between the two groups were observed when analyzing NT-proBNP and TnI ratio. Pts with TTC had almost 30 times higher NT-proBNP/TnI ratio that pts with STEMI. NT-proBNP and CK MBmass as well as NT-proBNP and EF ratio was also higher in TTC than STEMI.

Conclusion: TnI, CK MB mass and NTproBNP concentration is performed routinely in all pts admitted to the hospital with chest pain. By correlating with EF which can be quickly calculated by echocardiography we can distinguish TTC from STEMI at early stage. High NT-proBNP/TnI, NT-proBNP/CK MBmass and NT-proBNP/EF ratio suggest TTC rather than STEMI.

Results in TTC and STEMI group

	TTC	STEMI	p value
TnI (ng/ml)	2,1	19	<0,05
CK MBmass (ng/ml)	9,5	73,3	<0,05
NT-proBNP (pg/ml)	4702	2138	<0,05
EF (%)	41	50	<0,05
NT-proBNP/TnI	2235,2	81,6	<0,05
NT-proBNP/CK MBmass	678,2	27,5	<0,05
NT-proBNP/EF	110,4	39,4	<0,05

P287

Clinical heterogeneity of left ventricular non-compaction patients

A Rocha¹; A Sousa¹; T Pinho²; A Madureira²; F Rocha Gonçalves¹; E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Sao Joao Hospital, Porto, Portugal

Introduction: Left ventricular noncompaction (LVNC), is a still misunderstood cardiomyopathy, although increasingly recognized. Its etiology is not definitely established and its natural history is largely unknown. The clinical presentation is very heterogeneous and the best therapeutic strategies have yet to be determined.

Purpose: We aimed to describe clinical characteristics and outcomes in adult patients with isolated LVNC followed at our referral center.

Methods: We retrospectively analyzed the medical records of patients followed in a tertiary care center with the diagnosis of LVNC, confirmed by CMR (3-T scanner, Siemens, Erlangen, Germany), interpreted by two experienced investigators (Radiologist/Cardiologist). Clinical data and echocardiographic, resting and 24 h-ECG parameters were collected.

Results: Thirty patients, mean age 50 ± 15 years, 20 (67%) men, were included. Clinical presentation was heart failure in 8 (27%) patients, chest pain in 5 (17%), including 2 acute coronary syndromes, 5 (17%) patients had an arrhythmic event, with one episode of ventricular tachycardia (VT), 3 (10%) patients presented a syncopal episode and 9 (30%) were asymptomatic. Thromboembolic complications were documented in 4 (13%) patients. Neuromuscular disease was present in 4 (13%) patients and Fabry disease, disorder of fatty acid oxidation and systemic lupus were present in another 3. Nine patients (30%) had family history of cardiomyopathy (with 2 cases of familial forms of LVNC) and 5 (17%) had family history of sudden cardiac death. MYH7 gene mutations were present in 2 patients. Six (20%) of them had implanted an ICD, one a CRT device, one a CRT-D and another a conventional pacemaker. Mean LVEDV was 120 ± 34 mL/m² and LVEF was $41 \pm 15\%$, with 11 (37%) patients presenting severe systolic dysfunction. Ventricular wall

thickness was within normal limits or slightly increased, except in 2 patients (22mm and 24mm). Apical segments of lateral wall and apex were the most frequently affected segments (in 80% and 53% of patients, respectively). Late gadolinium enhancement was presented in half. ECG was altered in 24 (80%) patients, the most common alteration being left bundle branch block (in 10 patients). Holter monitoring (available in 23) revealed no episodes of nonsustained VT or atrioventricular conduction disturbances. Of the 10 patients who underwent coronary angiography, only 3 had coronary artery disease.

Conclusions: Beyond the controversy around LVNC classification and morpho-functional development, our work illustrates the diversity of clinical scenarios where LVNC can be diagnosed and the requirement of a multidisciplinary approach in the diagnostic workup.

Differential impact of statin treatment on clinical outcomes between patients with or without ischemic cardiomyopathy

J Y Jae Yeong Cho¹; K H Kim¹; H J Yoon¹; S S Kim²; D H Kim³; S C Cho⁴; Y Ahn¹; M H Jeong¹; J G Cho¹; J C Park¹

¹Chonnam National University Hospital, Cardiology, Gwangju, Korea Republic of; ²Gwangju Christian Hospital, Gwangju, Korea Republic of; ³Saint Carollo Hospital, Suncheon, Korea Republic of; ⁴Gwangju Veterans Hospital, Gwangju, Korea Republic of

Background: Generally, statin treatment in heart failure is not recommended for reduction of mortality and rehospitalization rate according to recent American College of Cardiology / American Heart Association (ACC/AHA) guideline for heart failure (HF). We aimed to investigate whether statin is beneficial in patient with ischemic cardiomyopathy (ICMP) and old myocardial infarction (OMI).

Methods: Between November 2005 and August 2013, a total of 2,853 patients (64.7 ± 12.2 years, 2,133 men) with left ventricular (LV) dysfunction after acute myocardial infarction (AMI) enrolled in a nationwide AMI registry. Patients were divided into two groups (ICMP Group: LV dysfunction with LV dilation, OMI Group: LV dysfunction without LV dilation). LV dysfunction was defined as ejection fraction (EF) of less than 50% and LV dilation was defined as LV end diastolic dimension index (LVEDDI) of more than 32 mm/m². LVEDDI was defined as LVEDD divided by body surface area. Primary endpoint was composite of major adverse cardiac event (MACE). MACE was comprised of death, stroke, myocardial infarction, stent thrombosis, target lesion revascularization, and target vessel revascularization.

Results: There were no differences in baseline characteristics between the two groups except older age in ICMP group (69.9 ± 11.7 vs. 64.0 ± 12.1, p < 0.0001). Also medical histories such as hypertension, diabetes, and smoking showed no significant differences, except more frequent smoking history in OMI group (62.5% vs. 53.6%, p = 0.002). In ICMP group, statin treatment showed no difference in composite MACE (13.6% vs. 15.5%, p = 0.652). In OMI group, however, statin was still effective in reduction of MACE (6.4% vs. 8.9%, p = 0.040).

Conclusion: Statin treatment in ischemic HF patients was effective before progression to ICMP.

P289

Factors associated to the occurrence of the burn out stage in patients with left ventricular noncompaction

O Olga Azevedo¹; NUNO Marques²; B Marmelo³; C Gomes⁴; K Domingues⁵; L Reis⁶; R Santos⁷; S Leao⁸; R Faria¹; B Picarra⁹

¹Hospital Guimaraes, Guimaraes, Portugal; ²Faro Hospital E.P.E., Faro, Portugal;

³Hospital Sao Teotónio, Viseu, Portugal; ⁴Hospital Garcia de Orta, Almada,

Portugal; ⁵Hospital of Santarem, Santarem, Portugal; ⁶University Hospitals of

Coimbra, Coimbra, Portugal; ⁷Hospital Centre do Tâmega e Sousa, Penafiel,

Portugal; ⁸Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal;

⁹Hospital Espírito Santo de Evora, Evora, Portugal

Background: Left ventricular noncompaction (LVNC) is a cardiomyopathy characterized by variable prognosis, that may evolve to LV dilation and dysfunction, known as burn out stage.

AIM: To determine the prevalence and factors associated to the development of the burn out stage in LVNC.

Methods: Retrospective multicenter study including all patients diagnosed with LVNC in 10 hospital centers. We evaluated clinical and genetic data, ECG, echocardiographic and cardiac MR (CMR) data. Mean follow up 3.4 years. Burn out stage was defined as the presence of LV ejection fraction (EF) below 50%. Statistical analysis was performed to find the factors associated to the development of the burn out stage (SPSS 20.0).

Results: The study included 86 patients with LVNC, 57% males, with mean age 51 ± 19 years. Clinical presentation was predominantly heart failure (30,2%), followed by dysrhythmia (15,1%) and embolic events (EE) (8,1%). The burn out stage was detected in 42% of patients (n=36).

The patients on burn out stage were older (58 ± 17 vs. 47 ± 18; p = 0.006), but no differences were found regarding gender (p = 0.187) or family history of LVNC

(p=1.000).

Clinical presentation in patients on burn out stage was more frequently heart failure (50% vs. 16%; p = 0.002) and less frequently an incidental finding (22% vs. 74%; p < 0.001). No differences were found regarding the frequency of dysrhythmias (19% vs. 12%; p = 0.518) or EE (14% vs. 4%; p = 0.210) on clinical presentation.

Symptoms tended to be more frequent in patients on burn out stage (75% vs. 52%; p = 0.052), with emphasis on dyspnea (61% vs. 20%; p < 0.001), unlike palpitations (28% vs. 32%; p = 0.855) or syncope (0% vs. 4%; p = 0.625).

Patients on burn out presented more frequently atrial fibrillation (AF) (20% vs. 4%; p = 0.045) and left bundle branch block (LBBB) (23% vs. 0%; p = 0.002). No differences were found regarding the occurrence of ventricular tachycardia (VT) on Holter monitoring.

On echocardiography, patients on burn out stage had lower values of EF (35 ± 11 vs. 62 ± 7%, p < 0.001), mitral S' at septal (6.4 ± 1.8 vs. 8.2 ± 1.9cm/s; p = 0.054) and lateral sites (6.3 ± 2.1 vs. 9.3 ± 2.8cm/s; p = 0.027) and mitral E' at septal site (6.1 ± 1.6 vs. 9.5 ± 3.6, p = 0.014). However, they had higher LV diameter (61 ± 9 vs. 52 ± 6%; p < 0.001) and higher prevalence of mitral disease (56% vs. 14%; p < 0.001).

On CMR, patients on burn out stage presented higher prevalence of late enhancement (41% vs. 5%, p = 0.002) and lower EF (33 ± 12 vs. 57 ± 9%; p < 0.001).

The burn out stage was not associated to higher risk of mortality (p = 0.391), EE (p = 0.704) or dysrhythmias (p = 0.118).

Conclusion: In this multicenter study, the burn out stage was detected in 42% of patients with LVNC. Factors such as age, heart failure on clinical presentation, the presence of symptoms and namely dyspnea, AF and LBBB, values of mitral S' and E', the presence of mitral disease and late enhancement on CMR were associated to development of the burn out stage in patients with LVNC.

Prevalence of myocardial infarction with normal coronary artery in patients with multiple sclerosis. a new type of diastolic heart failure

E Giallalos¹; P Kokkotis²; S Katsanos¹; V Haina²; E Andreadou²; M Anagnostouli²; J Parissis¹; K Kilidireas²; J Lekakis¹; G Filippatos¹

¹Attikon University Hospital, Athens, Greece; ²University of Athens, Athens, Greece

Introduction: Myocardial Infarction with Normal Coronary Artery (MINCA) is a rare clinical entity. It's incidence in general population varies between 1% and 8.5%. Although several mechanisms have been proposed, the exact mechanism is unknown. Recently, patients with Multiple Sclerosis (MS) were reported with MINCA as a complication of autonomic nervous system dysfunction. Aim of our study was the prevalence of MINCA in MS and its possible association with ANS dysfunction.

Methods: A retrospective analysis of 183 hospitalized patients with MS (86 males) was performed and divided in two groups according to the presence of MINCA (group A) or not (Group B). Clinical profile of patients, predisposing factors for coronary artery disease, namely arterial hypertension (BP), diabetes mellitus (DM), hyperlipidemia (HLP), smoking (SM) and thyroid disease (TD) and the different treatment modalities were noted. Group A patients were also tested for Ewing's Test namely: (1) resting heart rate (HR), (2) HR variation in response to deep breathing, (3) HR response to standing, and (4) postural changes in systolic and diastolic blood pressure (SBP and DBP) namely orthostatic tolerance, inspiration-expiration test, the handgrip and the Valsalva Test implying sympathetic and/or parasympathetic abnormalities.

Results: Eleven patients were identified as MINCA (6%). The clinical profile of the patients MINCA patients had similar age (48.55 ± 8.2 y.o vs 44.52 ± 11.3 y.o (p=NS) and disease severity (EDSS scoring was 2.75 ± 1.6 vs 3.8 ± 1.9, p=NS) while the disease duration was significantly lower in Group A compared to Group B (4.25 ± 3.97 vs 10.26 ± 7.22, p = 0.001). MINCA's group had more predisposing factors than Group B (p < 0.05) while similar was the presence of thyroid disease in both groups. The Ewing Tests were abnormal in all patients of MINCA group. Discussion: The prevalence of MINCA in MS is 6% and seems to be correlated with the ANS dysfunction. This dysfunction might be either due to the presence of the predisposing factors or/and due to the lesions of MS and can.

P291

speed of recovery of left ventricular function is not related to the prognosis of takotsubo cardiomyopathy. A portuguese multicenter study.

N Nuno Marques¹; K Domingues²; C Lourenco³; R Santos⁴; C Gomes⁵; L Abreu⁶; L Reis³; B Picarra⁷; P Magalhaes⁸; O Azevedo⁹

¹Faro Hospital E.P.E., Faro, Portugal; ²Hospital of Santarem, Cardiology, Santarem,

Portugal; ³University Hospitals of Coimbra, Coimbra, Portugal; ⁴Hospital Centre do

Tâmega e Sousa, Penafiel, Portugal; ⁵Hospital Garcia de Orta, Almada, Portugal;

⁶Hospital Sao Teotónio, Viseu, Portugal; ⁷Hospital Espírito Santo de Evora, Evora,

Portugal; ⁸Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal;

⁹Hospital Senhora da Oliveira, Guimaraes, Portugal

Introduction: Takotsubo cardiomyopathy (TC) is characterized by a transient left ventricular (LV) dysfunction. The speed of recovery of LV function is variable. The impact of the rate of LV function recovery on prognosis of TC is currently unknown.

Aim: To determine whether patients diagnosed with TC who have a faster recovery of LV function have better medium term prognosis.

Methods: A multicenter study involving 10 hospital centers and including all patients diagnosed with TC in the last 10 years. Echocardiography was analyzed at admission, discharge and follow-up of patients. Complete recovery was defined as the normalization of the segmental motility abnormalities present in the initial echocardiogram. The timing of discharge was defined as a cut-off point for the determination of recovery of LV function. We evaluated whether patients with a faster recovery of LV function had better medium term prognosis.

Results: We included 192 patients with TC. Full recovery of LV function was observed in 45% of patients at discharge. A mean follow up of 45 ± 32 months was performed. Complete recovery of LV function during hospitalization was not associated with a lower incidence of death (3.5% vs 2.7%, $p = 0.764$) or stroke / TIA (1.2% vs 4.0%, $p = 0.249$) or lower recurrence of TC (3.5 % vs 4.0%, $p = 0.864$) in the follow-up. In the multivariate analysis, a faster recovery of LV function was not an independent predictor of cardiovascular events in the medium term follow-up.

Conclusion: In this Portuguese multicenter study, patients with TC that present a faster recovery of LV function do not have a better medium term prognosis. However, the low rate of complications in the follow-up may have limited the study results.

P292

The features of clinical course and echocardiographic parameters in patients with senile amyloidosis

AA Poliakova¹; EN Semernin¹; AN Krutikov¹; KL Avagyan¹; VG Davydova¹; SA Pyko¹; DE Korzhevskii²; MM Shavlovsky²; AYA Gudkova²

¹Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation; ²St.Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation

Introduction: To date, senile amyloidosis is difficult to diagnose.

Purpose: To establish the occurrence of senile amyloidosis in the structure of left ventricular hypertrophy (LVH) of various origins in elderly patients, and explore the echocardiographic parameters of hypertrophic phenotype and the clinical course of the disease. **Methods:** In the study were included 196 symptomatic patients (age: ≥ 60 years) with a wall thickness of the left ventricle ≥ 15 mm of various origins (ESC Guideline on diagnosis and management of Hypertrophic Cardiomyopathy, 2014). The standard clinical - laboratory and instrumental methods of diagnosis sarcomeric and nonsarcomeric hypertrophic cardiomyopathy (HCM) were applied.

Results: In accordance with the classification of the World Health Organization, patients with senile amyloidosis (71 patients, 80% women, 20% men) were divided by age into 3 groups: group 1 - elderly age (60-74 years) - 17%, group 2 - senile age (75 - 89 years) - 21%, group 3 - long-living persons (≥ 90 years) - 62%. 83% of patients with senile amyloidosis from all age groups (in accordance with clinical cases and conclusions of outpatients cards of died patients) had a cardiovascular form of amyloidosis, characterized by congestive heart failure (II-IV NYHA). In 17% of patients (all patients in the group of long-living persons) were revealed amyloid deposits (on the results of post-mortem diagnosis), and these patients didn't have a clinical manifestations of the disease in their life. In 7% cases were found a combination of two forms of amyloidosis: AL- and senile amyloidosis. According to echocardiography in patients with senile amyloidosis were indicated moderate left ventricular hypertrophy, less expressed than in patients with sarcomeric HCM in the elderly (IVSd 16.4 ± 3.48 mm, LVPWd 15.71 ± 3.28 mm and IVSd 19.57 ± 4.26 mm, LVPWd 13.02 ± 3.02 mm, respectively, $p < 0.001$). 20% of patients with senile amyloidosis had a wall thickness of the left ventricle less than 15 mm, but the LVMI were above the normal values (LVMI 152.13 ± 77.62 gr/m²).

Conclusions: Senile amyloidosis was detected at the age of 75 years and older in the most cases, mainly in women, and was characterized by cardiovascular forms of the disease. Patients with asymptomatic senile amyloidosis were identified. Patients with senile amyloidosis and AL-amyloidosis didn't have significant differences in echocardiographic parameters.

P293

Profile of cytokines th1, th2 and th17 in patients with chronic chagas disease and systemic arterial hypertension

R Bestetti¹; R Dellalibera-Joviliano¹; R Furlan-Daniel¹; G Lopes¹; L Santos¹; K Lopes²; D Batista¹

¹University of Ribeirao Preto, Ribeirao Preto, Brazil; ²Clinica Sao Rafael, Piumhi, Brazil

Background: Chronic Chagas disease is a major health problem in Latin America, and has become globalized because international immigration. The disease is caused by the protozoan *Trypanosoma cruzi*. Chronic cardiomyopathy is the leading clinical manifestation of the disease. In areas where the disease is endemic, about 30% of patients with chronic Chagas disease have concomitant Systemic Arterial Hypertension (ChD-SAH). In the context of Chagas disease, the study of inflammation elicited by *T. cruzi* is very important for better understanding the pathophysiology of the disease. In addition, the study of parasite immune response capable of causing heart damage could provide insights into new therapeutic strategies. Little

is known about plasma cytokine profile in patients with ChD-SAH.

Purpose: Accordingly, this study was undertaken to determine the profile of cytokines plasma levels in patients with this condition.

Methods: Eleven patients with chronic Chagas disease diagnosed by a positive serology (G1 group), 9 patients with ChD-SAH (Group 2), and 28 healthy controls (Group 3) matched by age and sex were studied. The cytokine concentration of TH1 (IL-12, INF-Gamma), TH2 (IL-13, IL-5, and IL-10), and TH17 (IL-17, IL-23) was determined by ELISA (expressed as medians and equivalent units pg/mL plasma). The Kruskal-Wallis Test was used for statistical analyses.

Results: Median plasma levels of IL-12 in the G1 group was 250, in the G2 group 300, and in G3 group 70 ($p < 0.001$). Median INF-Gamma was 140 in the G1 group, 180 in the G2 group, and 70 in the G3 group ($p < 0.001$). Median plasma levels of IL-13 was 150 in the G1 group, 180 in the G2 group, and 50 in the G3 group ($p < 0.001$), whereas median plasma levels of IL-5 was 140 in the G1 group, 190 in the G2 group, and 50 in the G3 group ($p < 0.001$). Median plasma levels of IL-10 was 220, 250, and 180 in the G1 group, G2 group, and G3 group, respectively ($p < 0.001$). Median plasma levels of IL-17 was 140 in the G1 group, 180 in the G2 group, and 70 in the G3 group ($p < 0.001$), whilst median plasma levels IL-23 was 110 in the G1 group, 230 in the G2 group, and 80 in the G3 group ($p < 0.001$). Interestingly, plasma cytokine activities in Chagas disease patients were increased in the G2 group in comparison with G1 group ($p < 0.05$ for each comparison).

Conclusion: We have shown for the first time that patients with ChD-SAH have more activation of TH1 and TH2 cytokines pattern, modulated by TH17 pattern, than that seen in patients with isolated chronic Chagas disease. Such alterations could lead to more severe amplification of vascular inflammation, activation of other inflammatory mediators, and cell recruitment in patients with this condition.

P294

Race differences in timing of presentation in 1137 peripartum cardiomyopathy patients compared with 2.1 million delivering mothers without peripartum cardiomyopathy

University of Colorado Center for Women's Health Research Seed Grant
DP David Peter Kao¹; ET Gamabahaya²

¹University of Colorado Denver, Denver, United States of America; ²University of Zimbabwe College of Health Sciences, Medicine, Harare, Zimbabwe

Background: Peripartum cardiomyopathy (PPCM) is a rare and life-threatening complication of pregnancy that is more common in patients of African ancestry (AA) than other racial groups. Some risk factors for PPCM have been identified, but race differences in patients presenting at or before delivery (antepartum) vs. those presenting postpartum are unknown.

Purpose: To characterize race differences in characteristics of PPCM patients presenting antepartum vs. postpartum.

Methods: Administrative records for all hospitals in the state of Florida from 2004-2013 were obtained. Patients hospitalized for delivery were identified (ICD-9 code V27.x). Hospital readmissions following delivery were identified using unique patient identifiers. All hospital records reporting PPCM were identified (ICD-9 code 674.5x). Antepartum presentation was defined as presence of PPCM during hospitalisation for delivery. Postpartum presentation was defined as hospitalization with PPCM within 5 months of hospitalisation for a delivery where PPCM was not reported. Patient characteristics were stratified by white, AA, and Hispanic race.

Results: In total, 2,142,363 delivering mothers were identified including 510 antepartum PPCM patients and 627 postpartum PPCM patients. AA patients had the highest rate of PPCM (1/1000 deliveries) followed by white (4/10,000 deliveries) and Hispanics (2/10,000 deliveries). AA patients more frequently presented post-partum (322/513, 63%) compared to 233/436 (53%) white patients and 41/124 (33%) Hispanic patient ($p < 0.001$). Most (83%) postpartum PPCM patients presented within 30 days of delivery, and AA patients made up 78/108 (72%) of those presenting > 30 days of PPCM. Diabetes mellitus, hypertension, tobacco use, chronic obstructive pulmonary disease/asthma, multiple gestations, anaemia, mood disorders, obesity, and Caesarean section were associated with PPCM in all races. Of these, anaemia, obesity, and diabetes mellitus were stronger predictors of postpartum presentation in AA patients, chronic obstructive pulmonary disease and asthma were stronger predictors of postpartum presentation in Hispanic patients, and mood disorders and tobacco use were stronger predictors in white patients.

Conclusions: Important race differences exist in risk factors and timing of presentation in PPCM. These differences may reflect different race-based interactions between acquired and genetic predispositions to PPCM.

P295

Prevalence of left ventricular systolic dysfunction in a portuguese population of left ventricular non-compaction cardiomyopathy - A multicentre study

L Reis¹; J Guedes²; K Domingues³; H Antunes⁴; A Almeida⁵; B Picarra⁶; P Magalhaes⁷; R Faria⁸; R Santos⁹; O Azevedo⁹

¹University Hospitals of Coimbra, Coimbra, Portugal; ²Faro Hospital, Faro, Portugal; ³Hospital de Santarém, Santarém, Portugal; ⁴Hospital Sao Teotónio, Viseu, Portugal; ⁵Hospital Garcia de Orta, Almada, Portugal; ⁶Hospital Espirito Santo de Évora, Évora, Portugal; ⁷Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁸Alto Ave Hospital Center, Guimaraes, Portugal; ⁹Hospital Centre do Tamega e Sousa, Penafiel, Portugal

Introduction: Left ventricular non-compaction cardiomyopathy (LVNC) may be complicated with left ventricular (LV) systolic dysfunction and heart failure. The prevalence of LV systolic dysfunction in patients with LVNC ranges from 58 and 82% of cases in previous studies. However, natural history of LVNC is not clearly established and recent studies show that prognosis of LVNC seems to be better than previously described. Aim: The aim of this work is to characterize a Portuguese population of patients with LVNC and to determine the prevalence of LV systolic dysfunction in patients with LVNC.

Methods: Portuguese multicenter study involving 11 hospital centers and including all patients diagnosed with LVNC. We evaluated the clinical, electrocardiographic, echocardiographic and cardiac MRI data. We determined the prevalence of LV systolic dysfunction, considering it to be present when a LV ejection fraction was below 50%.

Results: We included 86 patients with LVNC, 57% males, with mean age 51 ± 19 years. Symptoms were present in 46% of patients, and dyspnea (38%) and palpitations (28%) were the most common symptoms. Most patients were in sinus rhythm (89%). A history of atrial fibrillation was present in 12% of the patients and non-sustained ventricular tachycardia in 22% of the cases. Family history of LVNC was identified in 8% of cases. Diagnosis of LVNC was established by echocardiogram in 80% of patients: Chin criteria at 31%, Stollberger criteria at 78% and Jenni criteria at 96%. In this Portuguese population of patients with LVNC, the prevalence of patients with LV systolic dysfunction is 50%. The average LV ejection fraction was 48% and 42% patients had EF <50%. Mitral regurgitation was detected in 15% of cases. Delayed gadolinium enhancement on cardiac MRI was found in 20% of patients. Cardiac death occurred in 4.7% of cases (mean follow-up of 48 months).

Conclusions: In this Portuguese population of patients with LVNC, the prevalence of LV systolic dysfunction is 42%, lower than previously reported in the literature, which supports the current idea that prognosis of LVNC may be better than previously described. Larger studies are needed to better understand the natural history of LVNC.

P296

Post-myocarditic dilated cardiomyopathy: characterization and long-term prognosis

M Merlo¹; M Anzini¹; R Bussani²; J Jessica Artico¹; G Barbat¹; D Stolfo¹; M Muca¹; A Di Lenarda¹; B Pinamonti¹; G Sinagra¹

¹University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ²University Hospital Riuniti, Trieste, Italy

Background: Dilated cardiomyopathy (DCM) is the final common pathway of different pathogenetic processes and presents a significant prognostic heterogeneity, possibly related to its etiological variety. The characterization and long-term prognosis of post-myocarditic dilated cardiomyopathy (PM-DCM) remain unknown.

Objective: This study assesses the clinical-instrumental evolution and long-term prognosis of a large cohort of patients with PM-DCM.

Methods: We analyzed 175 DCM patients consecutively enrolled from 1993 to 2008 with endomyocardial biopsy (EMB) data available. PM-DCM was defined in presence of borderline myocarditis at EMB or persistent left ventricular dysfunction 1 year after diagnosis of active myocarditis at EMB. Other patients were defined as affected by idiopathic dilated cardiomyopathy (IDCM). Analysis of follow-up evaluations was performed at 24, 60 and 120 months.

Results: We found 72 PM-DCM out of 175 enrolled patients (41%). Compared to IDCM, PM-DCM patients were more frequently females and less frequently presented a familial history of DCM. No other baseline significant differences were found. During the long-term follow-up (median 154, 1st-3rd interquartile range 78-220 months) PM-DCM patients showed a trend towards slower disease progression. Globally, 18 (25%) PM-DCM patients vs 49 (48%) IDCM patients experienced death/Heart Transplantation (HTx) (p: 0.045). The prognostic advantage for PM-DCM patients became significant beyond 40 months of follow-up. At multivariable time-dependent Cox analysis, PM-DCM was confirmed to have a global independent protective role (HR = 0.53, 95% CI 0.28-0.97, p = 0.04).

Conclusions: PM-DCM is characterized by better long-term prognosis compared to IDCM. An exhaustive etiological characterization appears relevant in the prognostic assessment of DCM.

HTx-free survival in PM-DCM vs IDCM.

P297

Predictors of ventricular tachyarrhythmias in patients with dilated cardiomyopathy

T Tatiyana Vaikhanskaya¹; TV Kurushka¹; TM Kaptsiukh¹; AV Frolov¹

¹Republican Scientific and Practical Center "Cardiology", Minsk, Belarus

Purpose of this study is to investigate the markers of myocardial electric instability: microvolt T-wave alternations (mTWA), heart rate turbulence (HRT) and QT dispersion (QTd) in patients with dilated cardiomyopathy (DCM) with ventricular tachyarrhythmic (VTA) events.

Methods: the study enrolled and followed up $38,1 \pm 12,6$ months 160 pts with DCM (78% male, aged $47,2 \pm 11,7$ years, LVEF $28,7 \pm 10,1\%$; NYHA class $3,0 \pm 0,3$). We analyzed age, gender, NYHA, 6-MWT, peak VO₂, EchoCG, Holter ECG (PVEct, sVT, nsVT, VF), QRS width, device telemonitoring and ECG (Intecard-7) assessment HRT, mTWA, QTd. For multivariate regression model as the primary endpoint had been taken VTA (nsVT/sVT without syncope) and the secondary end points were SCD, successful resuscitation, sVT with syncope, discharges of CRT-D/ICD.

Results: By multivariate regression analysis for primary end point ($F = 7,1$; $R^2 = 0,99$; $p = 0,000$) as independent predictors of VTA are defined: PVEct ($p = 0,00004$), LV systolic dimension ($p = 0,0003$), QRS width ($p = 0,0006$), LV End Diastolic Volume ($p = 0,002$), 6-MWT ($p = 0,002$) and LBBB ($p = 0,01$). For secondary end points by multivariate analysis ($F = 5,7$; $R^2 = 0,77$; $p = 0,0022$) were revealed independent predictors of fatal VTA as positive mTWA test ($p = 0,0033$) and pathological HRTs parameter ($p = 0,043$).

Conclusions: Positive mTWA test and pathological HRTs were identified as independent predictors of life-threatening VTA. The use of these markers for screening stratification of DCM pts allows to select of potential candidates for preventive ICD therapy.

Genotype-phenotype correlations: association between mutation status and left ventricular reverse remodeling in idiopathic dilated cardiomyopathy

M Dal Ferro¹; D Stolfo¹; M Merlo¹; M Gigli¹; A Alessandro Altinier¹; A Pivetta¹; F Brun¹; A Di Lenarda²; L Mestroni³; G Sinagra¹

¹University Hospital Riuniti, Cardiovascular Department, Trieste, Italy;

²Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy; ³University of Colorado Health, Denver, United States of America

Backgrounds: Next-generation sequencing (NGS) increases diagnostic yield of genetic testing in Dilated Cardiomyopathy (DCM), but genotype-phenotype correlations have been poorly investigated, and the association between mutated genotype and therapeutic response remains unknown.

Purpose: To explore the genetic landscape of a highly selected DCM cohort and to assess genotype based clinical characterization, including the possible association with left ventricular reverse remodeling (LVRR). **Methods:** We performed commercially available NGS panels targeting 103-149 cardiomyopathies associated genes in 152 DCM patients from the Heart Muscle Disease Registry of Trieste. According to NGS results, patients were grouped in different "clusters" with functionally homogeneous genetic background. LVRR was defined by a LV ejection fraction (LVEF)

increase ≥ 10 points (or LVEF $\geq 50\%$ for baseline LVEF ≥ 45 and 45 and $\leq 49\%$) associated to a reduction in indexed LV end-diastolic diameter (LVEDDI) $\geq 10\%$ (or a LVEDDI ≤ 33 mm/m²), at a mean follow-up of 24 months.

Results: A disease-related mutation was identified in 127 patients (84%): 28 (18%) TTN, 7 (5%) Lamin A/C, 24 (16%) Structural Cytoskeleton-Z Disk genes; 17 (11%) Desmosomal genes; 7 (5%) MYBPC3; 18 (12%) Motor Sarcomeric genes and 26 (17%) Other genes. Baseline clinical features were similar between different subgroups. A significant relationship was found between gene clusters subgroups and LVRR, with a low observed LVRR rate in Structural Cytoskeleton-Z Disk genes mutation carriers (10 %, $p < 0.05$ Vs all the subgroups).

Conclusions: NGS provides a powerful diagnostic tool for genetic characterization of DCM. A genetic "clusters" classification, based on functional similarities in different genes, might be helpful in the clinical management of genetically determined DCM. In our population, structural Cytoskeleton-Z Disk genes mutations were associated with a low therapeutic response.

Natural history and prognostic factors in dilated cardiomyopathy

PTDC/BIM-MEC/0650/2012

A Sousa¹; P Canedo²; B Moura³; S Amorim⁴; AR Almeida⁵; A Belo⁶; F Rocha Gonçalves¹; J Silva Cardoso¹; JC Machado²; E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Institute of Molecular Pathology and Immunology at the University of Porto, Porto, Portugal; ³Regional Military Hospital n°1, Porto, Portugal; ⁴Sao Joao Hospital, Porto, Portugal; ⁵Garcia de Orta Hospital, Lisbon, Portugal; ⁶Portuguese Society of Cardiology, Lisbon, Portugal

Background: Dilated cardiomyopathy is a heart muscle disease that affects 1:2500 adults and is characterized by ventricular dilation and impairment of systolic function. The main clinical features are heart failure, arrhythmias and sudden cardiac death. However, clinical course varies greatly between different patients and also among members of the same family, in case of familial forms.

Purpose: We aimed to determine the natural history of idiopathic (IDCM) and familial dilated cardiomyopathy (fDCM), and to identify predictors of poor outcome.

Methods: We studied patients with fDCM (defined as the presence of ≥ 1 family member with DCM or a first-degree relative with unexplained sudden death < 35 year) irrespective of age and patients < 50 years with IDCM. Patients underwent extensive clinical evaluation, ECG, 24h-Holter, echocardiogram and molecular analysis (including search of mutations in LMNA/C gene). For follow-up, assessment of vital status, heart transplantation and cardiac-related hospitalizations were registered.

Results: We included 92 patients, 51 (57%) male, with mean age at diagnosis 37 ± 14 years, mean left ventricular ejection fraction $33 \pm 12\%$ and left ventricular end-diastolic diameter 64 ± 9 mm. Forty-eight (52%) patients presented criteria of fDCM and 47 (55%) were in NYHA class I. After a mean follow-up of 20 ± 9 months (range 2-73), 12 (13%) patients experienced adverse events. Five patients were subjected to heart transplantation and 2 have died. Two patients experienced aborted cardiac arrest/appropriated ICD shock and 9 were hospitalized from cardiac causes (4 from heart failure, 3 with ventricular arrhythmia, one because of atrial fibrillation and another patient due to embolic acute coronary syndrome). For identification of prognostic predictors we used logistic regression analysis (the model included all variables associated with adverse event at a significance level of $p < 0.10$). Presence of edemas (OR 46.9; 95%CI 3.5-629.2; $p = 0.004$), previous pacemaker implantation (OR 16.1; 95%CI 2.1-121.1; $p = 0.007$) and previous hospitalization from arrhythmic cause (OR 10.1; 95% CI 1.9-55.1; $p = 0.007$) were independent predictors of adverse events.

Conclusions: In our study, 13% patients experienced a dismal outcome. Edemas, pacemaker (not biventricular) implantation and arrhythmia-related hospitalization were associated with worse outcome. These findings may help to identify patients at higher risk, whom might benefit from a more aggressive clinical vigilance and timely interventions.

P300

Retrospective assessment of immunosuppressive agents in virus-negative inflammatory cardiomyopathy: a long-term survival analysis.

J J Jort Merken¹; M Hazebroek¹; P Van Paassen¹; V Van Empel¹; C Knackstedt¹; HP Brunner - La Rocca¹; P Hoermann²; C Ensinger³; G Poelzl²; SRB Heymans¹

¹Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands; ²Innsbruck Medical University, Clinical division of Cardiology and Angiology, Innsbruck, Austria; ³Innsbruck Medical University, Institute of Pathology, Innsbruck, Austria

Background/Purpose: The ESC defines virus-negative inflammatory cardiomyopathy (infi-CMP) as a cardiomyopathy with ≥ 14 infiltrating inflammatory cells per mm² without viral presence in endomyocardial biopsy (EMB). This study assesses

the -till now yet unknown- impact of immunosuppressive agents in infi-CMP on long-term transplantation free survival.

Methods: Within an international cardiomyopathy registry, a total of 209 DCM patients who fulfilled the ESC criteria for virus-negative infi-CMP were included between 2008 and 2015. Ninety-nine patients did not, and 110 did receive additional immunosuppressive therapy. One on one propensity score matching using age, gender, duration of symptoms, NYHA class, hypothyroidism, and diastolic blood pressure corrects for possible selection bias, resulting in 90 untreated and 90 treated patients. Primary outcome was assessed using heart transplantation-free survival at 10 years.

Results: Baseline characteristics, including optimal standard heart failure (HF) medical treatment, did not differ between untreated and treated patients. During a mean follow-up time of 31 (15 – 47) months, a total of 14 (8%) patients reached the primary endpoint, including 13 (7%) deaths and 1 (0.5%) HTx. Additional immunosuppressive therapy resulted in an improved HTx-free survival as compared to conventional HF therapy alone (Log-rank $p = 0.036$; Figure 1). Echocardiographic LVEF significantly improved in both groups at a mean follow-up of 1 year compared to baseline (LVEF baseline vs. follow-up: 33 ± 14 to 40 ± 14 in the standard HF therapy group, $p < 0.001$; and 31 ± 11 to 44 ± 12 in the group who additionally receive immunosuppressive therapy, $p < 0.001$). Of note, patients with additional immunosuppression had a significantly higher absolute increase in LVEF after 12 months, as compared to those not receiving immunosuppression (5% [-1,5 – 15] vs 10% [1,3 – 22]; $p = 0.028$).

Conclusion: This retrospective study illustrates that immunosuppression on top of HF medication improves long-term outcome in patients with virus-negative infi-CMP. This conclusion triggers further prospective trials.

Figure 1: Htx-free survival

P301

A new predictor of outcome in non-infiltrative dilated cardiomyopathy: the presence of low voltage qrs in both limb and chest leads

E Hatzinikolaou-Kotsakou¹; M Kotsakou¹; M Konstantinidou¹; E Reppas¹; P Latsios¹; G Moschos¹; TH Belevsili¹

¹Saint Lukes Private Hospital , Electrophysiology Department , Thessaloniki, Greece

Introduction: Low voltage on the surface electrocardiogram (ECG) is defined as QRS voltage less than 5 mm in all limb leads and less than 10 mm in all precordial leads. There can be little question that, in many instances, low voltage complexes (LQRSV) are a result of severe myocardial disease. Infiltrative cardiomyopathies may lead to LQRSV involving both the limb and the precordial leads. As far as we are aware, the literature contains no study of the clinical significance of an ECG with LQRSV in all leads on the prognosis in patients with no- infiltrative dilated cardiomyopathy and heart failure.

Aim: The purpose of this study was to examine the association between QRS voltage and survival in patients with no-infiltrative dilated cardiomyopathy and heart failure.

Methods: We performed a retrospective analysis to examine the association between LQRSV in all limb and precordial leads and mortality in a study population included 362 patients with no-infiltrative dilated cardiomyopathy and heart failure. All the patients underwent Coronary Angiography, Magnetic Resonance Imaging and in some cases Myocardial Biopsy for establishing diagnosis. Two groups, on the basis of voltage QRS (< 5 mm in limb leads and < 10 mm in chest leads) were identified. All the patients were on sinus rhythm. The groups were compared with respect to total mortality and sudden death. Subgroups were also stratified by age , sex, left bundle branch block ,ejection fraction (EF) $< 30\%$ and $> \text{or} = 30\%$ to 40% , and the NYHA Heart Failure Class.

Results: The LQRSV was associated with a significant increase in mortality (51.2.3% vs 35.0%, $P = .0001$) and sudden death (28.9% vs 18.4%, $P = .0004$). Left bundle branch block was associated with worse survival ($P = .004$) but not sudden death. In patients with an EF $< 30\%$, LQRSV continued to be associated with a significant increase in mortality (53.6% vs 34.6%, $P = .001$) and sudden death (29.8% vs 19.8%,

$P = .002$). After adjustment for baseline variables, independent predictors of mortality were found to be LQRSV ($P = .0029$, risk ratio 1.48) depressed EF ($P = .0001$, risk ratio 0.965) and age < 49 years ($p = 0.03$, risk ratio 1.53). In those with an EF of 30% to 40%, LQRSV was associated with a significant increase in mortality (41.8% vs 22.9%, $P = .0034$) but not in sudden death (12.9% vs 11.0%, $P = 0.625$). The sex and the NYHA Class were not predictive of mortality.

Conclusion: The low QRS complexes voltage in both limb and chest leads is an independent predictor of both increased total mortality and sudden death in patients with no-infiltrative dilated cardiomyopathy and heart failure.

P302

Linear and cubic measurement of left atrial size are equally predictors of atrial fibrillation development in patients with hypertrophic cardiomyopathy.

A Giamundo¹; G Canciello¹; A Rapacciuolo¹; F Musella¹; G Savarese¹; T Strisciuglio¹; E Stabile¹; R Izzo²; B Trimarco¹; MA Losi¹

¹Federico II University of Naples, Department of Advanced Biomedical Sciences, Naples, Italy; ²Federico II University Hospital, Department of Translational Medicine, Naples, Italy

Introduction: Left atrial (LA) enlargement evaluated by echocardiography is a very strong predictor of cardiovascular (CV) outcomes such as atrial fibrillation (AF), stroke, congestive heart failure, and CV death in multiple clinical settings. Recently, in patients with hypertrophic cardiomyopathy (HCM), the measure of LA diameter has been taken into account for sudden death risk stratification in the European Society of Cardiology guidelines and for cardio-embolic risk assessment. Nevertheless, the measure of LA diameter disappeared in the last chamber quantification, and in the European Association for Cardiovascular Imaging recommendations for HCM multimodality imaging.

Purpose: To clarify the contradictory data between medical literature and current recommendations for LA size assessment, we investigated the role of LA size measured by different methods (linear and cubic ones) in predicting AF development in a group of patients with HCM.

Methods: 248 HCM patients (age 42 ± 16 years, 65% men), without history of AF, were enrolled. LA size was assessed by linear dimension from parasternal 2D images and by volume from 4 chambers view. Data obtained from both methods were considered as continuous variables, both absolute and indexed for body surface area, and categorized to identify LA dilation.

Results: During a follow-up of 8.1 ± 5.8 years, 50 patients (20%) developed a first episode of AF. At univariate Cox regression analysis age, NYHA functional class, significant left ventricular outflow tract obstruction and mitral regurgitation, and each of the LA size measures, were associated with AF development. Cox multivariate analysis was constructed by using significant variables at univariate analysis, and, because of their collinearity, using in turn LA variables. LA size, in each of the method evaluated, was the only predictor of AF development ($p < 0.0001$), whereas the other variables were no more predictors of AF development. Furthermore, ROC curve analysis demonstrated that there were no differences between the linear or cubic assessment of LA size, neither their absolute or indexed measures, in the power of predicting AF development (Figure).

Conclusions: This study confirmed that LA size, irrespective of the way it is measured and categorized as dilated, is a strong predictor of AF development in HCM patients. Furthermore, for the first time, we confronted different methods to assess LA size demonstrating that LA diameter is still a valid echocardiographic measure in the prediction of AF even in small group of patients, encouraging its evaluation in the specific field of HCM.

P303

Impact of gender on heart failure development in nonobstructive hypertrophic cardiomyopathy

S-H Sung-Hee Shin¹; S-D Park¹; S-W Kwon¹; S-I Woo¹; D-H Kim¹; K-S Park¹; J Kwan¹

¹Inha University Hospital, Incheon, Korea Republic of

Background: Little is known about the impact of gender difference on heart failure (HF) development in non-obstructive hypertrophic cardiomyopathy (HCM).

Purpose: We evaluated the association with gender and HF presentation in the patients with non-obstructive HCM and investigated clinical and echocardiographic parameters according to gender.

Methods: We studied 146 consecutive patients with non-obstructive HCM (age= 63 ± 13 years, male:female=98:48). Clinical parameters and conventional echocardiographic measurements including tissue Doppler measurements were evaluated and compared according to gender. Additionally, left ventricular (LV) deformation was assessed with global longitudinal strain utilizing 2D speckle tracking software.

Results: Of the 146 patients, 43 patients (30%) were presented with HF and female patients were more frequently had HF (52% vs. 18% in male patients, $p < 0.001$). Females were older and had increased indexed left atrial (LA) volume and the ratio of early diastolic mitral inflow to early annular velocity (E/Em) than males (71 ± 9 years vs. 60 ± 14 years for age, $p < 0.001$; 53.5 ± 24.1 mL/m² vs. 42.3 ± 17.1 mL/m², $p = 0.005$ for indexed LA volume; 18.0 ± 6.6 vs. 13.1 ± 5.1 , $p < 0.001$ for E/Em). Whereas LV mass and LV ejection fraction were comparable between men and women, global longitudinal strain was significantly more decreased in female patients (141.2 ± 32.6 g/m² vs. 137.1 ± 30.2 g/m², $p = 0.46$ for indexed LV mass; 63.0 ± 5.2 % vs. 64.2 ± 5.4 % for LV ejection fraction, $p = 0.21$; 9.5 ± 1.5 % vs. 12.1 ± 3.1 % for global longitudinal strain). Even after adjusting for clinical factors, female was independently associated with HF ($p < 0.001$).

Conclusion: In patients with non-obstructive HCM, female patients were presented with HF more frequently. LA volume, E/Em and LV mechanics were different between the genders, suggesting these might contribute to greater susceptibility to HF in women with HCM.

P304

Association of NT-proBNP level with disturbance of microcirculation and intracardiac hemodynamic parameters in hypertrophic cardiomyopathy patients with heart failure with preserved ejection fraction

G A Gayane Shkaryants¹; MV Kozhevnikova¹; AA Shchendrygina¹; VYU Kaplunova¹; MI Tishman¹; EV Privalova¹; YUN Belenkov¹; NV Khabarova¹

¹I.M. Sechenov First Moscow Medical State University, Moscow, Russian Federation

Purpose: to assess the association between NT-proBNP level, parameters of intracardiac hemodynamic and disturbance of microcirculation in hypertrophic cardiomyopathy (HCM) patients with heart failure with preserved ejection fraction (HF/pEF).

Methods: 40 patients (21 men, 19 women) with HF/pEF included in the study. 47,5% (n = 19) of patients had a progressive course (PC) of the disease and 52,5% (n = 21) - stable course (SC). All patients were investigated according standard cardiac algorithm. We estimated NT-proBNP level, assessed endothelial function of large vessels (phase shear (PS, ms) and microcirculation (occlusion index (IO) by video-capillaroscopy. Remodeling of large vessels (stiffness index (SI, in/s), arteriols (index of refraction (RI)) and skin capillaries (capillary densities (CD, cap/mm²), maximal capillary densities (CD max, cap/mm²) were evaluated.

Results: Patients with PC of HCM are characterized by maximal left atrium (LA) size and atrio-ventricular ratio (AVR) (AVR = 1.205 ; LA = 4.9 cm). Elevation of NT-proBNP level ($> = 42.56 + 5.21$ (< 0.001)) is associated with unfavorable prognosis of HCM. Enlargement of LA size is associated with increase of NT-proBNP level ($r = 0.3629$, $p = 0.04$) and capillary remodeling (RI 33.14 ± 21 ; $r = 0.849$; $p = 0.0002$). A positive correlation between NT-proBNP and RI ($r = 0.563$; $p = 0.09$) was revealed. Elevation of CD max were associated with increase of NT-proBNP level ($r = 0.613$; $p = 0.0596$) and it might occur due to compensatory reaction.

Conclusion: 1. The association between NT-proBNP level, parameters of microcirculation (RI and CD max) and intracardiac hemodynamic parameters (LA size) was revealed in patients with HCM. 2. It was found that RI is correlated with LA size and NT-proBNP level. 3. It was determined that CD max associated with increase of NT-proBNP level. 4. This interactions are common for patients with progressive course of HCM.

P305

Sudden cardiac death in hypertrophic cardiomyopathy: can perfusion defects improve risk stratification?

A R Godinho¹; M Vasconcelos¹; V Araujo¹; JS Cardoso¹; MJ Maciel¹

¹Sao Joao Hospital, Cardiology, Porto, Portugal

Introduction: Sudden cardiac death (SCD) continues to be the most devastating complication of hypertrophic cardiomyopathy (HCM). However risk stratification in these patients (pts) is still a challenge. Our aim was to investigate the value of

perfusion abnormalities as an additional predictor of SCD, in these populations.

Methods: We studied 28 HCM ambulatory patients, in our hospital. All of them performed, after a transthoracic echocardiogram, cardiac magnetic resonance (CMR) with late gadolinium enhancement (LGE) for fibrosis analysis and Tc-99m tetrofosmin single-photon emission computed tomography (SPECT) for perfusion defects evaluation. SCD risk was calculated by current guidelines. All statistics analyses were performed using SPSS 20.0 version.

Results: The mean age of our population was 56 ± 16 years and 71% were male. The majority of pts were in NYHA class I (48%) or II (48%) and had septal HCM (58%). By 2014 guidelines, we found (89%) without ICD indication, fewer pts with a class IIa recommendation for ICD (8%) and 4% of pts had a class IIb indication. The mean of HCM SCD risk was $2.4 \pm 1.5\%$. LGE was present in 23% pts, SPECT perfusion fixed defects in 25% and reversible defects in 7%. There was no correlation between LGE-CMR and SPECT perfusion fixed ($p=0.727$) or reversible defects ($p=0.453$). HCM SCD risk by current guidelines did not correlate with the presence of LGE-CMR ($p=0.372$) or SPECT perfusion reversible defects ($p=0.224$). However HCM SCD risk correlate with the presence of fixed defects ($p=0.028$).

Conclusion: These results support the existence of perfusion defects in HCM pts involving distinct mechanisms. Fixed abnormalities can be related to areas of microvascular disruption or perfusion mismatch and do not necessarily translate into fibrosis. Our data suggest that imaging perfusion modalities, like SPECT, can improve risk stratification in this population.

Recording of clinical characteristics of hospitalized patients due to heart failure and comparison between age groups with emphasis to the elderly

E Emmanouil Foukarakis¹; E Rogdakis¹; E Lamprogiannakis¹; M Pitarokollis¹; G Garidas¹; P Kafarakis¹; S Xatzakis¹; TH Dermitzaki¹; I Anastasiou¹; A Dermitzakis¹

¹ Venizelion General Hospital, Iraklion Crete, Greece

Purpose: Large proportion of pts with HF are elderly, who have a large number of comorbidities. The purpose of study was recording and comparison of characteristics among hospitalized elderly and nonelderly HF pts.

Methods: HF hospitalized pts in cardiac dept from Jan 2014 until Dec 2015 recorded. 712 patients included (76.15 ± 8.86 43-95 years). Recorded data: demographic, cardiological and general history, signs and symptoms, ECG and echo findings. Pts grouped to subgroup A1 of 485 pts above 70 - 68.11% - and A2 227 pts below 69 years and subgroup B1 of 297 pts above 80 - 41.7% - and B2 of 415 pts below 79 years. Results in table

Conclusions: elderly and elderly over 80s with HF less often are men, more rarely have PCI history and ventricular arrhythmias, adhere less dietary-exercise and have more often preserved EF, anemia, CKD, dementia, AF, rheumatological disorders, pleural effusions and NYHA III - IV than younger pts.

Elderly with HF less often suffer depression and comply better with therapy than younger pts. Moreover elderly over 80s more often have infection as decompensation, have more often history of stroke and endocrine disorders.

Azilsartan medoxomil improves central and brachial 24-h ambulatory blood pressure control in diabetic hypertensive patients

E Ekaterina Starostina¹; Y Kotovskaya¹; Z Kobalava¹

¹ Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Aim: Ambulatory monitoring of central blood pressure (BP) and arterial stiffness is a new technique for evaluation of antihypertensive drugs efficacy. The aim of the study was to assess changes in ambulatory brachial and central BP and Alx after AM 40 mg adjunction to treatment regimen in hypertensive type 2 diabetic patients. **Methods:** AM 40 mg was given as substitution drug to ACEI to 20 hypertensive patients (8 male, age 58 ± 10 years) with clinic BP $>140/90$ mmHg, 24-h BP $>130/80$ mmHg and/or daytime BP $>135/85$ mmHg previously treated with an ACEI and a second drug from another class. ABPM was done with BPLab VASOTENS ("OOO Petr Telegin", Nizhny Novgorod, Russia). Brachial and aortic BP changes as well as changes in 24-h, day- and nighttime Alx were evaluated. $p < 0,05$ was considered significant.

Results: Significant ($p < 0,05$ vs baseline) decrease in 24-h, day- and nighttime BP after 4 weeks of Azilsartani medoxomil adjunction was observed: for brachial SBP, respectively, from 150 ± 10 to 134 ± 8 , from 150 ± 10 to 134 ± 10 , from 148 ± 15 to 132 ± 12 mmHg, for brachial pulse pressure (PP) from 54 ± 10 to 48 ± 9 , from 54 ± 8 to 46 ± 8 , from 56 ± 10 to 48 ± 7 mmHg. For aortic SBP corresponding changes were from 139 ± 10 to 126 ± 9 , from 140 ± 10 to 126 ± 8 , from 138 ± 12 to 128 ± 10 mmHg, for aortic PP, respectively, 46 ± 6 to 38 ± 5 , from 44 ± 6 to 36 ± 8 , from 46 ± 7 to 38 ± 6 mmHg. Alx@HR75 bpm decreased at daytime from $28,3 \pm 12,6$ to $21,7 \pm 10,1\%$, at night-time from $32,2 \pm 10$ to $26 \pm 9\%$. Increase in PP amplification was observed also and was more evident in nighttime: baseline difference between brachial and aortic PP was $10,0 \pm 3,2$ for daytime, $10,0 \pm 3,2$ mmHg for nighttime, after azilsartan medoxomil treatment $10,7 \pm 2,6$ and $10,2 \pm 2,8$ mmHg, respectively ($p < 0,05$).

Conclusion: zilsartan medoxomil decreases significantly either brachial or aortic SBP and PP, as well decreases aortic PP augmentation. In hypertensive diabetic patient PP amplification was similar at day- and nighttime before and after treatment meaning proportional decrease of brachial and central SBP and PP.

Clinical implications of coronary artery disease after transcatheter aortic valve implantation in patients with severe aortic stenosis.

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; AJ Dominguez-Franco³; MF Jimenez-Navarro³; JH Alonso-Briales³; JM Garcia-Pinilla³; JJ Gomez-Doblas³; JM Hernandez-Garcia³; E De Teresa-Galvan³

¹ Department of Cardiology, Malaga, Spain; ² Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³ University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background: coronary artery disease (CAD) influence negatively prognosis of patients undergoing surgical aortic valve replacement and revascularization is generally recommended at the time of surgery. Implications of CAD in the setting of transcatheter aortic valve implantation (TAVI) are not known. The aim of this study was to determine the prevalence and impact having coronary artery disease in patients undergoing percutaneous valve implantation.

Methods: Between April 2008 and December, 2015 500 patients with severe symptomatic aortic stenosis were treated with high surgical risk, percutaneous aortic CoreValve prosthesis. All patients underwent coronary angiography prior.

Results: A total of 215 p (43%) had coronary disease. In 157 patients (31.4%) were performed PCI, 36 patients (7.2%) had CABG and 9 both techniques. Revascularization was complete in 65.3%. Patients with CAD were characterized by increased ventricular dysfunction than patients without CAD (24.7% vs. 11.2% , $p=0.001$) and predominantly male (53% vs. 31.9% , $p < 0.001$). The occurrence of periprocedural myocardial infarction was 2.3% . After a mean follow-up of 34 ± 23 months, the total mortality was similar in both groups (44.3% vs. 42.6% , $p=0.739$) and there were lower mortality for patients with complete revascularization versus partial, 19.4% vs. 27.3% , $p=0.210$. Mean left ventricular ejection fraction increased from 57.7 ± 15 mmHg to 61.5 ± 13 mmHg after TAVI and 61.2 ± 10 mmHg at 1-year (p for post-TAVI trend 0.023).

Conclusions: The prevalence of coronary artery disease in patients undergoing TAVI is high, but it was not associated with any increase in overall death, due to the majority of patients had complete revascularization. However, TAVI did have a positive effect on left ventricular function over time.

P309

Cerebrovascular and other concomitant diseases in female and male patients with heart failure-results from CRO-HF Registry

D Duska Glavas¹; D Milicic²; B Jurcevic Zidar¹; K Novak¹; S Polic¹

¹ Split University Hospital, Split, Croatia; ² University of Zagreb-School of Medicine, Zagreb, Croatia

Introduction: Co-morbidities in heart failure (HF) could vary in different populations. The aim of this trail was to analyse cerebrovascular and other concomitant disease

that contribute to HF development in female and male HF patients from CRO-HF Registry.

Results: A total of 2203 in-hospital HF patients from CRO-HF Registry were analyzed: 1028 (46.7%) females (f) and 1175 (53.3%) males (m); median age was 76 y. One third had acute HF. Preserved left ventricular systolic function (LVEF \geq 50%) was recorded in 37.8% patients. Males had frequently reduced LVEF (m-70.7%, f-50.7%) and females-preserved LVEF (f-49.3%, m-29.3%, $P < 0.001$).

History of hypertension was recorded in 67.5% patients (58.7% f, 52.7% m), coronary disease in 18.5%, myocardial infarction in 22.7%, diabetes mellitus (DM) in 34.3%, renal failure in 19.2%, COPD in 17.3%, dilated cardiomyopathy in 32.8% and cerebrovascular disease in 16.5% patients. Atrial fibrillation or undulation was noted in 53.7% patients. Overweight was 46.3% patients. History of transient ischemic attack (TIA) had 8.9% and stroke 7.6% patients. TIA had 54.4% males and 52.9% females; stroke had 45.6% males and 47.1% females ($P = 0.807$).

Active smokers were 11.1% patients and former-15.6%. Males were frequently active smokers (m-14.8%, f-6.4%, $P < 0.001$). No differences in smoking habit was detected in HF patients with diabetes, renal failure and stroke (9.4% were active smokers, 11.7%-former and 15.6% non-smokers, $P = 0.141$). COPD had 30.6% active smokers and 13.9% non-smokers ($P < 0.001$). COPD was frequently disease in males (m-19.7%, f-14.7%, $P = 0.009$) as well as renal dysfunction (m-23%, f-14.8%, $P < 0.001$). Diabetes had 36.1% males and 32.6% females. DM I had 8.5% males and 11.9% females, $P = 0.144$. DM II had 91.5% males and 88.1% females. The leading "triggers" of HF were: hypertension 55.5%, arrhythmia 51.3%, valvular disease 32.8%, acute coronary syndrome-ACS 19.7%, infections 19.6% and non-compliance 5.1%. ACS was important "trigger" in males (m-22.1%, f-17%, $P = 0.010$) and hypertension in females (f-58.7%, m-52.7%, $P = 0.009$). No significant gender differences was detected according to arrhythmia, valvular disease and infection.

Lower haemoglobin value was recorded in 51.9% patients, higher creatinine in 46.8%, ALT in 29.8%, cholesterol in 32.7%, triglycerides in 31.9%, uric acid in 79.3% and hyperglycaemia in 99.8% patients. Females had higher values of ALT (f-33%, m-27%, $P = 0.012$), cholesterol (f-36.8%, m-29.1%, $P = 0.009$), triglycerides (f-36.1%, m-28.3%, $P = 0.014$), and uric acid (f-82.9%, m-76.4%, $P = 0.007$). Males had lower haemoglobin levels (m-58%, f-44.8%, $P < 0.001$). In-hospital mortality rate was 13.8%.

Conclusion: Hypertension was important "trigger" of HF in females and ACS in males. There were no significant differences in TIA or stroke condition. Nevertheless, the concomitant disease in female and male HF patients could be different and we should hard work on prevention.

P310

Diabetes in recipients after heart transplantation

M Maria Simonenko¹; Y Sazonova¹; P Fedotov¹; V Rubinchik¹; A Berezina¹; N Gussava¹; M Sitnikova¹; G Nikolaev¹; M Gordeev¹; M Karpenko¹

¹Federal North-West Medical Research Centre, Cardiopulmonary test, Saint-Petersburg, Russian Federation

Purpose: To estimate the impact and the frequency of development diabetes after heart transplantation (HT).

Methods: From 2010 to November 2015 we performed 62 HT (mean age 44.2 \pm 14.6 yrs; BMI - 24.3 \pm 4.7 kg/m²), 16% (n = 10) of them had family history of diabetes. Before HT 11% (n = 7) of recipients had diabetes mellitus (DM) (HbA1c - 6.5 \pm 0.52%), 29% of them were only on a diet, 71% - on oral medications (biguanides). After HT all patients were treated by triple-drug therapy - steroids, calcineurin inhibitors (tacrolimus) and mycophenolate mofetil. The induction therapy were basiliximab (69%), thymoglobulin (31%). Since early postoperative period we did follow-up of the glucose level. Every 6 months the level of HbA1c in patients with diabetes was controlled.

Results: After HT 86% (n = 6) patients from DM group required insulin, during first yr HbA1c increased to 7.1 \pm 1.4%. In 3 months after HT post-transplanted diabetes (PTD) was diagnosed in 37% (n = 23) recipients, 91% of them (n = 21) were treated by insulin, others - on oral medications. The level of HbA1c in PTD group was 6.2 \pm 0.9%. The level of glucose got normal in 1.5-2 yrs after HT, that is why insulin therapy was cancelled (78%, n = 18), others recovered in 3-4 yrs after HT.

Conclusion: After HT glucose level needs to be under control in all recipients. PTD is full reversible without secondary end-organ disease.

P311

Hyponatremia in heart failure: clinical correlations and prognosis

CC Diaconu¹; D Popescu²; LA Balaceanu³

¹University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Floreasca, Bucharest, Romania; ²University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; ³University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Sf. Ioan, Bucharest, Romania

Introduction: The association between heart failure and hyponatremia has a major impact on clinical evolution and prognosis of hospitalized patients. The purpose of

the study was to analyze the frequency of hyponatremia and outcomes in patients with chronic heart failure admitted in the Internal Medicine Clinic of a University Emergency Hospital, between 1st of January 2014 and 31st of August 2015 (1 year and 8 months).

Methods: A total of 402 hospitalized patients with chronic heart failure were included. The level of serum sodium was recorded at the day of admission, several times during hospitalization and at discharge. Patients were classified with normonatremia (sodium level > 135 mEq/L on admission), corrected hyponatremia (≤ 135 mEq/L on admission and increased to > 135 mEq/L during hospitalization) and with persistent hyponatremia (≤ 135 mEq/L on admission and throughout hospitalization). We retrospectively analyzed data from the hospital database record.

Results: Hyponatremia was encountered in 60 patients with chronic heart failure (14.92%). Persistent hyponatremia was present in 37 patients; in 23 patients the serum sodium was normalized at discharge. Hemoglobin level on admission was lower than normal in 10 patients (27%) with persistent hyponatremia, in comparison with patients with corrected hyponatremia, where anemia was less frequent (21%). The mean glomerular filtration rate was lower in patients with persistent hyponatremia (68.9 \pm 32 ml/min/1.73m²) compared to patients with normal sodium at discharge (79.8 \pm 29 ml/min/1.73m²). Patients with persistent hyponatremia had higher in-hospital mortality rates compared with normonatremic ones (18.91% vs 1.46%). **Conclusions** Hyponatremia is a frequent comorbidity in patients with chronic heart failure. Persistent hyponatremia is correlated with heart failure severity and is associated with higher mortality rates in hospitalized patients. Persistent hyponatremia is also associated with lower glomerular filtration rates and hemoglobin level in patients with chronic heart failure.

Characteristics of studied patients

Clinical characteristics and investigations results	Persistent hyponatremia n = 37	>Corrected hyponatremia n = 23	Normonatremia n = 342
Age, mean [years]	72 \pm 13	73 \pm 8	77 \pm 9
Serum sodium on admission, mean [mEq/L]	132.4 \pm 5.0	133.2 \pm 3.4	137.9 \pm 2.2
Serum sodium at discharge, mean [mEq/L]	132.3 \pm 3.4	138.9 \pm 2.1	138.6 \pm 1.8
Systolic blood pressure, mean [mmHg]	158 \pm 38	170 \pm 41	151 \pm 35
Anemia at admission [%]	n = 10 (27%)	n = 5 (21%)	n = 62 (18%)
Glomerular filtration rate, mean [ml/min/1.73m ²]	68.9 \pm 32	79.8 \pm 29	84.3 \pm 24
Rate of death during hospitalization	18.91%	4.34%	1.46%

P312

Prevalence and prognosis of different patterns of cardiohepatic syndrome in acute decompensated heart failure

A Anzhela Soloveva¹; S Villevalde¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Over the last several years different mechanisms of cardiohepatic syndrome (CHS) in acute decompensated heart failure (ADHF) have been discussed. Hepatocellular liver function tests pattern predominated in left sided forward AHF, cholestatic pattern occurred mainly in bilateral and right sided AHF. The purpose of the study was to assess the prevalence and prognostic value of different patterns of CHS in patients with ADHF.

Methods: In 322 patients with ADHF (190 male, 69.5 \pm 10.7 years (M \pm SD), arterial hypertension 87%, myocardial infarction 56.5%, atrial fibrillation 65.5%, diabetes mellitus 41.6%, known chronic kidney disease 39.1%, chronic anaemia 29.2%, ejection fraction (EF) 37.6 \pm 12.6%, EF $< 35\%$ 39.1%) alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase (AP) and gamma-glutamyl transpeptidase (GGT) were measured on admission. LFTs were considered abnormal when levels exceeded local upper normal limit. Only ALT and/or AST increase was considered as hepatocellular CHS, only GGT and/or AP increase - as cholestatic CHS. The simultaneous increase of markers of cytotoxicity and cholestasis was considered as mixed CHS. Mann-Whitney test and multivariate logistic regression analysis were performed, $p < 0.05$ was considered statistically significant.

Results: Abnormal LFTs occurred in 166 (51.6%) of patients. Increase of ALT and/or AST were detected in 68 (21.1%) patients (alone ALT/ alone AST/ both TA - in 35.3, 26.5, 38.2% respectively), increase of AP and/or GGT in 140 (43.4%) patients (alone AP/ alone GGT/ both of them - in 27.15, 35.7, 37.15% respectively). Hepatocellular, cholestatic and mixed pattern of CHS was detected in 8.1, 30.4 and 13.1% of patients with ADHF. In patients with CHS the prevalence of hepatocellular, cholestatic and mixed pattern was 15.7, 59, 25.3% respectively. Patients with mixed

CHS comparing with hepatocellular or cholestatic patterns had lower BMI (28.4 ± 5.3 vs 30.2 ± 7.6 or 31.4 ± 5.6 kg/m², $p < 0.05$), total protein (64 ± 4.8 vs 64.7 ± 6.7 or 68.9 ± 7.3 g/l, $p < 0.01$), eGFR (47 ± 17 vs 57 ± 17 or 56 ± 20 ml/min/1.73 m², $p < 0.01$), higher heart rate (118 ± 35 vs 91 ± 17 or 101 ± 30 per min, $p < 0.01$), Hb (137 ± 20 vs 120 ± 22 or 129 ± 24 g/l, $p < 0.05$), serum creatinine (146 ± 71 vs 117 ± 39 or 117 ± 34 µmol/l, $p < 0.001$). Only mixed CHS was associated with negative prognosis. In patients with versus without mixed CHS the incidence of all-cause death in 6 months was 24.2 vs 12.1% , $p < 0.05$.

Conclusions: Abnormal LFTs occurred in 51.6% of patients with ADHF. In patients with CHS the prevalence of hepatocellular, cholestatic and mixed pattern was 15.7, 59, 25.3%. Patients with mixed compared with hepatocellular or cholestatic pattern of CHS had a worse prognosis.

P313

Impact of malnutrition on long-term mortality in outpatients with chronic heart failure.

JL Bonilla Palomas¹; AL Gamez Lopez¹; M Moreno Conde¹; MC Lopez Ibanez¹; E Ramiro Ortega¹; P Castellano Garcia¹; Y Pimentel Quezada¹; AL Villar Ruez¹
¹Hospital San Juan de la Cruz, Úbeda, Spain

Introduction: Malnutrition determined by the Mini Nutritional Assessment (MNA) test is an independent predictor of long-term mortality in acute HF patients. The sum of the MNA score distinguishes between patients with: adequate nutritional status, MNA ≥ 24 ; undernutrition, MNA < 17 ; at risk for malnutrition, MNA between 17 and 23.5.

Purpose: The aims of this study were to evaluate the prevalence of undernutrition and risk of malnutrition determined by MNA test and their possible influence on long-term mortality in outpatients with chronic HF.

Methods: 258 patients with chronic HF from November 2011 to November 2015 were prospectively analysed. A global evaluation by the MNA test was performed. In addition, usual demographic, clinical, functional and treatment variables were collected. The association between nutritional status and long-term mortality was assessed with the use of Cox multivariate analysis.

Results: The mean age was 74.7 ± 10 years, 45.7% were female and the most frequent aetiology was ischemic heart disease (36.8%). At the median follow-up time (23 months, interquartile range 12-30 months), the overall mortality was 25.8%. 12% of the patients were classified as malnourished and 40.7% were classified as at risk of malnutrition. The remaining 47.3% had an adequate nutritional status. The three groups were homogenous in aetiology of heart failure (ischemic aetiology: 38.7%, 35.2% and 37.7%, respectively, $p = 0.38$). However, malnourished patients presented a poor functional class (NYHA III-IV 71%, 51.4% and 22.1%, respectively, $p < 0.001$), were older than those at risk of malnutrition or wellnourished (78.4 ± 7.9 , 75.8 ± 9.2 and 72.8 ± 10.8 years, respectively, $p = 0.008$) and presented lower hemoglobin levels (12.1 ± 1.7 , 13.2 ± 2 and 14 ± 1.6 g/dL, respectively, $p < 0.001$) and higher levels of serum creatinine (1.6 ± 1 , 1.2 ± 0.5 and 1.1 ± 0.4 mg/dL, respectively, $p < 0.001$) and NTproBNP (6313 ± 6237 , 3693 ± 4044 , 2255 ± 2124 pg/mL, respectively, $p < 0.001$). At 23 months of follow-up, all-cause mortality in patients with malnutrition was 67.3%, among patients at risk of malnutrition was 28.2%, while in patients with adequate nutritional status was 13.7% (Log-rank, $p < 0.001$). When Cox multivariate analysis was performed, the state of malnutrition determined by the MNA test was an independent predictor of mortality (with respect to adequate nutritional status: Hazard ratio 3.31; 95% confidence interval, 1.5-7.3, $p = 0.003$).

Conclusion: We have found that malnutrition defined by MNA test is an independent predictor of long-term mortality in outpatients with chronic HF.

P314

Erectile dysfunction in patients with heart failure, a matter of ejection fraction?

P Pablo Meras Colunga¹; O Gonzalez¹; V Rial¹; FJ Irazusta¹; R Dalmau¹; A Castro¹; AM Iniesta¹; C Alvarez¹; R Mori¹; JL Lopez-Sendon¹
¹University Hospital La Paz, Cardiology, Madrid, Spain

Background and purpose: Erectile dysfunction (ED) is a common problem among patients with coronary artery disease (CAD) and heart failure and it is often under-diagnosed and thus under treated. Our main objective was to determine if ventricular dysfunction was associated per se with this condition.

Methods: We analysed 250 patients, all of them male, who were referred to our cardiac rehabilitation centre and filled in a SHIM (sexual health inventory for men) questionnaire, in which a punctuation of 21 points or less implies ED. An echocardiogram and a treadmill exercise test were performed in order to determine their left ventricular ejection fraction (LVEF) and functional capacity (FC). Chi-square and t-student tests were used to analyze categorical and numerical variables, respectively.

Results: Mean age was 55.4 years, and patients had a high burden of cardiovascular risk factors (see table 1). 45.6% had a depressed LVEF (EF $< 52\%$ according

to new guidelines). The prevalence of ED was 63.6%: 64.9% in the low EF group vs. 62.5% in the preserved EF group ($p = 0.79$). Mean EF among patients with ED was 50.4% vs. 51.9% in the non-ED group ($p = 0.31$). Thus we found no association between LVEF and the presence of ED, obtaining the same results even when analysing the subgroup of patients with LVEF $< 30\%$. Interestingly, there was an association between ED and a poor FC: a mean of 7.9 METs in comparison to 9.2 METs in the non-ED group ($p < 0.001$). Advanced age and history of hypertension or diabetes were found to be predictors of ED. There was a good correlation between ED and the severity of CAD, with a prevalence of 46%, 60%, 64% and 72% if there was no CAD - single vessel - 2 - 3 or more vessels affected, respectively, although statistical significance was not achieved. Among patients with ED, only 30.8% received pharmacological treatment, 24.5% with sildenafil and 6.3% with vardenafil or tadalafil.

Conclusions: Prevalence of ED among patients with heart disease is high. Depressed LVEF does not correlate with the presence of ED.

Table 1: Patient characteristics

Patients characteristics (%)	Patients with ED	Patients without ED	p	Patients characteristics (%)	Patients with ED	Patients without ED	p
Age (years)	57	52.6		Nitrates	5.4	1.2	0.16
			< 0.001	Beta block-ers	92.6	97.7	0.14
Hypertension	51.6	33		Diuretics	9.5	3.5	0.12
			< 0.01	ACEI / ARA-II	75	69.8	0.45
Diabetes mellitus	28	12.2		LVEF (mean)	50.4	51.9	0.31
			< 0.01	LVEF $< 30\%$	4.4	3.3	0.75
Dyslipidemia	60.5	64.8	0.59	Exercise capacity (METs)	7.9	9.2	< 0.001
Obesity	27.8	23.3	0.46				
Smoking	57	57.8	1				
Sedentary lifestyle	59.5	53.8	0.43				

P315

Validity of an algorithm in implantable devices for the diagnosis of sleep-disordered breathing in heart failure

Funded by a research grant from Boston Scientific plc.

S Simon Pearce¹; MR Cowie¹; R Sharma¹; M Polkey²; A Vazir¹

¹Royal Brompton Hospital, Cardiology, London, United Kingdom; ²Royal Brompton Hospital, Respiratory Medicine, London, United Kingdom

Purpose: Sleep-disordered breathing (SDB) affects over half of patients with heart failure (HF). Both obstructive sleep apnoea (OSA) and central sleep apnoea (CSA) are associated with a poor prognosis and are under-diagnosed in the HF population. Current evidence demonstrates benefits for positive airway pressure therapy in those with OSA and HF, whilst optimal management of CSA is unclear. A novel pacemaker algorithm (ApneaScan, Boston Scientific, Marlborough, Ma.) has been developed to diagnose and quantify SDB. There are no published data on the accuracy of this algorithm compared with sleep polygraphy.

Methods: Patients with systolic heart failure and an ejection fraction $< 40\%$, not on nocturnal non-invasive ventilation and with compatible pacing or ICD devices underwent home sleep polygraphy (Embletta, Embla, Canada) at least 4 weeks following device implantation or box change, with concurrent download of ApneaScan data from the pacemaker. The data for the study night were compared with the download using correlation coefficients, Bland Altman plots and a receiver operating characteristic curve (ROC).

Results: 60 patients (mean \pm SD: age 69.1 ± 11.9 years, male 71%, NYHA 2.4 ± 0.5 , BNP 496 ± 466 ng/l, EF $29.3 \pm 9.4\%$) underwent home sleep polygraphy and pacemaker download. 10 patients (17%) had no recorded data from the algorithm. Mean apnoea-hypopnoea index by polygraphy (PG-AHI) was 16.3 ± 15.0 /hour and by ApneaScan (AP-AHI) 34.8 ± 13.8 /hour. The intraclass correlation coefficient (r) for all patients was 0.78 (0.61-0.88, $p < 0.01$). ApneaScan was more accurate in those with OSA ($r = 0.86$, 0.53-0.95, $p < 0.01$) than CSA ($r = 0.74$, 0.48-0.83, $p < 0.01$). It was accurate in those with moderate to severe SDB (AHI > 15 /h, $r = 0.79$, 0.42-0.92, $p < 0.01$), but inaccurate in those with mild or no SDB (AHI ≤ 15 /h) ($r = 0.22$, -0.60-0.62, $p = 0.25$). Correlation was closer in those with predominantly apnoeic events ($r = 0.83$, 0.37-0.955, $p < 0.01$) compared with hypopnoeic events ($r = 0.62$, 0.27-0.81, $p < 0.01$). On the ROC curve, the optimal ApneaScan cut-off for the

diagnosis of moderate to severe SDB was 30.5/hour, yielding a sensitivity of 89%, specificity 68%, positive predictive value 62% and negative predictive value 91%. The area under the ROC curve was 0.84.

Conclusion: ApneaScan over-estimates the severity of SDB compared with sleep polygraphy. At the cut-off of 30.5 events per hour, ApneaScan is a sensitive screening test for moderate to severe SDB with a high negative predictive value. The algorithm may be a useful means of screening for SDB in those with HF and an implanted device – particularly for those with apnoeic episodes; a value above 30.5/hour should be confirmed with a sleep study.

P316

Sleep-disordered breathing is associated with impaired cardiac sympathetic innervation and incrementally predicts prognosis in heart failure patients

S Paolillo¹; O Scala²; R Formisano³; T Pellegrino⁴; G Rengo³; P Gargiulo¹; D Leosco³; B Trimarco⁵; A Cuocolo⁴; P Perrone-Filardi⁵

¹SDN Foundation IRCCS, Naples, Italy; ²IRCCS MultiMedica, Cardiovascular Department, Sesto San Giovanni, Italy; ³Federico II University of Naples, Department of Translational Medical Sciences, Naples, Italy; ⁴Federico II University of Naples, Department of Advanced Biomedical Sciences, Section of Imaging, Naples, Italy; ⁵Department of Advanced Biomedical Sciences, Section of Cardiology, Federico II University of Naples, Naples, Italy

Background: Sleep-disordered breathing (SDB) is common in patients affected by heart failure (HF) and significantly impacts on disease progression and prognosis. Unfavorable effects of SDB in HF are mainly mediated by impaired sympathetic activity. However, few data are available on SDB and cardiac adrenergic impairment evaluated at myocardial level.

Purpose: Aim of the present study was to assess the relationship between SDB, cardiac sympathetic innervation assessed by 123I-MIBG imaging and prognosis in patients affected by HF with reduced left ventricular ejection fraction (LVEF).

Methods: Ninety-four patients (66.1±9.8 years) with moderate to severe HF (median LVEF 32% (IQR 7)) underwent nocturnal cardiorespiratory monitoring to assess presence and severity of SDB by Apnea/Hypopnea Index (AHI), and 123I-MIBG imaging to calculate heart-to-mediastinum (H/M) ratios and washout rate. Patients were prospectively followed for 29±18 months for the combined endpoint of cardiovascular death and HF hospitalization.

Results: Of 94 patients, 72 (77%) showed SDB and, compared to non-SDB, significantly reduced early H/M (1.67±0.22 vs. 1.77±0.13; p=0.019) and late H/M ratio (1.50±0.22 vs. 1.61±0.23; p=0.038). Patients with AHI above the median showed higher event rates and worse survival compared to patients with AHI below the median (35% vs. 9%; p=0.003). Similarly, event rates of the study endpoint significantly differed in patients with normal (≥1.60) or abnormal late H/M (<1.60) (11% vs. 29%; p=0.039). Adding SDB variables to the already known prognostic role of 123I-MIBG imaging, we observed an incremental prognostic discrimination with the worst survival in patients with both SDB and H/M impairment. Comparison of global χ^2 scores of four different hazard models showed an incremental prognostic value of AHI over the combination of clinical variables, LVEF and MIBG.

Conclusions: Patients with systolic HF and SDB show more impaired cardiac adrenergic innervation assessed by 123I-MIBG imaging, and more adverse prognosis compared to HF patients without SDB.

P317

Unpublished association between iron deficiency and left heart filling pressure in patients diagnosed of chronic heart failure and reduced ejection fraction

J A Jose Antonio Ortiz De Murua¹; M Ruiz Olgado¹; I Blanco Martinez¹; J Chimeno Garcia¹; JC Moreno De Vega¹; J Paniagua Olmedillas¹; J De Santiago Viqueiras¹; JL Santos Iglesias¹

¹C.A.Z.A. VIRGEN DE LA CONCHA H., CARDIOLOGY, ZAMORA, Spain

Introduction: There is an increasing interest among cardiologists in iron deficiency of patients with chronic heart failure, because it is known that its therapy with intravenous carboxymaltose improves these patients' well-being. However, it is unknown its correlation with echocardiographic variables.

Purpose: We want to show the prevalence of iron deficiency in chronic heart failure and depressed ejection fraction (EF) and its correlation with echocardiographic variables. We define absolute ferropernia as ferritin <100 ug/dl, relative ferropernia as ferritin <300 ug/dl + transferrin saturation <20%, anemia as hemoglobin <13 gr/(l men) and <12 gr/(l women)

Methods: This is a prospective study, including 50 consecutive patients attended at our heart failure clinic and diagnosed of chronic heart failure with EF depressed (EF<0.4). Aetiologies: 22 dilated cardiomyopathy, 19 ischemic cardiomyopathy and 18 other aetiologies. General features: 39 men, average age 72 years (CI 95% 70-75,2 years) and 4,74 years elapsed from the diagnosis (CI 95% 3,43-6,04 years). These patients were attended from October 2014 until June 2015 and had a compensated heart failure (without any hospital admission in the last 3 months). Our patients had many cardiovascular risk factors (40% arterial hypertension, 54% dyslipemia, 28% diabetes mellitus and 14% were smokers). 72% were in NYHA II functional class and 64% had chronic kidney disease (Glomerular filtration-MDRD- <60 cc/min/m2). 66% received optimum therapy (betablockers, diuretics, ACE inhibitors/ ARB, aldosterone antagonists and digoxin -this one only with atrial fibrillation. Only 20% diagnosed of ferropernia received iron therapy (oral or intravenous).

Statistical analysis: correlation tests (Pearson's test, contingency and ANOVA tables) and ROC curves.

Results: The prevalence of iron deficiency in our patients was 38% (10 patients had absolute ferropernia and 9 relative iron deficiency), 8% had ferropernic anaemia and 14% other aetiologies anaemia. Statistical analysis shows a significant correlation between iron deficiency and E/e' (p=0.003) and the ROC curve that E/e'>13 had a significant correlation with ferropernia (Sensitivity 74%, Specificity 64%, Positive Predictive Value 76% and Negative Predictive Value 60%). Patients with E/e'>15 had a systolic pulmonary arterial pressure =>33 mm Hg (Sensitivity 65,5%, Specificity 71,4%, Positive Predictive Value 76% and Negative Predictive Value 60%).

Conclusions: 1- The prevalence of iron deficiency in our patients diagnosed of chronic heart failure with EF depressed is very high and scarcely treated. 2-Our patients has many cardiovascular factors and cardiorenal syndrome. 3-This study shows an unpublished and relevant correlation between ferropernia and left ventricular filling pressure probably related to a higher stimulation of renin-angiotensin-aldosterone and sympathetic nervous system

P318

Chronic heart failure in diabetic patients with low extremity artery disease with/without anemia

E Shalaeva¹; B Janabaev¹; B Babadjanov¹; Q Matmurotov¹; N Dadabaeva²; A Shalaeva²

¹Tashkent Medical Academy, Republican Centre of purulent surgery and complications of diabetes, Tashkent, Uzbekistan; ²Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Prevalence of anemia in patients with chronic heart failure (CHF) and low ventricle ejection fraction (LVEF) range widely from 4% to 61% (median 18%). The aim of this study was to evaluate influence of anemia in diabetic patients with low extremity artery disease (LEAD) undergoing partial foot amputation

Methods: We evaluated 240 consecutive symptomatic patients (45-65 years old, 98 female and 142 male) with type 2 diabetes, CHF, LEAD and without history of coronary intervention or myocardial infarction, renal insufficiency undergoing partial foot amputation during January-May 2014. Physical and instrumental examination, laboratory tests were performed prior operation and in dynamics.

Results: Clinical coronary artery disease (CAD), atherosclerotic lesions of coronary and lower extremity arteries were similar to every patients (no clinically significant/obstructive stenosis). 120/240 patients had hemoglobin (Hb)>120 g/L, other half of patients had Hb<100 g/L. CHF Class I (NYHA) more often observed in patients without anemia 52(43.3%) vs. 12(10%). Class II detected in 38 patients (31.7%) without anemia vs. 50 (41.7%) with decreased Hb level. We found 2fold increase in prevalence of CHF Class III and IV in patients with anemia (p=0.0003). All patients in study received insulin therapy. We detected more increased HbA1c in anemic patients (p=0.001). Brain natriuretic peptide was significantly elevated in the group with low Hb (p=0.001). LVEF was below 55% in 103 anemic patients (85.8%) vs. 41 (34.2%) with Hb>120 g/L; p=0.0001 (Table).

Conclusion: Symptomatic diabetic patients with CAD, LEAD, undergoing partial foot amputation had more severe CHF in the group with anemia which characterized in increase heart failure NYHA Class, brain natriuretic peptide, decrease LVEF.

Parameters of symptomatic diabetic patie

Use of two-dimensional "2D" stain imaging for early detection of iron overload cardiomyopathy in polytransfused patients.

F Mroua¹; T Triki Faten¹; I Frikha²; R Hammami¹; S Charfeddine¹; S Ben Kahla¹; M Elloumi²; L Abid¹; S Kammoun¹

¹University of Sfax, Department of cardiology Sfax Tunisia, Sfax, Tunisia; ²University of Sfax, Department of Hematology Sfax, Sfax, Tunisia

Background: Iron overload cardiomyopathy in polytransfused patients is characterized by a restrictive cardiomyopathy with early diastolic dysfunction and a late systolic dysfunction. The aim of this study is to determine the value of the two-dimensional "2D" stain imaging in the early detection and screening of iron overload cardiomyopathy.

Methods: This is a case-control study comparing eleven polytransfused patients followed at the hematology department and twenty apparently healthy patients randomly selected. All patients underwent conventional transthoracic echocardiography with an analysis of myocardial deformation "speckle-tracking" or two-dimensional "2D" stain imaging in the cardiology department of the same hospital.

Results: Our patients mean age was 58.4 years (19, 80) with a sex ratio of 1.75. Diseases treated in the long-term by transfusions were myelodysplastic syndrome in 8 cases, thalassemia major in 2 cases and myelofibrosis in one case. All patients received more than 20 red blood cells units. The majority of patients were asymptomatic (10/11). Mean left ventricular ejection function was 59.9%. The S wave in the lateral mitral annulus was 9.7 ± 2.1 cm/s. Diastolic function was preserved in 10 patients. The global longitudinal strain was -18.5 % ± 3.2 with a significant difference from the control group (-20.8% ± 2.05), p=0.02. There is a significant correlation between the number of red blood cells units received and the global longitudinal strain (p=0.019).

Conclusion: The two-dimensional "2D" stain imaging is a new non invasive technique that can better assess the real state of left ventricular function. In our study we found a significant decrease in global longitudinal strain in polytransfused patients compared to controls. Our results confirm the value of this new technique in the early detection of iron overload cardiomyopathy.

P320

Iron deficiency and risk of early readmission after an admission for acute heart failure.

I Ingrid Cardells Beltran¹; J Nunez Villota¹; G Minana¹; S Garcia Blas¹; E Santas Olmeda¹; E Valero¹; J Sanchis¹; FJ Chorro¹; D Escibano¹; A Paya¹

¹University Hospital Clinic of Valencia, Valencia, Spain

Introduction: Early rehospitalizations after an episode of acute heart failure (AHF) remains excessively high and its prediction remains a challenge. Iron deficiency (ID) is a frequent finding in AHF but prognostic implications remains unclear.

Purpose: We sought to evaluate the association between ID and risk of 30-day readmission in a cohort of patients discharged for AHF

Methods: Serum ferritin and transferrin saturation (TSAT) were measure before discharge in 626 consecutive patients with AHF in a single teaching center. ID was defined as serum ferritin <100 µg/L (absolute ID) and as ferritin 100-299 µg/L with a TSAT <20% (functional ID). Cox regression adapted for competing event was used to determine the association between ID-related parameters and risk of 30-day readmission.

Results: Mean age was 75.6 ± 10.4, 48% were females and 52.1% showed left ventricular ejection fraction >50%. ID was identified in 463 patients (74%): 302 (48.2%) absolute ID and 161 (25.7%) functional ID. At 30-day after discharge, 20 (3.2%) patients died and 103 (16.5%) were readmitted. Patients with absolute ID showed an increase of rate of readmission compared to those with functional ID and no ID (19.9%, 13% and 13.5%, respectively, p=0.005). In multivariate setting, absolute ID remained associated to higher risk of readmission (HR=1.72; CI 95%: 1.13-2.60, p=0.011). Compared to patients without ID, functional IF was not related to the risk of readmission (HR=0.87; CI 95%: 0.46-1.62, p=0.652)

Conclusion: In patients with AHF, absolute ID, but not functional ID, was associated to an increased risk of early readmission.

Unpublished association between iron deficiency and left heart filling pressure in patients diagnosed of chronic heart failure

J A Jose Antonio Ortiz De Murua¹

¹C.A.Z.A. VIRGEN DE LA CONCHA H., CARDIOLOGY, ZAMORA, Spain

Introduction: There is an increasing interest among cardiologists in iron deficiency of patients with chronic heart failure, because it is known that its therapy with intravenous carboxymaltose improves these patients' well-being. However, it is unknown its correlation with echocardiographic variables.

Purpose: We want to show the prevalence of iron deficiency in patients diagnosed of chronic heart failure and its correlation with echocardiographic variables.

Methods: This is a prospective study, including consecutive 50 patients attended at our heart failure clinic and diagnosed of chronic dysfunction (EF<40%) with whatever aetiology (22 dilated cardiomyopathy, 19 ischemic cardiomyopathy and 18 other etiologies). General features: 39 men, average age 72 years (IC 95% 70-75.2 years) and 4.74 years elapsed from the diagnosis (IC 95% 3.43-6.04 years). These patients were attended from October 2014 until June 2015 and had a compensated heart failure (without any hospital admission in the last 3 months). The ECG show 16 LBB and the patients had 26 devices implanted (16 TCR and 10 ICD). Our patients had many cardiovascular risk factors (40% arterial hypertension, 54% dyslipemia, 28% diabetes mellitus and 14 % were smokers). Most of them were in functional class II NYHA and 64% had chronic kidney disease (GF<60 cc/m2). 86% of the whole patients received optimum therapy (beta-blockers, diuretics, ACE inhibitors and aldosterone antagonists and digoxin if atrial fibrillation was present) and only 20% iron therapy (oral or intravenous).

Statistical analysis: correlation tests (Pearson's test, contingency tables and ANOVA tables) and ROC curves

Results: the prevalence of iron deficiency in our patients was 38%, 8% had ferropenic anaemia and 14% other aetiologies anaemia. Statistical analysis showed a significant correlation between iron deficiency and E/e' (p=0.003) and ROC curve that E/e' >= 13 had a significant relationship with ferropenia (Sensitivity. 74%, Specificity, 64%, Positive Predictive Value 76% and Negative Predictive Value 60%). Patients with E/e' had a pulmonary arterial pressure >= 40 mm Hg.

Conclusions: 1- The prevalence of iron deficiency was very high in our patients and scarcely treated. 2- Our patients had many cardiovascular factors and cardiorenal syndrome. 3- This study shows and unpublished and relevant relationship between ferropenia and left ventricular pressure, probably related to a higher stimulation of renin-angiotensin-aldosterone and sympathetic nervous systems.

Assessment of myocardial iron in heart failure before and after correction of functional iron deficiency by intravenous iron therapy with ferric carboxymaltose using cardiac magnetic resonance imaging

A Sandek¹; M Valentova¹; P Freyhardt²; N Scherbakov³; N Ebner¹; T Bekfani⁴; S Von Haehling¹; W Doehner³; B Hamm²; SD Anker¹

¹University of Medicine Göttingen, Innovative Clinical Trials, Cardiology and Pneumology, Göttingen, Germany; ²Charité University Medicine Berlin, Radiology, Berlin, Germany; ³Charité - University Medicine Berlin, Center for Stroke Research CSB, Berlin, Germany; ⁴University Medicine Jena, Cardiology, Jena, Germany

Background: Chronic heart failure (CHF) is characterized by inflammation-related functional iron deficiency (ID). Its correction by intravenous iron has been shown to improve functional status independently of anaemia in CHF. However, the mechanism of improvement is not clear. As iron may play a key intracellular role in cardiac myocytes within mitochondria and in myoglobin, we hypothesize that myocardial iron content (IC) may change after intravenous iron application.

Methods: We prospectively quantified myocardial IC in 24 patients with systolic CHF (LVEF <40%) using cardiac T2* magnetic resonance imaging (MRI). T2* imaging was accomplished using 1.5-T scanner and multiecho gradient-echo sequence. Functional ID was diagnosed in 12 patients with ferritin <100 µg/L or between 100 and 299 µg/L, if the transferrin saturation (TS) was <20%, and a hemoglobin of 95 to 135 g/L. IC of heart, small and large intestines, spleen, liver, skeletal muscle and brain before and 12 weeks after intravenous iron therapy (IIT) using ferric carboxymaltose was assessed.

Results: Patients with functional ID had a lower ferritin and haemoglobin compared to patients with normal iron availability ($67 \pm 17 \mu\text{g/L}$ vs. $196 \pm 26 \mu\text{g/L}$ and $123 \pm 11 \text{ g/L}$ vs. $142 \pm 11 \text{ g/L}$, all $p = 0.0004$). In patients with functional iron deficit, TS correlated with low myocardial IC of the left ventricle (LV) indicating myocardial ID ($r = 0.69$, $p < 0.02$). Contrastingly, in patients with normal iron availability, there was no correlation of transferrin saturation with myocardial IC ($r = 0.32$, $p = 0.3$). After IIT, TS, ferritin and hemoglobin increased indicating therapeutic response (19.9 ± 1.3 vs. $28.4 \pm 1.4\%$, 90 ± 15 vs. $321 \pm 36 \mu\text{g/L}$, 124 ± 2 vs. $134 \pm 3 \text{ g/L}$, all $p < 0.0004$). Peak VO₂ increased after iron application (18.2 ± 1.3 vs. $20.9 \pm 1.3\%$, $p = 0.05$). IC of spleen and liver increased as expressed by a shortened T2* value by 40.2 and 18.2%, respectively, representing augmented storage of iron (78.3 ± 7.2 vs. $46.8 \pm 7.8 \text{ ms}$ $p < 0.002$; 33.5 ± 1.7 vs. $27.4 \pm 2.5 \text{ ms}$, $p < 0.02$). Myocardial IC of the left ventricle increased as expressed by a shortened T2* value by 28.7 % (54.3 ± 6.3 vs. $38.7 \pm 3.1 \text{ ms}$, $p = 0.05$). IC of the bone marrow and small intestine increased, too. However, this did not reach significance (9.8 ± 0.4 vs. $13.7 \pm 2.6 \text{ ms}$ $p = 0.14$, 34.3 ± 6.5 vs. $25.3 \pm 4.3 \text{ ms}$, $p = 0.19$). Contrastingly, IC of large intestine, brain and skeletal muscle remained unchanged (15.7 ± 3.2 vs. $13.6 \pm 3.3 \text{ ms}$, $p = 0.6$; 81.0 ± 1.8 vs. $82.9 \pm 2.9 \text{ ms}$, $p = 0.5$ and 31.8 ± 2.6 vs. $30.3 \pm 0.4 \text{ ms}$, $p = 0.6$). While IC in skeletal muscle of the limbs correlated with hemoglobin after IIT ($r = 0.60$, $p < 0.04$), increased myocardial IC did not correlate with haemoglobin level suggestive of implementation of iron into the myocardium independently of implementation into hemoglobin ($r = 0.18$, $p = 0.6$).

Conclusions: Myocardial IC increased after IIT using ferric carboxymaltose. IC in skeletal muscle remained unchanged. Increase in myocardial IC may contribute to clinical benefit of intravenous iron therapy.

P322

Iron status in patients with heart failure with reduced ejection fraction with ischaemic versus non-ischaemic aetiology.

Supported by the National Science Centre (Poland) grant allocated on the basis of the decision number DEC-2014/13/B/NZ5/03146

M Drozd¹; M Kasztura¹; P Rozentryt²; J Nowak²; L Polonski²; J Malyszko³; E Koc-Zorawka³; W Banasiak⁴; P Ponikowski⁵; EA Jankowska¹

¹Wrocław Medical University, Department of Heart Diseases, Laboratory for Applied Research on Cardiovascular System, Wrocław, Poland; ²Silesian Center for Heart Diseases (SCHD), Third Department of Cardiology, Zabrze, Poland; ³Medical University of Białystok, 2nd Department of Nephrology and Hypertension with Dialysis Unit, Białystok, Poland; ⁴Military Hospital of Wrocław, Centre for Heart Diseases, Wrocław, Poland; ⁵Wrocław Medical University, Department of Heart Diseases, Wrocław, Poland

Background: There are 2 major factors significantly contributing to the complex pathophysiology of heart failure (HF), namely impaired haemodynamics due to left ventricular dysfunction (a failure of mechanical pump) and in case of existing coronary artery disease (CAD) - myocardial ischaemia. It remains unknown if and how these 2 factors affect iron status in patients with heart failure with reduced ejection fraction (HFREF).

Methods: We prospectively analysed data of 732 stable patients with HFREF (confirmed CAD: 71%, mean age: 58 ± 11 years, New York Heart Association [NYHA] Class III/IV: 44%, mean LVEF [left ventricular ejection fraction]: $28 \pm 8\%$). ID was defined as serum ferritin $< 100 \mu\text{g/L}$, or serum ferritin $100\text{--}299 \mu\text{g/L}$ with transferrin saturation (TSAT) $< 20\%$. Additionally, we also measured serum hepcidin and soluble transferrin receptor (sTfR) as circulating biomarkers of iron status.

Results: Patients with CAD as compared with those without CAD (nCAD) had a more prevalent ID (borderline) (37% vs. 31%, $p = 0.08$), and also lower ferritin (165 (89–258) vs. 205 (117–325) $\mu\text{g/L}$, $p < 0.01$), lower hepcidin (52 (27–108) vs. 82 (45–170) ng/mL, $p < 0.001$), lower haemoglobin (13.8 ± 1.5 vs. $14.4 \pm 1.6 \text{ g/dL}$, $p < 0.001$), and lower GFR (73 (58–90) vs. 83 (66–97) mL/min/1.73m², $p < 0.001$) without any differences in sTfR, TSAT and hs CRP (all $p > 0.2$).

Both in CAD and nCAD groups, sTfR was higher in patients with markedly reduced LVEF: for those with LVEF 40–45%, 30–39%, 20–29% and $< 20\%$ - in the CAD group 1.23 (1.06–1.79), 1.21 (0.97–1.66), 1.24 (1.00–1.64) and 1.69 (1.16–2.49) ng/mL ($p < 0.01$) and in nCAD group 1.15 (0.97–1.41), 1.16 (0.91–1.60), 1.17 (0.95–1.52), and 1.50 (0.98–2.05) ($p = 0.11$). Also, in both patients with CAD and nCAD, plasma NT-proBNP correlated positively with sTfR (respectively for CAD and nCAD - $r = 0.29$, $p < 0.001$ and $r = 0.38$, $p < 0.01$) and negatively with Tsat ($r = -0.25$, $p < 0.01$ and $r = -0.33$, $p < 0.01$).

Along with the decreasing LVEF, there was a tendency for a higher prevalence of ID defined based on serum ferritin and Tsat, but only in a nCAD group (LVEF $< 20\%$ vs. 40–45%: 44% vs 22%, $p = 0.08$). Serum ferritin was higher in nCAD as compared to CAD patients, but did not differ across LVEF groups in both aetiology subgroups ($p > 0.2$). Serum hepcidin was higher in nCAD as compared to CAD patients, and among nCAD patients there was a tendency for even higher hepcidin in patients with lower LVEF ($r = -0.21$, $p = 0.07$). Neither in CAD nor in nCAD, ferritin and hepcidin correlated with hsCRP (both $p > 0.2$).

Conclusions: Iron status differs in patients with HFREF depending on HF aetiology and LVEF value. Patients with ischaemic HFREF have markedly reduced iron stores

reflected by low ferritin and hepcidin. Regardless of aetiology, the magnitude of intracellular iron depletion (high sTfR) is the greatest among those with severely impaired LV systolic function and augmented neurohormonal activation without any association with inflammatory process.

P323

Cardiorenal relations in patients with septic conditions

T S Getiya¹; E O Kotova²; V L Filatov¹; G K Kiyakbaev²; V S Moiseev²

¹M.V. Lomonosov Moscow State University, Moscow, Russian Federation;

²Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Purpose: To study the features of type 5 cardiorenal syndrome in patients with sepsis and infective endocarditis (IE).

Material and methods: 25 patients with IE (Duke 2015; group 1) and 28 patients with sepsis (group 2) were included. Median age in group 1 was 65 [62–74], in group 2 — 62 [34–75] years. We evaluated the anamnesis, echocardiogram, renal function (GFR, proteinuria, microscopic hematuria, serum cystatin C, urinary Kim-1), heart failure (NYHA) rates, NT-proBNP values, acute kidney injury (AKI; KDIGO 2012) and mortality rates.

Results: Sex and age distribution did not differ between two groups. Condition severity in groups with IE and with sepsis were comparable. NYHA FC III/IV heart failure were more common in group 1 than in group 2 [21 (84%) vs. 13 (47%), $p < 0.05$], that was confirmed by higher levels of NT-proBNP [5500 (3200–9200) pg/ml vs. 5200 (1900–8800) pg/ml, $p > 0.05$]. Kidney injury occurred equally often in both groups [21 (84%) and 24 (86%), $p > 0.05$]. However, AKI was observed more frequently in patients with IE than in patients with sepsis [14 (56%) vs. 13 (47%), $p > 0.05$]. Proteinuria were also more common in group 1 [14 (56.0%) vs. 6 (21.4 %), $p < 0.05$].

Values of serum cystatin C were higher in patients with IE [2.01 (1.76–2.66) mg/ml vs. 1.72 (1.29–2.37) mg/ml, $p = 0.13$], but urinary Kim-1 levels were slightly higher in patients with sepsis [1.68 (1.63–1.75) ng/ml vs. 1.60 (1.51–1.77) ng/ml, $p = 0.29$].

Mortality rates were similar in both groups [7 (28.0%) and 6 (21.4%), $p > 0.05$].

Conclusion: Patients with IE showed more severe heart failure, higher levels of NT-proBNP and more severe kidney injury presented by higher incidence of AKI and proteinuria compared with group of sepsis. Mortality rates did not differ between two groups.

P324

Circadian blood pressure profile in patients with ischemic chronic heart failure with renal dysfunction

D Dmytro Lashkul¹; VD Syvolap¹

¹Zaporizhzhya State Medical University, Zaporizhzhya, Ukraine

The role of ambulatory blood pressure monitoring not been studied in patients with chronic heart failure, the prevalence of which is constantly growing, and there are practically no data on the nature of the daily profile of arterial pressure in chronic heart failure associated with renal dysfunction.

Purpose: The aim of the study was to investigate the characteristics of ambulatory blood pressure monitoring in patients with ischemic chronic heart failure (CHF) depending on renal function. Methods. The study involved 106 patients with ischemic CHF (90 men), mean age 56.2 ± 8.8 years. In 35 (33.1%) patients were diagnosed II functional class (FC) CHF, in 71 (66.9%) - III FC. 24-hours ambulatory blood pressure monitoring (ABPM) was performed with the use of CardioTens. Variation row glomerular filtration rate (GFR) was divided into quartiles. A comparative analysis was conducted between CHF patients with $\text{GFR} < 70.1 \text{ mL/min/1.73 m}^2$ (lower quartile) and $> 86.5 \text{ mL/min/1.73 m}^2$ (upper quartile).

Results: Decreasing GFR in patients with ischemic CHF was associated with a more senior age ($p < 0.0001$), FC of heart failure ($p = 0.02$), more common history of hypertension ($p = 0.04$), lower ejection fraction ($p = 0.02$). Office arterial hypertension was found in 14 (13.2%) patients, ABPM established hypertension in 23 (21.7%) for SBP and 19 (17.9%) patients for DBP. Arterial hypotension was detected in 5 (4.7%) for SBP and in 11 (10.4%) patients for DBP. Increased variability for SBP in 44 (41.5%) and for DBP in 14 (13.2%) patients were revealed. Insufficient degree of nocturnal decline (non-dipper) SBP was observed in 43 (40.6%), DBP - in 32 (30.2%) patients. Excessive nocturnal decline (over-dipper) SBP detected in 6 (5.6%), DBP - in 29 (27.4%) patients. Raising a night (night-picker) SBP was observed in 12 (11.3%), DBP - 5 (4.7%) patients. In CHF patients with $\text{GFR} \leq 70.1 \text{ mL/min/1.73 m}^2$, compared with a group $\text{eGFR} \geq 86.5 \text{ mL/min/1.73 m}^2$ revealed a lower average daily standard deviation for DBP ($p = 0.02$), the daily index DBP ($p = 0.05$) and the standard deviation of daytime DBP ($p = 0.05$) and night ($p = 0.03$) time. Multivariate regression analysis showed that eGFR is associated with age, FC CHF, ejection fraction, daily index for SBP and DBP ($R^2 = 0.45$; $p = 0.0001$).

Conclusion: ABPM in patients with ischemic CHF can significantly increase detectability hypo-hypertension, certain deviation daily index, variability BP. Level GFR correlated with age, functional class and the degree of blood pressure reduction at night.

P325

Validated-internally kidney protection program (vkpp) scoring system as a predictor of worsening renal function among hospitalized acute decompensated heart failure patients

V Vebiona Surangayudha¹; P Yamin¹; N Hersunarti¹; D Tobing¹; R Soerarto¹; B Siswanto¹

¹National Cardiovascular Center Harapan Kita, Department of Cardiology and Vascular Medicine, Jakarta, Indonesia

Background: Worsening renal function (WRF) is associated with worse outcomes among patients who are hospitalized with acute decompensated heart failure (ADHF). Clinical characteristics at admission may help identify patients at increased risk of WRF.

Purpose: The aim of this study was to create in admission scoring system to simplify identification patients at risk of WRF in ADHF setting. Methods. A retrospective data of 614 patients admitted with ADHF was analyzed. By the definition WRF occurred when serum Creatinin increased at anytime during hospitalization by ≥ 0.3 mg/dL or by $\geq 25\%$ from admission.

Results: Worsening renal function developed in near 26% patients. The independent predictors of WRF analyzed with backward selection logistic regression were: age > 75 years old ($p < 0.0001$), female ($p = 0.034$); history of hypertension ($p = 0.001$); anemia ($p = 0.005$); and in admission serum Creatinin ($p = 0.013$). A scoring system was generated from this final model. An internal validation with bootstrap method showed good optimism (0.01088808).

Conclusion: A new scoring system could predict in-hospital worsening renal function among patients hospitalized with acute decompensated heart failure.

P326

Short-term rosuvastatin therapy reduced risk of contrast-induced acute kidney injury in patients with delayed percutaneous coronary intervention

A Anna Gaskina¹; S Villevalde¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFRU), Moscow, Russian Federation

Introduction: Contrast-induced acute kidney injury (CI-AKI) is a common complication of intra-arterial administration of iodinated radiographic contrast medium that may prolong hospitalization, increase costs, short- and long-term morbidity and mortality. Despite the obvious progress in modern interventional cardiology and angiology the question of effective prevention of CI-AKI remains relevant. We performed a single-centre prospective study to determine the effect of addition of rosuvastatin to routine preventive measures on the incidence of CI-AKI in patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) and delayed percutaneous coronary intervention (PCI).

Methods: 84 patients with NSTEMI-ACS scheduled to early invasive strategy were randomised by the method of blind envelopes were randomized to receive rosuvastatin 40 mg followed by 20 mg/day (intervention group, $n = 42$) or routine atorvastatin 20-40 mg/day (control group, $n = 42$). patients in intervention group continued treatment with rosuvastatin 20 mg/day at discharge. All patients received routine prevention - intravenous hydration with 0.9% sodium chloride for 12 h both before and after PCI, 1 ml/kg/h. Non-ionic low osmolar contrast agent iodaxol (Omnipaque 350) was used. We use transradial access for PCI in 98% of patients. Both groups were comparable in age (63 ± 13 and 66 ± 12 years), comorbidity (hypertension 91 and 94%, chronic kidney disease 12 and 14%, diabetes mellitus 21 and 18%) and therapy. CI-AKI was defined using 2012 KDIGO Guidelines. Mann-Whitney test and multivariate logistic regression analysis were performed. $P < 0.05$ was considered statistically significant.

Results: The incidence of CI-AKI in intervention group was significantly lower than in the control group (4.8 and 19%, $p < 0.05$). Clinical follow-up at 6-month was completed for all 84 patients. Patients who developed CI-AKI presented a significantly higher rate of 6-month rehospitalizations for cardiovascular disease (70 and 47%, $p < 0.05$) than patients without CI-AKI. The 6-month cardiovascular rehospitalizations was significantly lower in the statin than in the control group (31 and 52%, $p < 0.05$). Patients in the statin group presented a significantly lower rate of persistent renal damage (24 and 45%, $p < 0.05$) than patients in the control group.

Conclusion: Short-term rosuvastatin therapy significantly reduced the risk of CI-AKI in patients with NSTEMI-ACS and delayed PCI and improved short-term clinical outcome.

Incidence and outcomes of contrast-induced acute kidney injury in patients with elective percutaneous intervention

A Anna Gaskina¹; S Villevalde¹; A Milto¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFRU), Moscow, Russian Federation

Aims: Contrast-induced acute kidney injury (CI-AKI) is one of the most common complications after percutaneous coronary intervention (PCI) using intravascular radiocontrast media. CI-AKI has been associated with high in-hospital mortality and

poor long-term survival. The aim of the study was to evaluate the incidence, risk factors and outcomes of CI-AKI in patients with elective PCI.

Methods: 150 patients with stable angina pectoris (SAP) and elective PCI (102 male, 61.3 ± 11.2 years ($M \pm SD$), arterial hypertension 88%, previous MI 56%, diabetes mellitus 25%, known chronic kidney disease (CKD) 33%, anemia 17%, heart failure 67%, left ventricular ejection fraction $42 \pm 16\%$) were examined. CI-AKI was defined using 2012 KDIGO Guidelines. Isoosmolar contrast media iodixanol (Visipaque-320) or low-osmolar contrast media iohexol (Omnipaque-350) were used. Transradial access for PCI was used in 98% of patients. Mann-Whitney test and multivariate logistic regression analysis were performed. $P < 0.05$ was considered statistically significant.

Results: 21 (14%) patients developed CI-AKI. Stages 1 and 2 of CI-AKI were found in 92 and 8% of cases accordingly. Main independent predictors of CI-AKI were contrast media volume (CV)/eGFR ≥ 4.35 (odds ratio (OR) 20.2; 95% confidence interval (CI) 3.4-120.8; $p < 0.01$), CKD (OR 17.4; 95% CI 3.8-79.8; $p < 0.05$), Mehran risk score > 10 (OR 14.7; 95% CI 1.2-66.6; $p < 0.0001$), CV > 350 ml (OR 8.7; 95% CI 1.4-21.5; $p < 0.05$), age ≥ 74.5 years (OR 6.9; 95% CI 1.4-34.1; $p < 0.01$), baseline eGFR ≤ 61 ml/min/1.73 m² (OR 6.5; 95% CI 1.6-26.0; $p < 0.01$), baseline serum creatinine (SCr) ≥ 96 μ mol/l (OR 5.5; 95% CI 1.4-21.5; $p < 0.05$), anemia (OR 3.0; 95% CI 1.1-8.4; $p < 0.05$). Patients with versus without CI-AKI had higher risk of 6 months rehospitalizations (59 vs 33%, $\chi^2 = 8.53$, $p < 0.05$).

Conclusions: CI-AKI in patients with SAP and elective PCI developed in 14% of cases, predominantly stage 1. Main independent predictors of CI-AKI were factors related to the contrast media (CV/eGFR, CV) and factors related to the patient (CKD, Mehran risk score > 10 , age ≥ 74.5 years, baseline eGFR ≤ 61 ml/min/1.73 m², baseline SCr ≥ 96 μ mol/l, anemia). CI-AKI had negative impact on of 6 months rehospitalizations.

P328

Hemodynamic predictors of plasma NGAL concentrations and its response to intervention

Supported, in part, by an operating grant from the Canadian Institute for Health Research (RN136292 – 260133)

L Goldreich¹; DZ Cherney²; J D Parker³

¹University of Toronto, Toronto, Canada; ²University Health Network, Toronto, Canada; ³Mount Sinai and University Health Network Hospitals, Medicine, Toronto, Canada

Background: Neutrophil gelatinase-associated lipocalin (NGAL) has been reported as an indicator of acute renal injury and as an indicator of prognosis in patients with congestive heart failure (CHF).

Purpose: We explored the relationship between plasma NGAL, invasive hemodynamics and measures of renal function in patients with and without CHF. We also examined the impact of an acute hemodynamic intervention (dobutamine and nitroprusside) on NGAL concentrations.

Methods: We measured plasma NGAL concentrations and carried out right heart catheterization as well as arterial hemodynamic assessments in 29 patients with preserved left ventricular (LV) function and normal hemodynamics (the no CHF group) and 46 patients with reduced LV systolic function (EF $< 40\%$) and a history of CHF (CHF group). We also made direct measures of GFR (inulin) and renal plasma flow (RPF; para-amino hippurate). Univariate and multivariate (stepwise) linear regression were used to explore the relationships between hemodynamics, renal function parameters and NGAL concentrations. After baseline measures were obtained, all subjects received an intravenous infusion of either dobutamine or nitroprusside with repeat measures of hemodynamics, renal function and NGAL concentrations

Results: Plasma NGAL concentrations were elevated in the CHF vs. the no CHF group (202 ± 109 versus 119 ± 42 ng/ml; $P < 0.001$). In the no CHF group, in both the univariate and multivariate analysis, the only significant independent predictor of baseline plasma NGAL was RPF. In those with CHF, only right atrial mean pressure made an independent contribution to the multivariate model predicting NGAL. Right atrial mean pressure had a positive relationship with NGAL, with higher right atrial pressures associated with higher values of NGAL. In both groups, the administration of dobutamine and nitroprusside was associated with a highly significant decrease in plasma NGAL (table).

Conclusions: These data reveal that plasma concentrations of NGAL are dependent on baseline hemodynamic status in patients with CHF with an independent positive correlation with right atrial pressure in that population. We also demonstrate that common hemodynamic interventions cause highly significant reductions in plasma NGAL concentrations in both patients with and without CHF. These findings have importance to our understanding of the utility of NGAL as a biomarker used in the assessment of acute renal injury and patient prognosis.

Table. NGAL pre and post intervention

	control	dobutamine	control	nitroprusside
Plasma NGAL non-CHF (ng/ml)	124 \pm 45	87 \pm 37*	108 \pm 32	49 \pm 30*
Plasma NGAL CHF (ng/ml)	206 \pm 88	148 \pm 73*	199 \pm 120	128 \pm 75*

* $P < 0.01$ vs control

P329

Demographic and clinical outcomes of patients admitted for acute decompensated heart failure (adhf) with worsening renal function(wrf) in a district general hospital in malaysiaWEIJYUNG Patrick Tiau¹; ADRIAN Mark¹; CM Ang¹; SX Foo¹; S Shahrani¹; A Zainal¹; R Yusoff¹; R Abdullah¹¹Hospital Sultan Haji Ahmad Shah, Medical Department, Temerloh, Malaysia

Backgrounds: Worsening renal function (WRF) is known to increase adverse clinical outcome in patients admitted with acute decompensation of heart failure (ADHF). We looked at admissions of ADHF, its etiologies and causes of admission, incidence of worsening renal function; its factors and outcomes in a district general hospital in Malaysia for 2014. Method and

Results: Worsening renal function is defined as increase in serum creatinine by at least 0.3mg/dL (26.5 mmol/L) or at least 25% increased from baseline. We looked into factors associated with worsening renal function and the clinical outcome of patients admitted for ADHF with worsening renal function. There were 197 patient admissions with ADHF during the year 2014 that accounted for 4.9% of total medical admissions in Hospital Sultan Haji Ahmad Shah, Malaysia. Fifty percent were males with a median age of 65 years (range 12-90). Median length of stay was 5 days (range 2-20). Seventy-seven percent had hypertension (n = 153), 50% had diabetes (n = 99), 42% had ischemic heart disease (n = 83), 17% had chronic kidney disease (n = 34). The precipitating factors for ADHF hospitalization was acute coronary syndrome (48.7%), followed by non-compliance (41.1%), uncontrolled hypertension (33.5%), infections (21.4%) and other causes 1.5%. Thirty percent (n = 60) of patients had worsening renal function. Use of inotrope (OR:3.09 P = 0.034) and concomitant in-hospital infection (OR:5.0 P = 0.023) were the only significant factors associated with worsening renal failure. Patient admitted with ADHF and developed WRF had higher in-hospital mortality (OR: 2.93 P = 0.009). However, this did not significantly affect 30-day and 180-day readmission rates (OR 2.3 P = 0.07 and OR: 0.8 P = 0.54) respectively.

Conclusion: Worsening renal function in ADHF is common in our cohort. This is associated with significant in-hospital mortality and a trend towards increase 30-day readmission in our study.

P330

In patients with CHF creatinine-based measures of GFR in response to acute intervention are directionally opposite to those obtained with inulin and cystatin-c

Canadian Institute for Health Research (RN136292 – 260133)

L. Goldraich¹; DZI Cherney²; J D John David Parker³¹University of Toronto, Toronto, Canada; ²University Health Network, Toronto, Canada; ³Mount Sinai Hospital of the University Health Network, Medicine and Cardiology, Toronto, Canada

Background: Creatinine-based estimates of GFR are used to track changes in renal function over time. However, little is known about their ability to follow changes that occur in response to short-term therapeutic interventions.

Purpose: We explored the relationship between plasma cystatin-c (cys-c), invasive hemodynamics as well as direct measures of renal function in patients with chronic CHF. We measured the effect of dobutamine and nitroprusside on measures of GFR based on creatinine, cys-c and inulin.

Methods: We measured plasma cys-c and invasive hemodynamics in 46 patients with reduced LV systolic function (EF <40%) and a history of CHF. We calculated GFR based on creatinine (modified diet in renal disease (MDRD) and the chronic kidney disease epidemiology [CKD-epi] formulae), cys-c (CKD-epi cys-c formula) and inulin clearance. Univariate and multivariate (stepwise) linear regression was used to explore the relationships between hemodynamics, inulin-based GFR and plasma cys-c concentrations. All subjects received an intravenous infusion of either dobutamine (n = 16) or nitroprusside (n = 30) and repeat measures of hemodynamics, renal function, creatinine and cys-c concentrations were obtained.

Results: The multivariate regression analysis revealed that the only significant independent predictor of both plasma creatinine and cys-c was GFR measured by inulin. The administration of dobutamine and nitroprusside caused small, but significant increases in plasma creatinine (dobutamine 88 ± 31 vs. 92 ± 31 µmol/litre; nitroprusside 85 ± 40 vs 88 ± 38 µmol/litre, P < 0.01 for both). By contrast both dobutamine and nitroprusside caused significant reductions in cys-c (dobutamine 1.62 ± 0.62 vs. 1.43 ± 0.58 mg/L; nitroprusside 1.39 ± 0.54 vs 1.23 ± 0.48 mg/L, P < 0.001 for both). Based on these changes there was a decrease in GFR when measured using creatinine-based estimates. In contrast GFR increased when estimated with cyst-c and measured with inulin (table).

Conclusions: These findings serve to demonstrate that changes in creatinine-based estimates of GFR can be very misleading as compared to estimates obtained with cys-c or measurements made using inulin.

Table, GFR responses to intervention

P331

The role of urinary NGAL in acute heart failure

Project is supported by Slovak Society of Cardiology research grant.

M Marcela Dankova¹; T Pazmanova¹; V Hricak²; B Zitny³; J Gerget⁴; P Pontuch¹¹University Hospital, 4th Department of Internal Medicine, Bratislava, Slovak Republic; ²The National Institute of Cardiovascular Diseases, Department of Emergency Cardiology, Bratislava, Slovak Republic; ³STU Vital Ltd., Bratislava, Slovak Republic; ⁴Medirex OJSC, Bratislava, Slovak Republic

Purpose: The aim was to evaluate differences in the levels of urinary NGAL and serum NT-proBNP in patients with acute heart failure (AHF) in relation to the loop diuretic treatment and development of acute kidney injury.

Methods: We analysed 60 patients admitted to coronary care unit with AHF. Urine samples were collected immediately at admission and after 24 hours. The samples were stored at -72°C and examined by enzyme-linked immunosorbent assay (Bioporto, Denmark). Acute kidney injury was defined according to KDIGO and patients were divided into groups without AKI (AKI-, n = 49) and with AKI (AKI+, n = 11).

Results: Sixty patients with median age 67 (IQR 61-79) and gender distribution 40/20 (M/F) were enrolled. Patients in the AKI+ group had significantly higher median admission u-NGAL levels compared with the AKI- patients (87 vs. 18,2 ng/ml; p = 0,003), also after 24 hours (163,7 vs. 34,5 ng/ml; p = 0,0004). Urinary NGAL/urine-creatinine ratio was higher in the AKI+ group compared with AKI- (at admission: 31,2 vs.2,5; p = 0,03 and after 24 hours: 18,2 vs. 3,1; p = 0,002). Significant increase in serum creatinine was recorded in the AKI+ group after 24 hours (117,6 vs. 94,5 µmol/l, p = 0,02). Urinary NGAL positively correlated with s-NTproBNP (r = 0,39, p = 0,003). The average initial parenteral dose of furosemide was higher in the AKI+ compared with AKI- (85,9 vs. 32,4 mg, p = 0,002) and correlated with u-NGAL at admission (r = 0,39, p = 0,006) and after 24 hours (r = 0,38, p = 0,01).

Conclusions: Patients with the development of AKI had significantly higher u-NGAL concentrations at admission and after 24 hours correlated with increasing serum creatinine, admission NTproBNP and initial parenteral dose of furosemide.

P332

Cancer treatment-related left ventricular dysfunction: retrospective evaluation of a small group of patient treated with ivabradineM Matteo Sarocchi¹; V Sicbaldi¹; E Arboscello²; A Bellodi¹; P Ghione¹; F Gualandri²; C Bighini²; R Murialdo²; C Brunelli¹; P Spallarossa¹¹University of Genoa, Genoa, Italy; ²San Martino Hospital, Genoa, Italy

Heart failure patients with cancer treatment related left ventricular dysfunction (CTR-LVD) often require a first-line treatment with inhibitors of angiotensin-converting enzyme (ACEi) or angiotensin receptor blockers (ARB) and β -blockers. Unfortunately, several cancer patients are susceptible to hypotension, fatigue and dizziness, limiting the use of these drugs.

AIM OF THE STUDY is to evaluate the efficacy and safety of the addition of Ivabradine to an optimized treatment of CTR-LVD.

Methods: We retrospectively analysed patients attending our cardio-oncologic ambulatory, with CTR-LVD defined as a drop in left ventricular ejection fraction (EF) to less than 50%, who received Ivabradine with a follow up of at least 3 months.

Results: We identified 30 patients with a mean age was 53 ± 16 y and prevalence of female sex (23/30). The most represented cancer diagnoses were breast cancer, acute leukaemia and non-Hodgkin lymphoma. No patient had less than 9,0 g/dl of haemoglobin. 27 patients had received a typically cardio-toxic anticancer treatment such as Trastuzumab, Anthracyclines or haematopoietic stem-cell transplant (HSCT); in 4 patients other chemotherapies were involved. 18 patients were symptomatic for typical dyspnoea, while 12 reported only atypical symptoms (fatigue, palpitation on exertion). Concomitant medications included a β -blocker and/or an ACEi or ARB in 17 patients; clinical reasons (hypotension, fatigue, renal function) had precluded any other introduction or further titration of these drugs. After a variable follow up (mean: 5,3 months), echocardiographic EF improved from 45,1(%) ± 6,4 to 52,0 ± 6,4 (p < 0,001), and NYHA class improved in 11/30 patients, from a mean of 1,8 ± 0,8 to 1,4 ± 0,6 (p < 0,01). Patients with palpitation or fatigue generally reported symptom amelioration. Heart rate was reduced from 84(bpm) ± 17 to 68 ± 10. Mean systolic and diastolic blood pressure slightly increased from 100(mmHg)

± 17 to 117 ± 22 and from 71 ± 13 to 75 ± 12 respectively (both not significant). EF improvement was significant in any group of anticancer treatment (Trastuzumab, Anthracyclines, HSCT). In addition, EF and NYHA class improvement was similar in patients who completed the programmed anticancer treatment and in those who did not, stopping or changing the treatment. The starting dose of Ivabradine was $7.0(\text{mg}/\text{die}) \pm 2.5$ and it had been titrated up to 8.1 ± 3.1 during follow up. No patient had severe bradycardia or serious adverse events, two patients experienced transient phosphenes.

Conclusions: we found that a moderate dose of Ivabradine could be safe, effective and well tolerated in patient with CTR-LVD on top of the maximal tolerated treatment with β -blockers and ACEi/ARB. Such an integrated intervention improved EF, NYHA class and fatigue. Limitation is the heterogeneity of cancer treatments and the concomitant cardioactive therapy.

P333

Echocardiographic indicators of left and right ventricular diastolic dysfunction in cancer patients complaining of an excessive fatigue

M Zechowicz¹

¹University of Warmia and Mazury, Department of Oncology, Olsztyn, Poland

Introduction: Fatigue is one of the most frequent symptoms reported by patients with neoplastic diseases and often results in specialist consultations and diagnostic tests. It may indicate a cardiac dysfunction, either as an independent co-morbidity, or as a complication of the anticancer therapy. Recently, an increasing number of diastolic dysfunction (DD) in patients with cancer is reported and it is said to precede systolic dysfunction (SD).

Aims: The purposes of the study were selection and validation of the optimal scale to assess fatigue, as well as distinguishing a set of parameters for the echocardiography assessment that correlate with the extent of fatigue.

Methods: 52 subsequent patients (6 males, 46 females), white, with a history of cancer (breast 71.3%, colon 11.5%, lung and mediastinum 7.7%, others 9.5%), referred to a cardiologist due to an excessive fatigue, were analysed for clinical data and a further three steps evaluation was performed. 1. Fatigue scales (FS) suitable for cancer patients (Fatigue Severity Scale – FSS, Cancer Fatigue Scale – CFS, Piper Fatigue Scale-12 – PFS-12) were implemented after their validation in polish; 2. Echocardiography (Echo) with tissue Doppler imaging (DTI) was performed – the mitral inflow velocity ratio (E/A), the septal and lateral mitral annular velocities and their ratio (Sep. and Lat. e'/a'), tricuspid annular velocities and their ratio (RV e'/a') were obtained; 3. A six-minute walking test (6MWT) with an assessment of the reference distance according to Enright's regression equation was performed. The Kaiser-Mayer-Olkin (KMO) test and alpha-Cronbach's internal consistency test were used for scales validation. The obtained results were analysed using Pearson's correlation coefficient, Shapiro-Wilk test, t-test, Mann-Whitney U test and Kruskal-Wallis test.

Results: All implemented scales showed a high level of adequacy in the selection of the sample with KMO>0.7 and a very high internal consistency (the FSS 0.946, the CFS 0.836 and the PFS-12 0.967). In 17 patients (32.7%), DD of the left ventricle and a tendency towards DD of the right ventricle was observed. It correlated with the level of fatigue ($P < 0.05$): E/A -0.37, -0.36 and -0.35 for CFS, PFS-12 and FSS respectively; Sep. e'/a' and Lat. e'/a' -0.39 and -0.38 respectively for CFS physical subscale (-0.31 and -0.29 for total CFS); RV e'/a' -0.28 both for PFS-12 and FSS and -0.27 for CFS physical. The physical fatigue was confirmed in the 6MWT, where 53.8% of patients did not reach the reference distance. No significant statistical influence of the comorbidities or the anticancer treatment was shown as correlated with the results of FS, 6MWT and Echo.

Conclusions: FSS, CFS and PFS-12 scales are an optimal tool for assessment of fatigue in cancer patients. In Echo the E/A, septal, lateral and tricuspid e'/a' are the main indicators of a DD presence or possible occurrence in cancer patients with an excessive fatigue.

P334

Wasting is not an independent risk factor of mortality in chronic heart failure patients with type 2 diabetes mellitus

J T Niedziela¹; B Hudzik¹; N Niedziela²; P Rozentryt¹; J Nowak¹; A Ociessa¹; M Gasior¹

¹Medical University of Silesia, 3rd Department of Cardiology, SMDZ in Zabrze, Katowice, Poland; ²Medical University of Silesia, Department of Neurology, SMDZ in Zabrze, Katowice, Poland

Body wasting is an independent risk factor of mortality in chronic heart failure (HF). Type 2 diabetes mellitus (DM) modifies the prognostic value of body mass index in HF, as among diabetic HF patients obesity paradox does not exist.

The purpose of the study was to analyze the prognostic value of body wasting in diabetic patients with HF with reduced ejection fraction (HFrEF).

Patients with stable HFrEF (without any clinical signs of congestion) treated in the heart failure outpatient clinic were included into the study. The body wasting was defined as at least 7.5% body mass reduction during HF (since the "dry" body

mass before first symptoms of HF). The probability of 1-year survival was compared between the groups with or without body wasting using log-rank test. The multiple Cox hazard model adjusted for age, sex, body-mass index, NYHA class, estimated GFR, left ventricular EF, peak oxygen consumption (peak VO₂), NT-proBNP levels, HF etiology and HF duration was performed. The forward regression model was applied for 1-year follow-up mortality.

Results: Among 877 patients with HFrEF, 271 (30.9%) with DM were included into the analyses: age 55.6 ± 7.7 ; 13.3% of them were women; BMI 27.9 ± 4.7 ; LVEF 23.8 ± 5.8 ; NT-proBNP 2552 ± 3051 pg/ml; NYHA class III or IV: 67.5% and mean weight change -7.43 ± 12.2 %.

The median of HF duration (and body wasting) was 40.2 [IQR 40.8] months.

There were no differences between the probability of survival between the two groups with or without body wasting – 80.7% vs 83.3%, log-rank $p = 0.56$. In multivariate Cox model only peakVO₂ (HR 0.86 (0.79-0.94), $p = 0.0006$) and LVEF (0.73 (0.53-0.99), $p = 0.04$ for 5% LVEF increase) were independent predictors of 1-year survival. Body wasting $\geq 7.5\%$ during HF was not included into the model ($p > 0.2$).

Conclusion: Among patients with HFrEF and type 2 diabetes mellitus, body wasting was not an independent predictor of mortality in 1-year follow up.

P335

Effect of trimetazidine on exercise capacity and muscle strength in patients with HFrEF

Ricerca corrente Italian Ministry of Health

G Caminiti¹; G Marazzi¹; F Iellamo¹; M Volterrani¹; G M C Giuseppe M C Rosano¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Patients with heart failure and reduced ejection fraction (HFrEF) have reduced exercise capacity in part related to a progressive loss of muscle strength. Trimetazidine (TMZ) has been shown to improve left ventricular function and exercise capacity in patients with HFrEF and to improve muscle performance in cachexia. We performed a randomised double blinded study to assess the effect of TMZ on exercise capacity and muscle strength in patients with HFrEF patients with >5% weight loss in the previous 6 months receiving optimised therapy and undergoing a cardiac rehabilitation programme.

Thirty-two patients were randomly allocated to receive TMZ 20 mg three times/day or matching placebo for 12 weeks. Compared to baseline, the distance walked on the 6-min walking test significantly improved in the TMZ group (28% vs 12% $p < 0.01$), as did peak VO₂ ($+3.6 \pm 1.6$ vs -0.4 ± 1.3 mL/kg/min, $p < 0.05$). A significant decrease in the slope VE/VCO₂ and an increase in peak workload were observed in the TMZ group but not in the placebo group.

Maximal voluntary contraction of the quadriceps increased significantly with TMZ (34%) while remained unaltered in patients receiving placebo (-5%), $p < 0.03$. The isokinetic torque of the quadriceps improved with TMZ (+19 Nm) but not with placebo (+4 Nm), $p < 0.03$. Total work increased significantly with TMZ (14 ± 7 J) but not with placebo (2 ± 5 J), $p < 0.03$. The fatigue index significantly improved in patients randomised to TMZ ($-41.1 \pm 9.1\%$) but not in those receiving placebo ($-16.3 \pm 7.3\%$), $p < 0.02$. A significant correlation was found between change in muscle strength and change in exercise capacity.

In conclusion, TMZ improves muscle strength and performance in patients with HFrEF. The effect of TMZ on exercise performance appears to be related, at least in part, to the improvement in muscle function.

P336

Breast cancer chemotherapy-induced cardiotoxicity; a 10-year observation.

JSS Jagdeep Singh Surmukh Singh¹; B Soujeri¹; S Chew¹; S Hawkey¹; M Ferguson²; CC Lang¹

¹University of Dundee, Cardiovascular and Diabetes Medicine, Dundee, United Kingdom; ²Ninewells Hospital, Dundee, United Kingdom

Background: Breast cancer is the leading cause of cancer in women. There has been significant progress in breast cancer therapeutics especially with the development of targeted therapy such as trastuzumab (Herceptin) resulting in remarkable improvements in cancer-free survival. However, with improving prognosis, there has also been an increasing incidence of chemotherapy-induced cardiotoxicity in this patient population. Contemporary guidelines mandate routine baseline and follow-up assessment of cardiac function prior to and following chemotherapy, however compliance to these recommendations is unknown.

Purpose/Methods: We aim to, firstly, determine the compliance to guideline recommendations and, secondly, the incidence of chemotherapy-induced cardiotoxicity among patients treated for breast cancer. We extracted data over a 10-year period (2003-2013) from a large regional cancer database in Scotland. This data was then linked to a health informatics database that tracks prescribing, investigational, morbidity and mortality data of patients across Scotland.

Results: A total of 1262 patients were given chemotherapy following a diagnosis of breast cancer. Mean age was 59.3 (± 11.1) years, there were 2 (0.2%) male

patients. 1039 (82.2%) patients received anthracycline monotherapy (MONO) while the rest were given combination therapy (COMBI) of anthracycline and trastuzumab. 683 (54.1%) patients had undergone baseline cardiac function assessment, all with normal left ventricular (LV) function. However, only 290 (23.0%) patients had follow-up assessments as per guideline recommendation. Of these 290 patients, 32 (11.0%) patients had incident LV dysfunction. 27 (84.3%) were on COMBI and the rest were on MONO.

Conclusions: Our observation demonstrates poor compliance to guideline-mandated surveillance of LV function in patients treated with chemotherapy. We also found a significant incidence of LV dysfunction early after initiation of chemotherapy, the vast majority of which were among patients on COMBI therapy. Prompt detection of LV dysfunction in this group is essential as trastuzumab-induced cardiotoxicity has been shown to be reversible, thereby underscoring the importance compliance to surveillance recommendations.

Introduction: Assessment of symptoms plays a key role in patient evaluation. However, little is known about how symptoms change after aortic valve replacement (AVR), and how they evolve over time in non-operated patients with severe aortic stenosis (SAVS).

Purpose: To describe changes in prevalence of symptoms from inclusion to one year after AVR or refusal of intervention in patients with SAVS. Method: Of 480 patients with SAVS evaluated for AVR, 389 patients were operated (351 surgical, 38 trans catheter) (OP) and 91 were declined surgery (NON-OP). We collected data on symptoms at inclusion and follow-up using a self-reported questionnaire. We present paired analysis.

Results: Operated patients were younger than non-operated (mean 74 vs. 81 years) and a higher proportion were men (59 % vs. 48 %).

Conclusion: AVR reduces prevalence of symptoms in patients with SAVS. Patients declined for operation experience an increase in prevalence of dyspnoea, chest pain and dizziness, but a reduction in syncope during one year of observation. Our results advocate AVR in patients with SAVS.

Symptoms at inclusion and at one-year follow-up

	OP Inclusion	NON-OP Follow-up p	Inclusion	Follow-up p
Dyspnoea n (%)	n=282	<0,001	n=45	<0.001

Utility of biomarkers in evaluating the success of percutaneous mitral commissurotomy in patients with severe rheumatic mitral stenosis

M-F Marie-France Seronde¹; AC Mogenet¹; B lung²; A Mebazaa³; N Meneveau¹

¹University Hospital of Besancon - Hospital Jean Minjoz, Besancon, France;

²Hospital Bichat-Claude Bernard, Paris, France; ³Hospital Lariboisiere, Dept of anesthesiology and intensive care, Paris, France

Introduction: Percutaneous mitral commissurotomy (PMC) is the gold standard technique for the management of severe rheumatic mitral stenosis (MS). We investigated the utility of BNP, NT pro-BNP, MR pro-ANP, CD146 and sST2 in evaluating the success of the PMC procedure.

Methods: All 5 biomarkers were measured one day before and one day after the procedure in 43 patients presenting with severe MS (defined as mitral valve area (VA) by planimetry < 0.2cm²) and submitted to PMC in 2 large university hospitals in France (CHU Bichat; CHU Jean Minjoz, Besancon). Patients were classified as procedural success (VA > 1.5cm² or increase in VA > 0.5cm²) or failure (VA < 1.5cm² or increase in VA < 0.5cm²) by echocardiography. The relative decrease in each biomarker between before and after the procedure was compared for each patient using the paired Student t test.

Results: In total, 43 patients were included (80% women, average 63.7 years), of whom 30 (70%) were judged to have a successful procedure by echocardiography; 11 (25%) were classed as procedural failure, and 2 (5%) had a major complication (1 mitral insufficiency requiring surgery, 1 tamponade). Among the 30 patients with procedural success, there was a significant decrease in MR pro-ANP (-40 ± 74, p=0.02) and CD146 (-43 ± 105, p=0.03). There was no significant decrease in these same biomarkers among patients classed as procedural failures. There was no significant decrease in BNP, NT pro-BNP or sST2 in patients with either successful or failed procedure.

Conclusion: There is a significant decrease in MR pro-ANP and CD146 after successful PMC. The difference is more pronounced in younger patients and in those in sinus rhythm. These two biomarkers could be of use in evaluating the immediate success of PMC.

P339

Determinants of one-year survival in infective endocarditis

H Helena Nascimento¹; M Braga¹; L Flores¹; V Ribeiro¹; F Melao¹; P Dias¹; MJ Maciel¹; P Bettencourt¹

¹Sao Joao Hospital, Porto, Portugal

Background and purpose: Infective endocarditis (IE) is a serious condition associated with a significant mortality burden. Our aim was to identify determinants of long term survival in patients with infective endocarditis.

Material and methods: This study consisted in a retrospective cohort analyses of a registry base of 173 consecutive patients admitted in a tertiary hospital from July 2011 and July 2014, with the diagnosis of definite or possible IE.

Results: The mean follow up time was 12.7 months. During this period the all-cause death rate was 37.6%. From the demographic data studied, sex (males 70.1% vs females 30.6%, p=0.008) and age (≥ 65 years-old: 51.1% vs <65 years-old: 75.9%, p=0.001) were predictors of survival. At admission, a higher hemoglobin level and a lower natriuretic peptide value were significantly associated with one-year survival (p=0.007). Community-acquired IE opposing to health-care associated IE (43.8% vs 73.3%, p<0.001) was a predictor of survival. The microbiological agent did not have impact on outcome (p>0.05). Appropriate antibiotics (67.6% vs 14.3%, p<0.001) and surgical treatment (76.9% vs 40.6%, p<0.001) during in-hospital stay were also determinants of survival. On the other hand, de novo heart failure and uncontrolled infection were associated with mortality. Independent predictors of one-year survival by multivariate logistic regression modelling were age under 65 years-old (OR 2.4, 95% CI 1.1-5.3, p=0.025), community-acquired IE (OR 3.4, 95% CI 1.5-7.6, p=0.003), absence of acute heart failure (OR 4.1, 95% CI 1.8-9.1, p=0.001) and controlled infection (OR 3.0, 95% CI 1.3-6.5, p=0.007), as well as surgical treatment (OR, 95% CI 2.0-9.9, p<0.001).

Conclusion: The heterogeneity of this condition justifies the major role of a multimodal diagnostic and therapeutic approach. Therefore, identification of severity predictors is critical to select and reference complicated patients to Endocarditis Team Centres.

P340

Echocardiographic score, survival and event free-survival after mitral balloon valvuloplasty. follow-up of 25 years.

I P Ivana Borges¹; ECS Peixoto²; RTS Peixoto¹; RTS Peixoto²; AAB Aragao¹; VF Marcolla¹

¹Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; ²Fluminense Federal University, Rio de Janeiro, Brazil

Introduction: Percutaneous mitral balloon valvotomy (PMBV) has become an accepted alternative for surgical commissurotomy for the treatment of mitral stenosis.

Objectives: To identify the independent predictors of death and combined events (death, new mitral balloon valvotomy, or mitral valve surgery) in long-term follow-up of patients undergoing PMBV.

Methods: From 1987 to 2013 a total of 312 patients were followed-up 54.0 ± 31.0 (1 to 126) months. The techniques were the single-balloon (84.4%), Inoue-balloon (13.8%), and double-balloon techniques (1.7%). The total group was divided in two: echocardiographic score > 8 and ≤ 8 points groups. Multivariate Cox regression analysis was performed to identify independent risk factors of long-term survival and event free survival.

Results: The mean age were 38.0 ± 12.6 years old (range, 13 to 83). Before the procedure, 84.42% patients had echo score ≤ 8 , and 15.57% score > 8 . Females comprised 85%, and 84% patients were in sinus rhythm. During follow-up, survival of the total group was 95.5%, echo score group ≤ 8 was 98.0% and echo score > 8 was 82.2% ($p < 0.0001$), whereas combined event-free survival was 83.4%, 86.1%, and 68.9%, respectively ($p < 0.0001$). In multivariate analysis, independent risk factors of death were pre procedure echo score > 8 and the presence of severe mitral valve regurgitation during the procedure. The predictors of combined events were a previous history of mitral valvular commissurotomy, atrial fibrillation, the presence of severe mitral valve regurgitation during the procedure and post procedure mitral valve area < 1.5 m².

Conclusion: PMBV is an effective procedure. Survival was high, even higher in the group with lower echocardiographic scores. Over 2/3 of the patients were event-free at the end of follow-up. Independent predictors of survival were pre procedure echo score ≤ 8 and the absence of severe mitral valve regurgitation during the procedure.

Tricuspid annuloplasty: a ring or not?

S Charfeddine¹; R Hammami¹; F Triki¹; M Jabeur¹; L Abid¹; S Kammoun¹; S Elleuch²; I Souissi²; I Frikha³

¹Hédi Chaker hospital, cardiology, Sfax, Tunisia; ²Habib Bourguiba University Hospital, Anesthesia department, Sfax, Tunisia; ³Habib Bourguiba hospital, cardiovascular department, Sfax, Tunisia

Introduction: Uncorrected tricuspid regurgitation (TR) has serious long-term morbidity and mortality. We reviewed our experience with DeVega tricuspid versus ring tricuspid annuloplasty for treatment of TR.

Methods: From 1999 to 2013, clinical and echocardiographic data of patients who underwent Tricuspid annuloplasty were recorded. Pre and postoperative transthoracic echocardiograms were assessed for severity of TR. Moderate or greater TR was considered significant. Development of recurrent TR was evaluated by COX analysis. TR and risk factors for recurrent regurgitation were identified and analysed by multivariable ordinal longitudinal methods.

Results: Ninety-one patients underwent tricuspid annuloplasty for TR as part of their cardiac surgical procedure. De-Vega annuloplasty was performed in 46 patients and ring annuloplasty in 45 patients. Preoperatively, all patients had moderate or greater TR with a median regurgitation of 3+. The mean follow-up time was around 3 years. At 3 years postoperatively, TR in patients treated by DeVega annuloplasty was significant in 30.4% of patients. In those undergoing ring annuloplasty, TR was significant in only 13.3%. There was a significant difference between the two groups ($p = 0.04$). Risk factors for recurrent TR included higher pre and postoperative pulmonary artery systolic pressure.

Conclusion: Ring annuloplasty had lower rate of recurrence TR compared with De Vega's suture repair.

P342

The association between hs-CRP, hs-TnT and NT-proBNP, and all-cause mortality in operated versus non-operated patients with severe aortic valve stenosis.

University of Oslo, Oslo University Hospital and the National Union of Public Health in Norway.

A Auensen¹; Al Hussain¹; Kl Pettersen¹; T Ueland²; L Gullestad¹

¹University of Oslo, Faculty of Medicine, Department of Cardiology, Oslo, Norway;

²Oslo University Hospital, Research Institute of Internal Medicine, Oslo, Norway

Introduction: A proper evaluation and risk stratification is important in patients with severe aortic stenosis (SAVS) as operation is associated with improved survival and quality of life, while refusal is associated with high mortality. We investigated whether use of high sensitivity C-reactive protein (hs-CRP), high sensitivity troponin T (hs-TnT) and N-terminal pro brain natriuretic peptide (NT-proBNP) and could be useful in risk stratification in patients with SAVS.

Purpose: To examine the prognostic value of hs-CRP, hs-TnT, and NT-proBNP levels in relation to all-cause mortality in patients with SAVS

Method: Of 480 patients with SAVS evaluated for AVR, 351 had surgical- and 38 transcatheter-AVR (OP), while 91 were declined operative treatment (NON-OP). On day of operation for OP and day of inclusion in the study for NON-OP, plasma levels of hs-CRP, hs-TnT and NT-proBNP were analyzed by enzyme immunoassay.

Results: During a median follow-up of 418 (103) days, 45 (9.4%) patients died. At inclusion, all patients had echocardiographic evidence of SAVS. The strongest conventional predictors of death were AVR (Hazard ratio, HR [95% CI] 0.29 [0.16-0.54] $p < 0.001$), diabetes (2.53 [1.29-4.96] $p = 0.007$), NYHA class 1.84 [1.19-2.84] $p = 0.006$ and LVEF (2.20 [1.11-4.36] $p = 0.024$). Analyzed separately and adjusting for these covariates in multivariable analysis revealed that hs-CRP (HR 1.38 [1.05-1.80] $p = 0.021$), NT-proBNP (HR 1.67 [1.16-2.41] $p = 0.002$) and hs-TnT (HR 1.30 [1.01-1.67] $p = 0.042$) were independently associated with death. However, NT-proBNP was the only biomarker that remained in the model when all three biomarkers were included in a stepwise approach. When analyzed separately, NT-proBNP gave similar prognostic information in patients who had AVR (HR 2.04 [1.30-3.22] $p = 0.002$) or not (HR 2.16 [1.30-3.59] $p = 0.003$) in univariate analysis. None of the 60 patients with all three biomarkers in the normal range (i.e. hs-CRP ≤ 2.0 , hs-TnT ≤ 14 and NT-proBNP ≤ 35) died during follow up.

Conclusion: Results from this study show that for patients with SAVS, NT-proBNP is associated with all-cause mortality at 14 months in adjusted analysis. High sensitivity CRP or hs-TnT gave no additional prognostic information. This suggest that the level of NT-proBNP should be considered when deciding whether to operate or not in patients with SAVS.

P343

Mitraclip percutaneous mitral valve repair, results in clinically-unstable heart failure patients

A Manovel Sanchez¹; A Ana Lopez Suarez¹; R Cardenal Piris¹; M Marquez Fernandez²; JF Diaz Fernandez¹

¹Hospital Juan Ramon Jimenez, Cardiology Service, Huelva, Spain; ²Hospital Juan Ramon Jimenez, Intensive Care Unit, Huelva, Spain

Percutaneous edge-to-edge mitral valve (MV) repair with MitraClip System has become established as an alternative treatment in high surgical risk patients with severe mitral regurgitation (MR), presenting different heart failure (HF) stages. We performed the present study to report the outcomes of Mitraclip implantation in unstable HF patients with severe MR. Twelve HF patients were consecutively treated with Mitraclip (2013–2015) at a hospital without onsite cardiac surgery. Six procedures (50%) performed in clinically-unstable (NYHA IV) patients. Groups (unstable vs stable) were similar in gender and age: men represented 33.3% vs 50% ($p = 0.55$), with a median age of 63.5 (interquartile range IQR 56.25–71.50) vs 71 years old (IQR 62.5–76.75; $p = 0.18$). Unstable patients exhibited higher non-significant functional-ischemic MR (83.3% vs 66.7%, $p = 0.51$) and left ventricular (LV) severe dysfunction (50% vs 33.3%, $p = 0.56$). LV sizes were similar EDLVD 59 mm (IQR 52.5–67) vs 60 mm (IQR 55–66.5, $p = 1$). There was no differences regarding MR reduction measured by transesophageal echocardiography (\leq grade 2 MR: 66.7% vs 83.3%, $p = 0.5$), residual transmittal-gradient (2 mmHg, IQR 2–3.5, vs 3, IQR 2.5–3.5, $p = 0.37$) or > 1 clip implantation (33.3% vs 66.6%, $p = 0.24$). One stable patient was reoperated due to early partial-clip-detachment. Post-procedure hospital stay showed no significant difference: 11 days (IQR 7.5–50) vs 7.5 days (IQR 4.75–32.5, $p = 0.41$). 30-days post-procedure mortality were similar (16.7% vs 0%, $p = 0.29$) and 30-days NYHA functional class was 100% \leq II in both groups. Median follow-up was 15.5 months (IQR 3–26) and 11 months (IQR 3–16.75) respectively. Finally, no significant differences were found in all causes death (50% vs 16.6%, $p = 0.4$), however it tends to be higher in unstable group. In conclusion, Percutaneous MV repair seems to be equally effective and safe in clinically stable and unstable patients, affording hospital discharge for acute-refractory HF patients with severe MR.

Functional improvement analysis 1 year after per-cutaneous mitral valve repair

The study was supported by Valtech Cardio

Y Yan Topilsky¹; NG Nickenig²; VA Vahanian³; BS Baldus⁴; AO Alfieri⁵; CA Colombo⁶; KH Kuck⁷; MS Maisano⁸

¹Sourasky Medical Center, Cardiology, Tel Aviv, Israel; ²University Hospital Bonn, Cardiology, Bonn, Germany; ³Hospital Bichat-Claude Bernard, Paris, France;

⁴University of Cologne, Cologne, Germany; ⁵San Raffaele Hospital of Milan (IRCCS), Milan, Italy; ⁶San Raffaele Scientific Institute, Milan, Italy; ⁷Asklepios

Clinic St. Georg, Hamburg, Germany; ⁸University Heart Center, Zurich, Switzerland

Aim: The purpose of the study was to describe the changes in exercise tolerance (6MWT) after Cardio-band per-cutaneous mitral annuloplasty and the predictors of improvement.

Methods: Between February 2013 and October 2015, 49 patients with functional mitral regurgitation (MR) underwent transfemoral transseptal valve repair with Cardioband system of which 31 patients reached 1 year follow up. All patients had \geq moderate-severe functional MR at baseline and were considered high risk for surgery. Fourteen matched cases of 6 minute walk distance are available at one year follow up; 8 patients failed to perform the 6MWT at 1 year follow up or baseline, 5 patients died during the first year post procedure (unrelated to the Cardioband device) and 4 patients withdrew from the study.

Results: The six minute walking distance increased significantly from 279 ± 108 at baseline, to 351 ± 151 at one year post procedure ($p < 0.001$). Improvement in walking distance was associated with improvement in MR ($p = 0.04$), and stroke volume ($p = 0.05$), but not necessarily with changes in LV size or function. One patient (7%) exhibited worsening and 5 patients (36%) showed no change of distance walked compared to 8 patients (57%) with improved exercise tolerance 1-year after Cardioband implantation. Patients with worsened distance had higher right atrial pressure ($p = 0.04$), and less MR at baseline ($p = 0.07$). Univariate analysis using all clinical, demographic and echo parameters identified only higher right atrial pressure ($p = 0.03$), and less MR at baseline ($p = 0.02$ for grade, $p = 0.02$ for regurgitant volume), to be predictive of no improvement in 6-minute walk distance.

Conclusion: Most patients undergoing Cardioband per-cutaneous mitral repair show enhanced exercise capacity (assessed by the 6MWT), associated with improved MR and increased stroke volume, extending to at least 1-year after the procedure.

P345

Timing and mid-term outcomes for valve replacement in adult patients with pulmonary regurgitation following right ventricular outflow tract reparative surgery - Single center experience

P Pedro Pinto-Teixeira¹; A Agapito¹; L Sousa¹; J Oliveira¹; L Branco¹; R Rodrigues²; J Martins³; F Pinto³; J Fragata²; R Ferreira¹

¹Hospital Santa Marta, Department of Cardiology, Lisbon, Portugal; ²Hospital de Santa Marta, Department of Heart Surgery, Lisbon, Portugal; ³Hospital de Santa Marta, Pediatric Cardiology, Lisbon, Portugal

Purpose: Surgical relief or right ventricular (RV) outflow tract obstruction in patients with tetralogy of Fallot (TOF) or similar physiology often results in pulmonary regurgitation (PR). The resultant chronic volume overload can lead to RV dilation, heart failure symptoms and arrhythmias, prompting pulmonary valve replacement (PVR). Our aim is to characterize the population and assess the mid term outcomes for bioprosthetic pulmonary valve replacement (PVR) in adult patients (P) with a previous corrective surgery resulting in PR.

Methods and Results: We retrospectively analysed 41 P (39.2 ± 8.4 years; 66% male) who underwent bioprosthetic PVR in our centre due to PR. All P had previous RV outflow tract (RVOT) reparative surgery, namely: TOF (33 P), pulmonary stenosis (6 P) and double outlet right ventricle (DORV) with pulmonary atresia (2 P). Mean age at corrective surgery was 9.2 ± 8.5 years; 44% had previous palliative procedures. Within TOF patients, 85% had RVOT reconstructive surgery with transannular patch. Bioprosthetic PVR occurred at a mean age of 36.4 ± 8.7 years with a mean interval between initial reparative surgery and PVR of 27.2 ± 5.9 years. Indication for PVR were symptoms and signs attributable to RV volume overload and/or RV end diastolic volume index (RVEDVI) $> 150 \text{ mL/m}^2$ on magnetic resonance imaging (MRI). Mean pre-operative MRI parameters for this population were: RVEDVI $186 \pm 51 \text{ mL/m}^2$, RV ejection fraction $44 \pm 9\%$, PR fraction $51 \pm 11\%$, left ventricular ejection fraction $58 \pm 9\%$. Bioprosthetic valve type used was CE Perimount Magna in 38 P and St Jude Epic in 3 P, with valve sizes implanted of 25mm ($n = 33$) and 23mm ($n = 8$). Half of the patients had concomitant procedures, mainly RVOT reconstruction or tricuspid valve annuloplasty. Mean cardiopulmonary bypass and aortic cross-clamp times were 72 ± 32 and 54 ± 22 minutes respectively. 15 P (36.5%) performed surgery under beating heart. Perioperative morbidity was low (significant bleeding in 1P, hemothorax in 1P and early RV dysfunction with ventricular arrhythmias in 1P). There was no early or late mortality. Mean post-PVR follow-up time was 35 ± 18 months. Patients experienced significant NYHA functional class improvement (from 2.05 ± 0.50 to 1.22 ± 0.42 , $p < 0.001$).

Patients were regularly followed with transthoracic echocardiography and there were no signs of valve dysfunction during the follow-up time (maximum pulmonary systolic gradient 20.9 ± 9 mmHg and regurgitation grading below moderate in all patients).

Conclusions: In this population of adult patients with pulmonary regurgitation, referral to PVR seems to be adequately timed, avoiding RV function deterioration and enabling functional improvement after surgery. Bioprosthetic valves in pulmonary position have low perioperative morbidity and show excellent mid-term outcomes.

P346

The improvement of right ventricular function following percutaneous mitral valve repair using MitraClip system: a two-dimensional speckle-tracking study

O M Galuszka¹; S Rutschow¹; M Gross¹; U Rauch¹; U Landmesser¹; M Kasner¹

¹Charité - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany

Background: Chronic mitral regurgitation (MR) often results in right ventricular (RV) dysfunction due to long-standing pressure and volume overload. Previous studies showed that concomitant tricuspid regurgitation (TR) and pulmonary hypertension in patients undergoing conventional surgery for mitral valve (MV) increases morbidity and mortality, especially in case of a poor right ventricle. It is widely known that percutaneous mitral valve repair (PMVR) improves left ventricular function, but to what extent this affects the right ventricle, remains the area of current research.

Aims: The main objective of present study was to investigate the role of preprocedural right ventricular dysfunction and pre-existing severe pulmonary hypertension assessed by means of two-dimensional echocardiography for patient clinical recovery following PMVR. Moreover, we tried to assess the potential for right ventricular remodeling after volume and pressure overload due to MR has been reversed.

Methods: 58 patients (52% women, 76 ± 6 years) with moderate-to-severe mitral regurgitation (MR 2+) undergoing PMVR using the MitraClip system underwent transthoracic echocardiography at baseline and at six-month follow-up. Right heart echocardiographic parameters included RV diameter, RV systolic strain, TAPSE (tricuspid annular plane systolic excursion), tricuspid regurgitation grade and right atrial volume (RA Vol) whereas severe pulmonary hypertension was defined as systolic pulmonary arterial pressure (sPAP) $> 60 \text{ mmHg}$.

Results: MitraClip implantation resulted in significant improvement of RV systolic strain ($-15.7 \pm 2.3\%$ vs. $-19.1 \pm 2.9\%$, $p < 0.001$), improved New York Heart Association (NYHA) class (3.0 ± 0.5 vs. 2.3 ± 0.7 , $p < 0.05$), diminished RA volumes ($46 \pm 10 \text{ mL}$ vs. $38 \pm 10 \text{ mL}$, $p < 0.001$) as well as reduced estimated pulmonary pressure (sPAP; $52.5 \pm 11.5 \text{ mmHg}$ vs. $42.5 \pm 14.1 \text{ mmHg}$, $p < 0.05$). However, no change in TR grade was noted. In the subgroup of patients with pulmonary hypertension (PAH, $n = 12$ patients) baseline RV systolic strain was lower, yet showed a tendency for improvement ($-13.7 \pm 2.1\%$ vs. $-16.1 \pm 2.7\%$, $p < 0.001$), accompanied by reduced sPAP ($68.1 \pm 7.5 \text{ mmHg}$ vs. $55.7 \pm 7.2 \text{ mmHg}$, $p < 0.05$). Most importantly, neither improvement in terms of NYHA class nor significant changes in any of the other RV parameters was observed in patients with severe PAH.

Conclusions: Our results confirm that percutaneous MV repair, in contrast to conventional MV surgery, does not negatively affect RV function. Due to the reduction in RV afterload, PMVR alleviates pressure overload thus leading to reduced RA volumes, improved RV contractility and ameliorated patient clinical status. In PAH patients, PMVR reduces sPAP and improves RV systolic function, but adversely affects NYHA functional class. Basing on our results, one might conclude that patients with pre-existing severe PAH exhibit little clinical benefit from the procedure.

Effectiveness of transcatheter aortic valve implantation in patients with pure native aortic valve regurgitation

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; AJ Dominguez-Franco³; JM Garcia-Pinilla³; JJ Gomez-Doblas³; MF Jimenez-Navarro³; JH Alonso-Briales³; JM Hernandez-Garcia³; E De Teresa-Galvan³

¹Department of Cardiology, Malaga, Spain; ²Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

There are patients with severe aortic regurgitation and at high or extreme surgical risk for whom conventional surgical aortic valve replacement may be unsuitable and who might benefit from transcatheter-based therapy. The aim this study was to evaluate the use of Transcatheter Aortic Valve Implantation (TAVI) in patients with pure native aortic valve regurgitation and comparing them with patients with aortic stenosis.

Methods: From April 2008 to December 2015, the CoreValve prosthesis, was implanted in 13 (2.6%) consecutive high-risk surgical patients with symptomatic severe aortic regurgitation (AR) and in 487 patients with aortic stenosis (AS).

Results: The mean age was lower in AR 71.3 ± 19 vs. 79.3 ± 6 years, $p = 0.001$ and logistic EuroSCORE was similar in both groups (AR vs. AS) and $16.5 \pm 8\%$ vs. 17.2 ± 12 , $p = 0.787$. There were significant differences in measurement of annulus and ascending aortic size (24.2 ± 1.8 vs. $22.1 \pm 1.8 \text{ mm}$, $p = 0.001$ and 34.1 ± 4.4

vs. 31.6 ± 4 mm, $p=0.034$, respectively). Implantation of a TAVI was performed successfully in all patients with AR and the post-procedure aortic regurgitation grade was: absent in 30.8%, middle in 30.8%, moderate in 23.1% and moderate-severe in 15.4%. The NYHA functional class improved from 3.2 ± 0.6 to 1.6 ± 0.5 and remained stable at one year. The mortality at 30 days was 7.7 % in patients with AR compared to 3.5% in patients with AS, $p=0.422$ and there was non significant differences with late mortality (16.7% vs. 19.9%, $p=0.780$) after a mean follow-up of 34.3 ± 23 months. The patients with AR had more acute kidney injury after procedure and lower occurrence new onset left bundle branch block than patients with AS 38.5% vs. 15.7% [OR=3.35 (95% CI 1.07-10.5), $p=0.045$] and 8.3% vs. 47.4%, [OR=0.101 (95% CI 0.01-0.791) $p=0.006$], respectively.

Conclusions: Treatment of high-risk patients with pure native aortic regurgitation using a self-expandable prosthesis is a safe and efficient option in long-term follow-up

Comparison of transcatheter aortic valve implantation versus surgical aortic valve replacement and medical treatment: A systematic review and meta-analysis

A Ak¹; I Porokhovnikov¹; F Kuethe²; M Noutsias³; P Schlattmann¹

¹Institute of Medical Statistics, Friedrich-Schiller University Jena, Jena, Germany;

²HELIOS Klinik Herzberg/Osterode, Department of Cardiology, Herzberg am Harz, Germany; ³University Hospital Jena, Department of Cardiology, KIM I, Jena, Germany

Introduction: Transcatheter aortic valve replacement (TAVI) is a promising therapy option for patients with severe aortic stenosis, multiple comorbidities and high risk for surgical aortic valve replacement (SAVR).

Purpose: To compare TAVI with SAVR and with medical therapy (MT) by meta-analysis.

Methods: A systematic review was conducted by two independent investigators. We carried out literature search using Medline (via PubMed), the Cochrane Library and Embase, and reference lists of identified primary studies. We included articles written in English, German, or Turkish that compared TAVI with other treatment options based on all cause-mortality, and which contained baseline characteristics of Gender, Age and EuroSCORE. Patients without aortic stenosis, healthy subjects and data with less than 30-days follow-up time were excluded. Relative Risk (RR) was calculated and graphically displayed in forest plots. We used I^2 for heterogeneity and determined the source of it by metaregression. Funnel plots were investigated by Egger's regression test of asymmetry.

Results: 22 studies, existing of 19 observational studies and three randomized controlled trials, with a total of 6.539 patients were included. Compared with MT, TAVI showed a statistically significant benefit for all-cause mortality at 12 months (RR=0.68, 95% CI 0.49-0.95) and at 24 months (RR=0.75, 95% CI 0.44-1.27). TAVI versus SAVR, overall result on 12 months showed significant advantage for SAVR (RR=1.23, 95% CI 0.95-1.60). To be in contrast with that our subgroup analysis with two randomized controlled trials militated here a minimal better result for TAVI (RR=0.91, 95% CI 0.91-1.14). Long-term outcome between SAVR and TAVI at 2 years presented no significant difference (RR=1.09, 95% CI 1.01-1.17). Mean age showed a substantial influence on long-term survival (OR=7.375, 95% CI 0.78-69.43).

P349

Outcome predictors in ICD patients with ischemic left-ventricular dysfunction

H Helena Nascimento¹; M Braga¹; V Ribeiro¹; F Melao¹; SM Oliveira¹; M Vasconcelos¹; P Dias¹; C Frutuoso¹; MJ Maciel¹

¹Sao Joao Hospital, Porto, Portugal

Background and objective: Left ventricular (LV) dysfunction is a strong predictor of prognosis. Apart from the benefits of optimal medical therapy, the importance of implantable cardioverter-defibrillator (ICD) is undeniable. The goal of this study was to recognise prognostic indicators in patients with ischemic cardiomyopathy regarding appropriated therapy (defined as occurrence of ATP or shock triggered by ventricular arrhythmia at first event), hospital readmissions and mortality.

Material and methods: We performed a retrospective analysis of patients with LV systolic dysfunction who were submitted to ICD implantation from June 2012 to December 2014. Clinical data was collected and inserted in a registry base.

Results: From a total of 112 patients, 62 had a diagnosis of ischemic cardiomyopathy, the majority of those were male (93.5% vs 6.5%, $p=0.008$) and older (mean age 65.0 ± 9.6 vs 61.1 ± 10.8 years, $p=0.048$). At least one cardiovascular risk factor was present in 98.4% of these patients, being hypertension the most frequent (68.9%). Comparing the echocardiographic findings before implantation, there was no significant difference in the LV ejection fraction (26.4 ± 9.5 vs 23.9 ± 8 %, $p<0.05$); however, the telediastolic LV diameter was significantly higher (66.4 ± 11.1 vs 62.4 ± 8.4

mm, $p=0.042$). In the group of patients with ischemic cardiomyopathy, 58.1% had ICD implanted for secondary prevention. The most common first event trigger was ventricular tachycardia (77.3%), and appropriated therapy was delivered in 30.6%. The only predictor of appropriated therapy at the first event was non-sustained ventricular tachycardia (OR 6.1, 95% CI 1.6-24.1, $p=0.01$). During a mean follow up period of 20.5 ± 9.2 months, 24 patients were readmitted to the hospital, 9 deaths occurred, and only 1 case of device-associated infective endocarditis was recorded. The occurrence of ICD shocks was a predictor of both hospital readmission and death.

Conclusion: ICD role in preventing sudden cardiac death (SCD) is well established in different groups of patients. Our study highlighted the occurrence of events like episodes of non-sustained ventricular tachycardia as predictors of appropriated therapy. These findings emphasize the importance of rhythm surveillance in patients with ischemic cardiomyopathy and LV systolic dysfunction in order to prevent SCD.

Effect of left ventricular assist device placement on preexisting implantable cardioverter-defibrillator leads

A Aggeliki Gkouziouta¹; D Millopoulos¹; A Kostopoulou¹; G Poulos¹; TH Maounis¹; E Livanis¹; G Theodorakis¹; L Louca¹; N Kogerakis¹; S Adamopoulos¹

¹Onassis Cardiac Surgery Center, Athens, Greece

Purpose: The left ventricular assist device (LVAD) is a therapy for patients with end-stage heart failure, many of whom have a preexisting implantable cardioverter-defibrillator (ICD). We investigated whether the implantation of a LVAD affects ICD function.

Methods: Patients implanted with a LVAD between December 2003 and April 2015 were studied. Right ventricular (RV), right atrial, and left ventricular lead impedance, sensing, and capture thresholds were recorded before and after LVAD placement and subsequent lead-related interventions were noted. Of the 35 patients receiving a LVAD, data were collected from 28 patients who had preexisting ICDs. Significant pre-post differences were noted for all RV lead parameters: sensing amplitude decreased from 8.2 ± 2.1 to 4.7 ± 2.6 millivolts ($P<.001$); impedance decreased from 479 ± 118 to 418 ± 94 ohms ($P=.008$); and threshold increased from 4.3 ± 6.7 to 11.0 ± 16.8 microjoules ($P=.021$). As a result of alterations in lead parameters, 2 patients required lead revisions and all the patients required ICD testing every 6 months.

Conclusion: Differences in ICD lead function were observed after LVAD placement resulting in clinically significant interventions. These data suggest that ICD interrogation be performed post-LVAD placement and that patients be counseled for the potential need for lead revisions and ICD testing when consented for a LVAD

Non-invasive hemodynamic assessment in LVAD patients: validation of a bed-side echocardiographic approach.

F Giordana¹; S Frea¹; S Stefano Pidello¹; V Bovolo¹; A Galluzzo¹; S Bergerone¹; A Baronetto¹; P Centofanti¹; M Rinaldi¹; F Gaita¹

¹Hospital 'Città della Salute e della Scienza di Torino', Turin, Italy

Introduction: Non-invasive hemodynamic evaluation of patients with LVAD represents a pivotal tool in order to optimize medical therapy and pump setting and to identify any malfunctions. However, no data exist about the accuracy and reliability of echocardiographic hemodynamic evaluation.

Purpose: Aim of the study was to validate a prespecified echocardiographic protocol for the estimation of invasive parameters.

Methods: In this pilot observational study we enrolled LVAD (HeartWare) patients who underwent right heart catheterization (RHC) according to clinical judgment. Within 1 hour before the procedure, transthoracic echocardiogram was performed by two independent operators blinded to hemodynamic data. According to an internal protocol, right atrial pressure (RAP) was estimated matching inferior cava vein diameter and collapsing with hepatic vein flow and right E/E', while left atrial pressure (LAP) combining RAP first with inter-atrial septum position (eLAP1) and then with mitral inflow pattern and Tissue Doppler variables (eLAP2). Results We enrolled 12 patients (age 52.3 ± 14.3 years; 11 males; 8 with ischemic cardiomyopathy; all in sinus rhythm at the time of evaluation) between September and December 2015. At RHC mean systemic arterial pressure was 83.6 ± 8.1 mmHg, mean cardiac index 2.5 ± 0.3 l/min/m², mean systolic pulmonary arterial pressure 44.9 ± 11.4 mmHg, mean LAP 20.6 ± 8.1 mmHg, mean RAP 11.1 ± 4.5 mmHg. We found a strong correlation between estimated and invasive RAP ($r=0.94$, $r^2=0.88$, $p<0.001$) and LAP ($r=0.96$, $r^2=0.92$, $p<0.001$). The estimation of LAP was mildly improved by Doppler analysis ($r=0.88$ vs. 0.96) as the evaluation with only RAP and inter-atrial septum position moderately underestimated LAP (eLAP1 vs. eLAP2, 11.9 ± 5.9 vs 17.2 ± 5.6 mmHg, $p=0.08$).

Conclusion: In this pilot observational study we validated a simple bed-side non-invasive protocol for the estimation of RAP and LAP in LVAD patients.

P352

The role of left ventricular assist device therapy for patients with end-stage heart failure - serbian experienceE Emilija Nestorovic¹; N Milic²; S Putnik¹; D Terzic¹; M Ristic¹¹Clinic for Cardiac Surgery, UC Clinical Centre of Serbia, Belgrade, Serbia;²Institute for medical statistics and informatics, Belgrade, Serbia

Background: Heart transplantation (HTx) is a realistic option for only a small number of end-stage heart failure (HF) patients. Due to organ donor shortage and a growing number of HTx ineligible patients, left ventricular assist device (LVAD) has become a more beneficial option.

Purpose: The goal of this study was to report our single-center experience concerning the treatment of patients with advanced HF with LVAD support.

Methods: Overall, 38 patients received long-term LVAD from 2013 to 2015; 7,9 % underwent HTx after a median duration of LVAD support of 13 months. The majority of subjects were male gender (94,7%). The most frequent etiology of the HF was ischemic cardiomyopathy (52,6%). Regarding the INTERMACS profile, the 52,6% of patients were profile 4, and 26,3% profile 2. The median follow up for consequent outcomes (overall survival and adverse events) was 7 (23) months.

Results: The mean age of patients was $50,24 \pm 14,6$. Median duration of LVAD support was 7 (23) months. The overall 30 day, 6-months and 1-year survival were 91,2%, 88,5% and 76,2%. Any kind of adverse events were present in 20 (52,6%). Serum creatinine, blood urea nitrogen, total bilirubin, infection and renal failure were associated with a significant decrease of overall survival rate in the Univariate Cox regression analysis ($p < 0,05$), and renal failure was found to be an independent risk factor for the overall survival in multivariate Cox regression analysis ($p = 0,035$).

Conclusion: LVAD is associated with acceptable mortality rate, similar to heart transplant. It represents an effective treatment option for patients with end-stage HF. Renal failure is common following LVAD implantation and is an independent risk factor for overall survival. The resolution of optimal timing of LVAD implantation will contribute in better survival rate.

P353

Can a preoperative management checklist improve outcome after LVAD implantation?V Bovolio¹; S Frea¹; S Pidello¹; A Galluzzo¹; S Bergerone¹; A Baronetto²; P Centofanti²; M Rinaldi²; F Gaita¹¹Hospital 'Città della Salute e della Scienza di Torino', Cardiology, Turin, Italy;²Hospital 'Città della Salute e della Scienza di Torino', Cardiac Surgery, Turin, Italy

Background: Left ventricle assist device (LVAD) is a reliable and effective treatment in selected patients with advanced heart failure. Adequate candidate preparation is mandatory.

Purpose: To evaluate the impact on short-term outcome of a checklist (CL)-guided pre-operative management of candidate patients to LVAD implantation.

Methods: Since July 2013 we conceived and implemented a pre-operative CL-guided approach for LVAD candidates (a brief version of CL is shown in Figure 1). The CL focuses on accurate evaluation of post-implantation thrombotic and hemorrhagic risk, research and treatment of silent infections, assessment and improvement of psychological and nutritional status, appraisal of arrhythmias impact on LVAD and right ventricular (RV) function, achievement of optimal hemodynamic (decongestion, LV download, reduction of end-organ damage, sildenafil for out-of-proportion pulmonary hypertension and pre-operative levosimendan). This overall evaluation is divided into 3 stages (once LVAD implantation is indicated, 7 days and 48 hours before LVAD implantation). We prospectively enrolled consecutive LVAD candidates who underwent CL-guided management and compared their short-term events (survival, stroke, bleeding, infections, RV failure) with patients implanted before CL implementation.

Results: We enrolled 25 patients in the CL-guided approach. 5 patients (20.8%) did not undergo LVAD implantation after the overall evaluation (3 for high bleeding risk, 1 for cancer, 1 for psychosocial issues). 20 patients underwent CL-guided LVAD implantation (all continuous-flow devices) were compared to 39 patients implanted before CL implementation. At 1 year after LVAD implantation, 19/20 CL-patients survived vs. 30/39 non-CL patients (HR 0.19, $p = 0.08$), while stroke occurred in 4/20 CL patients vs. 7/39 non-CL patients (HR 0.68, $p = 0.58$), bleeding 2/20 vs 7/39 (HR 0.5, $p = 0.18$), infection in 7/20 vs. 19/39 (HR 0.41, $p = 0.04$), RV failure in 4/20 vs. 3/39 (HR 1.82, $p = 0.42$).

Conclusion: A CL-guided management of LVAD candidates improved both short term survival after LVAD implantation. This result may be driven by a more accurate selection of patients and a more comprehensive pre-operative management.

Brief LVAD Preparation Checklist

P354

Veno-arterial ECMO in terminal cardiogenic shock; lactate role as prognostic factorE Ervis Hiso¹; E Rossi²; L Brugnaro¹; M Perazzolo Marra¹; G Tarantini¹; T Bottio²; L Babuin¹; G Gerosa²; S Illiceto¹; L Cacciavillani¹¹University Hospital of Padova, Cardiology Department, Padua, Italy; ²University Hospital of Padova, Cardiac Surgery Department, Padua, Italy

Introduction: terminal cardiogenic shock is characterized by severe hemodynamic instability with high mortality rate (>70-80%). In most critical patients, unresponsive to inotropic agents and intra-aortic balloon pump (IABP), extracorporeal membrane oxygenation (ECMO) is the only therapy available nowadays that gives a possibility to survive because it guarantees continuous organs perfusion waiting for cardiac function recovery, left ventricular assist device or transplantation.

Purpose: a) improve outcome in terminal cardiogenic shock; b) find prognostic factors.

Methods: from 1st January 2009 to 30th April 2015 we prospectively analyzed patients admitted for acute heart failure in cardiac intensive care unit who developed terminal cardiogenic shock which required veno-arterial ECMO.

Results: 52 patients affected by myocardial infarction (30%), ventricular malignant arrhythmias (29%), dilated cardiomyopathy (25%), myocarditis (12%), pulmonary embolism (4%). 72% male gender, median age 57. Duration of ECMO support: 10 ± 9 days. Outcome: 14 patients (27%) died during ECMO because of multi organ failure, sepsis and bleeding; recovery: 13 patients (25%); bridge to ventricular assist device as destination therapy: 15 patients (29%); bridge to heart transplantation: 10 patients (19%). 12/38 patients died during hospitalization after ECMO removal; 26/52 (50%) were discharged with one year overall survival of 88%.

About prognostic factors, applying binary logistic regression model we found that serum lactate's level was the most important one with a mean peak value equal to 3.1 mmol/L. Serum peak value over than 5.2 mmol/L during ECMO support predicted in ECMO mortality with an area under the curve (AUC) of 0.9236 and a p value < 0.001 ; combination between Sequential Organ Failure Assessment (SOFA) score and peak lactate's level during ECMO support over than 2.9 mmol/L predicted in hospital mortality with an AUC of 0.8426 and a p value of 0.003.

Conclusions: a) ECMO allowed us to reduce in hospital mortality with an optimal percentage of survival after discharge; b) in literature different scores have been proposed to predict cardiogenic shock mortality as SOFA, APACHE (Acute Physiology and Chronic Health Evaluation) and SAVE (Survival After Veno-arterial ECMO). Applying serialised dosage of serum lactate in addition to these scores we obtained better results in predicting outcome.

²University Hospital Puerta de Hierro Majadahonda, Cardiac Surgery, Madrid, Spain;

³University Hospital Puerta de Hierro Majadahonda, Anesthesia, Resuscitation and critical care, Madrid, Spain

Introduction: Heart transplantation (HTx) has been the treatment of choice for patients with advanced heart failure for the last three decades. However, the scarcity of organ donors fails to meet the demands of an increasing waiting list. To alleviate this burden ventricular assist devices (VADs) have emerged for support as a bridge to transplantation (BTT) and destination therapy (DT). Patients with VADS who undergo HTx have operative conditions that differ from patients without VAD. Although they have better end-organ function and nutritional status, risks such as bleeding, infection and surgical times may be higher.

Purpose: To describe the immediate postoperative outcomes of patients who undergo HTx with pulsatile LVAD compared to those without VAD.

Methods: Patients with advanced heart failure who underwent HTx between 2009 and 2015 were retrospectively evaluated. Patient characteristics and perioperative variables up to the time of discharge were compared between patients who had received HTx with pulsatile VAD support and those without VAD.

Results: 16 patients underwent HTx with previous VAD implantation vs 53 without VAD during the study period. All 16 patients with VAD and 33 (62%) without VAD were male. Age at the time of HTx in patients with VAD was 45 years (+/- 12.6) and 52 (+/- 11.5) in patients without VAD. Mean duration of VAD support was 137 days (+/- 79). Cardiopulmonary bypass time was on average 133 (70-215) minutes in patients without VAD vs 196 (74-360) with VAD ($p = 0.145$); median ICU stay was 4 (1-90 days) days in patients without VAD and 3 (1-26) days with VAD ($p = 0.024$), initial intubation lasted a mean of 8.5 days (0.25-54) in patients with VAD vs 4 (0.25-62) days in patients without VAD ($p = 0.5$). Patients with VAD received a mean of 15 RBC units vs 6.7 units in those without VAD ($p = 0.145$), 5.9 platelets apheresis units vs 2.4 ($p = 0.002$) and 27 fresh frozen plasma vs 7.2 U ($P = 0.001$). Rate of infection identified by procalcitonin levels > 2 mcg/L were observed in 8 (66.7%) patients with VAD vs 21 (42%) without VAD ($p = 0.197$); 5 (9.4%) patients without VAD had stroke vs none of the patients with VAD ($p = 0.58$); cellular allograft rejection occurred in 3 (18.7%) patients with VAD and in 15 (28.3%) patients without VAD ($p = 1.0$). Three patients (18.7%) with VAD died in the immediate postoperative period vs 16 (28%) without VAD ($p = 0.533$).

Conclusions: Patients who undergo pulsatile VAD implantation as bridge for heart transplantation have similar outcomes during the early posttransplant period compared to patients without VAD, though they receive more blood products to reverse anticoagulation and have a slightly shorter ICU stay.

P356

Copeptin in heart failure, post left ventricular assist device and post heart transplantation

Swedish Research Council, the Swedish Heart Lung Foundation and the Stockholm County Council

S Stanislava Zabarovskaja¹; C Hage¹; A Gabrielsen¹; L Mellbin¹; L H Lund¹

¹Karolinska Institute, Cardiology, Stockholm, Sweden

Background: Heart failure (HF) is associated with pathological activation of arginine vasopressin, measured in plasma by the pre-hormone fragment copeptin.

Purpose: To test the hypothesized that copeptin is elevated and associated with worse prognosis in HF, and that left ventricular assist device (LVAD) therapy and heart transplantation (HTx) are associated with lower levels in copeptin.

Methods: We measured copeptin in groups of 49 patients with advanced HF, 13 patients one year post-LVAD and 22 patients one year post-HTx and correlated with clinical data and cardiac output. In HF we assessed the prognostic role of copeptin with Kaplan-Meier analysis and multivariate Cox regression.

Results: In HF, median (interquartile range) copeptin was 28 (18-45) pmol/L, after LVAD 16 (6-27) pmol/L, and after HTx 12 (5-20) pmol/L (p overall < 0.001). In HF, copeptin was an independent predictor of death, LVAD or HTx (hazard ratio for log copeptin, 3.28 [95% confidence interval: 1.66-6.50], $p = 0.001$). Conclusions Copeptin was elevated in and independently predicted prognosis in HF. Copeptin was progressively lower after LVAD and HTx. This suggests that improvement in cardiac output with LVAD and HTx may induce progressively reduced activation of vasopressin, which may be a marker for the beneficial effects of LVAD and HTx.

⁴UKB Berlin, Berlin, Germany; ⁵Eberhard-Karls University of Tübingen, Tübingen, Germany;

⁶University of Erlangen-Nuremberg, Erlangen, Germany; ⁷Hannover Medical School, Hannover, Germany;

⁸Royal Brompton and Harefield NHS Foundation Trust, Middlesex, United Kingdom; ⁹Cardio Centrum Berlin, Berlin, Germany

Background: Despite optimal medical and device therapy, patients with NYHA Class III/ambulatory IV HF experience high rates of morbidity and mortality. Due to the progressive nature of the disease, patients remain symptomatic requiring hospitalization, transplantation or LVAD thereby placing a significant burden on hospital resource utilization. A novel approach is the use of a para-aortic counterpulsation device (EACD), consisting of an extra-vascular cuff implanted on the ascending aorta. EACD operates on principle of counterpulsation to enhance myocardial perfusion and reduce cardiac afterload, and previous results demonstrate these may potentially be mediated through neuromodulatory mechanisms.

Methods: Data reported were collected following a specified protocol from a European multi-center, post-market study designed to observe the clinical outcomes of heart failure patients treated with EACD.

Results: EACD system implant occurred in 15 patients. EACD significantly improved QOL, 6 min Walk Distance and LV ejection fraction (Table 1). A non-significant trend was observed in pulse pressure and end-systolic volume. No patients experienced stroke or sepsis. Infection rate was 13.3% (2/15) for the entire cohort. Treatment effects were assessed by repeated-measures statistics.

Conclusions: In this cohort of patients with advanced HF, EACD demonstrated improvements in quality of life, functional capacity and cardiac remodeling with a favorable safety profile. Changes observed in the end-systolic volume have been shown to correlate with improved outcomes from several large trials. The modular design and non-obligatory features of the device will facilitate future studies to assess the potential for weaning from therapy.

Right - left ventricular interdependence in patients supported by extracorporeal life support: an echocardiographic study

J Caudron¹; J Caudron¹; N Aissaoui²; A Combes³; P Leprince⁴; E Puymirat¹; J-Y Fagon²; B Diebold⁵

¹Hôpital Européen Georges Pompidou, Université Paris Descartes, Service de cardiologie, Paris, France; ²Hôpital Européen Georges Pompidou, Université Paris Descartes, Service de réanimation médicale, Paris, France; ³Hôpital Pitie-Salpetriere, Service de réanimation médicale, Paris, France; ⁴Hôpital Pitie-Salpetriere, Service de chirurgie cardiaque, Paris, France; ⁵Hôpital Cochin, Service de cardiologie, Paris, France

Background: Right - Left ventricular interdependence may occur in severe heart failure. This dependence (Dep+) can be defined as an abnormal decrease of the left ventricular dimensions in the presence of a right ventricular dilatation induced by an increased preload. In cardiogenic shock patients (pts) supported by Extracorporeal Life Support (ECLS), weaning tests (wt) with decrease of the pump output induce severe pre- and post-load manipulations during which some pts could appear as Dep+.

Aims: To detect the presence of Dep+ pts in a cohort of pts supported by ECLS and to assess its prognostic value, and its echographic correlates. Methods. 33 pts were assessed by echocardiography at D1 (The first day following ECLS implantation) and at DL (The last day before death, heart transplantation or weaning). Weaning success from VA-ECMO was defined as device removal and no further requirement for mechanical support because of recurring cardiogenic shock over the following 30 days. We recorded at each level of support during wt: Left and right ventricular

volumes, Aortic ITV, E mitral flow velocity, Tissue Doppler (Ea and Sa, lateral (L) and Septal (S)).

Results: At D1, 14 pts were Dep+ and 19 Dep-. At D1, the number of post-cardiotomy was similar in the 2 groups. During wt, Dep- pts increased left ventricular volume of 28ml (+/- 26) on D1 ($p < 0.05$) and 31ml (+/-14) on DL whereas Dep+ pts decreased left ventricular volume of 13 ml (+/- 9) on D1 and 27 +/- 21ml on DL ($p < 0.05$). On D1, Dep+ pts and Dep- pts had similar ventricular volumes and LVEF. On DL, Dep+ pts had lower LVEF $14\% \pm 12$ vs 30 ± 14 ($p = 0.001$), lower longitudinal velocities: Sa $S = 4.4\text{cm/s} \pm 1.2$ vs 5.5 ± 1.4 ($p = 0.017$) and lower Aortic ITV $6.3\text{cm} \pm 3$ vs 11 ± 5 ($p = 0.03$). On DL, aortic ITV increased significantly during wt in case of Dep- ($p = 0.04$). At DL, among Dep+ pts, 12 remained Dep+ and none was weaned. The 2/14 Dep+ pts which became Dep-, were weaned. Among the 19 pts who were initially Dep-, 14 remained Dep- and were weaned. 4 Dep- pts became Dep+ and were not weaned. X2 Dep vs weaning: $p < 0.05$.

Conclusion: Right - Left ventricular interdependence is frequent in cardiogenic shock patients assisted by ECLS. It seems to have a strong negative prognostic value which could be helpful to predict weaning from ECLS.

P359

Patient engagement with a novel e-counselling program for heart failure predicts therapeutic change in self-care and quality of life outcomes

Canadian Institutes for Health Research; Peter Munk Cardiac Centre Innovation Fund

RP Nolan¹; H Ross²; B D'antonio³; M White³; S Chan⁴; M Toma⁴; M Farkouh²; M McDonald²; A Payne¹; S Liu¹

¹UHN - University of Toronto, Cardiac eHealth Research Unit, Toronto, Canada;

²UHN - University of Toronto, Toronto, Canada; ³Montreal Heart Institute, Montreal, Canada; ⁴Providence Health Care Research Institute (PHCRI), Cardiology, Vancouver, Canada

Background: A major challenge for e-health programs for heart failure (HF) is to sustain patient engagement to improve therapeutic outcome. Our aim was to identify prototypical patterns of patient engagement with a multifunctional e-platform that proactively sent links over 16 weeks to connect patients with our e-counseling program. We evaluated the dose-response relationship between patient engagement and HF outcomes for self-care and quality of life. Method: We used a k-means partitioning algorithm to evaluate patient engagement (cumulative % e-pages accessed) over 16 weeks for 77 patients with NYHA HF Class I-III. Between- and within-cluster covariance was optimized using the Calinski and Harabatz criterion. Statistical differences between Clusters over time were assessed with spline models. Baseline differences between patient Clusters were examined for demographic and medical features, self-care (6-minute walk test, 6MWT; 4-day step count; Diet History Questionnaire, DHQ, for daily fruit and vegetable intake), stress (Perceived Stress Scale, PSS) and quality of life (Kansas City Cardiomyopathy Questionnaire, KCCQ). The independent dose-response relationship between patient engagement and self-care and quality of life was evaluated with multilinear regression.

Results: Four clusters of patient engagement were identified: $p < 0.001$. For Group 1 (Optimal Engagement, $n = 24$), e-pages were accessed weekly, with engagement above 80% at week 16. In Group 2 (Suboptimal Engagement, $n = 19$) access to e-pages was stable and above 50% at week 16. Group 3 (Disengagement, $n = 14$) failed to respond to the proactive links to our e-platform, and less than 10% of e-pages were accessed at week 16. Group 4 (Habituation, $n = 15$) decreased progressively in engagement with less than 20% of e-pages accessed at week 16. Groups did not differ by sex, age or NYHA Class. Weeks 3, 9 and 12 were critical time-points where trajectories for patient Clusters differed significantly ($p < 0.01$ for each comparison). Cumulative % e-pages accessed over 16 weeks was independently associated with improved KCCQ ($p = 0.01$; dose response, $\beta = 12.6$, 95%CI, 2, 22), 4-day step count ($p = 0.03$), 6MWT ($p = 0.01$), and PSS ($p = 0.03$), but not DHQ fruit and vegetable intake ($p = 0.7$).

Conclusion: Our findings indicate that it is feasible for HF e-counseling programs to (i) monitor patient engagement over time, (ii) identify critical time points in patient response, and (iii) specify the dose-response relationship for outcomes. This information can guide tailoring of program content or incentives to optimize outcomes.

Telemonitoring and teleconsultation in the management of patients with chronic heart failure or chronic obstructive pulmonary disease (progetto Telescopico)

L De Gennaro¹; V Donadeo¹; G Bulzisi¹; G Ricci¹; G Citarelli¹; M Resta¹; ND Natale Daniele Brunetti²; P Caldarola¹

¹Ospedale San Paolo, Bari, Italy; ²University of Foggia, Foggia, Italy

Introduction: A system of tele-monitoring, tele-consultation, and telecare for patients with chronic heart failure (CHF), which allows a continuous interaction between general practitioners (GPs) and hospital cardiologists in the urban area of Bari (Apulia, Italy) has been implemented.

Methods: The project aims to enroll 200 GPs' outpatients with at least one hospitalization for HF in the last year and a NYHA class II/III; all the patients will be followed for one year using an integrated protocol hospital-GP. The study network includes 6 groups of associated GPs and 5 hospitals. All patients will be evaluated at baseline by a cardiologist (blood pressure, ECG, echocardiogram, therapy, quality of life questionnaire), at one month by remote assessment with ECG, every three months by remote assessment and laboratory tests, and finally at 12 months.

The telemedicine system consists of central hospital stations and stations located at the GPs' office permanently interconnected through physical or virtual server (cloud). Direct video communication between multiple locations is also possible by microphone and integrated HD camera (video calls can also be made by mobile devices such as notebooks, smartphones, tablets).

Every GP's unit allows to perform a 5-lead ECG, to monitor vital signs (heart rate, blood pressure, oxygen saturation, respiratory rate (data can be viewed on the high resolution TFT display), to deliver oxygen therapy, or vacuum aspiration, to forward a request for assistance from the central control, to display graphics trends for at least 72 hours.

Central units allows the cardiologist to visualize in real-time waveforms and vital signs recorded by GP's units, to receive video-communications and alerts from any peripheral unit connected, to access clinical data, structured in the form of medical records, and to export data for further analysis and statistical evaluation.

Results: In 6 months 65 patients have been enrolled (41 males, mean age 70 years, 67% with ischemic heart disease, 19% with hypertensive cardiopathy, 14% with valvular heart disease; 65% with NYHA Class II, 45% with NYHA class III, 79% with preserved ejection fraction 21% with systolic dysfunction, with one hospitalization in the previous year in 73% of cases, two in 21%, >3 in 6%.

ACE inhibitors were used in 36% of patients, spironolactone in 16%, beta-blockers in 50%, diuretics in 62%; 43% of patients had chronic obstructive pulmonary disease, 20% renal failure, 20% diabetes, 38% dyslipidemia, 12% were hypertensive. Complete follow-up at three months it is available for the first 20 patients; none of them was hospitalized.

Conclusions: The implementation of an integrated model of telemedicine applied to the follow-up of patients with CHF, strictly linking cardiologists, GP and patient, was feasible and reliable. In a preliminary evaluation, the number of hospitalizations seems extremely low; patient's satisfaction was excellent.

P361

Implementation of telemonitoring with daily measurements of the pulmonary artery pressure (PAP) in advanced systolic heart failure: first experience with the PAP-sensor

Unrestricted research grant from St. Jude Medical

E Ester Judith Herrmann¹; B Luu¹; A Ecke¹; S Fichtlscherer¹; S Hohnloser¹; AM Zeiher¹; B Assmus¹

¹JW Goethe University, Cardiology, Frankfurt am Main, Germany

Patients with advanced heart failure suffer from frequent hospitalizations. Non-invasive hemodynamic telemonitoring using daily measurement of pulmonary artery pressures (PAP) has been shown to reduce hospitalizations. We report on the first 13 patients, in whom a pulmonary pressure sensor was implanted in our Heart Failure Center.

Methods: Patients in NYHA class III with documented prior cardiac decompensation received the PAP-sensor via right heart catheterization.

Results: Implanted patients were 69 ± 8 years old and suffered from systolic heart failure (LVEF $26 \pm 9\%$, cardiac index 2.1 ± 0.5). In a total of 2606 active telemonitoring days, there were 284 telephone calls to the patients with a modification of therapy. Through intensive telemonitoring-guided therapy adjustments (mean follow-up 6.7 ± 4.0 months), PAP was significantly reduced in 8 of 13 patients (delta PAPsys -7 ± 5 , delta PAPmean -7 ± 4 , delta PAPd -6 ± 2 , $p < 0.05$). No patient died and there was one hospitalization for cardiac decompensation.

Conclusion: The implantation of the PAP-sensor is a safe procedure in severe heart failure patients. PA-pressure telemonitoring-guided therapy is associated with significant reductions in PA-pressure over time. Taking into account the high number of telemonitoring alert-triggered telephone contacts, a reimbursement within the respective health care systems is essential for implementation of hemodynamic telemonitoring.

Telemonitoring favours health-related quality of life in patients with chronic heart failure: a randomised controlled longitudinal study

G Giamouzis¹; D Mastrogiannis¹; A Chroub-Papavaoui¹; G Karayannis²; K Kouttrakis¹; G Dafoulas³; P Stafylas⁴; J Skoulargis¹; F Triposkiadis¹

¹University General Hospital of Larissa, Department of Cardiology, Larissa, Greece;

²Harefield Hospital, London, United Kingdom; ³Laiko University General Hospital, A Department of Internal Medicine, Athens, Greece; ⁴Ahepa University Hospital, Cardiology Department, Thessaloniki, Greece

Background: Chronic heart failure (CHF) is one of the major threats to public health worldwide. CHF patients are often hospitalized and face adverse prognosis. Telemonitoring of CHF patients seems promising and adds great benefits in health-related quality of life (HRQoL).

Purpose: To investigate the effects of a telemonitoring intervention in CHF patients through wireless devices following training in their use by a nurse, on HRQoL after a one year follow-up period.

Methods: A case-control interventional longitudinal survey design was selected. Study population consisted of 60 CHF patients of NYHA class II-IV, at the outpatients Heart Failure Clinic of a tertiary University Hospital. Data were processed and analyzed with a software package from Quality Metric Inc and the Statistical Package for Social Sciences (SPSS) v.22. Following examination of data and according to findings, Pearson's r and Spearman's r_s were used to examine variables' correlations, t-test and Mann-Whitney test were used to compare two independent groups, paired t-test and Wilcoxon Signed-Rank test were used to compare a group in two separate time points, ANOVA test and Kruskal-Wallis test were used to compare more than two independent groups.

Results: At baseline, there was no difference between the two groups with regard to MLHF and SF36v2 scores. At 12 months, control group's scores in MLHF questionnaire deteriorated while scores in intervention group improved. Control group's scores in SF36v2 deteriorated in 5 subscales (PF, RP, VT, SF, RE) and 2 dimensions (PCS, MCS) and improved in three (BP, GH, MH). Intervention group's scores in SF36v2 improved in all subscales and dimensions. Between the two groups there was a statistically significant difference favoring the intervention group in 5 subscales (PF; $p=0.030$, BP; $p=0.048$, GH; $p=0.029$, SF; $p=0.036$, MH; $p=0.014$, 1-sided) and one dimension (PCS; $p=0.046$, 1-sided).

Conclusions: The present study showed that telemonitoring of CHF patients can contribute towards improving HRQoL, after one year of use. The findings suggest that the addition of such a method in current practice may have a favorable effect and accentuates nurses' involvement in planning and materializing implementations to holistically and effectively manage this patient population.

P363

Evaluation of the effect of cardiac resynchronization therapy on left ventricular function in patients with chronic heart failure

MARIAM Mohamed Fathy Mohamed Abdalhakim Gomaa¹; M Nawar¹; E Elsharkawy¹; M Loutfy¹

¹Alexandria University, Cardiology and angiology, Alexandria, Egypt

Background: Heart failure (HF) is a complex clinical syndrome that results from any structural or functional impairment of ventricular filling or ejection of blood. Cardiac resynchronization therapy (CRT) is associated with significant clinical improvement in patients who have advanced heart failure and left bundle branch block (LBBB). Echocardiography plays an important role in the assessment and follow-up of heart failure patients treated with cardiac resynchronization therapy.

Purpose: The current study was done in order to evaluate the effect of cardiac resynchronization therapy on left ventricular systolic function using echocardiography and tissue Doppler imaging (TDI).

Methods: 30 patients who were considered candidates for CRT according to the current guidelines were included. Echocardiographic examination, TDI, quality of life and NYHA functional class were assessed in all patients. Echocardiographic examination included the measurement of end systolic and end diastolic dimensions, ejection fraction (EF) and degree of mitral regurg. TDI included the measurement of peak systolic velocity, time to peak systole, isovolumetric contraction time, isovolumetric relaxation time and the calculation of myocardial performance index in the interventricular septum, lateral wall, anterior wall and inferior wall as well as the basal septum of the right ventricular free wall.

Results: The study demonstrated that, there was statistical significant improvement after CRT regarding EF, stroke volume, end systolic diameter, degree of mitral regurg, isovolumetric relaxation time, myocardial performance index, septal to lateral delay and the interventricular mechanical delay. Moreover, there was statistically significant correlation between the baseline standard deviation of the time to peak systole in all segments and the improvement of EF and between the acute and chronic changes in the EF. Our study also showed significant improvement in the quality of life and NYHA functional class after CRT.

Conclusions: CRT is an effective procedure for treatment of moderate to severe heart failure. CRT improves left ventricular systolic function and quality of life in HF patients with left ventricular systolic dysfunction and LBBB. Acute effects of CRT on EF can predict long-term effects on the EF. Baseline systolic dyssynchrony can predict improvement of EF after CRT.

P364

Mitral valve coaptation depth as an independent predictor of response to CRT

R Ruslan Babukov¹; V Bazilev¹; F Bartosh¹; R Marchenko¹

¹Penza Center for Cardiovascular Surgery, Penza, Russian Federation

Purpose: to assess echocardiographic predictors of response to CRT in patients with chronic heart failure (CHF).

Materials and methods: We performed retrospective analysis of 120 clinical cases of patients with CHF after CRT implantation. All patients were divided into 2 groups: responders and nonresponders. The main selection criteria were: heart failure, II-IV NYHA functional class, left ventricular ejection fraction $<35\%$, LBBB with QRS duration >120 ms. All echocardiographic parameters were assessed according to ASE guidelines. Statistical analysis was performed using Poisson regression.

Results: Both groups were similar in gender characteristics ($=0,3$), age ($=0,6$), presence of atrial fibrillation ($0,008$), volumetric characteristics of the heart, ejection fraction, severity of mitral regurgitation ($p>0,05$). Significant differences of mitral valve leaflet coaptation depths were revealed ($p\leq0,001$). Poisson regression analysis showed that increase of coaptation depth is a significant risk factor that affects response to CRT OR = 0,2; CI [0,091; 0,52] ($p\leq0,001$).

Conclusions: 1) Mitral valve leaflet coaptation depth in patients with mitral regurgitation is a significant predictor of response to CRT. 2) CRT implantation in patients with mitral valve leaflet coaptation depth more than 11 mm does not lead to mitral regurgitation regression. This cohort of patients needs prior surgical reconstruction.

P365

The old dilemma revisited: which patient will more likely respond to cardiac resynchronization therapy? Retrospective identification of the baseline factors influencing short and long term outcome.

A Fontana¹; A Vincenzi¹; A Ciro¹; G De Vito²; A Vincenti¹; G Trocino¹; F Achilli¹

¹San Gerardo Hospital, Department of Cardiology, Monza, Italy; ²Università Milano-Bicocca, Department of Health Sciences, Monza, Italy

Cardiac resynchronization therapy (CRT) is a mainstay for patients (pts) with advanced heart failure, although in up to 30% of subjects mechanical dyssynchrony does not improve despite this intervention. Several studies have evaluated the baseline echocardiographic and clinical factors more likely to influence response to CRT.

Aims & Methods: We aimed to assess the efficacy of CRT in a population of pts treated at our institution between 01/2008 and 12/2009. We retrospectively evaluated which baseline clinical characteristics of the pts were highly linked to 5-year outcome.

Results: 99 pts received CRT (6 females, mean age 69.3 ± 8.1 years). From an echocardiographic point of view (reduction in left ventricular end systolic volume $\geq 15\%$), 72 pts (72.7%) responded to treatment, whereas 27 pts (27.3%) did not. Twelve additional pts were clinically non-responder despite good echocardiographic results, since they experienced at least one of the followings: death or hospitalization for heart failure, episodic need for intravenous diuretic or inotropes, increased dosage of home diuretic, worsening of NYHA class, enduring wide QRS. Thus far, the total number of non responder was 39 (27+12), with 60 responder. At 5 years follow up, 19 pts had died: 11 non-responder (15.3%) and 8 responder (11.1%). Mortality was mainly cardiovascular (14 pts, 73.7%). Other causes of death were sepsis (1 patient), pneumonia (2 pts), and malignant tumours (2 pts). Ten pts showed significant clinical improvement, with a marked overall benefit in terms of end systolic volume (reduction greater than 30%), ejection fraction, NYHA class, and pharmacological therapy. They were considered super responder. At the covariate analysis, outcome was significantly (positively or negatively) linked to the age at the time of CRT implantation, baseline ejection fraction, disease aetiology, presence of atrial fibrillation (AF, $p=0.019$), degree of mitral regurgitation, preserved renal function ($p=0.0006$) and QRS duration. Thirteen pts among the non-responder (33.3%), were treated with intermittent infusions of levosimendan approximately every 3-4 weeks for a median of 2.3 years. Although levosimendan was initially used as destination therapy in all 13 pts, it ended up to be a bridge to heart transplant in two cases, and a bridge to left ventricular assist device for one patient. Two pts on periodic levosimendan infusions died of end stage heart failure, whereas the remaining 8 pts are still alive, ongoing monthly cycles of therapy with levosimendan.

Conclusion: Several factors, mainly the status of renal function and the presence of AF, should be properly weighted in the selection of pts eligible to CRT, as these factors are directly linked to the overall clinical outcome. Moreover, since mortality rate in non-responder is higher than in responder, further therapeutic strategies should be evaluated for non-responder, such as for example intermittent infusions of Levosimendan.

P366

Multi-centre asian data on risk factors for non-response to cardiac resynchronization therapy

KH Kwang How Mok¹; SY Cheng²; CG Foo¹; PL Chia¹; VH Tan³; WS Teo⁴; CK Ching⁴; CK Wong³; KKL Chung¹

¹Tan Tock Seng Hospital, Cardiology, Singapore, Singapore; ²Singapore General Hospital, Medicine, Singapore, Singapore; ³Changi General Hospital, Singapore, Singapore; ⁴Singapore General Hospital, Cardiology, Singapore, Singapore

Introduction: Up to 30% of patients with heart failure do not respond to Cardiac-Resynchronisation-therapy (CRT). Guidelines specify clear inclusion

criteria for CRT, but little is written to predict non-response. We hypothesized that patients with left-ventricular ejection fraction (LVEF) < 20%, left-ventricular internal dimension in diastole (LVIDd) > 7.5cm represent a late stage of heart failure that may not respond to CRT. Prior literature has been conflicting regarding response to CRT in those with very long QRS duration (> 180ms).

Objective We sought to determine if patients with the above risk factors (EF < 20%, LVIDd > 7.5 cm and QRS > 180ms) we more likely to be clinical non-responders.

Methodology We retrospectively evaluated patients from 3 centres implanted with CRTD from 2006 to 2014 with the above characteristics. Clinical non-response was defined by no reduction in New York Heart Association (NYHA) class.

Results: Available data from 118 patients were analysed, of these 47.1% were clinical non-responders. Comparison of non-response rates between patients with and without the above risk factors are tabulated below.

Conclusion: There were no significant differences in terms of clinical response between those with or without dilated hearts > 7.5cm or EF < 20%. However, our findings suggest that patients with a very wide QRS duration are more likely to respond to CRT in terms of functional class.

Risk factors for non-response

LVEF < 20%	Yes (n = 40)	No (n = 78)	
Non-responder	19 (47.5%)	38 (48.7%)	0.90 [^]
LVIDd > 7.5cm	Yes (n = 16)	No (n = 94)	
Non-responder	9 (56.2%)	43 (45.7%)	0.59*
QRS > 180ms	Yes (n = 15)	No (n = 90)	
Non-responder	3 (20.0%)	51 (56.7%)	0.01*
2 or more risk factors	Yes (n = 17)	No (n = 101)	
Non-responder	9 (52.9%)	48 (47.5%)	0.80*

Factors affecting cardiac resynchronisation therapy and defibrillator (CRT-D) response in heart failure: a retrospective study.

G Giuseppe Di Stolfo¹; S Mastroianno¹; C Centra¹; G De Luca¹; C D'ariento¹; R Massaro¹; A Facciorusso¹; A Russo¹; R Fanelli¹; DR Potenza¹

¹Scientific Institute Casa Sollievo della Sofferenza, Department of Cardiology, San Giovanni Rotondo, Italy

Background: Cardiac resynchronization therapy and defibrillator (CRT-D) has proven to be an effective treatment for patients affected by heart failure with left branch bundle block (LBBB) and severe contractile dysfunction, despite optimal medical therapy. Aim: Evaluate factors associated to better CRT-D response.

Methods: We have retrospectively evaluated seventy-eight patients (62 males and 16 females; mean age: 74.7 ± 10.5 years), affected by heart failure and already treated by CRT-D. We considered responder to a 10% increased in LVEF. All patients were assessed for ischemic heart disease, atrial fibrillation and chronic kidney disease (CKD). QRS reduction at implantation, left ventricular lead type (bipolar, quadripolar) and stimulation percentage were considered. Biochemical parameters, cardiovascular risk factors and treatments were evaluated.

Results: Patients were divided in two groups, responders and non-responders. Responder group was characterized by increased stimulation percentage, quadripolar lead implantation, greater QRS reduction. Severe CKD was associated to non-responder. No further difference was found.

Conclusions: This analysis shows the factor affecting better response to CRT-D are greater QRS reduction at implantation, left quadripolar lead and greater stimulation percentage, while severe CKD is a negative predictor for CRT-D response.

⁸Polyclinic Santa Maria alle Scotte, Cardiovascular and Thoracic Department,

Siena, Italy; ⁹San't Andrea Hospital, Vercelli, Italy; ¹⁰Santo Spirito Hospital, Casale Monferrato, Italy

Introduction: In CRT, left ventricle (LV) quadripolar leads offer the chance to overcome implant difficulties (phrenic nerve stimulation (PNS), unsatisfactory thresholds or pacing site) and potentially to reduce the need for reoperation, but few prospective data are available about effects on patient's response.

Purpose: This study aims to observe the evolution of CRT-D with quadripolar LV lead in terms of electrical parameters and patient's outcome, observing the differences between Responders and Non-Responders.

Methods: Were prospectively observed, in 15 Italian hospitals, 152 patients [Age(y) 69.4 ± 9; 76.3% Man; 42% Ischemic; 68% NYHA 3; LV EF(%) 27.6 ± 5.5] in which the CRT-D device was programmed with LV pacing from one distal dipole, when possible (142 distal, 93%). After 47(6M FU) and 1014(12M FU) months the patient clinical outcome is evaluated and the LV lead programming is recorded. Definition of Responder: improvement of HF Clinical Composite Index (CCI improved = no major clinical events and NYHA + health state improved) and at least one between improvement of EF more than 5 percentage points and 10% reduction of the LVESV, measured with echo.

Results: Were analyzed 117 "6M FUs"; 35 patients (30%) were classified as Non-Responder (NR), 8 (23% of NR) due to echo parameters not improved, while 12 patients (34% of NR) had echo improved but CCI not improved). It was noticed a mean increase in EF (+9 percentage points [95% C.I. 8 10], p < 0.001) from baseline in all patients; in NR patients the mean increase of EF was less than 5 percentage points (p < 0.001). Reduction of the LVESV from baseline was significant for all patients and in particular in Responder group (mean LVESV reduction = 27.7 %, n = 60, [95% C.I. 21.1 34.4], p < 0.001), but not in NR group. In 21 patients (60% of NR) the LV configuration was changed from distal to proximal dipoles, while it was not possible, for high threshold or PNS, in 5 patients (14%). Otherwise it was considered not clinically relevant.

Were also preliminarily analyzed 81 "12M FUs"; of 26 patients (32%), classified as NR at 6M FU, 15 of them had the LV configuration changed from distal to proximal dipoles at 6M FU, 8 (53%) of whom were classified as Responder at 12M FU. The other 11 NR patients, with no LV configuration change at 6M, became Responders at 12M only in 4 cases (2 of 8 LV distal; 2 of 3 LV proximal).

Conclusion: Data indicate a rate of NR with LV stimulation on distal dipoles as expected from previous studies. Follow-up data at 12 months, though preliminary, show potential benefit of quadripolar lead availability on this population.

P369

Middle-term stability of epicardial left ventricular electrodes for cardiac resynchronization therapy

M Marian Fedorco¹; A Bulava¹; M Taborsky¹; P Santavy²; A Mokracek³; V Lonsky²; L Dusek⁴

¹Palacky University, Faculty of Medicine and Dentistry, 1st Dept of Internal Medicine-Cardiology, Olomouc, Czech Republic; ²University Hospital Olomouc, Cardiosurgery Department, Olomouc, Czech Republic; ³Regional Hospital of Ceske Budejovice, Cardiosurgery, Ceske Budejovice, Czech Republic; ⁴Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic

Introduction: The standard for LV lead implantation is transvenous access via the coronary sinus. If unsuccessful, a possible alternative is to achieve stimulation of the left ventricle with an epicardial LV lead implantation.

Goals

The primary objectives were to determine medium-term electrical parameters of LV epicardial leads and to compare them with endocardially implanted electrodes, to compare the electrical performance and stability of epicardial leads from different manufacturers, and to determine whether epicardial lead stimulation parameters could be influenced by various clinical and demographic factors. Secondary objectives were to identify the main causes of transvenous LV lead implantation failures, to compare the clinical and echocardiographic resynchronization effect in both patient groups and to compare the safety of both approaches.

Methods: The study included consecutive patients undergoing implantation of a pacemaker with CRT function (CRT-P) or an implantable cardioverter-defibrillator with CRT function (CRT-D). The study group of cases was composed of patients with epicardial LV lead implantation, while the control group included patients with a completely transvenous system for CRT.

Results: 92 patients were included in each group (26 women, 66 men). LV pacing thresholds were significantly higher in the epi patient group at the 1 month, 1-year and 2-year follow-up compared to endocardially implanted LV leads (1.62 V vs. 1.06, $p < 0.001$, 1.57 V vs. 1.09 V, $p < 0.001$, and 1.54 V vs. 1.21 V, $p < 0.010$, respectively). Values of pacing thresholds of epi and endo LV leads at the 3-year follow-up were very similar, without a statistically significant difference due to counteracting trends in the pacing threshold curves (1.44 V vs. 1.25 V, $p = 0.119$). Energy delivered by the device to achieve LV stimulation in the epi group of patients was significantly higher at all time points, which resulted in earlier battery depletion. Improvement of NYHA class by at least one grade occurred in 71.4% of patients in the epi group and in 68.1% of patients in the endocardial group. A positive echocardiographic response was comparable in both groups. A significantly higher one- and three-year total mortality was recorded in the epicardial group compared to the endo group (17.4% vs. 6% and 21.7% vs. 6.5%, respectively).

Conclusion: Epicardial leads are capable of effective LV stimulation over a medium-term period of three years. They have a higher pacing threshold, and lower pacing impedance in comparison with endocardial leads, which leads to a greater energy consumption per pacing impulse. Additionally, resynchronization effects in patients with LV epi electrodes is similar to patients with transvenously implanted LV leads, both in terms of clinical and echocardiographic response. However, overall mortality of patients with LV epicardial leads is higher compared to patients with endocardially implanted LV leads.

Prognostic relevance of pulmonary haemodynamic response to exercise in patients with chronic left heart failure

A Andreas Rieth¹; M J Richter²; H Gall²; W Seeger²; HA Ghofrani²; V Mitrovic¹; CW Hamm²

¹Kerckhoff Heart Center, Bad Nauheim, Germany; ²Justus-Liebig University of Giessen, Giessen, Germany

Background: Exercise right heart catheterization (RHC) is emerging as a diagnostic tool in pulmonary hypertension (PH). However, the prognostic relevance of hemodynamic parameters derived from exercise RHC in heart failure with preserved ejection fraction (HFpEF) or heart failure with reduced ejection fraction (HFrEF) with or without the presence of resting pulmonary hypertension (HFpEF-PH or HFrEF-PH) is unknown. We hypothesized that exercise hemodynamics with assessment of pressure/flow slopes are of prognostic and clinical relevance.

Methods: We conducted an analysis of 305 patients enrolled in the Kerckhoff Clinic prospective heart failure registry. Patients with established diagnosis of HFrEF or HFpEF who were assessed by means of exercise RHC were included. A total of 130 of all patients (43%) had no resting PH, 175 (57%) had resting PH with mean pulmonary artery pressure (mPAP) > 24 mmHg and mean PA wedge pressure (PAWP) > 15 mmHg. The primary outcome was transplant-free survival; 21 patients were lost to follow-up. Factors shown to be of prognostic relevance in univariate Cox

regression analysis were entered into the multivariate model. Receiver operating characteristic (ROC) analyses were performed, while cut-offs were determined using the Youden Index.

Results: A total of 305 patients (124 female (40.7%), mean age 69.1 ± 12.3 years) with a diagnosis of HFpEF ($n = 138$; 45.2%) or HFrEF ($n = 167$; 54.8%) were included. In all patients, resting diastolic PAP (dPAP) and maximum cardiac output during exercise (CO max) were independently associated with a favorable outcome (dPAP: hazard ratio (HR) 0.82; 95% CI [0.71-0.94], $p = 0.006$; CO max: HR 0.26; 95% CI [0.12-0.58], $p = 0.001$, cutoff 5.3 l/min). The increase of PAWP was not an independent predictor of outcome in our cohort. In patients with HFpEF diastolic PAP/CO slope (slope = Δ pressure / Δ CO) was an independent predictor of a favorable outcome (HR 0.57; 95% CI [0.34-0.96], $p = 0.035$). In HFrEF patients, resting systolic PAP, dPAP, PAWP, and the exercise parameters mPAP/CO slope, systolic PAP/CO slope, dPAP/CO slope, and the absolute increase in mPAP were independently associated with a favorable outcome. Moreover, HFrEF patients with a mPAP/CO slope < 7.4 mmHg/l/min had a significantly better 5-year survival (Kaplan-Meier-Analysis: 69% versus 44.7%; log rank $p = 0.02$).

Conclusions: In the current study, we demonstrated the prognostic relevance of exercise haemodynamics in HFrEF and HFpEF patients independent of the presence of resting pulmonary hypertension. The maximum achieved CO during exercise seems to be of major relevance in all heart failure patients. In addition, exercise pressures and pressure/flow slopes are of prognostic significance in specific heart failure subgroups.

P371

Exercise hemodynamics in relation to cardiac amyloid deposit burden

Health Research Fund of Central Denmark Region and the Danish Heart Association

T S Tor Skibsted Clemmensen¹; H Moelgaard¹; H Eiskjaer¹; J Soerensen²; LP Tolbod²; H Harms²; SH Poulsen¹

¹Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark; ²Aarhus University Hospital, Department of Nuclear Medicine & PET Centre, Aarhus, Denmark

Aims: The present study aimed to characterize alterations in hemodynamics and oxygen consumption during exercise in patients with various cardiac amyloid (CA) deposits degrees.

Methods: Sixteen cardiac amyloid deposit patients underwent 11C-PIB positron emission tomography (PET) and 11C-acetate PET in order to quantify the burden of cardiac amyloid deposits. The patients were subjected to a symptom-limited, semi-supine exercise test with simultaneous right heart catheterization (RHC) and oxygen consumption assessment. Based on PET results, patients were divided into three groups: A: Genetically disposed ATTR-CA patients (PET negative) ($n = 5$); B: ATTR-CA patients (PET positive) ($n = 4$); and C: Wild type or AL amyloid patients ($n = 7$). We considered pulmonary capillary wedge pressure (PCWP) > 15 mmHg at rest and > 25 mmHg during stress abnormal. The data are preliminary as we expect to include ten more patients.

Results: At rest, only a tendency towards increased LV and RV filling pressure was noted in CA patients (RAPrest: Group A: 5 ± 3 mmHg, group B: 5 ± 3 mmHg, group C: 8 ± 5 mmHg, $p = 0.23$; PCWPrest: Group A: 9 ± 4 mmHg, group B: 12 ± 7 mmHg, group C: 17 ± 5 mmHg, $p = 0.06$). With exercise a pronounced increase in LV and RV filling pressure was noted (RAPpeak: group A: 5 ± 3 mmHg, group B: 11 ± 2 mmHg, group C: 18 ± 11 mmHg, $p < 0.05$; PCWPpeak: group A: 17 ± 4 mmHg, group B: 30 ± 4 mmHg, group C: 32 ± 5 mmHg). All patients in group B and C had exercise PCWP > 25 mmHg. Interestingly, pulmonary vascular resistance (PVR) was significantly higher in CA positive patients (PVR: Group A: 1.6 ± 1.0 wood units, group B: 1.3 ± 0.3 wood units, group C: 3.5 ± 1.6 wood units) and pulmonary arterial compliance significantly lower, especially at peak exercise (PACpeak: group A: 9 ± 2 mmHg/l group B: 4 ± 1 mmHg/l, group C: 2 ± 0 mmHg/l, $p < 0.0001$).

At rest, cardiac index was significantly reduced in CA patients ($p < 0.05$) whereas oxygen consumption was not. In contrast, peak exercise cardiac index and oxygen consumption was significantly reduced in CA patients (CIpeak: group A: 9.6 ± 0.4 l/min/m², group B: 6.5 ± 1.3 l/min/m², group C: 3.3 ± 1.3 l/min/m², $p < 0.0001$; V02 peak: group A: 2380 ± 806 ml/min, group B: 1690 ± 543 ml/min, group C: 998 ± 416 ml/min, $p < 0.01$).

Conclusions: Cardiac amyloid deposits are strongly associated with exercise induced elevated left and right ventricular filling pressure and reduced systolic capacity. Furthermore, CA patients have increased PVR and severely reduced PAC, which may contribute to the reduced exercise capacity in these patients.

P372

Absolute cerebral oximetry in different types of syncope during head-up tilt test in adults

E Erasmus Bachus¹; H Holm¹; M Magnusson¹; R Sutton²; O Melander¹; A Fedorowski¹

¹Skane University Hospital, Malmö, Sweden; ²Imperial College London, London, United Kingdom

Background: Absolute cerebral oximetry is a non-invasive technology, able to measure cerebral oxygen saturation (SctO₂). We applied near-infra-red-spectroscopy (NIRS) to monitor SctO₂ during head-up tilt test (HUT) in patients investigated for unexplained syncope.

Methods: Thirty-two patients (mean-age 50 years; 34% male) were examined with NIRS during HUT (Italian protocol). Beat-to-beat blood pressure (BP), ECG, peripheral oxygen saturation (SpO₂) and SctO₂ were continuously recorded using a non-invasive beat-to-beat monitor and an absolute cerebral oximetry monitor. The monitors were synchronized.

Results: HUT was diagnostic in 29 patients. Of these, 9 (31%) were diagnosed with orthostatic hypotension (OH) (classical OH; n=5, delayed; n=4), 23 (79%) with vasovagal syncope (VVS) (nitroglycerine (NTG) induced; n=14, spontaneous; n=9), 1 (3%) with postural tachycardia syndrome (POTS), and 2 (7%) with orthostatic intolerance (OI). Three (10%) participants were diagnosed with the combination of delayed OH and spontaneous VVS and one (3%) individual with classical OH and spontaneous VVS. During syncope, a significant decrease in absolute SctO₂ from $72 \pm 5\%$ right frontal and $71 \pm 4\%$ left frontal at baseline to $57 \pm 6\%$ right frontal and $54 \pm 6\%$ left frontal at the time of loss of consciousness (LOC) ($p < 0.0001$) was observed. SpO₂ remained at a constant level during HUT, both at baseline ($96 \pm 3\%$) and at the time of LOC ($96 \pm 2\%$).

Conclusions: We observed a significant decrease in SctO₂ in patients with all types of syncope. SpO₂ remained stable. Patients experienced syncope at SctO₂ below 60% and mean arterial pressure (MAP) below 60mmHg. Positive results during HUT were predicted by a progressive SctO₂ decrease independently of haemodynamic parameters in patients with spontaneous VVS.

Cerebral desaturation in VVS during HUT

P373

Uncovering the timeline of cardiogenic shock

A Andre Correia¹; R Rodrigues¹; B Silva¹; M Neto¹; J Monteiro¹; D Pereira¹

¹Hospital Funchal, Funchal, Portugal

Introduction: Cardiogenic shock (CS) remains the leading cause of mortality in patients hospitalized with acute myocardial infarction (AMI). Significant therapeutic advances have emerged throughout the last decades improving the outcomes of these patients.

Purpose: Review the evolution of cardiogenic shock, after an acute coronary syndrome (ACS), throughout the past 3 decades.

Methods: Single-center registry of 137 patients, admitted for ACS, which developed cardiogenic shock in the first 72 hours. They were divided into 3 groups: between the years of 1989-1994 (Group A: n=53; 62.3% men); between 1999-2004 (Group B: n=39; 46.2% men); and between 2009-2014 (Group C: n=45; 66.7% men). The groups were compared regarding their baseline characteristics, therapeutic procedures and prognosis during in-hospital stay and at 1-year follow-up.

Results: Group A had lower age [median/years (A=69 vs B=71.5 vs C=75)]. They had more history of smoking habits (A=50.9% vs B=20.5% vs C=15.6%, $p < 0.001$), angina (A=49.1% vs B=23.1% vs C=6.7%, $p < 0.001$) and acute myocardial infarction (A=26.4% vs B=12.8% vs C=8.9%, $p < 0.048$). No differences were found regarding arterial hypertension, Diabetes Mellitus, dyslipidemia or family history of cardiovascular disease. Group C was less submitted to thrombolysis (A=30.2% vs B=15.4% vs C=2.2%; $p < 0.001$), performed more PCI (A=18.9% vs B=43.6% vs C=88.9%; $p < 0.01$) and was more medicated with aspirin (A=45.3% vs B=53.8% vs C=97.8%; $p < 0.001$). Intra-aortic balloon pump was introduced later, being used only in Group C (17; 38%). No differences in ischaemic arrhythmias. Group C had a lower mortality rate during in-hospital stay (A=84.9% vs B=92.3% vs C=55.6%; $p < 0.001$) and at 1-year follow-up (A=90.6% vs B=94.9% vs C=62.2%; $p < 0.001$).

Conclusion: Medical advances have permitted a different management of patients with cardiogenic shock, leading to an increase in survival. Unfortunately, the mortality rate is still high.

P374

Natural history of vessel remodeling in heart transplant recipients - an IVUS substudy with long term follow up

A Aggeliki Gkouziouta¹; K Goto²; A Maehara²; GS Mintz²; GS Karavolias¹; E Leontiadis¹; V Voudris¹; S Adamopoulos¹; J Iakovou¹

¹Onassis Cardiac Surgery Center, Athens, Greece; ²Cardiovascular Research Foundation, Clinical Trial Center, New York, USA (Columbia University Medical Center, New York, United States of America)

Background: There is limited long-term data on vessel remodeling after heart transplantation (Tx).

Methods: We compared baseline vs follow-up IVUS evaluation of the LAD in 60 consecutive heart Tx recipients. Proximal LAD segments were matched among time points, a ≥ 20 mm long segment was analyzed every 1mm, and results were normalized for analysis length and reported as mm³/mm. Excluding 6 pts with a history of rejection, we divided Tx recipients into an Early group (n=36, last IVUS <5 yrs post-Tx) vs a Late group (n=18, last IVUS >5 yrs post-Tx).

Results: In the Early group vessel area (16.0 ± 4.6 mm³/mm vs 15.8 ± 4.3 mm³/mm, $p=0.7$) and lumen area (11.7 ± 3.6 mm³/mm vs 11.1 ± 4.0 mm³/mm, $p=0.21$) did not change between the 2 time points, although plaque area increased (4.3 ± 2.2 mm³/mm vs 4.7 ± 2.3 mm³/mm, $p=0.04$); the change in lumen area (-0.4 ± 1.4 mm³/mm/yr) was well correlated to the change in vessel area (-0.2 ± 1.3 mm³/mm/yr) ($r=0.91$, $p < 0.01$), but not to the change in plaque area (0.2 ± 0.6 mm³/mm/yr) ($p=0.07$). In the Late group vessel area (15.5 ± 4.4 mm³/mm vs 15.2 ± 3.4 mm³/mm, $p=0.6$), lumen area (11.7 ± 4.0 mm³/mm vs 11.2 ± 2.9 mm³/mm, $p=0.4$), and plaque area (3.8 ± 1.2 mm³/mm vs 4.0 ± 1.6 mm³/mm, $p=0.4$) did not change; again, the change in lumen area (-0.3 ± 0.1 mm³/mm/yr) was well correlated to the change in vessel area (-0.3 ± 1.1 mm³/mm/yr) ($r=0.98$, $p < 0.01$), but not to the change in plaque area (0.0 ± 0.3 mm³/mm/yr) ($p=0.12$).

Conclusion: In the absence of rejection, lumen area is preserved for a long period after heart Tx due to vessel remodeling despite plaque progression that was noted within 5yrs post-Tx.

P375

Inferior vena cava diameter predicts renal function and outcomes in patients with heart failure.

JSS Jagdeep Singh Surmukh Singh¹; AHM Iqbal¹; B Soujeri¹; S Hawkey¹; D Levin¹; CC Lang¹

¹University of Dundee, Cardiovascular and Diabetes Medicine, Dundee, United Kingdom

Background: Renal dysfunction in patients with heart failure (HF) has traditionally been attributed to poor cardiac output. There is currently a growing body of evidence to suggest that renal venous congestion (VC) plays a more important role than hypo-perfusion. However, a vast majority of them have been invasive studies measuring pulmonary artery and central venous pressures as markers of venous congestion. We, therefore, aimed to determine if VC as determined by inferior vena cava (IVC) dilatation using echocardiography was associated with worsening renal function, HF hospitalisation and all-cause mortality. **Methods:** We designed a population-based, longitudinal cohort study of 1034 unselected (acute/chronic) HF patients. All patients were symptomatic and required the use of loop diuretic therapy. VC was defined as IVC diameter > 2.1 cm as determined by echocardiography performed nearest to the time of recruitment into study. Renal function was determined by estimated glomerular filtration rate (eGFR) using the abbreviated MDRD equation. Logistic regression models were used to examine the association between VC and eGFR. Cox proportional hazard models were applied to examine the influence of VC on all-cause mortality and CHF hospitalisations.

Results: Logistic regression models showed that those with severe renal impairment (eGFR<30) were more likely to have VC compared to those with an eGFR > 60 (Odds Ratio=7.7; 95% CI(1.6-10.5), $p=0.012$). Multivariate analysis showed that those with VC had significantly worse survival than those without VC after adjusting for age, sex, eGFR and furosemide daily dose (hazard ratio [HR]: 1.6, 95% CI: 1.15-1.96; $p=0.002$). There was also a nonsignificant trend towards shorter time to first hospitalisation for HF in the VC group compared to those without VC (hazard ratio [HR]: 1.22, 95% CI:0.96-1.56; $p=0.103$).

Conclusions: VC as determined by dilated IVC on echocardiography is associated with worsening renal function in an unselected group of HF patients. This readily available and non-invasive test can also be used to predict HF hospitalisation and all-cause death in this patient group.

P376

Congenital arterio-venous and arterio-systemic coronary artery fistulae - prevalence and clinical significance in patients undergoing coronary intervention

B Schneider¹; K Peters¹; J Stein¹

¹Sana Kliniken, Luebeck, Germany

Background: Congenital coronary artery anomalies have been reported in up to 1.3% of patients undergoing cardiac catheterization. Most frequent are abnormalities of coronary origin and distribution. Coronary artery fistulae are rare (0.2%), more than 90% being arterio-venous. Arterio-systemic fistulae so far have been described only sporadically.

This study aimed to assess the prevalence and clinical significance of coronary artery fistulae in patients undergoing coronary angiography.

Methods: Over an 8-year period, 11842 patients underwent coronary angiography with or without coronary intervention. Patients with a coronary artery anomaly prospectively identified by 2 independent observers were included in a data base.

Results: Among 11842 patients undergoing cardiac catheterization, 202 with a coronary anomaly were identified (1.7%). An abnormal origin of a coronary artery was seen in 123 patients (1%). Coronary artery fistulae were diagnosed in 78 patients (0.7%), 55 female, 23 male, mean age 66 years (range 39–88).

Arterio-venous fistulae were present in 15/78 patients (19%), connecting LAD with pulmonary artery ($n=12$) or right ventricle ($n=1$), RCA with right ventricle ($n=1$) and CX with pulmonary artery ($n=1$). The shunt size was negligible and the arterio-venous fistulae were coincidental findings without clinical relevance in all patients.

Arterio-systemic fistulae with multiple small fistulous channels draining into the left ventricle (LV) were present in 63/78 patients (81%). Origin of the fistulous communication was LAD ($n=24$), LAD and CX ($n=19$), LAD and RCA ($n=12$), CX ($n=2$), and all major vessels ($n=6$). Associated cardiac lesions were present in 35/78 patients (significant CAD: $n=28$, valve disease: $n=6$, apical hypertrophic cardiomyopathy: $n=1$). 22 patients with isolated arterio-systemic fistulae complained of anginal chest pain and showed ECG changes in the anterior leads attributable to ischemia due to a coronary steal mechanism. Intracoronary injection of nitroglycerine resulted in increased shunting into the LV. In 1 patient with anterior myocardial infarction and an occluded LAD, attempted LAD recanalization resulted in enlargement of a small fistulous arterio-systemic channel with significant shunting from the LAD into the LV. Subsequently, the dilated fistulous channel closed spontaneously.

Conclusion: In contrast to previous reports, diffuse arterio-systemic coronary artery fistulae draining into the LV are more common than arterio-venous fistulae. Chest pain and ECG changes are typical clinical findings. Nitrate therapy may aggravate the coronary steal phenomenon.

P377

Primary percutaneous coronary intervention in diabetic patients with acute myocardial infarction

I P Ivana Borges¹; RTS Peixoto¹; RTS Peixoto¹; RTS Peixoto¹; AAB Aragao¹; VF Marcolla¹

¹Polícia Militar do Rio de Janeiro, Rio de Janeiro, Brazil

Introduction: Some studies showed that diabetic patients (D) group (DG) had a worse outcome when compared to nondiabetic (ND) patients group (NDG), after primary percutaneous coronary intervention (PCI).

Objective: The objectives were to compare mortality and major coronary events (MACE) at 30 days and 1 year of DG and NDG submitted to primary PCI and to study whether another conditions were related to worst outcome of patients in 30 days or one year.

Methods: Prospective study with 450 consecutive patients submitted to PCI from 01/01/2001 to 12/31/2006 (121 D and 329 ND) with ST-segment elevation acute myocardial infarction (AMI) in the first 12 hours of symptoms presentation treated with balloon catheter or bare metal stent and without cardiogenic shock. We used in statistical analysis: Student t test, chi-square test, Fischer exact test, and multivariate analysis: logistic regression and Cox analysis.

Results: DG and NDG had similar age (63.1 ± 10.0 and 62.3 ± 11.7 years, $p=0.443$),

male gender (63.6% and 69.9%, $p=0.205$) and multivascular disease (66.1% and 60.8%, $p=0.301$). The diabetic group had more dyslipidemia ($65.3\% \times 51.7\%$, $p=0.009$) and severe left ventricular dysfunction ($15.7\% \times 8.2\%$, $p=0.019$). The stent implantation rate was (83.5% and 81.1%, $p=0.863$) and glycoprotein (GP) IIb/IIIa inhibitors utilization (79.3% and 82.2%, $p=0.831$) were similar. The mortality at 30 days (2.5% and 2.7%, $p=1.000$) and at 1 year (5.0% and 6.7%, $p=0.650$) and MACE at 30 days (4.1% and 6.4%, $p=0.496$) and at 1 year (19.4% and 15.4%, $p=0.3492$) were similar. The absence of TIMI III flow after the procedure (procedure failure) was the only independent hospital mortality (30 days) predictor ($P<0.001$, OR=8,045, CI95 2,327-27,816). Procedure failure ($p=0.023$, HR=3,364, CI95 1,182-9,578) and age ≥ 65 years ($P=0.035$, HR=3,391, CI95 1,091-10,543) were independent predictors of mortality at 1 year. The multivessel coronary disease ($p=0.023$, OR=4,218, CI95 1,223-14,545) and procedure failure ($P<0.028$, OR 3.155, CI95 1,132-8,799) were independent predictors of MACE at 30 days and multivessel coronary disease was independent of MACE at 1 year ($p=0.034$, HR=1.854, CI95 1,048-3,280).

Conclusion: The diabetic patients submitted to primary PCI had mortality rate and MACE similar to none diabetic patients at 30 days and 1 year. The absence of TIMI III flow were predictor of mortality at 30 days and 1 year and age ≥ 65 years at 1 year. Independent predictors of MACE at 30 days were multivessel coronary disease and absence of TIMI III flow (procedure failure) and at 1 year was multivessel coronary disease.

P378

Management of ST-elevation myocardial infarction according to European guidelines in a university hospital in Tunisia: Results of RESCAs registry

T Ellouze¹; T Triki Faten¹; C Hamza¹; R Hammami¹; S Ben Kahla¹; S Mallek¹; D Abid¹; S Kammoun¹

¹University of Sfax, Department of cardiology Sfax Tunisia, Sfax, Tunisia

Background: Early reperfusion therapy has proven benefit in reducing mortality in patients with ST-segment elevation myocardial infarction (STEMI). Expert guideline committees have defined recommendations to improve the management of patients with STEMI and decrease their mortality rates. Our Registry of ST-Segment-Elevation Myocardial Infarction (STEMI) was designed to assess the situation in our city regarding the clinical profile, diagnostic and therapeutic management and medium-term prognosis, as well as to evaluate compliance with contemporary clinical guidelines.

Methods: RESCAs registry was a 1-year, single-centre, prospective, multidisciplinary study, conducted between september 2012 and August 2013 in our hospital, including 215 consecutive patients with STEMI of less than 24 hours duration. Data were recorded during the emergency phase and after admission to cardiology. Baseline characteristics, treatments, in-hospital and mid-term outcomes were analyzed.

Results: Seventy-seven per cent of patients were men; the mean age was 62 years. The most prevalent risk factor was smoking, followed by diabetes. Killip class greater or equal to 2 was observed in 24% of cases. 87% received reperfusion treatment; twenty-nine (13%) patients underwent thrombolysis and one hundred fifty-nine (74%) had percutaneous coronary intervention (PCI). Among patients undergoing primary percutaneous coronary intervention, first medical contact (FMC) to treatment 135 min, symptoms to treatment 300 min. FMC to PCI delay was less than 120 min in 68% of patients residents in Sfax city, while only 39% of patients residents in the delegations within 40 km of the hospital and 12.5% of patients in the delegations of more than 40 km are supported within the 2 hours following the ESC guidelines ($p<0.001$). The only factor independently associated with guideline compliance was place of first medical contact. The radial access was used in 83% of patients. Thrombectomy with the use of a manual aspiration catheter was performed in 78 patients (49.5%). In-hospital mortality was 9.3% in all patients, and it was highest in the group of patients without reperfusion therapy (14.8%). Follow-up after a median of 9.3 months was obtained for 185 patients (94.8%). Overall 6-months mortality rate was 12.6%. The cumulative incidence of myocardial infarction, stent thrombosis and target-lesion revascularization was 7%, 4.12% and 8.8% at overall follow.

Conclusion: In contemporary community practice, achievement of quality performance measures in patients presenting with ST-segment-elevation myocardial infarction was high, regardless of time of presentation. Most of our patients presenting with STEMI undergo reperfusion therapy with percutaneous coronary intervention. However an important number of patients did not receive revascularization within the recommended time frame. Efforts should be made to improve the estimation of delay before reperfusion therapy.

P379

Endothelium dysfunction as pathogenetic factor of labile arterial hypertension in children with vegetative nervous system disturbances

M Maksimovich¹

¹Grodno State Medical University, Grodno, Belarus

Purpose: It was to investigate the role of the endothelial dysfunction at labile hypertension pathogenesis at children with vegetative nervous system pathology. Methods. It was examined 314 children with vegetative dysfunction and 190 healthy children (10-16 years) – control group in Grodno region (Belarus) by clinical, spectrophotometric, aggregatometric and statistic methods. The endothelium function with reactive hyperemia method was investigated.

Results: At patients with vegetative nervous system pathology and the severe degree of the risk factors influences the increasing of blood pressure and aggravating the clinical manifestations with decreasing the endothelium-dependent vasodilation, nitrite and nitrate (the metabolites of nitric oxide), the values of antioxidants (retinol and tocopherol) in the plasma of blood and activation of the platelets aggregation was noted. These changes were absent at children with vegetative dystonia and at all children of control group with mild and moderate degree of risk factors influences.

Conclusions: The endothelium dysfunction is the important factor of the arterial hypertension at the children with vegetative nervous system disturbances. Action of risk factors in the children organism with disturbances of the nervous system (hereditary, active or passive smoking, hypodynamia, atherogenic diet, stress) induces oxidative processes activation and endothelium dysfunction development.

P380

Primary percutaneous coronary intervention in women with acute myocardial infarction

I P Ivana Borges¹; RTS Peixoto¹; ECS Peixoto¹; AAB Aragao¹; VF Marcolla¹

¹Polícia Militar do Rio de Janeiro, Rio de Janeiro, Brazil

Background: Coronary heart disease is the leading cause of mortality and morbidity. A higher mortality risk for women with acute ST-elevation myocardial infarction has been a common finding in the past, even after acute percutaneous transluminal coronary angioplasty (PTCA). Prior studies have reported worse results after PTCA in women than in men. However, recent data suggest that this difference is less marked.

Objective: To determine gender-related differences and risk factors for death and major events, both in-hospital and at six-month follow-up, of patients that have been admitted within the first twelve hours of ST-segment elevation acute myocardial infarction (AMI) and primary PTCA in order to set out whether there are gender differences in a real-world contemporary treatment and outcome.

Methods: For two consecutive years, 199 consecutive patients were enrolled in the study, with ST-segment elevation AMI and primary PTCA without cardiogenic shock. The immediate outcome, in-hospital and six-month follow-up were studied. Multivariate Cox analysis were performed to identify independent predictors of death and major events.

Results: Clinical characteristics were similar in both groups, except that women were older than men (67.04 ± 11.53 x 59.70 ± 10.88, p < 0.0001). In-hospital mortality was higher among women (9.1% x 1.5%, p = 0.0171), as was the incidence of major events (12.1% x 3.0%, p = 0.0026). The difference in mortality rates remained the same at six months (12.1% x 1.5%, p = 0.0026). The independent predictors of death in multivariate analysis were: female gender and age > 80 years old. Independent predictors of major events and/or angina were: multivessel disease and severe ventricular dysfunction.

Conclusion: After ST-segment elevation AMI and primary PTCA, the independent predictors of mortality throughout the follow-up were female gender and age > 80 years, in both in-hospital and six months follow-up.

Events after primary PTCA x Gender

	WOMEN	MEN	P
AGE	67.04 ± 11.53	59.70 ± 10.88	P < 0.0001

Lipid profile in acute coronary syndrome: does age matter?

J G Julio Gil Goncalves Pereira¹; H Antunes¹; L Abreu¹; A Delgado¹; B Marmelo¹; L Goncalves¹; D Moreira¹; L Ferreira Dos Santos¹; J Costa Cabral¹

¹Hospital Sao Teotónio, Cardiology, Viseu, Portugal

Introduction: Several studies suggest the presence of a link between atherogenesis and hyperlipidemia. This fact plays a central role in the pathogenesis of acute coronary syndromes (ACS).

Objective: To compare the lipid profile of young and older patients admitted with a diagnosis of acute coronary syndrome.

Methods: Retrospective study of patients admitted for ACS. Clinical and laboratory parameters were evaluated, including total cholesterol (TC), HDL cholesterol (HDL), LDL cholesterol (LDL) and triglycerides (TG). The following ratios were calculated: TC/HDL, LDL/HDL and TG/HDL. Parameters in mg/dL. The patients were divided into 2 groups: group A (GA) with < 55 years vs group B (GB) with ≥ 55 years.

Results: Total sample of 1168 patients, 70.1% male, mean age 69 ± 12 years. The younger group accounts for 15.8% of the population. The sample had an average of CT of 176 ± 55 mg/dL, LDL of 111 ± 45 mg/dL, HDL of 40 ± 12 mg/dl and Triglycerides of 137 ± 102 mg/dL. The following average ratios were attained: TC/HDL 4.6 ± 1.9, LDL/HDL 2.9 ± 1.4 and TG/HDL 3.8 ± 3.5.

Conclusion: In this population, there was a consistently worse lipid profile in young patients with ACS. This data validate the role of dyslipidemia in the pathogenesis of coronary heart disease, contributing to an early and accelerated atherosclerosis process. This reinforces the importance of adopting a healthy lifestyle and therapeutic compliance in primary and secondary prevention of cardiovascular events.

	GA with <55 years	GB with ≥55 years	
Total cholesterol	199 ± 44	170 ± 56	p < 0.001
LDL cholesterol	128 ± 37	107 ± 46	p < 0.001
HDL cholesterol	39 ± 10	40 ± 12	p = 0.307
Triglycerides	195 ± 189	125 ± 66	p < 0.001
TC/HDL	5.3 ± 1.5	6.8 ± 2.0	p < 0.001
LDL/HDL	3.4 ± 1.1	2.8 ± 1.4	p < 0.001
TG/HDL	5.6 ± 6.3	3.5 ± 2.5	p < 0.001

Lipid profile differences based on age

P383

Effect of glycaemic status on left ventricular diastolic function detected by pulsed tissue doppler imaging in type 2 diabetes patients

M Moustafa Eldeib¹; M Mokarrab¹; K Marghany¹; A Motawea¹

¹Al-Azhar University, cardiology, Cairo, Egypt

Background: Diabetes mellitus is considering an important independent factor in developing diastolic dysfunction. Diastolic dysfunction comprises about 30 to 50% of all patients hospitalized for heart failure. The aim of this study was to determine the effect of glycaemic status on left ventricular diastolic function by pulsed tissue Doppler imaging in type 2 diabetic patients

Methods: our study included (100) subjects, 20 normal healthy subjects, 80 known to be Diabetic patients presented in our diabetic outpatient clinic and echocardiographic unit at Al-Hussein University Hospital between November 2010 and June 2011. The patient were classified according glycaemic status in to three groups: Group (A) Normal healthy control subjects. Group (B) well controlled diabetes HbA1C less than 7, Group (C) uncontrolled diabetes HbA1C more than 7.

Results: There was no statistically significant difference between the three groups as regard LVEDD, LVESD, LV EF% and LVFS%. There was statistically significant difference between the three groups as regard LA dimension mean E wave mean of A wave mean of E/A ratio diameter mean of DT mean of IVRT mean of Em wave mean of E/Em degree of diastolic dysfunction. There was statistically significant difference in patient have LV diastolic dysfunction between the three groups as regard E wave, A wave, DT, and IVRT. but there was no statistical difference between patient have diastolic dysfunction as regard mean of Em. There was negative correlation between HbA1c level and E wave, E/A, Em and positive correlation with LA dimension, A wave, IVRT, DT and E/Em.

Conclusion: The Glycemic status is well correlated with severity of diastolic dysfunction in asymptomatic type 2 diabetic patients. Tissue Doppler imaging has been shown to be more sensitive and more independent from various confounders, such as preload for assessment of diastolic function in asymptomatic type 2 diabetic patients and its results are significant correlated with glycemic state.

P384

Diabetes in cardiac rehabilitation programs: how does it influence outcomes in patients with systolic dysfunction?

V Veronica Angela Rial Baston¹; R Dalmau Gonzalez-Gallarza¹; A Castro Conde¹; FJ Irazusta Cordoba¹; P Meras Colunga¹; O Gonzalez Fernandez¹; AM Iniesta Manjavacas¹; I Ponz De Antonio¹; R Mori Junco¹; JL Lopez-Sendon¹

¹University Hospital La Paz, Cardiology, Madrid, Spain

Background and objectives: Cardiac rehabilitation programs (CPR) have shown to be specially beneficial for patients (P) with low ejection fraction (EF) and they allow to improve diabetes (D) control. We compared characteristics and functional

improvement in this particular subgroup according to the diabetes status.

Methods: Data were collected retrospectively of 509 P. with low EF (defined as EF<51%) referred to a CRP between May 2006 and October 2014 (97,4% after an acute coronary syndrome). They were categorized as diabetic whether they had previous history of D. or fulfill the criteria for the diagnosis of D. during the program. EF was determined using the Simpson method before starting the CRP and at the end of it; and functional capacity was evaluated with a treadmill exercise test (METs). Chi-square and t-student tests were used to analyze categorical and numerical variables, respectively.

Results: 88,6% were male with a mean age of 57,78 years. 124 P. (24,6%) had been diagnosed of D. and had a significantly higher prevalence of other cardiovascular risk factors. In P. with D., the mean EF was significantly lower (36,99% vs 38,91%, p=0,036) and severe systolic dysfunction was more frequent too (21% (43 P.) vs 11,3% (26 P.), p=0,007). Exercise capacity, which was significantly lower in diabetics before starting the CRP (5,98 vs 8,38 METs, p=0,01), improved in both groups with non-significant differences between them (6,64 vs 5,78 METs increase, p=0,66). The same results were obtained when evaluating the EF (9,27% vs 11,71% improvement, p=0,19), although systolic dysfunction continued to be more frequent in diabetics at the end of the CRP (49 P. (65,3%) vs 130 P. (53,9%), p=0,08). In fact, we observed in this subgroup a non-significant trend toward a worse metabolic profile when comparing them with P. with D. and normal EF, as it is summarized in table 1. **Conclusion:** The presence of D. is related to worse outcomes in cardiac patients. Cardiac rehabilitation has a key role in improving lifestyle and risk factor control of diabetic patients, in order to improve their cardiovascular outcomes.

Table 1

	Systolic dysfunction	Normal EF	Level of significance
HbA1c	9,64%	6,70%	p=0,34 (NS)
Glucose	134,09 mg/dL	130,80 mg/dL	p=0,75 (NS)
LDL	72,64 mg/dL	67,46 mg/dL	p=0,46 (NS)
Triglycerides	119,83 mg/dL	116,75 mg/dL	p=0,83 (NS)
BMI	27,69 Kg/m2	27,33 Kg/m2	p=0,85 (NS)

Metabolic control depending on the EF at the end of the CRP in diabetics with previous systolic dysfunction

P385

Heart failure following acute st-elevation myocardial infarction: prognostic role of hyperglycemia, cardiotrophin-1 and galectin-3 plasma levels

L Malinova¹; T Povarova²; R Podbolotov¹; T Denisova³

¹Saratov State Medical University, Research Institute of Cardiology, Saratov, Russian Federation; ²Saratov Road Clinical Hospital, Cardiology, Saratov, Russian Federation; ³Saratov State Medical University, Saratov, Russian Federation

Background: Hyperglycemia on admission in patients with acute coronary syndromes (ACS) is common, and is considered as a powerful predictor of survival and increased risk of adverse cardiovascular events. Cardiotrophin-1 (CT-1) is a factor enhancing cardiomyocyte survival and protection in response to biomechanical stress, and a key regulator of glucose and lipid metabolism. It has been shown that galectin-3 (Gal-3) deficiency exacerbates hyperglycemia. There are still many gaps in our understanding of the association between elevated glucose levels and myocardial remodeling in acute ST-elevation myocardial infarction (STEMI).

Purpose of the study was to assess the significance of changes in CT-1 and Gal-3 levels over time in patients with STEMI and hyperglycemia on admission.

Methods. 60 male patients with STEMI without prior detected impaired glucose tolerance aged 39...60 were included in prospective open local study. The plasma concentrations of CT-1 and Gal-3 were determined using commercially available immunoassay kits on admission and on 7th day. Patients were followed-up for duration of hospital stay, cardiovascular rehospitalization, cardiovascular death and heart failure signs and symptoms (shortness of breath, ankle swelling, weight gain>2 kg within 3 days).

Results: Hyperglycemia>7.1 mmol/L at baseline was in 16.7% patients included in the study. In patients with hyperglycemia on admission CT-1 baseline level was higher (260.6 (229.6; 277.9) pg/mL vs 226.2 (220.2; 253.1) pg/mL, p=0.035). There were no differences in Gal-3 level at baseline in patients with and without hyperglycemia (17.5 (15.4; 22.2) ng/mL vs 21.9 (14.6; 30.7), p=0.222). In 86.6% of patients, changes in CT-1 and Gal-3 levels over time were of same direction: CT-1 increase between baseline and 7th day was associated with augmentation in Gal-3, and vice versa. In patients whose CT-1 level increased, left ventricular myocardial mass index was significantly higher than in patients with the opposite dynamics of CT-1 (84 (73; 98) vs 97 (92; 104) g/m2, p=0.023) independent of blood glucose level at admittance. In studied patients CT-1 at admittance correlated with blood glucose level (Spearman R=0.42, p<0.05). Risk of CV death within 12 month since ACS manifestation was also higher in patients with Gal-3>17.8 ng/mL (HR 3.87 (CI 3.38; 4.43)). Using a multivariate binary logistic model, CT-1 decrease by>10% between

baseline and 7th day (HR 1.8, CI: 1.1-3.2, p=0.031) predicted death or heart failure onset within 6 month independent of age, serum creatinine, blood pressure and Killip class. The logistic model combining the CT-1, Gal-3 and blood glucose level yielded an AUC of 0.86 (p<0.05).

Conclusion: Hyperglycemia on admission, high levels of cardiotrophin-1 and galectin-3 with subsequent decrease are more informative at predicting cardiovascular death or heart failure than either marker alone in patients with acute ST-elevation myocardial infarction.

P386

Nutritional indices, weight change, and mortality in heart failure: the nutrition Day survey analysis

M Lainscak¹; S Anker²; J Farkas³; M Themessl-Huber⁴; A Laviano⁵; M Hiesmayr⁶; K Schindler⁷

¹General Hospital Celje, Celje, Slovenia; ²University Medical Center Gottingen (UMG), Innovative Clinical Trials, Department of Cardiology & Pneumology, Gottingen, Germany; ³National Institute of Public Health, Ljubljana, Slovenia; ⁴Medical University of Vienna, Core Unit for Medical Statistics and Informatics, Vienna, Austria; ⁵Sapienza University of Rome, Rome, Italy; ⁶Medical University of Vienna, Division Cardiac-, Thoracic-, Vascular Anaesthesia and Intensive Care, Vienna, Austria; ⁷Medical University of Vienna, Department of Internal Medicine III, Division of Endocrinology and Metabolism, Vienna, Austria

Background: Nutritional status and body weight trajectory are associated with outcome in patients with heart failure. To what extent this applies to hospitalized patients and whether there is association with appetite and nutritional intake during acute event is largely unknown.

Purpose: This analysis aimed to investigate relations between nutritional status, weight changes, nutritional intake, and all-cause mortality in patients with heart failure.

Methods. The NutritionDay survey is an ongoing multinational registry that collects comprehensive data about nutritional indices and in-hospital outcome. Body mass index (BMI), body weight changes within last 3 months, nutritional intake during last week and on the survey day were recorded; investigators reported about all-cause in-hospital mortality.

Results: We identified 10763 patients with HF (75±14 years, 51% men) with an average BMI of 27±7 kg/m2. Overall, 6% had BMI <18.5 and were classified as malnourished. Weight loss within last 3 months was self-reported by 48% of patients (most often 4-5kg - 7%). During last week, 30% reported to eat less than half of what they normally eat; on survey day, 50% ate half or less of their lunch/dinner. Lowest mortality risk was observed for patients with BMI 35-40 kg/m2 while malnourished patients had 4 times higher risk of death. Relative risk for mortality increased with decreased food intake on survey day or during week prior to survey day (p<0.001 for both). Weight loss in last 3 months was associated with increased mortality, irrespective of BMI (Figure).

Conclusions: Malnutrition, weight loss and poor food intake are common in hospitalized patients with HF and are associated with in-hospital mortality.

P387

Diabetes in chronic heart failure patients: the road to hell is sweet

CC Diaconu¹; Z Abdul Rehman²; A Nastasa²; LA Balaceanu³

¹University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Floreasca, Bucharest, Romania; ²Emergency Clinical Hospital Floreasca, Bucharest, Romania; ³University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Sf. Ioan, Bucharest, Romania

Introduction: Diabetes mellitus increases the risk of heart failure in patients with cardiovascular diseases. The purpose of the study was to analyze the characteristics of patients with chronic heart failure and diabetes, hospitalized in the Internal Medicine clinic of a University Clinical Emergency Hospital, as compared with those without diabetes.

Methods: The study included 80 patients with chronic heart failure, consecutively admitted in 2015. We have retrospectively and comparatively analyzed the characteristics of patients with heart failure and diabetes (group 1) versus patients without diabetes (group 2), using Analyse-it software.

Results: The distribution by sex in the group of study: 53.9% men, 46.1% women. The mean age of the whole group was 71.1 ± 11.6 years. 31.1% of the 180 patients had type 2 diabetes (41% on insulin). The distribution of comorbidities in diabetic patients was: 80.4% arterial hypertension, 47.7% coronary heart disease, 43.5% atrial fibrillation, 42.9% dyslipidemia, 35.2% chronic kidney disease, 34.1% anemia, 34.1% obesity, 23.3% pulmonary hypertension, 20.9% depression, 14% peripheral arterial disease, 35.7% mitral stenosis, 10.7% aortic stenosis. The frequency of chronic kidney disease was statistically significant higher in patients from group 1 ($p = 0.017$), as well as arterial hypertension (80.4% in group 1 vs 62.5% in group 2, $p = 0.046$). Obesity: 34.08% in group 1 vs 26.4% in group 2, $p = 0.46$. Anemia: 34% in group 1 versus 12.7% in group 2, $p = 0.007$. Less patients from group 1 had atrial fibrillation (statistically significant). There was a significant difference in the frequency of coronary heart disease (47.7% in group 1 vs 29% in group 2, $p = 0.04$). Dyslipidemia: 42.9% in diabetics and 32.5% in nondiabetics, $p = 0.2$. In conclusion, almost 1/3 of admitted patients with chronic heart failure had type 2 diabetes. Conclusions Chronic heart failure patients with diabetes had a higher frequency of arterial hypertension, chronic kidney disease, obesity, coronary heart disease, mitral stenosis and anemia compared with patients without diabetes.

P388

Blood glucose levels increase significantly across higher NYHA functional class categories in patients with chronic heart failure: results from TREAT HF

S Eraslan¹; H Kaya²; Y Yuksel Cavusoglu¹

¹Eskisehir Osmangazi University, Eskisehir, Turkey; ²Cumhuriyet University, Cardiology, Sivas, Turkey

Purpose: Dysglycaemia and diabetes have been shown to be common in patients with heart failure (HF) and associated with worse prognosis. NYHA functional class has also been known to be a strong marker of poor prognosis. TREAT HF (Turkish Research Team-HF) data were analyzed for the assessment of any relationship between fasting blood glucose levels and NYHA functional class in patients with HF and reduced ejection fraction (HFrEF).

Methods: TREAT HF is a network which undertakes multicenter, national, observational studies designed to evaluate HF patient's clinical characteristics and current treatment modalities. 887 patients with the diagnosis of HFrEF and > 18 years of age who had fasting blood glucose measurement were included in this analysis. Out of 887 patients, 109 patients (12.2%) were in NYHA class I, 399 patients (44.9%) in NYHA class II, 337 patients (37.9%) in NYHA class III and 42 patients (4.7%) in NYHA class IV. Patients with recent acute coronary syndromes, severe hepatic or renal dysfunction, severe chronic obstructive pulmonary disease, severe anemia, cancer, hyper-/hypothyroidism and pregnant women were excluded from the study.

Results: Mean blood glucose level was 135 ± 68 mg/dL in study population, 123.2 ± 53 mg/dL in those with NYHA class I, 131.2 ± 66 mg/dL in those with NYHA class II, 140.8 ± 71 mg/dL in those with NYHA class III and 156.4 ± 77 mg/dL in those with NYHA class IV and overall, mean blood glucose levels were found to gradually and significantly increase across NYHA functional class categories ($p = 0.01$). Hyperglycaemia defined as blood glucose level > 126 mg/dL was found in 32 patients (29.4%) in those with NYHA class I, 128 patients (32.1%) in those with NYHA class II, 138 (40.9%) in those with NYHA class III and 25 patients (59.5%) in those with NYHA class IV and overall, the rate of hyperglycaemia was also found to gradually and significantly increase across NYHA functional class categories ($p < 0.001$).

Conclusions: These results suggest that there is a close relationship between NYHA functional class and fasting blood glucose levels or hyperglycaemia in patients with HFrEF as the blood glucose level increases significantly across higher NYHA functional class categories.

DISEASE MANAGEMENT PROGRAMMES

P389

Experience in a cardiac rehabilitation unit with heart failure patients.

P Pablo Meras Colunga¹; O Gonzalez¹; FJ Irazusta¹; V Rial¹; R Dalmáu¹; A Castro¹; AM Iniesta¹; JL Lopez-Sendon¹

¹University Hospital La Paz, Cardiology, Madrid, Spain

Introduction: More and more patients (p.) with heart failure (HF) or left ventricular systolic dysfunction (LVSD) are being referred to cardiac rehabilitation units. This is

a challenge because their particular characteristics compel us to adapt the type of training as well as the objectives of the program.

Methods: We received 206 p. (89.8% men) with severe LVSD (LVEF $\leq 35\%$, 17.5% of all p.), 92% of them with coronary disease. We performed a comprehensive program combining educational talks with supervised exercise sessions 3 days a week during 6-8 weeks, including an individualized medical consultation. We analysed the risk profile of the p., as well as the results obtained during the program with t-Student test.

Results: There was a high burden of risk factors: 52.9% had hypertension, 28.6% diabetes, 53.4% dyslipidemia, 55.6% were smokers and 25.5% former smokers, 25.9% obese and 55.1% had a sedentary lifestyle. In addition, they had a high rate of cardiac and non-cardiac co-morbidities. Medical treatment was optimized with 94% receiving beta blockers, 89% ACE inhibitors or ARA-II, 78% aldosterone antagonists and 15% ivabradine, 28% were on diuretic treatment and 92% on ASA and statins. During the program, there was a significant improvement in metabolic profile, as seen in table 1. Weight loss (>5% of basal weight) occurred in 15% of overweight p. Moreover, smoking cessation was achieved in 77% of patients at 3 months. Mean functional capacity (FC) improved from 6.1 METs at the beginning of the program up to 9.7 METs at the end of it. Only 4.5% of p. presented a poor FC (≤ 5 METs) when finishing the program, in contrast with a 43.2% in the basal ergometry. Regarding LVEF, there was a >10% improvement in 81% of p.: mean LVEF went from 29.5% to 42% at the end of the program, although we have to keep in mind that revascularization after STEMI had been performed in 68% of them. An ICD (implantable cardioverter defibrillator) was implanted in 22% of the p. Throughout the program, the rate of inappropriate shocks or shocks during exercise was 0%. Abandon rate was 12%.

Conclusions: Patients with LVSD and HF benefit from a structured cardiac rehabilitation program, with improvement both in metabolic risk profile through lifestyle correction and in FC by means of adapted exercise training.

Table 1.

Metabolic parameters	Basal	End of program	p	Other parameters	Basal	End of program	p
LDL (% <70 mg/dl)	104 ± 37	75 ± 28 (20.3%)	(44.3%)	< 0.001	Body mass index	27.9 ± 4.9	27.3 ± 4.3
HDL (mg/dl)	36 ± 10	37 ± 10	0.54	Waist circumference	100.3 ± 12	98.4 ± 11	< 0.001

Day-care heart failure unit - a missing link in the management of refractory heart failure

M Gasior¹; J T Niedziela¹; J Sikora¹; P Rozentryt¹; M Hawranek¹; G Slonka¹; J Nowak¹; B Szygula-Jurkiewicz¹; M Zembala²; L Polonski¹

¹Medical University of Silesia, 3rd Department of Cardiology, SMDZ in Zabrze, Katowice, Poland; ²Medical University of Silesia, Department of Cardiac Surgery and Transplantation, SMDZ in Zabrze, Katowice, Poland

Background: Heart failure (HF) is an increasing medical and economic burden worldwide. Despite the progress in cardiology, the prevalence of HF is increasing and the outcome remains poor. In advanced HF 1-year mortality as well as 1-year rehospitalization rates may exceed 50%. The comprehensive medical day care unit may be a clue of novel HF management. Day-care unit may possibly fill a gap between hospital and outpatient HF treatment.

Purpose: The purpose of the study was to assess the safety and clinical usefulness of day-care HF unit (DCHFU) among patients with refractory HF.

Methods: The study is a prospective analysis of consecutive patients and visits in DCHFU. The unit is a part of the tertiary cardiology hospital with possibility of cardiac surgery, heart transplantation and mechanical circulatory support. Patients with refractory HF fulfilling followed criteria were included into the study: NYHA class II-IV, at least two HF hospitalizations during preceeding 12 months. Moreover, all possible methods of interventional treatment should be utilized – optimal revascularization, valvular correction and/or ablation performed, as well as ICD/CRT-D implanted if applicable. Optimally decongested patients qualified either for optimal medical therapy or heart transplantation were recruited during hospitalization. DCHFU is a hospital ward equipped with cardiac monitors, infusion pumps and other tools necessary to intravenous drug administration (diuretics, dobutamin). Furthermore, educational and dietetic activities, as well as diagnostic procedures and

ICD/CRT interrogations might be performed. Intervals between visits were individually arranged and two kinds of visits were scheduled depending on patients' clinical status - diagnostic (physical examination, body weight measurement, laboratory test, echocardiography etc.) and therapeutic (diagnostic + drug administration). The clinical parameters, procedures, events and the outcomes were monitored.

Results: During the initial 3 months of the project, 24 patients (age: 60.9 ± 13.5 years; 12.5% of them were women; NYHA class 2.88 ± 0.79 ; LVEF 21.1 ± 9.3 ; NT-proBNP 4130 ± 1922 pg/ml) were enrolled into the program. Out of first 140 visits, 100 (71.4%) had therapeutic

Purpose: Loop diuretics were administered during 92 (65.7%), low-dose dobutamine (<3.0 $\mu\text{g/kg/min}$ infusion) - 70 (50%) and kalium - 27 (19.3%) visits. Moreover there were 3 (2.1%) pleurocenteses. There were no adverse events during the visits in DCHF. In the course of the median 66 [64] days of observation, five (3.6%) patients were hospitalized, two (1.5%) patients died due to exacerbation of HF and four (2.9%) underwent heart transplantation.

Conclusion:

The day-care HF unit seems to be safe and useful option for refractory heart failure management.

P391

Multidisciplinary telehealth program for patients affected by chronic heart failure and chronic obstructive pulmonary disease.

This work was financially supported by the Italian Ministry of Health -CCM 2011; project n. 14)

S Scalvini¹; P Bernocchi²; D Baratti³; T Gatti³; M Paneroni³; MT La Rovere⁴; M Volterrani⁵; M Vitacca³

¹Fondazione Salvatore Maugeri, IRCCS, Cardiac Rehabilitation Division, Lumezzane, Italy; ²Fondazione Salvatore Maugeri, IRCCS, Care Continuity Unit, Lumezzane, Italy; ³Fondazione Salvatore Maugeri, IRCCS, Respiratory Rehabilitation Division, Lumezzane, Italy; ⁴Fondazione Salvatore Maugeri, IRCCS, Cardiac Rehabilitation Division, Montescano, PV, Italy; ⁵San Raffaele Pisana IRCCS, Cardiology Department, Roma, Italy

Background: Chronic heart failure (CHF) and chronic obstructive pulmonary disease (COPD) frequently coexist, significantly reducing quality of life (QoL) and increasing morbidity and mortality. For either single disease, a multidisciplinary disease-management approach supported by telecommunications technologies offers the best outcome in terms of prolonged survival and reduced hospital readmission.

Purpose: The aim of study was to investigate the feasibility and efficacy of an integrated medical/nursing intervention plus rehabilitation program running at home versus conventional care in patients with coexisting CHF/COPD.

Methods: Patients, after inpatient rehabilitation, were randomly assigned to Treatment group (TG) or Control group (CG), followed for 4 months at home, then assessed at 4 and 6 months. The TG followed a telesurveillance (phone-contacts by nurse and telemonitoring of cardio-respiratory parameters) and telerehabilitation program (≥ 3 sessions/week of mini-ergometer, calisthenic exercises and twice weekly pedometer-driven walking, plus phone-contacts by physiotherapist). Telephone follow-up served to verify compliance to therapy, maintain exercise motivation, educate for early recognition of signs/symptoms, and verify the skills acquired. At baseline and 4 and 6 months, the exercise capacity by the 6-min walk test (WT), dyspnoea and fatigue at rest (Borg scale), Physical Activity by a Scale for the Elderly (PASE), and QoL by Minnesota Living with Heart Failure Questionnaire (MLHFQ) and COPD assessment Test (CAT) were assessed. Serious clinical events were recorded and analysed as days free from hospitalization and death during 6 months of study.

Results: We enrolled 56 patients for group. 11 patients in the TG were lost to follow up (20%) as did 21 patients (37.5%) of the CG ($p=0.036$). After 4 months TG improved significantly respect to CG in the change (Δ) of exercise capacity (ΔWT 60 ± 133 in TG vs -15 ± 82 in CG, $p=0.004$), dyspnoea (ΔBorg -0.4 ± 1.2 in TG vs 0.7 ± 1.4 in CG, $p=0.0001$), muscular fatigue (ΔBorg -0.5 ± 1.5 in TG vs 0.8 ± 1.4 in CG, $p=0.0000$), physical activity (ΔPASE 18 ± 65 in TG vs -21 ± 47 in CG, $p=0.0015$) and QoL (ΔMLHFQ -10.5 ± 12.7 in TG vs -0.44 ± 14.5 in CG, $p=0.0007$ and ΔCAT -5.3 ± 5.6 in TG vs -1.6 ± 6.4 in CG, $p=0.0000$). After farther 2 months, the TG had maintained significantly improvement in the exercise capacity ($p=0.004$) and dyspnoea ($p=0.0266$). The free days of events were significantly higher in the TG ($p=0.0374$).

Conclusions: Our multidisciplinary telehealth program showed that this approach is feasible and effective in the management of such complex, frail patients with very high risk of exacerbation.

P392

The impact of a comprehensive acute heart failure service on clinical outcomes

Bristol NIHR Cardiovascular Biomedical Research Unit

Y Ismail¹; H Lightfoot¹; H Beswick¹; J Tagney¹; A K Angus K Nightingale¹

¹Bristol Heart Institute, Department of Cardiology, Bristol, United Kingdom

Background: Acute heart failure (AHF) is a frequent cause of admission to hospital and is associated with a high mortality rate. Recent ESC guidelines recommend a multidisciplinary team approach to improve outcomes. In 2014 we introduced an acute HF outreach service to our medical wards led by a HF specialist nurse and HF consultant. This included proactively seeking patients with AHF on medical wards, education programmes for staff and daily review. We also implemented a novel initiative to improve care for patients approaching end of life.

Purpose: To describe the impact of the specialist HF outreach service on mortality, length of stay and 30-day readmission on medical wards.

Methods: We performed a retrospective analysis of data from all patients admitted to a medical ward (excluding cardiology) in our institution with a diagnosis of AHF during a 12 month period before and after the service was introduced. Patients were included if AHF had contributed to their admission. We assessed 30-day readmission rates, length of stay and mortality rates. We documented the number of discussions about prognosis and end of life care.

Results: (Table 1) Mean age of the AHF patients was 81 years in both periods. Following introduction of the outreach service 116 additional AHF patients were seen; there was a significant reduction in mean length of stay by 2.3 bed days per patient and a 4% decrease in 30 day readmissions. In contrast, there was a (non-significant) increase in mortality (possibly due to failure of the UK flu programme in 2014/15). Prior to the outreach programme, few AHF patients were being identified prospectively as nearing end of life on discharge. After introduction of a comprehensive treatment programme including education and linking with palliative care services, this was significantly increased with 116 discussions about prognosis and patients' end of life wishes documented prior to discharge.

Conclusions: Introduction of a specialist AHF outreach service from cardiology to medical wards resulted in a significant reduction in length of stay and 30-day readmission rates. The old age of many of these patients and high mortality of AHF emphasise the need for difficult discussions with patients about prognosis and planning of appropriate end of life care on discharge.

Table 1

	Pre	Post	p value
number of patients	623	739	
30 day re-admission rate (% , n)	17.3% (108)	13.3% (98)	0.04
30 day mortality rate (% , n)	15.1% (94)	18.5% (137)	0.1
mean length of stay (days)	13.5	11.2	0.01

Clinical impact of the AHF multidisciplinary team

Distribution and organization of heart failure outpatient clinics in Italy: preliminary data from the national working group survey

I Battistoni¹; D Pini¹; R De Maria¹; M Iacoviello¹; A Mortara¹; A Navazio¹; M Gabriele¹; N Aspromonte¹; A Di Lenarda¹; MM Gulizia¹

¹Heart Failure Group Italian Association of Hospital Cardiologists, Florence, Italy

Background: The role of traditional Heart Failure (HF) outpatient clinics (HFOC) in evolving health systems is challenged by the advocated shift from tertiary-based care to community-based outpatient services for the management of chronic conditions. To fulfil the claim to enhanced quality of care HFOC should relocate across the spectrum of HF population care and network to ensure that ambulatory HF patients are followed-up by the most appropriate health care providers in the right setting.

Purpose: To describe the national distribution and characteristics of HFOC offer and to investigate whether a reciprocal referral system exists between centres with different capabilities as preliminary step to the establishment of a national HF network based on specific regional features.

Methods: We used data from the last cardiology units census carried out by our national scientific society to identify departments that declared an HFOC offer in 2010. We e-mailed a 18-item questionnaire to investigate HFOC characteristics in terms of facilities, equipment, staffing and patient volume and established connections for upstream and downstream patient referral.

Results: Out of 432 cardiology units, 268 (62%) answered the questionnaire and 251 declared they have a dedicated HFOC. Most HFOC (233, 93%) have a Cardiology inpatient unit. Only 17% HFOC are located outside the hospital. Two-hundred-two HFOC (80%) are staffed by dedicated physicians and 163 (65%) by dedicated nurses. Approximately two-thirds of HFOC (164, 65%) are located in centres with a CCU, catheterization and electrophysiology labs and cardiac surgery and 14% (36) have heart transplantation and/or mechanical circulatory support program. A formal system for upstream patient referral exists in 72% of centres without advanced facilities.

Conclusion: The survey highlights that formal upstream referral, although available in most national centres, needs to be further strengthened. Conversely, there is ample room to improve HFOC networking with community care services.

P394

The Italian heart failure care network guidance document

R De Maria¹; A Mortara¹; I Battistoni¹; M Iacoviello¹; A Navazio¹; D Pini¹; M Gabriele¹; N Aspromonte¹; A Di Lenarda¹; MM Gulizia¹

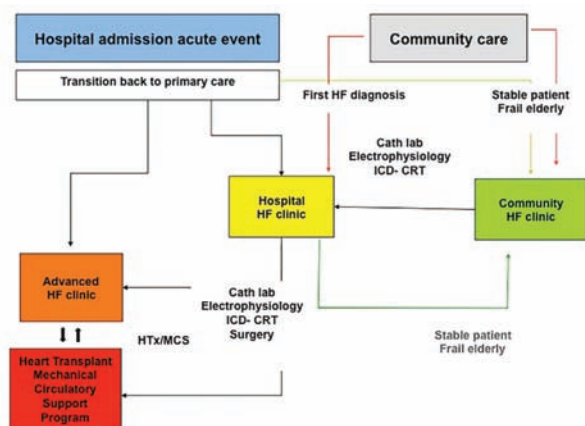

¹Heart Failure Group Italian Association of Hospital Cardiologists, Florence, Italy

Background: Changing demographics and an increasing burden of multiple chronic comorbidities in Western countries dictate refocusing of heart failure (HF) services from acute in-hospital care to better support the long inter-critical out-of-hospital phases of HF. In ours, as well as in other countries, needs of the HF population are not adequately addressed by current HF outpatient services, as documented by differences in age, gender, comorbidities and recommended therapies between patients discharged for hospitalised HF and those followed-up at HF clinics.

Purpose: Our national Working Group on Heart Failure has drafted a guidance document for the organisation of a national HF care network. Aims of the document are to describe tasks and requirements of the different health system points of contact for HF patients, and to define how diagnosis, management and care processes should be documented and shared among health care professionals.

Methods and Results: The document classifies HF clinics in 3 groups: 1) Community HF clinics, devoted to management of stable patients in strict liaison with primary care, periodic re-evaluation of emerging clinical needs and prompt treatment of impending destabilizations, 2) Hospital HF clinics, that target both new onset and chronic HF patients for diagnostic assessment, treatment planning and early post-discharge follow-up. They act as main referral for medicine units and community clinics, 3) Advanced HF clinics, directed at patients with severe disease or persistent clinical instability, candidates to advanced treatment options such as Heart Transplant or Mechanical Circulatory Support. Those different types of HF clinics are integrated in a dedicated network for management of HF patients on a regional basis, according to geographic features. By sharing pre-defined protocols and communication systems, these HF networks integrate multi-professional providers to ensure continuity of care.

Conclusion: This guidance documents is expected to promote a more efficient organization of HF care, in particularly for elderly patients and in transition phases from acute to chronic HF, by networking outpatient cardiology offer and primary care.

Effect of extended follow up in a specialized heart failure clinic on health related quality of life: northstar quality of life substudy

Roche Diagnostics

M Schou¹; L Videbaek²; PH Hildebrandt³; CD Tuxen³; F Gaborit¹; C Madelaire¹; G Gislason¹; L Kober⁴; JE Moller²; F Gustafsson⁴

¹Herlev and Gentofte Hospital, Cardiology, Herlev, Denmark; ²Odense University Hospital, Department of Cardiology, Odense, Denmark; ³Frederiksberg Hospital, Frederiksberg, Denmark; ⁴Rigshospitalet - Copenhagen University Hospital, Heart Centre, Copenhagen, Denmark

Background: The mortality rate for patients with heart failure (HF) and reduced left ventricular ejection fraction has been reduced and it has been suggested that physicians and researchers should pay more attention to quality of life in these patients. Health related quality of life might, therefore, be important clinical endpoint in future clinical trials. Purposes: In The NorthStar Quality of Life Substudy we evaluated the effect of extended follow up in aHF clinic on health related quality of life and the relationship between Minnesota Living with HF questionnaire (MLwHFQ) Score and risk of death and a re-admission.

Methods: Post hoc analyses on data from a randomized clinical trial. A total of 961 systolic HF patients educated in HF and on optimal medical therapy according to

European guidelines were randomized to either extended follow up in a HF clinic or follow up in Primary Care and followed for a period of 2.5 years (6 months- 4.5 years) and the effect of the intervention on MLwHFQ Score at follow up end was evaluated by paired a T-test. Patients were stratified according to MLwHFQ Score and the relationship to risk of readmission and death were evaluated by Cox Proportional Hazard Multivariate Models.

Results: The patients had an age of Mean age was 69 ± 10 years, 75 % were males, 59 % had ischemic heart disease 90 % were NYHA II-III, LVEF 0.30 ± 0.07, NT-proBNP 801 pg/ml (IQ range: 111- 6500 pg/ml) and MLwHFQ was 24 (IQ: 12-41). Extended follow up had no effect on health related quality of life (-1 versus 0 (P = 0.573)). MLwHFQ Score was associated with an increased risk of time to death or a cardiovascular admission (Hazard Ratio (HR): 1.43 (1.10-1.85, P = 0.007)), a HF admission (HR: 1.93 (1.25-2.97, P = 0.003) and an over all admission (HR: 1.43 (1.15-1.77, P = 0.001) in multivariate analyses adjusted for traditional confounders. Patients with a poor quality of life were more frequently admitted (58 % vs 45 %, P = 0.01, had more admission days (10 vs 7, P = 0.002) and had a higher number of admissions (1.6 vs 1.0, P = 0.003).

Conclusions: Extended follow up in a HFC had no effect on health related quality of life. However, a poor MLwHFQ Score was associated with an increased risk of death and re-admission. Improving health related quality of life may reduce admission rates in HF and this endpoint should be further evaluated by new interventions.

P396

Effect of successful treatment and non - pharmacological disease management program on severity of anxiety and depression symptoms in congestive heart failure patients.

JL Begrambekova¹; MY Drobizhev²; VY Mareev¹

¹M.V. Lomonosov Moscow State University, Medical Research and Education Center, Moscow, Russian Federation; ²I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: CHF is frequently associated with depression and anxiety. It is disputable that depressive symptoms may be reversible without specific therapy in parallel with improving of physical condition. Disease Management Programs (DMP), consisted of structured education and regular phone calls, have been shown significantly reduce risk of death and hospital readmission and in CHF patients.

Objectives: To evaluate - is it real connection between CHF symptoms reduction and improvement of depression and anxiety scores during CHF treatment plus DMP.

Materials and Methods: We analyzed the data from prospective, randomized, parallel group trial which investigate the effect of DMP on patient's outcome (Congestive Heart Failure: A multidisciplinary Non-pharmacological approach for Changing in re-hospitalization and prognosis in patients (CHANCE)). DMP did not include any special psychological intervention. Patients' assessment of depression and anxiety were determined at baseline, on 24 and 48 weeks by Hospital Anxiety and Depression Scale (HADS). Clinical symptoms and functional capacity of the patients were assessed by 'Scale of Heart failure Optimizing Clinical Status (SHOCS)', routinely used in Russia and with 6 minute walk test (6MWT).

Results: HADS questionnaire was performed in 737 patients at baseline. Clinically relevant depression (HADS > 10) was found in 272 (37%) of patients (III-IV NYHA FC, 34,6% women, average age - 62,7 ± 10,9). Symptoms improved at 48 weeks in all patients (univariate ANOVA for HADS p < 0,000001). But in DMP group, number of patient with clinically relevant depression (HADS > 10) decreased by 19,7% more, compare with usual care group (p < 0,001). There were positive correlations between the average clinical improving of CHF symptoms, assessed by SHOCS, or increased 6MWT distance and depression and anxiety score reduction (HADS) in both groups at 48 weeks of treatment.

In pts, whose clinical symptoms of CHF have not improved or deteriorated (N = 120), that underwent DMP more likely significantly reduce depressive OR 2,54 [95% CI:1,094-5,9] p = 0,02 and anxiety symptoms OR 2,82 [95% CI:1,21-6,56 p = 0,0139], than patients in usual care group.

Conclusions: Depressive and anxiety symptoms in patients with CHF in the majority of cases are reversible and decreasing without specific therapy is in parallel with improving CHF symptoms. But non-pharmacologic DMP even without specific psychological support give additional benefit due positive impact on emotional wellbeing of CHF patients, even in unsuccessful treatment of CHF.

HEART FAILURE IMAGING

P397

Right ventricular inflow tissue doppler time intervals in patients with left heart failure

M Tserava¹; DM Tserava²; E Khurtsidze¹

¹Tbilisi Iliia Chavchavadze State University, Tbilisi, Georgia Republic of;

²MediClubGeorgia Tbilisi Clinic, Medicime, Tbilisi, Georgia Republic of

The purpose of our research was to study the changes in right ventricular (RV) TDI parameters in patients with Heart Failure (HF). Material and

Methods: We studied 110 patients with II-IV NYHA functional class HF (I gr.) and 110 patients with Arterial Hypertension and Coronary Artery Disease but without HF. RV TDI was registered from lateral corner of tricuspid valve. In HF group 53 patients had systolic and 57 - diastolic HF. All patients where in sinus rhythm. We measured maximal systolic (S2), isometric contraction (S1), early diastolic (E) and late diastolic (A) velocities; ejection (RVET), Isovolumic Contraction (ICT) and Isovolumic Relaxation (IRT) time intervals, calculated RV Tissue TEI index as $TEI_{RV} = (ICT + IRT) / RVET$.

Results: The difference between patients with and without HF in TDI velocity parameters was not significant, but ICT (81.4 ± 35.4 msec. in I gr. versus 69.4 ± 17.2 msec. in II gr., $p < 0.05$), IRT (75.0 ± 30.2 msec. in I gr. versus 16.8 ± 12.8 msec. in II gr., $p < 0.001$) and TEI_{RV} (0.55 ± 0.24 in I gr. versus 0.35 ± 0.24 msec. in II gr., $p < 0.001$) were significantly greater in patients with HF. 94 % of patients with HF and only in 7% of patients without it had IRT more than 35 msec. The Sensitivity of $RVIRT > 35$ msec in diagnosis of HF was 0.94, specificity - 0.93. **Conclusion:** There are prominent changes in RV TDI Time Intervals in patients with left ventricular HF. The prolongation of IRT on RV TDI (> 35 msec.) is sensitive EchoCG marker of HF.

P398

Cardiovascular remodeling in patients with essential hypertension and concomitant type 2 diabetes depending on polymorphism of agtr1 gene

A Anna Shalimova¹; A Belovol²; L Bobronnikova²; M Kochueva¹; A Linskaya³
¹Kharkiv National Academy of Postgraduate Education, Therapy and Nephrology, Kharkiv, Ukraine; ²Kharkiv National Medical University, Clinical Pharmacology, Kharkiv, Ukraine; ³Institute of Neurology, Psychiatry and Narcology of NAMS of Ukraine, Clinical diagnostics with the group of Pathomorphology, Kharkiv, Ukraine

In recent years the researchers have been paying much attention to study of genetic components of essential hypertension (EH) and type 2 diabetes (DM2) - one of the most common noninfectious diseases in the world. The aim of the study was to investigate the polymorphism of angiotensin II receptor type 1 gene (AGTR1) and its associations with cardiovascular remodeling in patients with EH and concomitant DM2. The main study group consisted of 320 patients, aged from 45 to 60 years old with EH stage II, grade 2, heart failure I-II functional classes in combination with DM2 moderate, subcompensated. The group of comparison consisted of 90 patients with EH without DM2. The control group consisted of 31 healthy individuals with no EH and DM2, as they were excluded on the basis of the complex clinical and instrumental examinations. It was established that more than half of patients with EH both as in presence and absence of DM2 had A/C and C/C genotypes of AGTR1 (61,6% and 57,8% respectively), which are regarded as unfavorable for the development of the cardiovascular pathology. As to the spectrum of these genotypes the main group and comparison group significantly differ from control group ($p < 0,01$ and $p < 0,05$ respectively). It was found that allele C was present in about a third of patients with EH (both in presence and absence of DM2 (33,1% and 31,1% respectively)), while in control group it was present significantly much less frequently (in 19,4% of patients, $p < 0,05$). It was established that patients with A/C and C/C genotypes of AGTR1 had significantly higher blood pressure levels ($p < 0,001$), sizes of left ventricle (LV) and myocardial mass index (MMI) LV ($p < 0,01$), intima-media thickness (IMT) at lower degree of endothelium-dependent vasodilatation ($p < 0,01$) than in A/A genotype. Thus, no significant difference in hemodynamic indices between homozygous genotype C/C and heterozygous genotype A/C was found. However in patients with EH without DM2 as well as in patients with comorbidity, polymorphism of AGTR1 was associated with the difference of blood pressure ($p < 0,001$), severity of cardiac remodeling ($p < 0,001$) and less vessel remodeling (significant difference only in IMT, $p < 0,01$).

Conclusions: It was established that there is an association of A/C and C/C genotypes of AGTR1 gene with the development of comorbidity EH and DM2 in Ukrainian population. A/C and C/C genotypes of AGTR1 gene were characterized by significantly higher levels of blood pressure, more pronounced disorders of structural and functional parameters of the heart and vessels than A/A genotype.

P399

Evaluation of left and right ventricular systolic and diastolic function with tissue doppler, strain echocardiography imaging and myocardial performans Ttei) index

AS Abdulcelil Sait Ertugrul¹; DR Mutlu H¹

¹Istanbul University , Cerrahpasa Faculty of Medicine, Cardiology Department, Istanbul, Turkey

Introduction: Manifest Cardiac Sarcoidosis is readily diagnosed in only 5% of the cases. Nonetheless in post-mortem series pathologic investigation reveals

cardiac involvement in about 20-30% of sarcoidosis patients. There is variation in the prevalence of Cardiac involvement among different ethnic populations with numbers reported up to 58%. Early diagnosis and treatment can reverse pathological findings in cases with cardiac involvement. We aimed to investigate the prevalence of sub-clinical cardiac involvement by strain echocardiography imaging and myocardial performance (Tei) index calculated from tissue doppler echocardiography in sarcoidosis patients with normal conventional echocardiographic findings.

Methods and Materials: The study population were enrolled in between June 2015-January 2016 from the outpatient clinics of Department of Internal Medicine at an University Hospital. Sarcoidosis group consists of 31 patients, including 16 males and 15 females. Control group consists of 30 healthy volunteers including 15 males and 15 females. Tissue doppler, strain echocardiography and myocardial performance index values were analysed and compared between the patient and control groups.

Results: Mean age of the patient group was $41,32 \pm 7,56$ years. Age, sex, body-mass index (BMI), functional capacity, family history of cardiac disease and conventional echocardiographic findings except left atrial volume and left atrial area index values were similar between the groups. Global longitudinal strain, longitudinal strain rate, diastolic E and A strain rates were found to be lower in the patient group compared to the control group. ($p < 0,05$) Radial strain values were found to be similar between the patient and the control groups. ($p = 0,096$) While Left Ventricular MPI were found to be higher in patient group ($p = 0,01$), Right ventricular MPI were found to be similar. (0,193) **Conclusion:** Cardiac involvement of Sarcoidosis could be recovered with early diagnosis and treatment. Strain echocardiography and myocardial performance index investigations can guide early diagnosis and can be effective and feasible instruments in clinical follow up.

What is the best method to measure the left atrium in hypertrophic cardiomyopathy

P J Paulo Jorge Gomes Dinis¹; R Teixeira¹; L Reis¹; M Madeira¹; J Silva¹; A Botelho¹; MC Cachulo¹; L Goncalves¹

¹University Hospitals of Coimbra, Coimbra, Portugal

Introduction: Left atrium (LA) enlargement in hypertrophic cardiomyopathy (HCM) is associated with an increased risk of arrhythmias, thromboembolism and heart failure (HF). However, it remains unclear what is the best method to measure the LA. Our purpose was to assess the LA dimension by one-dimensional (M mode or 2D) and with the volumetric method. We subsequently analyzed which was more reliable to predict a clinical outcome.

Methods: Retrospective study of 80 consecutive patients with HCM, all in sinus rhythm. We evaluated demographics, cardiovascular history, medication, laboratorial data, electrocardiogram and echocardiogram. We measured the LA with one-dimensional method (M or 2D mode) and with the volumetric method (modified Simpson). A clinical follow-up (combined) for mortality, HF hospitalization and sustained ventricular arrhythmia was performed (mean time of 18 months). The sample was divided into two groups: Group A (no event), N = 60; Group B (with events), N = 20.

Results: The mean age of the sample was 58 ± 18 years with gender balance. 75% of patients had septal hypertrophy and 15% apical hypertrophy. Obstruction of the left ventricular outflow tract was present in 43,8% and about a quarter had an ICD. The mean LA diameter was $4,3 \pm 0,8$ cm and the mean volume was $87,7 \pm 34,5$ mL. The groups were homogeneous regarding the parameters described above. During follow up, patients with events (Group B), had a larger LA, either by one-dimensional ($4,6 \pm 0,7$ vs. $4,2 \pm 0,8$ cm; $P = 0.035$) or by the volumetric assessment ($103,0 \pm 45,7$ vs. $82,7 \pm 29,8$ mL, $P = 0.046$).

LA one-dimensional and the volumetric assessment had a similar accuracy to estimate the clinical outcome (area under curve one-dimensional: 0.62 vs. volumetric: 0.64, P for comparison = 0.72) - Figure 1.

Indexing to the body surface area did not improve both measurements discriminatory capacity.

Conclusion: According to our data, for HCM patients in sinus rhythm, LA volume was not superior to one-dimensional assessment to estimate a combined clinical outcome.

Area under curve comparison

P401

Apical vs non-apical HCM: myocardial deformation assessment using 3D wall motion tracking

A Adriana Pereira¹; N Moreno¹; L Marques¹; R Pontes Dos Santos¹; H Guedes¹; D Seabra¹; J Azevedo¹; P Pinto¹

¹Hospital Centre do Tamega e Sousa, Penafiel, Portugal

Introduction: Apical Hypertrophic cardiomyopathy (HCM) is a phenotypic variant of non-obstructive HCM, characterized by hypertrophy of apical segments, and is associated with a more favorable clinical outcome when compared with other types of HCM.

Objective: To evaluate the differences between patients with apical HCM and non-apical forms of HCM using three-dimensional echocardiography with 3D speckle-tracking (3DSTE).

Methods: Single-center study, including patients with HCM underwent assessment of atrial and ventricular strain by 3DSTE. Parameters of diastolic dysfunction were also assessed. Divided patients into 2 groups according to morphology: apical HCM and non-apical HCM. Statistical analysis was performed to assess differences among groups.

Results: 35 patients were included, mean age 61.4 ± 10.3 ; 62.9% male. 10 patients (28.5%) had apical HCM. The mean left ventricular function by 3D volumetric evaluation was $55.2 \pm 11.4\%$. No statistically significant difference between the two groups was found ($p=0.26$). Myocardial deformation parameters of the left ventricular: there were no statistically significant differences in global longitudinal strain (-10.4 ± 4.0 vs. -10.3 ± 2.9 ; $p=0.93$), global circumferential strain (-24.9 ± 9.4 vs. -23.8 ± 2.5 , $p=0.73$) global radial strain (28.9 ± 12.7 vs 26.8 ± 4.6 , $p=0.64$), area tracking (33.9 ± 10.2 vs 30.4 ± 4.4 , $p=0.19$) or twist (5.9 ± 2.8 vs 5.5 ± 3.7 , $p=0.73$). There were no statistically significant differences in the left atrial longitudinal strain (12.13 ± 7.9 vs 13.8 ± 7.4 , $p=0.81$), left atrial radial strain (13.9 ± 9.4 vs 19.6 ± 10.3 , $p=0.15$) or left atrial tracking area (32.5 ± 21.9 vs 33.2 ± 17.9 , $p=0.43$). The left atrial volume (systolic 59.7 ± 23.6 vs 54.6 ± 14.7 mL, $p=0.5$; diastolic 88.2 ± 26.8 vs 77.3 , $p=0.15$), left atrial ejection fraction (32.8 ± 12.7 vs $29.9 \pm 9.1\%$, $p=0.48$), ratio E / A (1.6 ± 0.9 vs 1.7 ± 1.2 ; $p=0.95$), ratio E / E' (13.5 ± 5.6 vs 11.5 ± 4.8 , $p=0.32$) and E wave deceleration time (0.20 ± 0.05 vs 0.20 ± 0.08 msec, $p=0.87$) were not statistically different in both groups.

Conclusions: Although considered a more benign form of HCM, patients with apical morphology when compared with non-apical HCM patients showed no significant differences in the parameters of ventricular or atrial global deformation. Similarly, there were no significant differences in diastolic function parameters between the two groups.

P402

Global longitudinal strain to identify patients with LVEF < 35% and LVEF < 30%

M Maximilian Krisper¹; C Koehncke¹; F Escher¹; U Primessnig¹; B Kossmann¹; B Pieske¹; C Tschoepe¹; D Morris¹

¹Charité - Campus Virchow-Klinikum (CVK), Medizinische Klinik mit Schwerpunkt Kardiologie, Berlin, Germany

Objectives: Current pathophysiological understanding of the interrelation and similarities between strain and volumetric indices like LVEF is limited. For identifying patients with certain LVEF values, GLS has not played a role so far.

Background: Measurement of global longitudinal strain may prove useful in subdivision and risk stratification of patients with reduced ejection fraction. In patients

with heart failure a closer linkage and correlation between longitudinal strain values with LVEF may be at hand.

Methods: A total of 633 patients have been studied via conventional echocardiography and clinical characteristics have been documented. Subsequently echocardiographic images were reviewed by expert echocardiographers and 2D speckle tracking based strain analysis was performed.

Results: Myocardial tissue deformation is closely and meticulously linked with conventional parameters of systolic function. Correlation of conventional volumetric parameters such as LVEF with GLS was statistically highly significant ($r=0.90$, $R^2=0.81$, $p<0.05$). For the subgroup of patients with LVEF 25-30% mean GLS was -6.48% ($\pm 0.12\%$ SEM), patients with LVEF 30-35% had a mean GLS of -7.88% ($\pm 0.13\%$ SEM). GLS values of -6.25% to -6.71% identified patients with LVEF 25-30% ($n=98$) with a 95% confidence interval. For patients with LVEF 30-35% ($n=107$) 95% confidence interval ranged from -7.63% to -8.13% . Further statistical correlation of GLS with LVEF allows objectifying the degree of left ventricular dysfunction: ROC analysis of the above mentioned GLS cut-off values proved GLS -7% to be optimal in identifying LVEF $<30\%$ (AUC 0.79, Youden's Index 0.45) and GLS -9% to identify LVEF $<35\%$ (AUC 0.86, Youden's Index 0.6) respectively. In a multivariate analysis parameters as age, sex, heart rate, arterial hypertension, body mass index, etc did not modify the relationship between GLS and LVEF significantly.

Conclusions: GLS possesses excellent potential in stratifying patients with heart failure and reduced ejection fraction according to LVEF and thereby possibly help to identify candidates for ICD (GLS $> -7\%$) and resynchronization therapy ($> -9\%$).

LVEF and mean GLS 95% CI

LVEF (%)	n	GLS mean \pm SEM (%)	GLS 95% CI	p

Difference in prognostic impact of E to E prime ratio between decreased and preserved left ventricular function in patients with acute decompensated heart failure

SY Se Yong Jang¹; DH Yang¹; NG Kim¹; CY Kim¹; J Son²; MH Bae¹; JH Lee¹; HS Park¹; Y Cho¹; SC Chae¹

¹Kyungpook National University Hospital, Daegu, Korea Republic of; ²Kyungpook National University Medical Center, Internal Medicine, Daegu, Korea Republic of

Background: The ratio of early transmitral velocity to tissue Doppler mitral annular early diastolic velocity (E/E') is widely used for estimating pulmonary capillary wedge pressure, which can be one potent prognostic marker in patient with heart failure. Recent studies have shown that this estimation is quite inaccurate in patients with decreased left ventricular (LV) function. We aimed to investigate difference in prognostic impact of E/E' on long term prognosis between decreased and preserved left ventricular function in patients with acute decompensated heart failure (ADHF).

Methods: A total of 836 patients (66.2 ± 14.7 years-old, 442 men) who suffered acute decompensated heart failure between Jan. 2005 and June. 2015 were included. Composite of all-cause mortality and re-hospitalization for ADHF was recorded for 5-years follow-up. Results During follow-up (22.0 ± 18.5 months), 343 (41.0%) events were recorded. In overall patients, E/E' was an independent prognostic

marker for adverse events (hazard ratio [HR] 1.01 [1.00-1.03], $p=0.023$) together with age, NYHA class, and serum creatinine. Kaplan-Meier analysis revealed that patients with high E/E' ($E/E' > 15$) exhibited significantly worse prognosis (49.7% vs. 25.7%, $p<0.001$) compared to those with low E/E' ($E/E' \leq 15$) in patients with preserved LV function (LV ejection fraction $>30\%$), whereas there is no significant difference in prognosis between high and low E/E' group (45.0% vs. 36.4%, $p=0.144$) in patients with decreased LV function (LV ejection fraction $\leq 30\%$). In crude analysis model, E/E' significantly predicted prognosis in patients with preserved LV function group (HR 1.05 [1.03-1.07], $p<0.001$), whereas E/E' could not (HR 1.00 [0.99-1.02], $p=0.611$) (p for interaction <0.001). In adjusted model including age, sex, body mass index, heart rate, hypertension, diabetes, serum sodium, serum creatinine and inotropics use, E/E' still significantly predicted prognosis in patients with preserved LV function (HR 1.04 [1.02-1.06], $p<0.001$) and it could not in patients with decreased ejection fraction (HR 0.996 [0.98-1.01], $p=0.634$). There was significant interaction in adjusted model (p for interaction $=0.011$).

Conclusion: E/E' significantly predicted long-term outcome in patients with heart failure of preserved LV function, whereas it could not in patients with decreased LV function in acute heart failure setting.

P404

Radial deformation of the left ventricular myocardium in patients with STEMI with different outcomes of revascularization as a stabilizing factor of systolic function of the heart

¹Penza State University, Penza, Russian Federation

Objective: to study alterations of different types of deformation parameters of the left ventricle (LV) for 3 months by a two-dimensional Strain (PAD) in patients with acute myocardial infarction (AMI) with segment ST elevation (STEMI) based on the results of revascularization by TIMI scale (0-4) and hemodynamic parameters.

Methods: The study included 49 patients (group 1) with STEMI (51.25 ± 9.05 years), confirmed by ECG, coronary angiography (CAG), the level of troponin I, CK-MB. Inclusion criteria were the absence of hemodynamically significant coronary artery stenosis in addition to the infarct-related, previous myocardial infarction and other cardiovascular diseases. Control group 2 consisted of 21 healthy volunteers, the average age - 44.9 ± 6.8 years. Echocardiography was performed by ultrasound scanner My Lab 900 (Esaote, Italy) at 7 day and 3 months from the onset of the disease. With the software X-Strain the global longitudinal, circular and radial deformation (%) (Global Longitudinal Strain - GLS), (Global Circular Strain - GCS), (Global Radial Strain - GRS) have been determined. Among the traditional echocardiographic parameters the index of end-diastolic volume (EDV index) and ejection fraction (EF) has been analyzed.

Results: Group 1 were divided into 2 subgroups based on TIMI scale: group 1a included 34 patients (69%) with good angiographic result (TIMI 2-3), in 1b - 15 patients (31%) with unsatisfactory result (TIMI 0-1). Patients of group 1a and healthy persons had a comparable level of EF, respectively 66.0 (61.0; 70.0), and $68.2 \pm 5.1\%$ (ns), in the group 1b values were decreased ($50.3 \pm 12.2\%$) ($p<0.01$). Patients with TIMI 0-1 and 2-3 had no significant deterioration of the EF. In groups 1a and 1b GRS was initially reduced to a lesser degree than other types of deformation, respectively 8.7 ($p<0.05$) and 31% ($p<0.01$), GLS -11.4 ($p<0.05$) 50% ($p<0.01$), GCS - 16.5 and 62.5% ($p<0.05$). After 3 months, the most positive trend (10%) had GRS in patients with TIMI 0-1.

Conclusion: Damage of the middle layer of the myocardium is not accompanied by significant reduction of global radial Strain which characterized its function. In groups with different outcomes of revascularization after 3 months radial deformation has been increased to a greater extent in the group TIMI 0-1. Increased radial deformation contributes more to the left ventricular contractile function in patients with TIMI 0-1 and promotes long-term maintenance of the pumping function of the heart.

New insights from 2D speckle-tracking echocardiography analysis in chronic heart failure.

L Rossi¹; A Malagoli¹; A Zanni¹; C Sticozzi¹; M Piepoli¹; G Villani¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Introduction: B-type natriuretic peptide (BNP) is secreted from the heart primarily in response to stretch due to left ventricular (LV) overload. BNP plasma levels increase in heart failure (HF) according to augmented LV filling pressure and dysfunction of left atrium (LA). Speckle-tracking two-dimensional strain echocardiography (2DSE) analysis is considered a feasible and reproducible approach to quantify LA dynamics.

Purpose: Accordingly, the purpose of the present study was to correlate the LA intrinsic myocardial function using 2DSE analysis to BNP levels in patients with chronic systolic HF and to assess its prognostic value to develop new-onset atrial fibrillation (AF).

Methods: We prospectively studied 121 consecutive outpatients with chronic HF of ischemic or non ischemic etiology. Eligible patients were 18 to 85 years of age, with left ventricular ejection fraction (LVEF) $<40\%$ and sinus rhythm. Exclusion criteria were refractory atrial arrhythmias to medical therapy, pregnancy, primary valvular disease, mechanical valve prosthesis, recent myocardial infarction or coronary intervention, severe obstructive pulmonary disease or severe renal failure (creatinine clearance <30 ml/min). Simultaneously to BNP determination, peak atrial longitudinal strain (PALS) were measured in all enrolled subjects. PALS values were obtained by averaging all segments (global PALS), and by separately averaging segments measured in the 4-chamber and 2-chamber views.

Results: At linear regression analysis, Log_BNP was directly correlated with age, NYHA class, LA volume and mitral effective regurgitant orifice area; inversely correlated to global PALS (Figure 1, $R=-0.47$, $p<0.0001$), LA and LV ejection fraction (EF). According to the multivariate regression analysis, reduced global PALS independently correlates to BNP levels ($\beta=-0.22$, $p=0.01$). During 3-year follow-up, AF occurred in 29 of 121 patients. Reduced global PALS had the highest accuracy to predict new-onset AF ($p<0.05$).

Conclusions: In chronic systolic HF-population, LA longitudinal deformation by 2DSE analysis independently correlates to BNP values reflecting LA dysfunction and predicts long-term new-onset AF.

Prognostic relevance of the pulmonary artery diameter in relation to the ascending aorta

A Andreas Kammerlander¹; S Aschauer¹; C Zotter-Tufaro¹; F Duca¹; ML Schwaiger¹; D Dalos¹; M Schneider¹; BA Marzluf²; D Bonderman¹; J Mascherbauer¹

¹Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; ²Otto Wagner Spital, Vienna, Austria

Background: The pulmonary artery (PA) diameter and its relation to the ascending aorta (PA:Ao ratio) by cardiovascular magnetic resonance (CMR) or computed tomography (CT) have been identified as non-invasive markers for pulmonary hypertension in heart and lung disease. However, the prognostic value of such measurements is largely unknown.

Methods and Results: 650 consecutive patients (47.2% female, mean age 56.1 ± 17.1 years) referred to CMR were prospectively enrolled. Diameters of the great arteries were measured in axial black blood images. Based on previous results, a PA:Ao ratio ≥ 1.0 was chosen as cut-off for further analysis. The primary endpoint was defined as a composite of cardiovascular hospitalization and death. 131 (20.2%) patients presented with a PA:Ao ratio ≥ 1.0 . These patients were more frequently female ($p=0.010$), presented with more atrial fibrillation ($p<0.001$), more diabetes ($p<0.001$), worse renal function ($p<0.001$), higher NT-proBNP levels ($p<0.001$), larger left ($p=0.023$) and right ventricles (RV, $p=0.002$), and worse RV function ($p<0.001$). Patients were followed for 17.8 ± 12.9 months, during which 110 (16.9%) experienced an event. Kaplan-Meier analysis revealed worse event-free survival rates in patients with a PA:Ao ratio ≥ 1.0 (log-rank, $p<0.001$). By multivariable Cox-regression analysis, a PA:Ao ratio ≥ 1.0 was independently associated with outcome, in addition to age, NT-proBNP serum levels, and RV size. **Conclusion:** The PA:Ao ratio is an easily measurable parameter by CMR and CT. A ratio ≥ 1.0 identifies patients at risk, most likely due to elevated pulmonary artery pressures. Based on these results, the PA:Ao ratio should routinely be assessed in CMR and CT scans.

Myocardial remodelling and fibrosis in nonischaemic dilated cardiomyopathy: insights from cardiovascular magnetic resonance

A Barison¹; A Ortalda²; G Todiere¹; C Grigoratos¹; S Chiappino¹; G Vergaro¹; G Mirizzi¹; GD Aquaro¹; C Passino³; M Ermini³

¹Fondazione "G. Monasterio" CNR - Regione Toscana, Pisa, Italy; ²San Raffaele Hospital of Milan (IRCCS), Milan, Italy; ³Scuola Superiore Sant'Anna, Pisa, Italy

Background: In nonischaemic dilated cardiomyopathy (DCM), myocardial fibrosis can be detected by cardiovascular magnetic resonance (CMR) as late gadolinium enhancement (LGE) and has been associated with worse prognosis.

Purpose: We investigated whether LGE is associated with left ventricular (LV) reverse remodelling in DCM.

Methods: Ninety-seven DCM patients (age 56 ± 14 years, 62 male) with LV ejection fraction $\leq 50\%$ were enrolled and underwent baseline CMR; patients with ischaemic, valvular, congenital heart disease, other cardiomyopathies or contraindications to CMR were excluded. After a median 29-month follow-up (interquartile range 16-46) on optimal medical therapy, all patients underwent a second CMR; patients who died, underwent device implantation or declined a second CMR, were also excluded from the study. LGE was quantified on post-contrast CMR images as percentage of LV mass. LV reverse remodelling was defined as a decrease $>10\%$ of LV end-systolic volume at follow-up.

Results: Mean LV ejection fraction was $37 \pm 10\%$ at baseline, $44 \pm 12\%$ at follow-up. LGE was present in 56 (58%) patients at baseline (median 6% of LV mass, interquartile range 3-11%), without significant differences at follow-up (median 7%, interquartile range 4-11%, $p=NS$). Patients experiencing LV reverse remodelling during follow-up ($n=53$, 55%) presented a baseline worse LV ejection fraction ($34 \pm 11\%$) than patients not experiencing LV reverse remodelling ($41 \pm 8\%$, $p<0.01$), greater LV end-diastolic volume (125 ± 38 vs. 112 ± 26 ml/m², $p=0.05$), worse right ventricular ejection fraction ($54 \pm 13\%$ vs. $59 \pm 10\%$, $p=0.03$), but significantly less fibrosis (median 5% of LV mass, interquartile range 2-9% vs. median 9%, interquartile range 3-15%, $p<0.01$); no age or gender differences were observed ($p=NS$). Multivariate regression analysis showed that LGE extent at baseline CMR was a negative predictor of LV reverse remodelling ($p<0.01$), even after correction for age, New York Heart Association class, LV volumes and systolic function.

Conclusion: In DCM patients, LGE extent was a negative independent predictor of LV reverse during follow-up, irrespective of the initial clinical status and the severity of ventricular dysfunction.

P408

Prognostic value of left ventricular dyssynchrony and diastolic dysfunction assessed by ECG-gated Tc-99m tetrofosmin SPECT with phase analysis in patients with chronic kidney disease and narrow QRS.

H Hirofumi Aoki¹

¹Kanazawa medical university, Ishikawa, Japan

Aim: Chronic kidney disease (CKD) is reported to be associated with poor outcomes in patients with CHF. On the other hand, left ventricular (LV) diastolic dysfunction adversely influences LV function and is therefore associated with a poor prognosis. The aim of this study was to assess prognostic value of quantitative measurement of left ventricular diastolic function of ECG gated SPECT MPI in Patients with CKD.

Materials and Methods: 112 (mean LVEF, $58 \pm 15\%$, mean estimated GFR 42 ± 17 ml/min, QRS width 109 ± 21 msec) with CKD underwent rest and exercise 99m Tc tetrofosmin SPECT examination.

PFR, 1/3FR, TPFF and Phase SD were assessed by using phase analysis of ECG-gated SPECT MPI. A cardiac event was defined as cardiac death, lethal arrhythmia, ACS, or progression of HF.

Results: 26 cardiac events (2 cardiac death, 9 ACS, and 14 HF progression, 1 lethal arrhythmia) occurred during a follow-up period of 30 ± 16 months. There is no difference between the both group for QRS width and eGFR. (110 ± 23.9 vs 105 ± 21.1 $p=0.853$, 40 ± 18 vs 43 ± 15 , $p=0.622$). The patients with cardiac events were associated with significantly diastolic abnormality PFR (1.86 ± 0.64 vs 2.4 ± 0.69).

The subgroup of 37 patients with ischemic group and cardiac events also had a significantly lower PFR (1.78 ± 0.54 vs 2.37 ± 0.62 , $p=0.013$, 1.92 ± 0.71 vs 2.31 ± 0.73 , $p=0.110$), than did the ischemic and non cardiac events.

When the patients with diastolic dysfunction (PFR <1.8) were divided into the low (>26) and high (PhaseSD >26) groups, High Phase SD group significantly had more cardiac event (CI: 0.2050-3.3846, $p=0.013$).

Conclusion: Our preliminary results indicate that diastolic abnormality using SPECT may provide prognostic information in patients with CKD.

The significance of serial changes of high sensitivity cardiac troponin I in coronary vs. non-coronary disease

I Ingrid Prkacin¹; PD Pocanic¹; D Mileta¹; D Balenovic²; I Horvat²; M Mircic¹; M Opasic¹; A Mehmedovic¹; A Radeljak¹; S Perkovic¹

¹Clinical Hospital Merkur, Zagreb, Croatia; ²Hospital I. Pedisic, Sisak, Croatia

Introduction: The new high-sensitivity assays (hsTnI) have been developed to increase the clinical sensitivity for detection of myocardial injury. It has been found that elevated levels of hsTnI, above the upper limit of the reference interval (RI) (men <34.2 ng/L; women <15.6 ng/L), occur in coronary and non-coronary disease.

Purpose: The aim of this study was to determine the limit of quantification for hsTnI analyzer Abbott Architect i1000SR in Croatia and compare the concentration hsTnI in patients regarding the diagnosis and clinical condition.

Methods: Retrospective analysis included 98 patients: 38 with coronary heart disease (20 with angina pectoris and 18 with acute transmural myocardial infarct), and 60 with non-coronary disease for which a initial measurement and a control measurement of the hsTnI level was conducted. The hsTnI concentration was determined by chemiluminescent immunoassay the microparticles (CMIA, Abbott Architect i1000SR). Limit of Quantification determined according to the protocol NCCLS EP17.

Results: The maximum concentration of hsTnI was measured in patients with acute myocardial infarct (186135.0 ng/L), and in the group of non-coronary disease in patients with peripheral atherosclerotic disease (4823 ng/L). For the following diagnoses the obtained concentration levels, presented as median and range to each diagnosis (ng/L) for initial/control test were: acute transmural myocardial infarct: $270(19.5$ to $4056)/904(36-186134)$; angina pectoris: $98(10-1478)/83(7-1363)$; For those with non-coronary disease: atrial fibrillation waveform: $20.2(5$ to $282)/22(4.5$ to $272)$; peripheral atherosclerotic disease: $428(3.0-4823)/2082(3.3-4696)$; diabetes mellitus: $22(1.3$ to $73)/20(1.9-80)$; chronic renal disease: $119(50-164)/84(26-163.0)$; hypertension: $12(3.3-17)/14(5-33)$. The limit of quantification was verified at the concentration of 4.71 ng/L with a CV% 8.41% . Central values (ng/L) patient samples were 1.72 , 4.80 , 4.82 , 5.08 , 6.44 and 8.56 with coefficients of variation (CV%) 23.04% , 8.59% , 8.22% , 9.88% , 8.33% and 5.76% . Median serum pool value was 4.71 ng / L with a CV% 8.41% .

Conclusion: The most common cause significantly elevated troponin was acute coronary syndrome. The resulting CV of 8.41% meets the criterion for total error (CV $<10\%$) and is confirmed by laboratory quantitation limit of 4.7 ng / L. Quantification of very low concentrations hsTnI reflect subclinical ischaemia and increases the possibility of more frequent and earlier detection of acute coronary disease with mandatory monitoring the dynamics of change in relation to the initial value.

HSP70-molecular marker of cardioprotection in ischemic heart disease patients in physical rehabilitation

N Nadezda Lyamina¹; S Lyamina²; E Kotelnikova¹; E Karpova¹; V Senvikhin¹; T Lipchanskaya¹; E Bizyaeva¹

¹Saratov Scientific Research Institute of Cardiology, Saratov, Russian Federation;

²Moscow State University of Medicine and Dentistry, Moscow, Russian Federation

Objective: assessment of cardioprotection effect formation by analyzing the relationship between HSP 70 level in ischemic heart disease (IHD) patients with documented ischemia and the value of myocardial ischemia index at the stage of physical rehabilitation.

Material and methods: The study included 65 IHD patients (men and women) aged $39 - 65$ y.o. (mean age 54.6 ± 9.2 y.o.) with incomplete myocardial revascularization according to the results of percutaneous coronary intervention (PCI). Patients were included in the first 10 days after PCI. All patients performed 10-days course of daily controlled physical exercise (CPE) (up to 80% of maximal threshold load power) under ECG control, assessment of ischemia index, blood pressure and heart rate, and analysis of laboratory markers of myocardial injury (myoglobin, troponin, CK-MB, BNP - using immunofluorescent analyser Biosite Triage Meter Pro, Germany, and measurement of stress protein HSP70 with the use of laboratory diagnostics. ELISA on immunofluorescent analyser Stat. Fax USA. Safety and effectiveness of CPE were proved by study methods.

Results: HSP70 analysis showed that in IHD patients before CPE HSP70 values varied depending on patients' clinical status and at first were determined firstly by the severity of ischemic manifestations (Spearman Rank Order Correlations (Data HSP70 and Ischemia Index.sta) MD pairwise deleted Marked correlations are significant at $p<0.05000$. During diagnostics test stress-resistance was increased in all patients after CPE with 80% intensity from threshold load and it was accompanied by the elevated expression of inducible form of HSP70; this was documented by the significant decreasing of HSP70 level in systemic circulation. High correlation ($r=0.88406$) was shown for HSP70 level and ischemic index interaction in IHD

patients with incomplete myocardial revascularization during physical rehabilitation with CPE based on ischemic preconditioning. At the same time the values of threshold ischemia were increased: maximum ST depression decreased, decreasing ECG leads with depression of ST > 1 mm Hg and time to initial ST recovery, elevation of peak Minpostexercise diagnostic stress-test. Increased induction of HSP70 proved elevation of physical activity threshold (stress-resistance) and cardioprotective effect on IHD patients; it was proved by HSP70 level in systemic circulation.

Conclusion: Activation of proper intracellular system targeted for protection of cardiomyocytes from ischemia in IHD patients during CPE took place. This can be proved by increasing induction and expression of inducible HSP70 and can be used as molecular marker of cardioprotective effect in IHD patients.

P411

Galectin 3 and chagas cardiomyopathy: relationship of this myocardial fibrosis marker with myocardial deformation measured by speckle tracking in patients with chagas disease.

COLCIENCIAS and RED CHAGAS COLOMBIA. BIOCHAGAS project, code 501453730398, CT 380-2011.

LE Luis Eduardo Echeverria¹; LS Calvo-Betancourt¹; ZM Roa-Diaz¹; LZ Rojas-Sanchez¹; RL Campo-Torrenegra¹; MC Villamizar¹; AM Redondo-Gelvez¹; AM Torres-Bustamante¹

¹ Foundation Cardiovascular of Colombia, Heart failure and cardiac transplant, Floridablanca, Colombia

Purpose: Global Longitudinal Strain (GLS) has emerged as a superior method to detect early systolic left ventricular dysfunction when compared to ejection fraction. Galectin-3 is a beta-galactoside-binding lectin released by cardiac activated macrophages, which has been extensively evaluated as a marker of inflammation and cardiac fibrosis, the latter contributing to ventricular remodeling and dysfunction. In patients with hypertrophic cardiomyopathy, galectin-3 has proven to be a good marker of myocardial dysfunction, however, the correlation between levels of galectin-3 and GLS in patients with chronic heart failure of chagas etiology has not been previously evaluated.

Methods: Analytical cross-sectional study. Patients older than 18 years with chagas disease were included. Those patients with uncontrolled hypertension, diabetes, history of coronary artery disease and valvular disease were excluded. The GLS was established by speckle tracking electrocardiography and blood levels of Galectin-3 were determined, both measures were taken the same day. A descriptive analysis was performed, the correlation between the GLS and Galectin-3 was evaluated by scatter plot and Spearman's rank correlation coefficient. Finally, a multiple linear regression analysis adjusted by sex and age was performed.

Results: A total of 100 patients were analyzed, 55% (55/100) were men; the mean age was 61 years (SD \pm 12 years); the median and interquartile range of LVEF was 42% (Q1 = 27; Q3 = 56), of galectin-3 was 14 ng / mL (Q1 = 11; Q3 = 19); of GLS was -12.6% (Q1 = -17.8; Q3 = -7.2). A positive correlation between GLS and galectin-3 values (ρ = 0.370, p = 0.000) was established; on the other hand, galectin-3 and LVEF presented a negative correlation (ρ = -0.374, p = 0.000). In addition, an association between GLS and galectin-3 (β = 0.309, p = 0.005) and LVEF and galectin-3 (β = -0.872, p = 0.000) both adjusted by sex and age was established.

Conclusions: Galectin-3 is a powerful marker of endomyocardial fibrosis. Chagas cardiomyopathy is a disease with apical and postero-basal fibrosis determined by NMR studies. In patients with Chagas cardiomyopathy, galectin-3 showed a moderate negative correlation with LVEF and a moderate positive correlation with the GLS. A linear regression model adjusted for sex and age showed association between these variables, suggesting its clinical utility as a marker of myocardial dysfunction in this group of patients.

P412

Serial changes and associated clinical variables of cardiac troponin release in patients with acute heart failure syndrome

Y Yuksel Cavusoglu¹; E Gencer¹; S Eraslan¹; F Mutlu¹; B Morrad¹

¹ Eskisehir Osmangazi University, Eskisehir, Turkey

Purpose: Cardiac troponin (cTn) elevation in acute heart failure syndrome (AHFS) has been well-established, and referred as a potent predictor of poor prognosis. However, less is known about serial changes in cTn during hospitalization and clinical variables associated with cTn increase. So, we evaluated serial changes and associated clinical variables of cTn release in AHFS.

Methods: This study enrolled 230 patients hospitalized with NYHA III-IV AHFS and LVEF <35% in whom an acute coronary syndrome was not suspected. Patients were treated with optimal pharmacologic therapy with oxygen, diuretics and intravenous vasodilators. Blood samples for cTn measurements were obtained from all patients at admission and after HF therapy. The detectable level of cTn for the assay used in this study was \geq 0.01 ng/ml and the 99th percentile of cTn concentration in normal healthy individuals was 0.07 ng/ml. So, cTn was considered to be abnormal if cTn was detected above this level.

Results: At admission, 196 patients (85.2%) had a detectable level of cTn (\geq 0.01

ng/ml) and 73 patients (31.7%) had an abnormal level of cTn ($>$ 0.07 ng/ml). A new cTn increase was observed in 44 patients (28.2%) during hospital stay. Patients with cTn $>$ 0.07 ng/ml had higher resting heart rate (HR) (85 [72-97] vs 79 [69-89] bpm, p = 0.02), lower LVEF (22 [20-28] vs 26 [21-31] %, p = 0.003), higher NT-proBNP (7604 [3434-10763] vs 4154 [1463-7248] pg/ml, p = 0.001), higher creatinine (Cr) (1.17 [0.96-1.41] vs 1.00 [0.87-1.30] mg/dl, p = 0.013), higher blood urea nitrogen (BUN) (29 [21-39] vs 24 [19-33] mg/dl, p = 0.03) and higher high sensitive C-reactive protein (hsCRP) levels (27.7 [12.7-64.5] vs 14.3 [5.1-25.8] mg/dl, p = 0.001). Furthermore, a significant positive correlation was found between cTn levels and NT-proBNP (p < 0.001), Cr (p < 0.002), BUN (p < 0.001) and hsCRP levels (p < 0.002).

Conclusions: This study suggests that majority of patients with AHFS have detectable or abnormal levels of cTn at admission and considerable proportion of patients shows cTn increase during hospital stay and cTn release is associated with lower LVEF, higher resting HR, NT-proBNP, Cr, BUN and higher hsCRP levels.

P413

Decreased miR-1 expression is associated with ventricular tachyarrhythmia in patients with post-myocardial infarction heart failure

M Mariusz Tomaniak¹; G Sygitowicz²; KJ Filipiak¹; O Blaszczyk³; L Koltowski¹; D Ochijewicz¹; D Sitkiewicz²

¹ Medical University of Warsaw, 1st Department of Cardiology, Warsaw, Poland;

² Medical University of Warsaw, Department of Medical Laboratory Diagnostics, Warsaw, Poland;

³ Medical University of Warsaw, Department of Pharmacogenomics, Warsaw, Poland

Purpose: Some preclinical trials suggest that miR-1 dysregulation may induce ventricular tachyarrhythmias by alteration in expression and function of connexin 43 located in gap junctions. The impact of this muscle-specific molecule on the development of life-threatening arrhythmias in humans has not been evaluated so far. The aim of this study was to compare the expression of miR-1 in ischaemic heart failure (HF) patients with and without symptomatic ventricular tachycardia (VT).

Methods: 49 consecutive patients admitted to the Intensive Cardiac Care Unit due to HF exacerbation underwent the research. miR-1 expression was evaluated by qRT-PCR. The serum concentrations of gal-3 and NT-proBNP were determined with the use of available diagnostic tests. A history of symptomatic non-sustained or sustained VT confirmed in ECG or Holter ECG monitoring was collected. In addition, all patients underwent a transthoracic echocardiographic examination. Subjects with acute coronary syndrome in the past 30 days were excluded.

Results: There were 9 patients aged 70.5 \pm 9.6yrs identified with symptomatic VT and 40 patients aged 71.7 \pm 0.9yrs without such arrhythmias in a medical history. The groups did not differ in terms of age, NYHA class, HF etiology and NT-proBNP levels. No significant differences between the groups were found for left ventricle ejection fraction, left ventricle end diastolic diameter, left atrium and right ventricle diameter or inter-ventricular septum (IVS) and posterior wall thickness as well.

The expression of miR-1 was decreased in patients with symptomatic VT (0.284 (0.189-1.74) change fold vs. 0.346 (0.163-0.69) change fold, p < 0.05). Noteworthy, there was a significant negative correlation between the IVS diameter and miR-1 expression (R s = -0.815, p < 0.05) and positive correlation between the RVd and NT-pro-BNP concentration (R s = 0.829, p < 0.05) in this group. There were no significant differences in miR-21 expression and galectin-3 concentration between HF patients with and without VT.

Conclusions: miR-1 downregulation might be associated with symptomatic VT in patients with post-myocardial infarction HF. Further prospective studies are necessary to confirm its role in the pathogenesis of arrhythmias.

P414

Use of biomarkers in the prognostic stratification of elderly patients with chronic advanced heart failure

G Gabriella Guglielmina Barbara Malfatto¹; A Villani¹; F Mariani²; B Ortis³; V Guida²; L Pasciuti²; G Parati²

¹ Ospedale San Luca, Istituto Auxologico Italiano IRCCS, Milano, Italy;

² Università Milano-Bicocca & Ospedale San Luca, Istituto Auxologico Italiano IRCCS, Milano, Italy;

³ Postgraduate School in Cardiovascular Sciences, Cardiology, Trieste, Italy

Background: – Biomarkers can be useful in the prognostic stratification of patients (pts) with chronic heart failure (CHF). Among them, Brain Natriuretic Peptide (BNP) prevalently indicates volume overload, while Galectin-3 (Gal-3) and Soluble ST2 (sST2) are linked to myocardial stretch and fibrosis.

Methods: We reviewed data from 82 pts (75 \pm 9 years, 68% males) followed by our Outpatients' CHF clinic (Table 1). In this group, values of BNP, Gal-3 and sST2 were assessed at the first visit; moreover, both six- and 12-months outcomes were known. Biomarkers were analyzed using Triage BNP Test for BNP, VIDAS Gal-3 for Galectin-3, and Presage ST2 Assay for sST2. ROC curves were built to determine optimal sensitivity and specificity of each biomarker in predicting cardiovascular mortality at six- and 12-months' follow-up. The interval of significance was 95%.

Results: BNP and Gal-3 levels were affected by age, NYHA class, HF duration, body weight, renal function and treatment with ACE inhibitors or angiotensin-receptor

blockers. On the contrary, sST2 levels were not influenced by any of these variables. Biomarkers' levels were higher in pts who died at follow-up (8 pts at six months, i.e. 9.8%; 10 pts at 12 months, i.e. 12.2%). From the analysis of ROC curves, BNP ≥ 600 pg/ml, Gal-3 ≥ 25.9 ng/ml and sST2 ≥ 35 ng/ml predicted mortality at six and 12 months ($p < 0.05$): AUC was 0.69 for BNP, 0.74 for Gal-3 and 0.89 for ST-2 (sensitivity 89%, specificity 100%). CONCLUSIONS – In this CHF population (older than those examined in the available literature), sST2 was the more reliable biomarker for the prediction of medium-term cardiovascular mortality. The cutoff value of 35 ng/ml accurately distinguished low risk patients, who might be safely followed up in community-based facilities, from high risk ones, who should be referred to more specialized centers.

Background: Endothelial damage is a crucial factor leading to heart failure (HF) and other cardiovascular diseases. Circulating endothelial cells (CEC) and endothelial progenitor cells (EPC) have been described as new non-invasive markers of endothelial damage. They are measurable in peripheral blood and their level correlates with other markers of endothelial function. Ability to quantify and observe changes in CEC and EPC levels reliably will open new doors in screening and supervision of treatment effects. However, uniform procedures to isolate and determine CEC/EPC numbers accurately still have to be established.

Aim: We carried out a test-retest-study by applying the same method of isolating and counting CEC/EPC levels at two time points and calculated the correlation between both visits.

Methods: Endo-CEC was a prospective observational trial in 100 patients (mean age 65 \pm 9.6, 69% male and 31% female) consisting of four different groups; 25 HFREF patients (HF with reduced ejection fraction, LVEF < 45%), 25 HFPEF patients (HF with preserved ejection fraction, LVEF \geq 45% and echocardiographic evidence of diastolic dysfunction), 24 patients with diabetic nephropathy and 26 patients with arterial hypertension. Blood samples were obtained at two separate visits (mean time interval 7 \pm 3). CEC and EPC were determined via flow cytometry and expressed both in CEC/EPC per ml and as a percentage of peripheral blood mononuclear cells (PMNC). Intraclass correlation (ICC) between both visits was assessed.

Results: When comparing CEC levels of visit one and two, neither of the groups showed a correlation (overall ICC, CEC/ml: 0.078; CEC/PMNC 0.191). In contrast, the ICC of EPC measurements was statistically significant in each group (overall ICC, EPC/ml: 0.904; EPC/PMNC: 0.811 with group-specific ICC, EPC/ml: HFREF: 0.946; HFPEF: ICC = 0.685; DiabNeph: ICC = 0.946; Arterial Hypertension: ICC = 0.683).

Conclusion: Our analysis shows that our method of flow cytometry is a reliable tool to assess EPC levels in cardiovascular patients but also suggests that the CEC measurement has to be enhanced by identifying disturbing factors and reasons for the invalid

Results: As understanding and estimating the occurrence of CEC and EPC promise high potential for further treatment and supervision of heart failure and endothelial dysfunction associated diseases, further research is warranted.

P416

Association of plasma fischer ratio with left ventricular function in patients with idiopathic dilated cardiomyopathy

M Minoru Wakasa¹; H Aoki¹; Y Kawai¹; K Fujibayashi¹; K Kajinami¹

¹Kanazawa Medical University, Ishikawa, Japan

Backgrounds: Fischer ratio is the molar ratio of branched-chain AAs (BCAAs: leucine, valine, isoleucine) to aromatic AAs (phenylalanine, tyrosine) and is important for assessing liver metabolism, hepatic functional reserve and the severity of liver dysfunction. It is recently known that Fischer ratio are decreased in heart failure patients. Furthermore in the failing heart, BCAA suppresses cardioprotective autophagy, repair mitochondrial biogenetic regulation in the heart and reduced reactive oxygen species (ROS). However, the associations between its levels and cardiac function are remain unclear. To explore in vivo evidence for potential role of Fischer ratio in human failing heart, we measured plasma Fischer ratio in patients with biopsy-proven idiopathic dilated cardiomyopathy (DCM) and evaluate association between its levels and the clinical parameters concerned with cardiac function.

Methods: Consecutive 51 patients with DCM (M/F: 37/14, mean age: 62 years) and 35 patients with normal cardiac function (Control group) were enrolled. Subjects showing abnormal liver enzyme level or chronic hepatitis viral infection were excluded. Plasma Fischer ratio were measured in peripheral blood samples. Left ventricular ejection fraction (LVEF) and fractional shortening (FS) as determined by echocardiography were used as LV function parameters.

Results: Mean plasma Fischer ratio in DCM were comparable to those in control subjects with normal LV function. However Fischer ratio in severely reduced LV function (LVEF < 30%) ($n = 21$) were significantly lower than those of remainings (2.98 ± 0.68 vs 3.32 ± 0.43 , $p < 0.05$). Also plasma Fischer ratio showed a significant positive association with LVEF ($r = 0.28$, $p < 0.05$) and FS ($R = 0.28$, $P < 0.05$). Plasma Fischer ratio showed a significant negative association with LVDD ($r = -0.37$, $p < 0.05$) and LVDs ($R = -0.46$, $P < 0.05$). Conclusions The plasma Fischer ratio could be a novel biomarkers of left ventricular dysfunction and the extent of heart failure in patients with DCM.

The role of postoperative measurement of cystatin C and NGAL in early detection of acute kidney injury after heart transplantation

Supported by the project of the Ministry of Health, Czech Republic for development of research organization 00023001 – Institutional support.

L Lenka Hoskova¹; J Franekova²; I Malek¹; J Kautzner¹; A Jabor²; O Viklicky³; V Melenovsky¹

¹Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czech Republic; ²Institute for Clinical and Experimental Medicine (IKEM), Department of Laboratory Methods, Prague, Czech Republic; ³Institute for Clinical and Experimental Medicine, Department of Nephrology, Prague, Czech Republic

Background: Acute kidney injury (AKI) following heart transplantation (HTx) is associated with dismal survival. During acute changes in the renal function, however, the serum creatinine level is not an accurate indicator. Early diagnosis of AKI may contribute to timely intervention aimed at improving outcome.

Purpose: We focused on serum cystatin C (S-cystatin C) and urinary Neutrophil gelatinase-associated lipocalin (U-NGAL). We aimed to identify the diagnostic and prognostic value of these biomarkers.

Methods: In the prospective study we evaluated 117 consecutive patients after HTx. Based on the AKI definition (KDIGO AKI Guidelines 2012) of the change in serum creatinine or diuresis, we have defined AKI as the serum creatinine increase by $\geq 50\%$ during the first seven post-HTx days or a worsening of the renal function requiring renal replacement therapy during the first week post-HTx. S-cystatin C as a marker of glomerular filtration and U-NGAL as a marker of tubular damage were serially measured.

Results: Overall 30 patients (25.6%) experienced the criteria of AKI. Preoperative renal function, demographics and comorbidities were similar between AKI and non-AKI groups. S-cystatin C showed the earliest separation between AKI and non-AKI group, with a significant difference already 3 hours after HTx ($p = 0.016$) and persisting on day 7 ($p = 0.0048$) and day 10 ($p = 0.0072$). The increase in S-cystatin C preceded the S-creatinine elevation by 4 days. In all HTx recipients, U-NGAL was elevated in the early postoperative period. However, an increase in U-NGAL level was significantly higher at day 3 ($p = 0.003$) in the AKI group compared to the non-AKI group. In a multivariate analysis, S-cystatin C > 1.6 mg/L at 3 hours after HTx predicted AKI with OR 4.3 (95% CI: 1.6-11.5). We found that elevated S-cystatin C (≥ 2.54 mg/L on day 7) could also predict one-year mortality after HTx ($p < 0.0001$).

Conclusion: Our results show that early elevation of postoperative S-cystatin C improve the ability to detect AKI and may determine the one-year prognosis after HTx.

Effects of a cardiac rehabilitation program on plasma cardiac biomarkers in patients with chronic heart failure

French Federation of Cardiology, HOMAGE, GREAT

G Billebeau¹; N Vodovar²; M Sadoune²; JM Launay³; F Beauvais¹; A Cohen-Solal¹

¹Hospital Lariboisiere, Department of Cardiology, Paris, France; ²Inserm UMR-S 942, Paris, France; ³Hospital Lariboisiere, Department of Biochemistry, Paris, France

Background: Cardiac rehabilitation (CR) improves symptoms, exercise capacity and quality of life of chronic heart failure (CHF) patients. Its effects on new plasma biomarkers of prognostic importance are unknown.

Objective: The present study aimed to analyze the effects of a structured CR program on plasma cardiac biomarkers in a large population of patients with CHF and reduced left ventricular ejection fraction (LVEF).

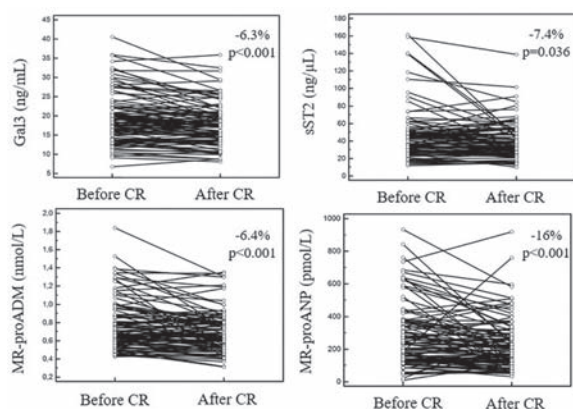

Methods: We enrolled 107 consecutive CHF patients with LVEF $\leq 45\%$ in an ambulatory CR program. Peak VO₂ and plasma levels of Galectin 3, MidRegional-proAdrenomedullin (MR-proADM), soluble Suppressor of Tumorigenicity 2 (sST2) and MidRegional-pro A-type natriuretic peptide (MR-proANP) were assessed at inclusion and at the end of CR. 24 unenrolled patients were managed with standard medical care and evaluated on a same period (no-CR group).

Results: Galectin 3, sST2, MR-proADM and MR-proANP plasma levels decreased after CR, with respective median reductions of 6.3% for Galectin 3 ($p < 0.001$), 7.4% for sST2 ($p = 0.036$), 6.4% for MR-proADM ($p = 0.001$) and 16% for MR-proANP ($p < 0.001$). MR-proADM negatively correlated with peak VO₂ (Rho = -0.529, CI [-0.654 to -0.375], $p < 0.001$) and so were their relative variations along the course of CR (Rho = -0.357, CI [-0.518 to -0.172], $p < 0.001$). No change occurred in terms of biomarkers in no-CR group. Plasma levels only decreased in patients who benefited the most from CR (peak VO₂ variation (Var(VO₂)) $\geq 14.5\%$, the median increase in the variation of peak VO₂).

Conclusions: Plasma cardiac biomarkers such as Galectin 3, MR-proADM, sST2 and MR-proANP all decreased after CR in CHF patients suggesting an overall improvement in the neuro-hormonal profile. MR-proADM was well correlated with peak VO₂ and emerges as an interesting predictor of beneficial response to CR.

Biomarkers according to benefit of CR

Plasma levels	Before reha-bilitation	After reha-bilitation	p	
Galectin 3 (ng/mL)	Var(VO ₂) $\geq 14.5\%$	19.0 [13.7;22.5]	16.9 [13.8;19.9]	< 0.001
	Var(VO ₂) $< 14.5\%$	17.3 [15.0;22]	17.7 [14.0;22.0]	0.057
MR-proADM (nmol/L)	Var(VO ₂) $\geq 14.5\%$	0.7101 [0.5975;0.8887]	0.6369 [0.5299;0.7963]	< 0.001
	Var(VO ₂) $< 14.5\%$	0.6630 [0.5556;0.8317]	0.6878 [0.5431;0.8309]	0.928
MR-proANP (pmol/L)	Var(VO ₂) $\geq 14.5\%$	262 [143;422]	176 [106;294]	< 0.001
	Var(VO ₂) $< 14.5\%$	202 [131;280]	202 [138;272]	0.502
sST2 (ng/ μ L)	Var(VO ₂) $\geq 14.5\%$	36.0 [26.4;52.4]	31.0 [24.4;47.7]	0.001
	Var(VO ₂) $< 14.5\%$	37.1 [30.1;48.0]	37.3 [27.5;53.0]	0.682

Role of oxidized low-density lipoprotein in the development of adverse events in patients with Non-ST-elevation acute coronary syndrome

EA Evgeniya Shmidt¹; SA Berns¹; OL Barbarash¹

¹Research Institute for Complex Issues of Cardio. Dis. - Siberian Branch RAMS Institution Scientific, Kemerovo, Russian Federation

Objective: to examine the relationship of oxidative metabolism of lipoproteins markers with the development of adverse outcomes in Non-ST-Elevation Acute Coronary Syndromes (NSTE-ACS) during one year of follow-up.

Materials and Methods: A total of 159 patients with NSTE-ACS have been included in the study. The average age of patients was 61.0 ± 9.19 years. Among the patients studied was 61.0% of men and 38.99% women. Determination of oxidized low-density lipoprotein (ox-LDL) and antibodies to ox-LDL serum in all patients was fulfilled by the 10th day of hospitalization. Follow-up was 12 ± 4 months for the study group. All patients were divided into two groups: with a favorable ($n = 123$) and unfavorable ($n = 35$) outcomes [death from cardiovascular causes, unstable angina (UA), myocardial infarction (MI)].

Results: The ox-LDL level in serum was significantly higher in patients with unfavorable outcome. It was found that increased levels of ox-LDL more than 2.4 mg/kg/ml increases the risk of an unfavorable outcome for the year in patients with NSTE-ACS more than 10 times (OR = 10.4, 95% CI: 2.38-45.7; $p < 0.0001$). The differences in the levels of antibodies to ox-LDL in the groups were not found.

Conclusion: The elevated levels of ox-LDL more than 2.4 mg/kg/ml in hospital period can be laboratory markers of adverse prognosis in patients with NSTE-ACS.

Red blood cell distribution width longitudinal changes in acute heart failure patients: a prospective study

A Xanthopoulos¹; J Skoularigis¹; E Paraskevopoulou²; P Paraskevopoulou³; S Patsilinos²; G Giamouzis¹; F Triposkiadis¹

¹University General Hospital of Larissa, Department of Cardiology, Larissa, Greece;

²Konstantopoulou General Hospital, Department of Cardiology, Athens, Greece;

³Konstantopoulou General Hospital, Department of Hematology, Athens, Greece

Background: Red Blood Cell Distribution Width (RDW) is a simple parameter of the standard full blood count and a measure of heterogeneity in the size of circulating erythrocytes.

Purpose: The aim of this study was to investigate the clinical correlates, prognostic value and longitudinal changes of RDW in patients initially admitted for acute heart failure (AHF).

Methods: We conducted a prospective study of patients presented in the emergency department with AHF (denovo or acute decompensation of chronic HF) between January 2014 and July 2014. A clinical, ultrasound and hematological assessment was performed at admission, discharge, 4, 8 and 12 months after discharge and at every rehospitalization. Exclusion criteria were presence of cancer, sepsis, Hb < 10 g/dL and previous transfusions. The endpoint was death from any cause and/or rehospitalization for HF at 1 year. There were no missing values.

Results: 104 AHF patients (mean age, 73.5 ± 12.0 years; male gender, 55.8%; mean LVEF, $38.9 \pm 14.7\%$) were enrolled in the study with 62.5% of them having reduced ejection fraction (HFrEF, i.e. LVEF $< 40\%$). Admission RDW (mean value, 15.0%) showed significant correlation with Brain Natriuretic Peptide (Rho: 0.351, $p < 0.001$), New York Heart Association class [$p < 0.01$, 95% CI (0.92-2.06)] and emerged as an independent prognostic marker regarding events at 1 year post discharge in the multivariate analysis, after adjustment for factors such as Hb and erythropoietin [adjusted OR: 1.67, 95% CI (1.18-2.38), $p = 0.004$]. RDW longitudinal changes post discharge showed no significant difference in HFrEF versus HFpEF patients ($p = 0.978$ adjusted for admission RDW) and in patients without events versus those with events ($p = 0.349$ adjusted for admission RDW), although the latter had significantly higher mean RDW values at every time point ($p < 0.001$). Patients on ACE-inhibitors (ACE-I) at admission had significantly lower mean RDW values compared to those who were not on ACE-I ($p < 0.0001$). In addition, a statistically significant difference in the changes over time of the RDW was observed between patients who received ACE-I and those who didn't ($p = 0.045$).

Conclusions: Admission RDW in AHF was found to be an independent prognostic marker for death or rehospitalization at 1 year after discharge. RDW longitudinal changes do not differ significantly among patients with or without events and in HFpEF versus HFrEF. The significantly lower RDW values in the population of AHF patients under ACE-I might be served as an insight to the pathophysiological mechanism of RDW change in HF, which remains unknown.

P421

Association of putative biomarkers with polymorphisms of ACE1 and NOS3 in hypertension and heart failure

L F Luiz Filipe De Menezes Falcao¹; A Matos²; A Gil²; A Pereira Da Silva²; T Sequeira²; J Ferreira²; I Pinheiro¹; M Bicho²

¹University of Lisbon, Faculty of Medicine, Lisbon, Portugal; ²Faculty of Medicine, University of Lisbon, Laboratory of Genetics and Institute of Environmental Health, Lisbon, Portugal

Introduction: EPO regulates many cellular functions and can be a biomarker for HF. Moreover Galectin-3 (an intercellular acute phase protein) is an emerging cardiac biomarker. The angiotensin I converting enzyme (ACE1) and endothelial nitric oxide (NOS3) polymorphisms have been associated with HF.

Objective: To assess the association of ACE1, NOS3 polymorphisms and cardiac biomarkers (Galectin-3 and EPO) in patients with HF.

Material and Methods: In patients with HF and preserved or decreased EF (EF<40%) were evaluated the genetic polymorphisms of ACE1 and NOS3 by PCR. There were also evaluated some possible cardiac biomarkers, NT-proBNP (pg/mL), Galectin-3 (ng/mL) and EPO (mIU/ml) determined by ELISA. The sample consisted in 162 patients with HF, aged 72.1 ± 12.5 , 80 women (49.4%) and 82 men (50.6%). Statistical methods were the chi-square, Student's t-test, ANOVA and binary logistic regression, or its nonparametric equivalent. Statistical significance were considered for $P < 0.05$.

Results: NOS3 AA genotype was more frequent in patients with decreased EF ($n = 6$ (14.3%), $P = 0.009$), being the carriers of allele A with 3.64-fold at risk (OR = 3.68, 95% CI [1.57-8.63], $P = 0.003$). There weren't significant differences in the distribution of ACE1 genotypes according with EF ($P > 0.05$). EPO levels were statistically significant lower in patients with EF<40% (median \pm std.error, EF<40% ($n = 26$): 6.2 ± 3.8 mIU/ml vs. EF>40% ($n = 34$): 14.8 ± 3.3 mIU/ml, $P = 0.025$). The risk associated to carriers of allele A of NOS3 in patients with EF<40% was significantly greater, 3.64-fold to 10.73-fold, when adjusted for EPO levels (OR = 10.73, 95% CI [1.66-69.52], $P = 0.013$). The levels of Galectin-3 and NT-proBNP weren't associated with EF or NOS3 or ACE1 genotypes ($P > 0.05$).

Discussion and Conclusions: Patients with lower levels of EPO and NOS3 allele A, were associated to lower EF, which may result in a physiologically effect of EPO on NOS3, reflecting the influence of hypoxia status in patients with HF.

P422

ST2 is an independent predictor of all-cause hospitalization in elderly patients.

Karolinska University Hospital

F Finn Thormark-Frost¹; M Olofsson²; A-C Bergman¹; A Larbol¹; K Boman²

¹Karolinska University Hospital, Clinical Chemistry, Stockholm, Sweden; ²Research unit, Department of Medicine, Skellefteå, Institution of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

Background: NtproBNP is a known predictor of hospitalization. A new biomarker, suppression of tumorigenicity 2 (ST2) has been introduced as a marker for fibrosis and hypertrophy and may thus predict hospitalization. There is a lack of knowledge about the predictive value of ST2 in elderly primary health care (PHC) patients.

Purpose: To compare ST2 with NTproBNP as a predictor of time to first hospitalization in elderly patients with clinical symptoms of heart failure (HF).

Methods: Explorative analysis of a 10-year longitudinal study. Patients were recruited from one selected PHC in northern Sweden between 2000 and 2003 and comprised both registry patients and incident cases with suspected HF identified by the general practitioner (GP) at the PHC. All patients had clinical symptoms of HF and significant co morbidities. Blood samples were collected at baseline and stored frozen for future analysis. NTproBNP was analyzed with Roche Elecsys proBNP immunoassay. ST2 was analyzed with Critical Diagnostics Presage ST2 immunoassay. ST2 and NTproBNP were used as continuous variables in the analysis. Departments of medicine and surgery records were used to identify hospitalizations. The association between baseline characteristics and hospitalization at 10 years of follow up was analyzed with Cox regression analysis. Adjustments were made for significant variables from the univariate Cox regression analysis and from fixed factors as age, gender and smoking habits.

Results: We studied 159 patients (mean age 80 years, 66% women). During 10 years of follow up 128 (81%) patients had at least one hospitalization. In the univariate Cox regression analysis significant associations with time to first all-cause hospitalization were found for ST2 (hazard ratio [HR]: 1.04; 95% confidence interval [CI]: 1.02-1.05), age (HR: 1.04; CI:1.02-1.07), kidney dysfunction, defined as creatinine $> 100 \mu\text{mol/L}$ (HR: 2.56; CI:1.67-3.93), all HF (HR: 1.64; CI:1.12-2.42), NTproBNP (HR: 1.0002; CI:1.0001-1.0002), male gender (HR: 1.65; CI:1.13-2.40), underlying heart disease (HR: 2.04; CI:1.21-3.43), atrial fibrillation (HR: 2.24; CI:1.37-3.68). In the following multivariate analysis ST2 (HR:1.05; CI:1.03-1.08), age (HR: 1.04; CI:1.01-1.08), kidney dysfunction (HR: 2.26; CI:1.19-4.30), smoking habits (HR: 2.25; CI:1.23-4.10), underlying heart disease (HR: 4.29; CI:1.75-10.52) and NTproBNP

(HR: 1.0001; CI:1.0000-1.0002), were independently associated with time to first hospitalization at ten years of follow up.

Conclusion: ST2 was an independent prognostic marker of time to first all-cause hospitalisation in elderly PHC patients with clinical symptoms of HF. In these patients the clinical value of ST2 as an additive prognostic marker to NTproBNP needs to be further evaluated.

P423

Significance of copeptin concentration in acute decompensated heart failure patients long-term risk stratification

V N Protasov¹; AA Skvortsov¹; OY Narusov¹; D Koshkina¹; TV Kuznetcova¹; VP Masenko¹; SN Tereshchenko¹

¹Russian Cardiology Research and Production Complex, Moscow, Russian Federation

Background: Copeptin concentration was strong predictors for of the adverse long-term prognosis in pts with ADHF.

Purpose: to evaluate the significance of copeptin concentration in risk stratification in patients (pts) with ADHF in one year follow-up period.

Methods: In our study were included 159 pts with ADHF III-IV FC NYHA. Blood samples to determine copeptin concentration were collected at the admission and at discharge from the hospital, and after 3, 6 and 12 months of follow-up. The primary end point was total cardiovascular events that included cardiovascular (CV) death and hospitalization due to HF.

Results: At admission all pts had elevated copeptin concentration: $41,56 \pm 19,68$ pmol/l. During the period of hospitalization mean copeptin concentration was decreased to $30,34 \pm 15,51$ pmol/l. During 1-year follow-up (mean 277 ± 115 days) 54 pts (33,96%) had CV events. At the admission copeptin concentration in low risk pts (without CV events) were significantly lower compared with high risk pts (with CV events): $35,79 \pm 15,72$ pmol/l versus $48,52 \pm 21,71$ pmol/l respectively, $< 0,0001$. The similar trend was observed and at discharge: $24,67 \pm 11,79$ vs $37,33 \pm 16,75$ respectively, $p < 0,0001$. At the discharge from the hospital copeptin concentration had the most predictive capacity relatively the primary end point during 1-year follow-up: AUC=0,745 (0,652-0,839), $< 0,0001$, sensitivity 83%, specificity 52,7% compared with copeptin concentration at the admission: AUC=0,682 (0,581-0,784), $< 0,0001$, sensitivity 66,7%, specificity 64,2%. Lack of copeptin concentration decrease below 23,9 pmol/l was associated with the highest risk of CV events (OR 5,597 (2,23-14,03), $p < 0,0001$). The copeptin concentration in pts with ADHF at the discharge was a predictor of adverse prognosis in the long-term follow-up (beta=0,626, $p < 0,004$).

Conclusion: The values of copeptin at the discharge from the hospital reflects the adverse long term prognosis in patients with ADHF.

P424

Detectable plasma levels of interleukin-9 are associated with impaired exercise capacity and poor survival in chronic heart failure.

AM Marra¹; M Arcopinto²; A Salzano³; E Bobbio³; F Ferrara⁴; O Vritz⁵; S Milano⁶; G Misiano⁶; E Bossone⁴; A Antonio Cittadini³

¹SDN Foundation IRCCS, Naples, Italy; ²IRCCS, Policlinico San Donato, San Donato Milanese, Italy; ³University Hospital Federico II, Naples, Italy; ⁴Cava de'Tirreni-Amalfi Coast Hospital, Salerno, Italy; ⁵Hospital of San Daniele del Friuli, Udine, Italy; ⁶University of Palermo, Palermo, Italy

Background: Inflammation plays a pivotal role in Chronic Heart Failure (CHF) through increased expression of pro-inflammatory cytokines. Previous reports showed increased levels of Interleukin-9 (IL-9) in CHF and their negative association with left ventricular systolic function.

Aim: To test whether increased IL-9 levels are associated with impaired exercise capacity and poor outcome in CHF.

Patients and methods: Seventy-five CHF patients were enrolled and divided according to IL-9 levels. All patients underwent cardiopulmonary exercise test, echocardiography and were regularly followed-up for 59 ± 29 months.

Results: As shown in table 1, patients with detectable IL-9 showed impaired exercise capacity compared to patients with undetectable IL-9. Moreover, detectable IL-9 was associated with lower survival (figure 1). Cox-Univariate and multivariate analysis indicated that IL-9 was independently associated with all-cause mortality (HR = 2.36, 95% CI = 1.42–5.23, $p = 0.01$).

Conclusions: Detectable IL-9 plasma levels are associated with impaired exercise capacity and independently predict reduced survival in CHF patients.

Table 1

Variable	All Patients (n = 75)	Undetectable IL-9 (n = 40)	Detectable IL-9 (n = 35)	p value*						
Age-years	65.73	±	9.53	64.7	±	10.2	67.5	±	8.6	0.35
BMI-m ² /Kg	27.48	±	3.86	27.9	±	3.4	27.1	±	4.2	0.28
Female sex (%)	15 (19.7%)	6 (17.1%)	9 (22.5%)	0.77						
T2DM prevalence (%)	23 (30.6%)	10 (28.6%)	13 (32.5%)	0.91						
ischemic etiology prevalence (%)	46 (60.5%)	21 (60%)	25 (62.5 %)	0.89						
NYHA class	2.34	±	0.68	2.1	±	0.6	2.5	±	0.7	0.04
NTproBNP (pg/ml)	2756	±	2920	2797	±	2491	2727	±	3269	0.91
GFR (ml/min)	79.9	±	19.9	78.1	±	19.5	81.4	±	20.4	0.51
Ejection Fraction (%)	32.74	±	4.31	32.4	±	4.7	33.1	±	4.1	0.49
Peak VO ₂ (ml/Kg/min)	16.75	±	4.1	18.2	±	3.3	15.5	±	4.2	0.004
VE/VCO ₂ slope	30.6	±	7.1	28.7	±	6.7	32.3	±	7.1	0.03
Peak Workload	91.1	±	26.9	100.9	±	25.5	82.6	±	24.5	0.003

Data shown as mean ± SD; * = detectable vs. undetectable; T2DM = Type 2 Diabetes Mellitus; NYHA = New York Class Association; NTproBNP = N-terminal of the prohormone brain natriuretic peptide; GFR = glomerular filtration rate according to Cockcroft-Gault formula; VO₂ = oxygen consumption; VCO₂ = carbon dioxide production; VE = ventilation per min.

Galectin-3 as a predictor of heart failure and other complications at long-term follow-up after right ventricular myocardial infarction

V Tseluyko¹; T Lozova²

¹Kharkiv National Academy of Postgraduate Education, Kharkiv, Ukraine; ²Clinical Hospital #1, Sumy, Ukraine

Background: Galectin-3 (Gal-3) is a mediator of cardiac fibrosis which has a prognostic value after acute coronary syndrome. The relationship between Gal-3 level, risk of heart failure (HF) and adverse cardiovascular events (ACVE) after posterior STEMI involving right ventricle (RV) is not studied.

Purpose: To evaluate the significance of Gal-3 as a predictor of ACVE and of HF at 30-month follow-up in patients with RV MI.

Methods: The study involved 155 patients with RV MI aged 64.11 ± 0.78 years. Gal-3 levels were determined in 6th month after RV MI by ELISA. Follow-up was 30 ± 2.5 month. Endpoints were: unstable angina (UA), recurrent MI (Re-MI), stroke, cardiovascular (CV) death and HF-hospitalizations.

Results: Study endpoints occurred in 65 (41.9%) patients: UA - 51 (32.9%), Re-MI - 16 (10.3%), stroke - 9 (5.8%), CV-death - 16 (10.3%), HF-hospitalization - 22 (14.2%). Median Gal-3 values at 6th month after RV MI (38.61 vs. 18.8 ng/ml; p < 0.0001) was higher in patients with study endpoints. Multivariable analysis revealed, that 6th month Gal-3 level was an independent risk factor for UA (p = 0.000028), CV-death (p = 0.00001), Re-MI (p = 0.002259) and stroke (p = 0.000514) at 30 month. Gal-3 level was also a predictor of HF-hospitalization (p = 0.0069) in 30-month follow-up after RV MI.

Conclusion: Gal-3 level at 6th month after RV MI could be useful as an additional

marker of progressive HF and as a predictor of adverse cardiovascular events during long-term follow-up.

Regression summary for Galectin-3

	Beta	B	The degree of influence	P
CV-death	0.43	15.65	14.1	0.00001
Unstable angina	0.34	9.77	12.5	0.000028
HF-hospitalization	0.76	6.98	8.6	0.0069
Stroke	0.24	12.39	7.9	0.000514
Re-MI	0.19	7.5	6.5	0.002259
Diabetes Mellitus	-0.17	-0.26	2.44	0.089
Arterial Hypertension	0.19	3.91	2.18	0.1453

P426

High serum d-dimer and alfa- tumor necrosis factor predict worse prognosis in systolic heart failure regardless of etiology

GE Germano Emilio Souza¹; JL Vieira¹; LR Moraes¹; AT Casolato¹; GA Braga¹;

VS Issa¹; LM Pessoa De Melo²; SM Ayub-Ferreira¹; EA Bocchi¹; JAF Ramires¹

¹Heart Institute -InCor, São Paulo, Brazil; ²Servico de Hematologia e Hemoterapia, Sao Jose dos Campos, Brazil

Purpose: Inflammation and thrombosis play an important role in systolic heart failure (SHF) physiopathology. Among SHF patients, Chagas' cardiomyopathy has higher inflammatory and pro-thrombotic markers. We sought to evaluate the prognosis of a long term cohort of SHF patients according to pro-inflammatory and pro-thrombotic biomarkers at baseline.

Methods: Non-randomized prospective Cohort study. Inclusion criteria: Left ventricle ejection fraction <45% and onset of symptoms time > 1 month. Exclusion criteria: varfarin or heparin anticoagulation, mechanic heart valve prothesis, neoplasia, pregnancy. We divided these patients in two groups: G1 - Chagas' cardiomyopathy and G2 non-Chagas' cardiomyopathy. Alpha-Tumor Necrosis Factor - TNF and Interleukin 6 - IL6) and pro-thrombotic (Anti-thrombin factor - ATF, fibrinogen -Fb, von-Willebrand factor antigen -vWFA, D-dimer and thromboelastography parameters) were determined in both groups. Sample size calculated for 90% power. P value significative if <0.05. Fischer's exact test for categoric variables; non-paired T-student test for parametric continuous variables and Mann-Whitney test for non-parametric continuous variables. Spearman Test was used to correlate baseline variables. Covariance analysis was performed. Kaplan-Meier method for survival estimates. Log-rank test for comparison between groups.

Results: From January 2008 to April 2009, 287 patients were prospectively included. Mean follow-up time was 7.8 years. G1 patients were younger, had lower body mass index, lower blood pressure and LVEF, and higher BNP levels. Hypertension, diabetes, tobacco use and dislipidemia were less frequent in G1. Previous stroke was more prevalent in G1. Aspirin use was more prevalent in G2. TNF and IL6 levels were higher in G1. Among prothrombotic markers, D-dimer (p < 0.0001) vWF (p < 0.0001) and sP-selectin (p0.0262) levels were also higher in G1 than in G2.

On the other hand, fibrinogen was higher in G2 than in G1 ($p=0.0424$, as well as TEG parameters MA($p=0.004$), G($p=0.002$) and TG ($p=0.001$), even though all of these were at the normal reference range in most patients in both groups. Only D-dimer and TNF differences persisted significant after covariance analysis. In G1 and G2, 5.6% and 6.8% were lost to follow-up, respectively. From these variables D-dimer and alpha-TNF positively correlated with each other ($R=0.312$; $p=0.0001$). D-dimer under the mean value of 230ng/mL predicted better transplante-free survival rates (58.3% vs 34.3%; log-rank=0.0001). Alpha-TNF D under the mean value of 17.9ng/mL predicted better transplante-free survival rates (56.3% vs 34.5%; log-rank=0.0001).

Conclusions: Inflammation markers measured by alpha-TNF was independently greater among Chagas' cardiomyopathy than non-Chagas' cardiomyopathy patients, as well as, pro-thrombotic status measured by D-dimer. These biomarkers were well correlated with each other and predicted prognosis in the long-term follow-up.

P427

Utility of bio-adrenomedullin (bio-ADM) and pro-enkephalin (pro-ENK) for the prediction of in-hospital mortality in patients with acute heart failure

S Silvia Navarin¹; R Marino¹; S Santarelli¹; D Volterra¹; C Berardi¹; L Magrini¹; A Bergmann²; O Hartmann²; J Struck²; S Di Somma¹

¹Sant'Andrea Hospital Sapienza University of Rome, Emergency Department, Rome, Italy; ²Sphingotec GmbH, Neuendorferstr. 15a, 16761 Hennigsdorf, Germany, Hennigsdorf, Germany

Background: Bio-Adrenomedullin (bio-ADM) and Pro-Enkephalin (pro-ENK) have already proved to be good predictors of short term mortality in patients with sepsis. No data are available so far on their predictive value for in-hospital mortality in patients with acute heart failure.

Methods: This was a prospective, observational trial conducted in intensive care unit. We enrolled patients admitted from the emergency department of Sant'Andrea hospital in Rome for acute heart failure. Clinical and laboratory data, bio-ADM and pro-ENK values were collected at arrival and patients were followed until hospital discharge.

Results: 209 patients with a final diagnosis of acute heart failure were recruited (44% male, mean age 78.4 ± 9.5). Regarding patients' characteristics we found out that 49.7% had prior history of heart failure, 58% had reduced systolic function, 17% presented with pulmonary edema, and 21% developed acute kidney injury, defined as serum creatinine increase by 0.3 mg/dl within 48 hours after hospitalization. Using Pearson's analysis, a significant correlation was found between bio-ADM and inferior vena cava index ($r=0.20$, $p=0.003$), suggesting a potential role of bio-ADM in the detection of intravascular congestion, that is considered to be the main cause of re-hospitalization for acute heart failure patients. Moreover, admission pro-ENK significantly correlated at Pearson's test with serum creatinine ($r=0.56$, $p<0.0001$) and chronic kidney disease ($r=0.31$, $p<0.0001$). This result seems to extend the already known role of pro-ENK for renal impairment identification to the heart failure condition. Finally, both analyzed biomarkers, bio-ADM and pro-ENK, proved their value in predicting in-hospital mortality in acute heart failure patients (bio-ADM: Area Under Curve = 0.65, $p=0.047$; pro-ENK: Area Under Curve = 0.73, $p=0.0011$).

Conclusions: bio-ADM and pro-ENK are suitable biomarkers for risk prediction of in-hospital mortality in patients hospitalized for acute heart failure. The pathophysiological mechanism of the two biomarkers for the prediction of in-hospital death for acute heart failure patients seems to be linked to intravascular congestion for bio-ADM and to renal dysfunction for pro-ENK.

P428

ST2 is an independent predictor of all-cause mortality in elderly patients.

M Olofsson¹; F Thormark Froest²; A-C Bergman²; A Larbool²; K Boman¹

¹Institution of Public health and Clin Med, Dept of Medicine, Skellefteå, University of Umeå, Umeå, Sweden; ²Karolinska University Hospital, Department of Clinical Chemistry, Stockholm, Sweden

Background: NtproBNP is a known predictor of mortality. A new biomarker, suppression of tumorigenicity 2 (ST2) has been introduced as a marker for fibrosis and hypertrophy and may thus predict mortality. There is a lack of knowledge about the predictive value of ST2 in elderly primary health care (PHC) patients.

Purpose: To compare ST2 with NTproBNP as a predictor of mortality in elderly patients with clinical symptoms of heart failure (HF).

Methods: Explorative analysis of a longitudinal study. Patients were recruited from one selected primary health care in northern Sweden between 2000 and 2003 and comprised both registry patients and incident cases with suspected HF identified by the general practitioner (GP) at the PHC. All patients had clinical symptoms of HF and significant co morbidities. Blood samples were collected at baseline and stored frozen for future analysis. NTproBNP was analyzed with Roche Elecsys proBNP immunoassay. ST2 was analyzed with Critical Diagnostics Presage ST2 immunoassay. ST2 and NTproBNP were used as continuous variables in the analysis. The association between baseline characteristics and mortality at 10 years of follow up was analyzed with Cox regression analysis. For mortality data death certificate were used. Adjustments were made for significant variables from the univariate Cox regression analysis and from fixed factors as age, gender and smoking habits.

Results: We studied 159 patients (mean age 80 years, 66% women). During ten years of follow up 80 (50%) patients had died. In the univariate Cox regression analysis significant associations with all-cause mortality at 10 years of follow up were found for ST2 (hazard ratio [HR]: 1.03; 95% confidence interval [CI]: 1.01-1.05), age (HR: 1.09; CI: 1.05-1.12), kidney dysfunction, defined as creatinine $>100\mu\text{mol/L}$ (HR: 2.31; CI: 1.43-3.74), all HF (HR: 2.00; CI: 1.20-3.31), NTproBNP (HR: 1.0001; CI: 1.0001-1.0002). In the following multivariate analysis ST2 (HR: 1.03; CI: 1.00-1.06), age (HR: 1.12; CI: 1.06-1.18), kidney dysfunction (HR: 2.12; CI: 1.08-4.17), smoking habits (HR: 4.27; CI: 2.22-8.23) and NTproBNP (HR: 1.0001; CI: 1.0000-1.0002) were independently associated with all-cause mortality at ten years of follow up. For cardiovascular mortality ST2 (HR: 1.03; CI: 1.00-1.05) was significant associated in univariate analysis but not after adjustment for age. **Conclusion:** ST2 was an independent prognostic marker of all-cause mortality in elderly PHC patients with clinical symptoms of HF. In these patients the clinical value of ST2 as an additive prognostic marker to NTproBNP needs to be further evaluated.

P429

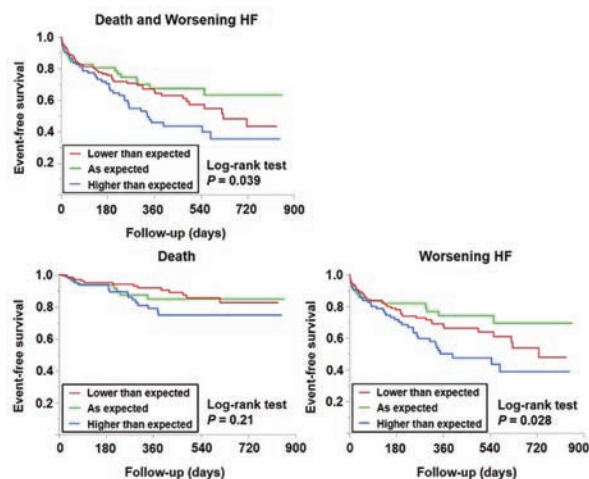

Impact of endogenous erythropoietin level on long-term clinical outcomes in patients with acute decompensated heart failure

T Nagai¹; K Nishimura²; T Honma¹; Y Sugano¹; Y Asaumi¹; T Noguchi¹; K Kengo¹; H Ogawa¹; S Yasuda¹; T Anzai¹

¹National Cerebral and Cardiovascular Center Hospital, Department of Cardiovascular Medicine, Suita, Osaka, Japan; ²National Cerebral and Cardiovascular Center, Preventive Medicine and Epidemiology Informatics, Suita, Japan

Backgrounds: Although previous reports suggest that an elevated endogenous erythropoietin (EPO) level is associated with worse clinical outcomes in chronic heart failure (HF) patients, the prognostic implication of EPO in patients with acute decompensated HF (ADHF) and underlying mechanisms of the high EPO level in severe HF patients who have poor prognosis remain unclear. Purpose; To investigate whether the high EPO level on decompensated phase of HF was associated worse clinical outcomes, and to explore the pathophysiological mechanisms of high EPO level in high-risk HF patients in a relatively large ADHF cohort.

Methods and Results: We examined 539 consecutive ADHF patients with EPO measurement on admission from our registry. During a median follow-up period of 329 days (IQR 110 - 541), higher EPO level on admission was independently associated with worse clinical outcomes (composite of death and worsening HF) (HR 1.25, 95%CI 1.06 - 1.48, $P=0.008$) in multivariate Cox proportional hazards model. Hemoglobin level was the strongest determinant of EPO level ($\beta=-0.30$, $P<0.001$), whereas estimated glomerular filtration rate (eGFR) was not significant ($P=0.13$) in multivariate regression analysis. In anemic subgroup of 318 patients, higher EPO level than expected on the basis of their hemoglobin level was related to increased adverse events (Figure), and was an independent determinant of worse clinical outcomes (composite of death and worsening HF) (HR 1.63, 95%CI 1.05 - 2.49, $P=0.028$) in multivariate Cox proportional hazards model. Moreover, estimated plasma volume excess rate was positively associated with EPO level ($\beta=0.15$, $P=0.003$), and anemic patients with higher-than-expected EPO level tended to have higher estimated plasma volume excess rate, plasma lactate level and lower systemic oxygen saturation level with the preservation of reticulocyte-production potential than those with lower-than-expected EPO level ($P<0.001$). Conclusions; High EPO level predicts long-term worse clinical outcomes in ADHF patients, independent of anemia and impaired renal function. Anemia and hypoxia due to severe congestion may synergistically contribute to high EPO level in high-risk HF patients.

Expected EPO Level and Clinical Outcomes

P430**Relevance between tolvaptan and RAS activation in severe heart failure.**Y Yoshifumi Ikeda¹; T Senbonmatsu¹; R Kato¹; S Iwanaga¹; K Matsumoto¹; S Nishimura¹¹Saitama International Medical Center, Cardiology, Hidaka, Japan

Background: Since tolvaptan is a selective vasopressin receptor inhibitor, which belongs to the water diuretic drug, it may be the ideal diuretic for heart failure due to minimum activation of renin angiotensin system (RAS). Thus, we investigated the relevance between tolvaptan and RAS activation in the patients who had severe heart failure by pharmacologic mechanisms.

Patients and methods: Twelve patients who were hospitalized and had severe heart failure with NYHA III or IV, and they took 50mg of furosemide, had been registered for the present study from May, 2013 to September, 2014. The combination therapy with tolvaptan and low dose thiazide was commenced, and circulatory dynamics had been well observed for three months. Plasma renin activity (PRA), plasma renin concentration (PRC) and soluble prorenin receptor (s-PRR) were evaluated.

Result: All patients were discharged by three months. However, four of them were readmitted because of aggravation in heart failure. There were no significant differences in PRA/PRC of the patients in the vicinity of this study. However, four patients who were readmitted showed significantly higher s-PRR level than those of non-readmitted patients (141.8 ± 2.9 vs 136.3 ± 3.6 ng/ml; $p = 0.026$).

Conclusion: There may be no advantage in the tolvaptan therapy on the patients who had severe heart failure. However, the s-PRR concentration may be a predictive factor of aggravation in heart failure.

P431**Effects of beta-blocker therapy on hs-CRP levels in elderly patients with ischemic and non-ischemic heart failure: Results from the CIBIS-ELD trial**HD Duengen¹; B Putnikovic²; P Milicevic²; S Radenovic¹; T Trippel¹; E Elväs Tahirovic¹; S Von Heahling³; F Edelmänn¹; B Pieske¹; E Isenovic⁴¹Charité - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Clinical Hospital Center Zemun, Department of Cardiology, Belgrade, Serbia; ³University of Göttingen, Department of Cardiology and Pneumology, Göttingen, Germany; ⁴Institute for Nuclear Science "Vinca", Belgrade, Serbia

Background: C reactive protein (CRP) is a biomarker indicating systemic inflammation. Elevated levels of this biomarker are associated with increased rates of cardiovascular disease, including chronic heart failure (HF). In the past years, high-sensitivity CRP assays were developed in order to measure lower levels of CRP, down to 0.3mg/l (hs-CRP). Up to now, beta blocker (BB) therapy in HF has been researched thoroughly, though still, very little is known about the effects of BB titration on hs-CRP levels in ischemic and non-ischemic HF patients. Also, little is known if this effect differs between selective vs. unselective BB.

Purpose: To explore the trajectories of hs-CRP before and after BB (carvedilol vs bisoprolol) titration in elderly HF patients depending on the type of BB used and the etiology of the disease (ischemic vs non-ischemic).

Methods: We measured plasma levels of hs-CRP and NT-proBNP in 520 HF patients ≥ 65 years (72.06 ± 5.24 y, 38% f, LVEF $41.8 \pm 13.8\%$; ischemic $n = 243$; non-ischemic $n = 277$) of the CIBIS-ELD trial. In this trial, patients were randomized to bisoprolol vs. carvedilol and doses were up-titrated to the target or maximally tolerated dose. hs-CRP and NT-proBNP levels were assessed at baseline (BL) and after 12 weeks (FU).

Results: In patients with ischemic HF, hs-CRP levels decreased in the bisoprolol group ($BL = 0.60 \pm 0.94$ mg/dl, $n = 166$; $FU = 0.43 \pm 0.694$ mg/dl, $n = 131$; $p = 0.010$), and were without a change in the carvedilol group ($BL = 0.60 \pm 1.69$ mg/dl, $n = 181$; $FU = 0.57 \pm 0.982$ mg/dl, $n = 136$; $p = 0.731$). There was also no change of hs-CRP levels in non-ischemic HF patients in both groups (bisoprolol: $BL = 0.64 \pm 1.175$ mg/dl, $n = 197$; $FU = 0.470 \pm 0.81$ mg/dl, $n = 152$, $p = 0.069$; carvedilol: $BL = 0.45 \pm 0.78$ mg/dl, $n = 198$; $FU = 0.41 \pm 0.701$ mg/dl, $n = 152$, $p = 0.420$). Plasma levels of NT-proBNP decreased in ischemic patients treated with bisoprolol, ($BL = 1594 \pm 2146$ pg/ml, $n = 169$; $FU = 1468 \pm 2110$ pg/ml, $n = 133$, $p = 0.04$), while changes in the carvedilol group were not significant ($BL = 1648 \pm 1991$ pg/ml, $n = 188$; $FU = 1567 \pm 2119$ pg/ml, $n = 135$, $p = 0.556$). In the non-ischemic group NT-pro levels did not change significantly in the carvedilol group, while there was an increase in non-ischemic patients in the bisoprolol group ($BL = 1427 \pm 3113$ pg/ml, $n = 208$; $FU = 1533 \pm 5385$ pg/ml, $n = 166$, $p = 0.017$).

Conclusion: Results indicate that bisoprolol might be associated with a decrease of hs-CRP and NT-proBNP levels only in ischemic HF patients, while in non-ischemic HF patients there was no change of hs-CRP and an increase of NT-proBNP levels. In carvedilol treated patients no significant changes was shown in neither group.

P432**Inflammatory biomarkers as predictors of acute decompensated heart failure in patients with atrial fibrillation**J B Augusto¹; M Borges Santos¹; D Roque¹; M Silva¹; J Castro²; J Sala¹; A Faustino¹; M Branco¹; F Frade¹; C Morais¹¹Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; ²Hospital de Cascais, Cascais, Portugal

Background: Atrial fibrillation (AF) is a frequent comorbidity in patients with heart failure (HF). There is a well-documented relationship between inflammatory markers and both AF and HF.

Purpose: We aimed to evaluate the diagnostic value of wide used routine inflammatory blood markers in the prediction of hospital admissions due to acute decompensated heart failure (ADHF) in patients with AF.

Methods: 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period were included retrospectively in our study. Among them, 423 patients were admitted for in-hospital management. All patients underwent routine clinical and laboratory exams. We also evaluated medical charts in order to identify patients with ADHF. Routine inflammatory biomarkers at hospital admission included: leucocytes, neutrophils and lymphocytes counts, and C-reactive protein (CPR). We also evaluated the diagnostic value of the neutrophil-to-lymphocyte ratio (NLR).

Results: 101 patients were admitted with both AF and ADHF (mean age of 77.2 ± 9.6 years, 40.6% males). In receiver-operating characteristic (ROC) analyses (figure) neutrophils count performed better than other inflammatory markers in predicting ADHF (neutrophils count - c-index 0.711, $p < 0.001$; NLR - c-index 0.662, $p < 0.001$; CPR - c-index 0.658, $p < 0.001$; Leucocytes count - c-index 0.581, $p = 0.020$; Lymphocyte count - c-index 0.544, $p = 0.208$). A neutrophils count $> 4.85 \times 10^9/L$ had a sensitivity of 83.7% and specificity of 52.6% (negative predictive value=76.5%, positive predictive value=63.9%) in prediction of ADHF.

Conclusion: Neutrophils count is a routine blood test which can prove an easy and simple tool with modest performance to predict the risk of admission due to ADHF in patients with AF.

P433

The incidence of chronic heart failure in patients with STEMI during therapy with different doses of atorvastatinV Valentin Oleinikov¹; L Salyamova¹; A Golubeva¹; N Burko¹¹ Penza State University, Penza, Russian Federation

Objective: To assess the incidence of congestive heart failure in patients after acute myocardial infarction with ST segment elevation (STEMI) against the backdrop of 24 weeks of treatment with different doses of atorvastatin.

Methods: The study included 45 patients with STEMI, confirmed by ECG, troponin I, CK-MB and the results of coronary angiography with hemodynamically significant stenosis of one artery (the infarct-related artery). In the first 24-96 hours of the onset of the disease, patients were randomized into two groups. Patients of the control group (C) (n=23) received atorvastatin 20 mg/day. Patients of the main group (A) (n=22) received atorvastatin 80 mg/day. Compared subjects were matched by age, height, BMI, office BP. At baseline at 7-9 hours and after 24 weeks of drug therapy brain natriuretic peptide (BNP) was determined; in addition, patients filled the rating scale of clinical condition in CHF (SHOKS, 2000). 6-minute walk test was carried out after 3 and 6 months after acute myocardial infarction.

Results: The mean values of BNP at baseline in Group C were 102,9 (49,3; 139,9) pg/ml, in group A - 60,8 (22,6; 104,8) pg/mL, respectively, ($p > 0,05$). After 24 weeks of treatment there was a significant decrease in BNP by 48% in patients receiving atorvastatin 20 mg (to 52,7 (15,8; 82,6) pg/ml, $p < 0,05$) in patients treated with high doses of the drug - 55% (to 27 (21,4; 42,8) pg/ml, $p < 0,05$). In the group C the baseline values of BNP, exceeded the threshold, were identified in 22% of cases (5 persons), at 24 weeks - 4% (1 person) ($p > 0,05$); in the group A, respectively, in 36% (8 people) and 9% (2 people) ($p < 0,05$). Analyses of SHOKS scale at 7-9 day from the onset of the disease in group C no signs of CHF have been found in 6 subjects (26%), 1st FC - in 17 persons (74%). After 24 weeks of follow-up, 0 point was determined in 6 patients (26%, $p > 0,05$), 1st and 2nd FC of CHF - in 14 (61%, $p > 0,05$) and 3 patients (13% $p < 0,05$) respectively. In group A, initially 6 patients (27%) with no signs of heart failure have been found, 1st FC - in 16 patients (73%). On follow-up 0 point was reported in 7 patients (32%, $p > 0,05$), 1st FC - in 15 subjects (68%, $p > 0,05$). According to the analysis of the 6-minute walk test after 12 weeks of treatment in the group C - 0 FC was detected in 17% of cases (4 subjects), 1st FC - in 44% (10 people), 2nd FC - 39% (9 patients). Against the background of the 24-week treatment 0 FC was registered in 26% of cases (6 people), 1st FC - in 44% (10 people), 2nd FC - 30% (7 people) ($p > 0,05$). In the group A at baseline: 0 FC - 36,4% (8 people), 1st FC - 45,4% (9 patients), 2nd FC - 18,2% (4 people), again, respectively, 36% (8 people), 59% (12 people), 5% (1 person) ($p > 0,05$).

Conclusions: the results of clinical and laboratory examinations in patients with STEMI, against the background of the 24-week treatment with atorvastatin 80 mg have shown a less frequent development of symptoms of chronic heart failure.

P434

CoQ10 treatment of patients with CHF and effects of BNP levelO Oleg Medvedev¹; OG Tokareva¹; EA Gorodetskaya¹; EI Kalenikova¹; ZM Sizova²¹ M.V. Lomonosov Moscow State University, Pharmacology, Moscow, Russian Federation; ² I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: CoQ10 is a powerful antioxidant and is one of recommended for CHF treatment. Decreased level of myocardial CoQ10 is correlated with the severity of symptoms and the degree of left ventricular dysfunction. Brain natriuretic peptide (BNP) is a peptide, which has recently been used in the differential diagnosis and follow-up of patients with heart failure. It is well known that the severity of the disease also correlates with the plasma BNP levels.

Purpose: To evaluate the effects of long-term coenzyme Q10 treatment as part of standard therapy in patients with NYHA class II-III chronic heart failure on plasma BNP levels, left ventricular ejection fraction, and the 6-minute walk test.

Materials and Methods: 78 patients with NYHA class II-III chronic heart failure aged from 40 to 70 years with EF less than 45% were randomized in clinical trial. During the study period (24 weeks) participants received solubilized oral form of CoQ10 (90 mg/d) or placebo in addition to standard medical therapy. Left ventricular ejection fraction, 6-minute walk test, plasma brain natriuretic peptide (BNP) (fluorescent analyser with test strips) and CoQ10 levels (HPLC with electrochemical detection) were measured in all patients prior to and after six months treatment.

Results: In 37 patients from 78 the baseline level of BNP was below 100 pg/ml. 6 months administration of CoQ10 did not change BNP level, but in placebo group BNP level increased by 176% ($p = 0,0092$). In group of 41 patients baseline level of BNP was above 100 pg/ml level. In this group administration of CoQ10 was followed by the decrease in BNP level by 6.8% ($p = 0,02$) whereas in placebo group BNP level did not change.

Conclusion: 6 months administration of coenzyme Q10 prevents progression of congestive heart failure in patients with reduced contractility and baseline plasma BNP levels within normal ranges (less than 100 pg/ml) and leads to a significant

reduction of BNP levels in patients with initial BNP levels higher than 100 pg/ml, increase in left ventricular ejection fraction and improvement in exercise tolerance.

P435

Serial changes in N-terminal pro-brain natriuretic peptide in heart failure patients after surgical ventricular reconstruction: the biomarker plus studyS Serenella Castelvaccchio¹; E Baryshnikova¹; F Ambrogio²; B Girardi³; A Camporeale⁴; R Tramarin⁵; E Costa⁵; L Menicanti⁶¹ IRCCS Policlinico San Donato, San Donato Milanese, Milan, Italy; ² University of Milan, Department of Clinical Sciences and Community Health, milano, Italy;³ IRCCS Policlinico San Donato, Department of Cardiac Rehabilitation, milano, Italy;⁴ IRCCS Policlinico San Donato, Department of Multimodality Cardiac Imaging, milano, Italy; ⁵ IRCCS Policlinico San Donato, Service of Laboratory Medicine, milano, Italy; ⁶ IRCCS Policlinico San Donato, Department of Cardiac Surgery, Milan, Italy

Background: Plasma concentrations of natriuretic peptides have been shown to predict long-term morbidity and mortality in heart failure (HF) patients with left ventricular (LV) dysfunction, although most of data comes from medical trial including relatively young patients affected by HF of ischemic aetiology in a small percentage and the results are not uniform. Furthermore, it is still unclear if changes after cardiac surgery predict therapeutic effect on mortality or risk of hospitalization.

Purpose: To prospectively investigate the longitudinal profile of serial changes in N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels from baseline to different time-points at follow-up in ischemic HF patients undergoing Surgical Ventricular Reconstruction (SVR) and how changes in NT-proBNP affect the prognosis. Methods. Between January 2010 and June 2014, one hundred and forty-three patients (122 men, 64 ± 9 years old) with previous myocardial infarction and LV remodeling referred to our Center for SVR had an assessment of NT-proBNP levels at baseline and at 6 months, 12 months and 18 months after surgery. The association between serial measurements of NTpro-BNP and the time to the composite event of all-cause death or first hospitalization was studied adjusting for gender, age and creatinin level at baseline. The analysis was performed using joint modeling of the serial measurements of NT-proBNP through mixed models together with Cox regression to analyze time to event data. The logarithm of the biomarker was used in the analysis.

Results: The estimated average level of the biomarker decreased by about 50% during the first year after the intervention. Serial measurements of NTpro-BNP were associated with the hazard of event with a parameter estimate of 1.09 (95% confidence interval [CI] 0.62 - 1.56). Therefore, considering the log transformation, a 1% increase in NTpro-BNP during follow-up was associated with 1.1% increase of the risk of the composite event (95% CI 0.6% - 1.6%).

Conclusions: Changes over time of NT-proBNP concentrations in ischemic HF patients undergoing Surgical Ventricular Reconstruction are associated with long-term prognosis. Serial changes (either in increasing or in decreasing) at different time points have resulted into a modulation of the risk of adverse events.

P436

The prevalence of elevated natriuretic peptide in a diabetic population without a history of heart failure

Irish Heart Foundation

G O' Carroll¹; V Harkins¹; J Gallagher¹; S James¹; E O' Connell¹; M Ledwidge¹; C Watson¹; K Mc Donald¹¹ St Vincent's University Hospital, Dublin, Ireland

Purpose: Patients with diabetes are at increased risk of several cardiovascular disorders including heart failure. The objective of this study is to determine the prevalence of elevated natriuretic peptide (NP) in a diabetic population, characterise diabetics with normal and elevated NP levels, and examine the association between

Echocardiographic parameters

	NTproBNP < 125 (n=17)	NTproBNP 125 - 250 (n=33)	NTproBNP > 250 (n=120)
Relative Wall thickness > 0.42	7 (41.2%)	13 (39.4%)	56 (47.1%)
E/e ratio > 13	2 (12.5%)	5 (20.0%)	28 (30.4%)
Lateral e velocity < 10	10 (62.5%)	26 (89.7%)	77 (75.5%)
LVEF > 50% 45 - 50% 35 - 45% < 35%	17 (100%) - - -	30 (90.9%) 1 (3.0%) 2 (6.1%) -	101 (84.2%) 8 (6.7%) 6 (5.0%) 5 (4.2%)
LAVI > 34	4 (23.5%)	3 (12.0%)	61 (64.2%)

NP and heart failure in this population to allow appropriate structuring of heart failure prevention services.

Methods: Patients enrolled in the HSE Midland Diabetes Structured Care Programme between May 2013 and Feb 2015 were included in this study. We measured the NP level of all participants and examined the characteristics of those with normal and elevated NP levels. We also determined the presence of heart failure in the elevated NP group using specific echocardiographic parameters.

Results: There were 611 patients with diabetes who had an NTproBNP level measured (58.6 % male, mean age 65.6 yrs). Two hundred and six patients (33.7%) had an NP level > 125 pg/ml. Those with an elevated NP (>125 pg/ml) had higher rates of atrial fibrillation (18% vs 0.74%), HTN (51.5% vs 32.1%) and hyperlipidaemia (35.9% vs 25.4%) compared with the normal NP group. The use of Angiotensin receptor blockers (27% vs 18.9%), loop diuretics (25.8% vs 3.9%) and B blockers (50% vs 16.8%) was higher in the elevated NP group. The rate of hypoglycaemic medication use between the two groups was higher in the normal NP group (63.2 vs 54.5%). Thiazolidinedione use was higher in the high NP group (7.9% vs 3.9%). The median HbA1C level was 47 (42 - 55) with no significant difference between the groups. Baseline echocardiography was performed in 170 patients. Twenty patients (11.7%) had LV systolic dysfunction (LVSD, EF <50%) and 68 (49.6%) had LV diastolic dysfunction (LVDD, LAVI > 34). An NP level > 250 pg/ml was most predictive of the presence of LV dysfunction (LVSD 16.9%, LVDD 64.2%)

Conclusions: Diabetic patients had a high prevalence of elevated NP. There was a high prevalence of LV dysfunction in those with elevated NP. Interval NP screening of this at risk population should be considered as part of the approach in reducing cardiovascular morbidity.

Laboratory aspirin resistance reversibility in coronary artery disease and chronic obstructive pulmonary disease patients after coronary stent implantation

I Pershukov¹; J Ramazanov²; A Omarov³; R Kalmatov⁴; O Uraimov⁵; B Akbalaeva⁶; N Bosak⁷; Z Karben⁷; T Batyraliev⁷; B Sidorenko¹

¹Presidential Medical Centre, Moscow, Russian Federation; ²Central Hospital of Oilworkers, Baku, Azerbaijan; ³Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan; ⁴Osh State University, Osh, Kyrgyzstan; ⁵Osh Cardio Clinic, Osh, Kyrgyzstan; ⁶Krasnodar City Clinical Emergency Hospital, Krasnodar, Russian Federation; ⁷Sani Konukoglu Medical Center, Gaziantep, Turkey

Background: Acetyl salicylic acid (ASA) resistance occurs most frequently in patients with comorbidities and is associated with poor prognosis. The purpose of this study was to evaluate the prevalence of aspirin resistance in a cohort of patients with CAD and COPD, who underwent coronary stent implantation, and whether it can be reversed using original enteric-coated aspirin.

Methods: Platelets function of 244 patients after PCI taking ASA 75 mg daily has been evaluated with VerifyNow. Patients found resistant by test (ARU > 550) were switched to original enteric-coated aspirin 100 mg. Platelets function was measured again after 24 h. Patients whose the resistance was reswitched to noncoated ASA 162 mg daily and their aggregation status was re-evaluated after 1 week of therapy.

Results: Prevalence of ASA resistance in our population was 15.9 % (39/244) with ARU from 554 to 793. In 37 out of 39 patients (95 %) aspirin resistance was reversed within 24 h from the change to original enteric-coated aspirin. 36 out of 37 patients (97 %) were found fully aspirin-sensitive after 1 month of oral therapy; two other patients were found with borderline value ARU=550 after 1 week of use noncoated ASA 162 mg daily. No adverse reactions were observed. Conclusion(s): A significant number of patients with CAD and COPD are resistant to ASA therapy 75 mg daily. A single dose of original enteric-coated acetylsalicylate 100 mg can reverse the platelet hyper-aggregability and laboratory aspirin resistance in large majority of patients.

P438

Temporal trends in the use of digoxin in patients heart failure

G M C Giuseppe M C Rosano¹; G Marazzi¹; G Caminiti¹; G Campolongo¹; G Savarese¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Digoxin is a recommended therapy for heart failure (HF) with reduced ejection fraction (HFrEF), but its use has recently casted doubts about its utility and safety. Furthermore, the use by specialist has been declining in the past decades. We conducted a retrospective analysis of 1216 patients admitted with HFrEF in a six year period and we assessed the temporal trends, and factors associated with digoxin use. Out of 1216 patients with HFrEF patients, 21.6% received digoxin at discharge. Digoxin prescription decreased by 3 fold in 6 years (P < 0.001). The trend was similar and significant across all age groups and sexes. Atrial fibrillation was associated with a greater probability of digoxin prescription at baseline (p < 0.001). Patients in AF had a 3.4 fold greater probability of being prescribed digoxin (OR 3.4, 95% CI 1.92-5.6). COPD was also associated with a greater probability of digoxin use (OR 1.71, 95% CI 1.12-2.08). In conclusion the use of digoxin is progressively decreasing in patients with HFrEF attending a tertiary hospital. Digoxin is mainly prescribed to patients with atrial fibrillation and COPD.

P439

P2Y12 inhibitors in acute coronary syndrome: relation to hemorrhagic events in routine clinical practice

A R Godinho¹; M Viana²; S Correia²; P Dias¹; R Almeida¹; O Aszczyńska²; C Araujo²; I Moreira³; MJ Maciel¹; A Azevedo²

¹Sao Joao Hospital, Cardiology, Porto, Portugal; ²Faculty of Medicine University of Porto, Cardiology, Porto, Portugal; ³Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal

Introduction: In the context of acute coronary syndromes (ACS), ticagrelor demonstrated to reduce cardiovascular death, myocardial infarction and stroke when compared to clopidogrel. These benefits did not seem to be associated with increasing rates of hemorrhagic events (HE) and, thus, ticagrelor has been introduced in routine practice. However, little is known about ticagrelor's safety in "real world" clinical practice, since available evidence comes mainly from clinical trials.

Objective: To assess the occurrence of major HE in ACS patients treated with ticagrelor or when the switch between both P2Y12 inhibitors (ticagrelor/clopidogrel) was required during hospitalisation, compared to clopidogrel.

Methods: This study is part of an ongoing prospective cohort study of ACS survivors consecutively recruited between August 2013 and December 2014, at the cardiology departments of two hospitals in Portugal. Data was collected through face-to-face interviews and medical records review. This evaluation comprised socio-demographic characteristics, clinical history and information during hospitalization. We evaluated 939 patients under dual antithrombotic therapy (aspirin and ticagrelor or clopidogrel) during hospitalization. Major HE were defined as a drop in hemoglobin (Hb) between 3 and 5 g/dL or over 5 g/dL, or intracranial hemorrhage (ICH). The association between the drug used and HE was estimated by logistic regression analysis, taking into account other demographic and clinical characteristics.

Results: The mean age was 64 years and 74.3% were male. Most patients (86.2%) were medicated with clopidogrel, 7% with ticagrelor and 6% switched between P2Y12 inhibitors (with another new loading dose) during hospitalization. The incidence of HE was 4.6%, with 2.9% having a drop of 3-5 g/dL in Hb, 1.2% a drop > 5 g/dL in Hb, and 0.5% considering ICH. There were no differences in HE in patients treated with clopidogrel, ticagrelor or who switched between the two drugs (4.6%, 6.4% and 1.9%, respectively, p=0.512).

Conclusion: Our results found that ticagrelor was safe in routine clinical practice, independently of patients' characteristics, and support the safety of P2Y12 inhibitors even when overlapping is required, with a new loading dose. However these interpretations need to be cautious, because the ticagrelor group is still small in our sample.

P440

Hyper-Kalaemia as cause for discontinuation of RAASi in patients with heart failure

G M C Giuseppe M C Rosano¹; G Marazzi¹; G Caminiti¹; G Campolongo¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

ACE inhibitors and Aldosterone antagonists (or mineralocorticoid receptor antagonists [MRAs]) are guideline-recommended therapy for patients with heart failure reduced left ventricular ejection fraction (HFrEF), and in postmyocardial infarction patients with HF.

Often the use of drugs acting on the renin angiotensin aldosterone system (RAASi) cannot be fully implemented because of the occurrence of hyperkalaemia.

Aim of the present study was to assess the occurrence of hyperkalaemia and the need for discontinuation of RAASi therapy because of high K levels in patients with chronic heart failure attending a tertiary health care centre over a period of 5 years. Amongst 968 patients with full available data 402 had to discontinue at least one RAASi because of hyperkalaemia. Hyperkalaemia was mild in 45% of patients discontinuing RAASi and moderate-severe in 55%.

Discontinuation of RAASi therapy was more frequent in patients with preserved or in those with severely impaired renal function while no correlation was found with NYHA class or LVEF.

In conclusion hyperkalaemia is a frequent occurrence in patients with heart failure, limits the implementation of life-saving medications. This may well translate into a negative prognostic effect.

P441

Effects of ivabradine on coronary flow reserve and left ventricular diastolic function in patients without coronary artery stenosis

E Tagliamonte¹; T Cirillo¹; F Rigo²; Q Ciampi³; A Caruso¹; C Astarita⁴; N Capuano¹

¹Hospital Umberto I, Division of Cardiology, Nocera Inferiore, Italy; ²Hospital "dell'Angelo", Department of Cardiology, Mestre-Venice, Italy; ³Fatebenefratelli Hospital of Benevento, Division of Cardiology, Benevento, Italy; ⁴Santa Maria della Misericordia Hospital, Operative Unit of Cardiology, Sorrento, Italy

Background: Doppler-derived coronary flow reserve (CFR) can be impaired in both obstructive coronary artery disease (CAD) and coronary microvascular disease (CMD). Otherwise, CMD has been regarded as an important cause of left ventricular (LV) diastolic dysfunction. In different trials, ivabradine showed to improve CFR and diastolic function, but these effects were never correlated. The aim of our study was to assess the combined effect of ivabradine on CFR and LV diastolic function and the correlation between these two parameters. **Methods:** 86 patients (52 M, 34 F; mean age 64 ± 7 years) without obstructive CAD were enrolled in the study. After baseline data were collected, all patients underwent Doppler-derived CFR. Coronary flow was assessed in the left anterior descending coronary artery (LAD), and was identified as the color signal directed from the base to the apex of the left ventricle, containing the characteristic biphasic pulsed-Doppler flow signals. CFR were determined as the ratio of hyperemic, induced by intravenous dipyridamole administration, to baseline diastolic coronary flow velocity. Doppler echocardiography included pulsed tissue Doppler of the mitral annulus. The ratio of mitral velocity to early diastolic velocity of the mitral annulus (E/e') was used as a surrogate marker of diastolic function. Patients were randomly assigned to ivabradine or placebo for one month (after up-titration phase). Doppler echocardiography and CFR assessment were performed again at the end of treatment period.

Results: There were no significant differences in baseline characteristics between ivabradine and placebo group. CFR was successfully performed in all patients. Baseline CFR was not significantly different in both groups. After treatment, in ivabradine group CFR significantly increased (3.34 ± 0.41 vs. 2.24 ± 0.36 - $p < 0.01$) and E/e' significantly decreased (8.3 ± 1.8 vs. 10.4 ± 2.1 - $p < 0.01$). At baseline, a significant inverse association between CFR and E/e' was observed. After treatment, a weaker correlation was observed.

Conclusions: CFR is associated with LV filling pressure in patients without obstructive CAD, and ivabradine is able to improve both CFR and diastolic function. A weaker correlation after treatment, is probably due to a more complex effect of ivabradine, beyond the single parameters.

P442

Analysis of changes of ECHO-cardiogram indices in patients with chronic heart failure during therapy with coenzyme Q10

G Kukharchik¹; L Sichinava¹; A Burbello¹; I Yubrina¹; L Gaykovaya¹; L Sorokin²; I Konstantinova¹

¹North-West State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation; ²Hospital St. Elizabeth, Saint-Petersburg, Russian Federation

Aim: To evaluate changes in echocardiogram (Echo-CG) indices in patients with chronic heart failure (CHF) in functional NYHA class II-III and a history of myocardial

infarction, who were treated with coenzyme Q10 in addition to standard therapy.

Method: 120 patients with class II-III CHF and a history of myocardial infarction were enrolled into the study. The patients were randomized into two groups: group I patients received optimal standard therapy and in addition coenzyme Q10 at a dose of 120 mg/day for 3 months; group II patients received optimal therapy only. Echo-CG was used for the evaluation of post infarction remodeling at the start of the study, at 3 months and at 12 months.

Results: Increase of the left ventricular end-diastolic volume index (iLVEDV) of more than 75 ml/m² was found in 24 (47.1 %) patients of group I and 26 (49.1 %) patients of group II. Significant differences were only found in group I patients ($p < 0.05$ for Wilcoxon criteria and Friedman criteria ANOVA). Thus, after 3 months of treatment patients in group I showed a decrease of iLVEDV with values of 65.67 (56.54; 77.94) ml/m² ($p < 0.05$), and only in 15 patients (29.4 %) this index was above 75 ml/m². In group II patients, the iLVEDV showed no change compared to the initial test and measured 71.86 (55.55; 89.83) ml/m² ($p > 0.05$), and 24 of these patients (45.3 %) showed an iLVEDV level of more than 75 ml/m². In group I patients the iLVESV initially was 24.87 (19.28; 35.43) ml/m², but after 3 months of therapy it measured 22.12 (16.74; 30.98) ml/m² ($p < 0.05$). In group II, the initial measurement of iLVESV was 25.54 (18.00; 33.18) ml/m² and after 3 months there were no significant changes at 25.12 (17.38; 33.74) ml/m² ($p > 0.05$). Overall, the median indices of iLVESV did not exceed the reference ranges, however the higher quartile of iLVESV in group II over 3 months exceeded 31.0 ml/m². Moreover, in 12 patients of group II the iLVESV was more than 35 ml/m², indicating an unfavourable course of post infarction remodeling process. In group I patients the left ventricle ejection fraction (LVEF) was initially 60.00 (54.00; 67.00) %, and at 12 months 64.00 (56.00; 70.00) %. The LVEF in group II was initially 63.00 (56.00; 69.00) %, and at 12 months 62.00 (55.5; 68.5) %. The left atrium index (iLA) was initially 21.62 \pm 2.17 ml/m² in group I patients, and outcome progression was 22.30 \pm 2.22 ml/m². In group II this was 21.80 \pm 2.14 ml/m² and 23.29 \pm 2.47 ml/m² correspondingly. The index of relative wall thickness in group I initially and at 3 months was 0.41 (0.37; 0.46) and 0.42 (0.37; 0.48) correspondingly, but in group II patients this index practically did not change: 0.42 (0.34; 0.48) and 0.42 (0.35; 0.48).

Summary: The prescribing of coenzyme Q10 in addition to the standard group of medications used in the treatment of patients with class II-III CHF (after myocardial infarction) resulted in improvement of echocardiogram indices.

P443

Prognostic impact of polypharmacy drugs across heart failure phenotypes: an unmet need.

A Iorio¹; M Senni¹; C Concetta Di Nora²; G Barbati²; A Cherubini³; A Gavazzi¹; G Cioffi⁴; G Pulignano³; G Sinagra⁴; A Di Lenarda³

¹Ospedale Papa Giovanni XXIII, Bergamo, Italy; ²University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ³Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy; ⁴Villa Bianca Hospital, Trento, Italy

Background: Data on prognostic role of polypharmacological therapy in HF phenotype (HFrEF - LVEF $< 50\%$ versus HFpEF - LVEF $\geq 50\%$) are lacking.

Objective: To compare the prognostic role of polypharmacy across EF-HF phenotype.

Methods: All outpatients with HF and available LVEF enrolled consecutively from November 2009 to October 2013 in the community-based population. Clinical variables of study population were derived from the E-chart for outpatient collected in a regional data warehouse. Polypharmacological therapy was defined as sum of non HF related treatment per patients.

Results: A total of 2314 patients (mean age 78 ± 8 , 57% men) were included. Of these 1373 (59 %) had HFpEF and 941 (41%) HFrEF. The high mean age, comorbidity rates (mean 3.2 ± 2.5 ; 54% patients with ≥ 3 non cardiac comorbidities) and numbers of drugs (6.1 ± 1.7) ran similarly between HF groups. 933 HF patients (42%) were treated with ACE/ARB and betablocker. At a follow-up of 28 ± 14 months, 472 (20%) patients died. Of these 225 (24%) had HFrEF, 247 (18%) had HFpEF. The increasing number of drugs per patient was associated with higher mortality rates (HR 1.3 [IC 1.2-1.6]; $p = 0.001$), all-cause hospitalization (HR 1.8 [IC 1.3-2.4]; $p < 0.001$), HF hospitalization (HR 1.7 [IC 1.3-1.9]; $p < 0.001$), and non cardiovascular Hospitalization (HF 1.7 [IC 1.3-2.3]; $p < 0.001$). This trend was revealed to have a similar prognostic impact among HF groups (interaction test analysis, $p = 0.917$). This adverse relationship remain unchanged in subgroups under optimal HF medical treatment. Finally, a multivariable model confirmed the polypharmacy therapy as independent predictor along with age, sex, non cardiac comorbidities, HF related treatment.

Conclusion: In an HF community-based population, predominantly elderly with high comorbidity burden, polypharmacy contributed significantly to high rates of mortality and morbidity irrespective of HF phenotypes and HF related medical treatment.

P444

Enoxaparin and fondaparinux better than unfractionated heparin improve endothelial function in patients with acute decompensated chronic heart failure

IV Shevchenko¹; AA Shavarov¹; GK Kiyakbaev¹; VS Moiseev¹¹ Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: to compare changing levels of endothelial dysfunction serum markers in patients with acute decompensated chronic heart failure (ADCHF), depending on a received anticoagulant.

Materials and Methods: The study included 60 ADCHF patients with sinus rhythm, mean age 69 ± 10 years, 35 women (58%), treated with standard ADCHF therapy. Patients with acute exacerbation of chronic diseases and active cancer were excluded from the study. All patients were randomized into 3 equal groups to prophylactic subcutaneous anticoagulants (fondaparinux, enoxaparin or UFH), using the envelope method. Serum levels of E-1,vWF:Ag, sICAM-1 and sVCAM-1 were measured before and after treatment with anticoagulants.

Results: Under standard treatment, including anticoagulants, all patients in three groups had decreased levels of serum endothelial dysfunction markers. Thus, in the heparin group vWF:Ag decreased from $1,70 \pm 0,07$ to $1,10 \pm 0,02$ IU/ml ($=0,001$), ET-1 – from $2,6 \pm 1,8$ to $1,9 \pm 0,7$ fmol/ml ($=0,02$), sVCAM-1 – from 1950 ± 193 to 1743 ± 174 ng/ml ($=0,02$) and sICAM-1 – from 441 ± 75 to 407 ± 57 ng/ml ($=0,03$). In the enoxaparin group vWF:Ag went down from $1,80 \pm 0,08$ to $1,00 \pm 0,02$ IU/ml ($=0,001$), ET-1 – from $3,05 \pm 2,00$ to $1,60 \pm 0,80$ fmol/ml ($=0,003$), sVCAM-1 – from 1997 ± 179 to 1604 ± 168 ng/ml ($=0,003$) and sICAM-1 – from 404 ± 85 to 358 ± 68 ng/ml ($=0,003$). In the fondaparinux group vWF:Ag decreased from $1,90 \pm 0,06$ to $1,00 \pm 0,04$ IU/ml, ($=0,001$), ET-1 – from $3,4 \pm 2,1$ to $1,5 \pm 0,6$ fmol/ml ($=0,001$), sVCAM-1 – from 2024 ± 186 to 1587 ± 170 ng/ml ($=0,001$) and sICAM-1 – from 492 ± 92 to 324 ± 64 ng/ml ($=0,015$). Being compatible in vWF:Ag delta rates, the groups were significantly different in delta ET-1 ($-0,7 \pm 1,0$ vs $-1,4 \pm 1,1$ and $-1,9 \pm 1,4$ fmol/ml, respectively; $=0,002$), sVCAM-1 (-191 ± 27 vs -235 ± 12 and -506 ± 15 ng/ml, respectively; $=0,01$) and sICAM-1 (-34 ± 23 vs -46 ± 26 and -168 ± 27 ng/ml, $=0,008$). The most noticeable delta rates were seen in patients, treated with either fondaparinux or enoxaparin.

Conclusion: Standard ADCHF treatment, including anticoagulants (unfractionated heparin, enoxaparin and fondaparinux) improved endothelial dysfunction, by significantly decreasing ET-1, sVCAM-1 sICAM-1, especially in patients under enoxaparin or fondaparinux.

P445

Mortality in patients exposed to Digoxin: a meta-analysis

G Savarese¹; C Vitale²; C D'Amore¹; F Musella¹; P Perrone-Filardi¹; GMC Rosano³

¹ Department of Advanced Biomedical Sciences; Federico II University, Naples, Italy, Naples, Italy; ² San Raffaele Pisana Hospital IRCCS, Rome, Italy; ³ St George's University of London, Cardiovascular and Cell Sciences Research Institute, London, United Kingdom

Background: Digoxin is authorized in European Union for the reduction of ventricular rate in patients with atrial fibrillation (AF) and for the management of chronic heart failure (HF). However, the data from randomized clinical trials about the use of digoxin in AF patients with and without HF are limited and a long-term assessment of mortality in patients taking digoxin is missing.

Purpose: To perform a meta-analysis of clinical trials and non-interventional studies to assess the digoxin-related mortality in patients with AF, with or without HF. Methods. A comprehensive MEDLINE search of literature was performed using the following search terms ((atrial fibrillation AND digoxin)) AND (mortality OR death). The following selection criteria were applied: 1) types of studies: randomized controlled trials, open-label studies, observational studies; 2) target population: patients with AF in adults; 3) treatment: digoxin; 4) outcome: all-cause mortality or death. Meta-analysis was performed to assess the influence of treatment on pre-specified end points.

Results: 14 studies including 157,392 patients, 70,799 treated by digoxin and 86,593 not using the drug, were selected. Median follow-up of the analysis was 34 months, the median age of the population enrolled was 72 years and 38% were women. Digoxin use, as compared with no-digoxin use, was associated with a 37% increased risk of mortality (RR:1.369; 95% CI: 1.247 to 1.503; $p < 0.001$)

Conclusions: The results of the current meta-analysis suggest an increased mortality in AF patients with and without HF using digoxin.

P446

Efficacy of long-term ivabradine therapy on prognosis, right heart and left atrial parameters in patients with severe systolic chronic heart failure

LR Liana Tumasyan¹; KG Adamyan¹¹ Institute of Cardiology, Yerevan, Armenia

The aim of study was to assess efficacy of long-term ivabradine (I, up to 15 mg) therapy on prognosis, right ventricular (RV), right (RA) and left atrial (LA) functional parameters, BNP, NT-pro-BNP and high sensitivity CRP levels in pts with III-IV NYHA FC systolic CHF. Methods. 106 pts (age 57.4 ± 0.4) were randomly assigned to group A (n=53, non-receiving I) and group B (n=53, receiving I), in addition to ACE inhibitors, beta-blockers, digoxin and diuretics. RV ejection fraction (EF), fractional area change (FAC), tricuspid annulus plane systolic excursion (TAPSE), RA and LA functional index (FI), fractional contribution (FC), relation of pulmonary vein (PV) systolic and diastolic fraction (S/D), systolic contribution (SC), difference between duration of reversal atrial flow (Ar) and late (A) transtmitral filling, pulmonary artery ejection (PAET) times, BNP, NT-pro-BNP and CRP levels were assessed at baseline, 3, 6, 12, 24 and 36 months.

Results: 1-year mortality, hospitalization rate and mortality and hospitalization (%) were, respectively, 34, 54.7 and 88.7 and 20.8, 32.1 and 52.8 in groups A and B. 2- and 3-year mortality were 39.6 and 50.9 and 28.3 and 39.6 in groups A and B. Event-free analysis showed lower probability (RR reduction, %) of 1-, 2- and 3-year mortality at 38.8, 28.5 and 22.2, hospitalization at 41.3 and mortality and morbidity at 40.5, respectively, in group B compared to A. 1-year treatment with I increased (% from baseline) RA EF at 38.1, FAC at 33.3, TAPSE at 59.6, RA and LA FI at 120 and 113.6, FC at 50.8 and 36.3, PA ET at 11.7, PV S/D at 53.5, SC at 63.7, decreased HR at 21.6, Ar-A at 34.2, BNP at 44, NT-pro-BNP at 40.6 and CRP at 38.1 ($p < 0.01$). Reduction from baseline of BNP, NT-pro-BNP $\geq 50\%$, CRP $\geq 40\%$ and HR $\geq 30\%$ was associated with significant improvement of prognosis compared to decrease of BNP, NT-pro-BNP $< 30\%$, CRP and HR $< 20\%$ (RR 0.35, 0.36, 0.32 and 0.33, $p < 0.01$). Similarly, decrease of Ar-A and increase of RV EF and FAC, RA and LA FC at $\geq 40\%$, FI $\geq 80\%$, PV SC at $\geq 50\%$ was associated with significant improvement of prognosis compared to changes of Ar-A, RV EF and FAC and RA and LA FC $< 20\%$, FI $< 60\%$ and PV SC $< 30\%$ (RR 0.36, 0.35, 0.34, 0.37, 0.39, 0.38, 0.35 and 0.34, $p < 0.01$), respectively.

Conclusions: 1) Decrease of BNP, NT-pro-BNP $\geq 50\%$, CRP and Ar-A $\geq 40\%$, HR $\geq 30\%$ and increase of RA and LA FI $\geq 80\%$, FC, RV EF and FAC $\geq 40\%$, PVSC $\geq 50\%$ identified pts with cardiac events reduction. 2) I use associated with lower mortality and morbidity due to significant improvement of right heart and LA functional parameters, neurohormonal and inflammation status and HR reduction.

Metolazone therapy in elderly heart failure patients - prognostic implications

H Hunain Shiwani¹; MM Anwar¹; N Ansari¹; DS Bulugahapitiya¹¹ Bradford Teaching Hospitals NHS Trust, Department of Cardiology, Bradford, United Kingdom

Background: Metolazone (MTZ), a thiazide-like diuretic is used together with loop diuretics in the management of refractory congestive heart failure.

Aim: The aim of this study was to identify the demographics of the patients over the age of 75 prescribed MTZ and to identify the 30 day and 1 year event rates in this

group.

Method: A retrospective analysis of data was taken of patients prescribed MTZ at Bradford Foundation Teaching Hospitals. The time period of prescription was from 1/1/14 to 31/12/14 and the 30 day and 1 year event rates in this group was studied.

Results: In the 12 month period, 50 patients were prescribed MTZ of which 37 (74%) patients were over the age of 75.

The mean age of patients receiving MTZ (over 75) was 86.2 years (standard deviation - 5.3) ranging from 76-95. The mean age of patients receiving MTZ (under 75) was 59.3 years (standard deviation - 13.4) ranging from 32-73.

In the elderly cohort, 15 (40.5%) patients had Atrial Fibrillation, 15 (40.5%) had Chronic Kidney Disease, 15 (40.5%) had Diabetes, 13 (35.1%) had Hypertension, 16 (43.2%) had known ischaemic heart disease, 3 (8.1%) had an ICD/Bi-vent in-situ and 2 (5.4%) had a previous/current malignancy. 28 patients (75.7%) were Caucasian, 7 (18.9%) were South-Asian and 2 (5.4%) were Afro-Caribbean.

In the elderly cohort, 16 patients (43.2%) had one or more readmission(s) within 12 months of which 8 patients (21.6%) were readmitted due to heart failure. 3 patients (8.1%) were readmitted within 30 days.

In the over 75 group, 9 patients (24.3%) died within their first 30 days from admission compared to no patient deaths in the under-75 group (Z-score is 1.96, $p < 0.05$).

In the over 75 group, 23 patients (54%) who took MTZ died within 1 year compared to 5 (38.5%) patients in the under-75 group (Z-score is 1.47, $p = 0.14$).

In the over 75 group, the average time to death was 121 days from the first dose of MTZ to the day of death.

Conclusion: 1. MTZ treatment is predominantly used in the elderly population in our local practice.

2. Patients over 75 prescribed MTZ have, in particular, a statistically significant higher 30 day mortality rate compared to the under 75 MTZ treated group.

3. MTZ prescription is associated with a high readmission and mortality rate at 1 year in the elderly.

4. Further study is advocated to investigate the safe prescribing of MTZ in the elderly population.

P448

The impact of gender, age, and education on depression among arab cardiovascular patients: findings from a middle-eastern study

TT Tam Truong Donnelly¹; JM Al Suwaidi²; A Al-Qahtani²; N Asaad²; T Fung¹; R Singh²; N Abdul Qader³; I Mueed⁴; S Sharara⁴; S Omar⁴

¹University of Calgary, Calgary, Canada; ²Hamad Medical Corporation Heart Hospital, Doha, Qatar; ³Hamad General Hospital, Doha, Qatar; ⁴University of Calgary-Qatar, Doha, Qatar

Introduction: Depression is associated with cardiovascular diseases. Early detection and intervention for depression among cardiovascular (CV) patients can reduce morbidity and mortality rates. Understanding how gender, age and educational level contributed as risk factors is necessary to adequately address the complex nature of depression as co-morbidity among Arab CV patients in the Middle East region.

Objectives: To evaluate the prevalence and severity of depression among Arab CV patients and to find ways to manage depression among male and female Arab CV patients.

Methods: A cross-sectional survey was conducted with 688 (69%) male and 312 (31%) females Arab CV patients admitted to 4 cardiology units at a hospital in the Middle East region. Inclusion criteria were ≥ 20 years of age, agreeing to participate in the study (98% response rate), and having final confirmation of acute cardiac conditions. Face-to-face interviews were conducted using structured survey questionnaires which included an Arabic demographic questionnaire and the Arabic version of the Beck Depression Inventory 2nd Edition (BDI-II). Descriptive and inferential statistics were performed using SPSS version 20.

Results: 80% of the patients had no depressive symptoms, 15% of the patients had Mild Mood Disturbance and 5% had symptoms of clinical depression. Almost twice as many females (29%) than males (16%) were found to suffer from Mild Mood Disturbance and Clinical Depression. Approximately half of both male and female patients who scored ≥ 17 on the BDI-II (suggesting symptoms of clinical depression) refused psychiatric assistance. Chi Square tests indicated that gender and age were significantly related to depression (all $p < 0.001$). Educational level was not statistically significantly related to depression, however, its relationship clearly reflected an U-shaped relation (i.e. no linear pattern, but quadratic).

Conclusion: (1) Health care providers should be aware and integrate gender, and age differences approach into their clinical practice; (2) routine systematic screening for depression and mental health counseling available for all CV patients, especially for patients of working age groups and females; and (3) Public awareness and education about mental health are critical in order to reduce the stigma associated with accessing treatment for it.

P449

Prevalence and in-hospital mortality of heart failure patients in the emergency department

J Johann Frick¹; AS Slagman¹; JS Searle¹; MM Moeckel¹

¹Charité - Universitätsmedizin Berlin, Division of Emergency Medicine (CVK, CCM), Department of Cardiology (CVK), Berlin, Germany

Background: Heart failure is the most common cause for hospitalisation in Germany. It is associated with a reduced quality of life and a poor prognosis. The prevalence will increase due to demographic changes, the epidemiological transition with more chronic conditions instead of infectious diseases and improved medical care. However, analyses of routine data of patients treated in the Emergency Department (ED) with heart failure are sparse. Aim: Our aim is the analysis of prevalence and mortality of hospitalised patients with heart failure in comparison to all inpatients in the ED. Methods: Administrative data of 34,333 patients (thereof 13,536 inpatients) were available for two ED's at our university for the period between 15.02.2009 until 15.02.2010. Inpatients were included if they had a main hospital diagnosis of I11; I13 or I50 according to the International Classification of Disease, version 10 (ICD-10). Patients with a hypertensive heart disease without (congestive) heart failure (I11.90 and I11.91) were excluded. The statistical evaluation was performed with SPSS 22.

Results: In total, heart failure was diagnosed in 388 of 13,536 hospitalised patients (median age: 71 years; male: 59%), who were treated in the ED (thereof 40% with NYHA IV). The prevalence of heart failure increased with age (< 30 years 0.3%; > 80 years 4.2%). From the age of 60 years patients with heart failure are older than all hospitalised patients (83.5% vs. 65.8%). Patients with heart failure had a longer hospital stay (median: 7 days vs. 5 days) and a higher proportion of patients was treated in intensive medical care units (30.2% vs. 18.25%). Dyspnoea was the leading chief complaint of patients with heart failure at the initial contact in the ED (63.9%). 8% of all admitted patients with heart failure in the ED died in comparison to 4.7% of all hospitalised ED patients during hospital stay. Most of them were older than 80 years (38.7% vs. 30%).

Conclusion: In comparison to all hospitalised patients in the ED, patients with heart failure are characterised by a higher age, a need for more intensive medical care, an increased length of stay and higher mortality. They are a vulnerable group, who require a complex diagnostic work up and treatment. More than likely this group will increase continually. Due to this background, an early risk stratification by appropriate routinely available parameters seems to be most valuable and should be the aim of future studies in the setting of emergency and acute medicine.

P450

Short- and long-term mortality and heart failure hospital re-admissions among patients hospitalised for heart failure: a regional population-based investigation from Italy

A Andrea Di Lenarda¹; G Barbati¹; M Russo²; D Radini¹; F Humar¹; F Ieva³; F Gasperoni⁴; S Gioia¹; A Scagnetto⁵; G Sinagra²

¹A.S.S. n. 1, Cardiovascular Center, Trieste, Italy; ²University Hospital "Riuniti", Department of Cardiology, Trieste, Italy; ³University of Milan, Department of Mathematics, Milan, Italy; ⁴Milan Polytechnic, MOX - Modeling and Scientific Computing, Mathematical Department, Milan, Italy; ⁵University of Trieste, Department of Medical Sciences, Trieste, Italy

Background: In population-based studies on patients admitted for HF, 1-y mortality ranged from 22% and 40%, while all-cause readmissions was higher than 50%.

Purpose: Aim of the present study was to identify short-term (30d) and long-term (1y) prognostic factors for HF re-hospitalization or death in a unselected population in the northern-east Italy, with structured pathways for outpatient HF care post discharge.

Methods: Data were retrieved from the Cardiovascular Observatory of Trieste area. Different databases were linked: hospital records with discharge diagnosis, cardiological chart, laboratory tests, outpatient drug prescriptions. Individuals hospitalised for HF at least once during the period 2009-2014 were identified. HF diagnosis included ICD-9th codes for heart failure (428.x) and hypertensive heart failure (402.01, 402.11 and 402.91) according to National Outcome Evaluation Program (PNE) made by the National Agency of Regional Health-Care Services. "Worsening" HF (WHF) was classified on the base of at least one HF hospitalization in the 5 years preceding the index admission. Cumulative incidence probabilities of re-hospitalization were computed taking into account death as a competing risk; cause-specific regression was applied to find factors associated with death or re-hospitalization.

Results: 4935 HF admissions were recorded, and 4666 were discharged alive (94%). Median age was 82 yrs (IQR: 75-87), 46% males. 40% had a Charlson Index ≥ 3 (CH) and 16% were 'WHF'. Most severe cases (709, 15%) received a phone call from nurse-led HF clinic to verify clinical stability and therapy adherence within 7d and ambulatory or home cardiological evaluation within 30d post discharge. Cumulative incidence of 30d re-HF hospitalization was 4%, rising at 22% at 1y; death was respectively 3% at 30d and 24% at 1y. Predictors of re-HF hospitalization were at 30d lower values of CKD EPI (< 50 ml/min, median), reduced LVEF ($< 50\%$) and

beta-blockers therapy. At 1y advanced age, reduced LVEF, CH \geq 3, 'WHF', prescribed CV therapy (aldosterone antagonists, ACE-I/sartans and diuretics) and a cardiological visit within 30d were all associated with an higher risk. Regarding death, early events were associated with advanced age, CH \geq 3, longer length of stay; CV therapy was instead protective. At 1 y these parameters were confirmed and were also significant male sex, reduced LVEF, higher BNP values, being hospitalized in a non-cardiology department and admission to home care services/intermediate care units within 30d after the index hospitalization.

Conclusions: Short- and long-term mortality and re-admissions for HF with structured pathways for outpatient care post hospital discharge is relatively low as compared with previous experience. Characterization of HF patients is very important in assisting clinicians in decision-making, targeting treatment and implementing clinical pathways for outpatients care in high-risk cases.

P451

The profile of Romanian hypertensive patients with heart failure

D T Dumitru Tudor Zdrenghea¹; A Sitar-Taut¹; B Caloian¹; D Pop¹

¹University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background: Heart failure is more and more a public health problem in Romania, with frequent hospitalization, high cost, low quality of life and decreased survival. Also the prevalence of hypertension in the general population is increasing.

Purpose: To analyze the clinical profile of hypertensive heart failure patients in a Romanian Hospital. **Methods:** There were enrolled a total of 187 patients admitted in the Cardiology Department of Rehabilitation Hospital, Cluj-Napoca, Romania, previously diagnosed with heart failure. The mean age was 70.70 \pm 8.99 years, 54% of the patients were women. Heart failure was defined according to 2012 ESC criteria. All patients were evaluated for cardiovascular risk factors, NT-pro-BNP levels and by echocardiography.

Results: The average NT-pro-BNP was 2032.71 \pm 2281.19 pg/ml, men presenting a tendency to higher levels compared to women: 2350.93 \pm 2609.61 vs. 1759.04 \pm 1927.1 pg/ml, $p=0.08$. 71.7% ($n=134$) of the patients enrolled in this study had arterial hypertension, with a significantly higher prevalence in female gender (78.2% vs. 64%, $p=0.023$). Both male and female hypertensive patients were older (71.85 \pm 7.92 vs. 67.83 \pm 10.78 years, $p=0.006$). There was no significantly difference between heart failure patients with or without arterial hypertension regarding the presence of diabetes mellitus (17.9 vs. 24.5%, $p=NS$), obesity (8.5 vs. 7.5%, $p=NS$) or dyslipidemia (38.8 vs. 34%, $p=NS$). Hypertensive patients had a higher prevalence of heart failure with preserved ejection fraction than normotensive subjects: 73.9 vs. 47.2%, $p=0.001$. Hypertensive patients had a lower NT-pro-BNP mean value than patients without hypertension (1715.18 \pm 1924.27 vs. 2829.53 \pm 2865.16 pg/ml, $p=0.002$) irrespective of the gender: females -1565.04 \pm 1679.92 vs. 2446.86 \pm 2554.26 pg/ml, $p=0.058$; males -1928.11 \pm 2224.51 vs. 3101.10 \pm 3078.74 pg/ml, $p=0.04$. A significant negative correlation between NT-pro-BNP and ejection fraction, not influenced by blood pressure values was observed in both genders: patients with vs without arterial hypertension $r=-0.4$, $p<0.0001$ vs. $r=-0.442$, $p=0.0011$; female patients with vs. without arterial hypertension $r=-0.29$, $p=0.010$ vs. $r=-0.42$, $p=0.05$; male patients with vs. without arterial hypertension $r=-0.52$, $p=0.0001$ vs. $r=-0.44$, $p=0.01$. When the medication administered to heart failure patients with and without arterial hypertension was analyzed, the only significant differences noticed were involving digitalis (21.6 vs. 39.6%, $p=0.01$) and ARBs (46.3 vs. 24.5%, $p=0.005$). There were no statistically significant differences regarding administration of diuretics (86.6 vs. 88.7%, $p=NS$), ACEIs (56 vs. 43.4%, $p=0.08$), beta-blockers (75.4 vs. 64.2%, $p=0.08$) and nitrates (47.8 vs. 39.6%, $p=NS$).

Conclusion: Hypertensive patients with heart failure have a different profile compared to those without arterial hypertension. This implies a special approach in the evaluation and therapy recommended for this high risk population.

P452

Risk score for incident heart failure: a subject-level meta-analysis from the heart omics in ageing database

L Jacobs¹; LE Efremov¹; R Latini²; S Masson²; P Sever³; C Delles⁴; J Butler⁵; T Kuznetsova¹; JA Staessen¹; F Zannad⁶

¹University of Leuven, Department of Cardiovascular Sciences, Leuven, Belgium;

²The Mario Negri Institute for Pharmacological Research, Milan, Italy; ³Imperial College London, London, United Kingdom; ⁴University of Glasgow, Glasgow, United Kingdom; ⁵SUNY Health Science Center, New York, United States of America; ⁶Clinical Investigation Centre Pierre Drouin (CIC-P), Nancy, France

Heart failure (HF) is a syndrome that leads to a diminished quality of life and costly hospital admissions, affecting especially the elderly. The Heart 'Omics' in Ageing (HOMAGE) database was used as a resource to conduct a subject-level meta-analysis to identify risk factors associated with new-onset HF and to develop a risk score for HF. Two population-based studies and two studies including patients at risk for cardiovascular disease were included. Time-to-event analysis was conducted by using Cox proportional hazard models stratified by study. A point-based

risk score for assessment of 5-year HF risk in each cohort was derived from the Cox regression model which was evaluated for discrimination (area under the receiver operating characteristic curve [AUC]) and calibration (Grønnesby-Borgan χ^2 statistic). In the population cohort, during a follow-up of 6.2 years, 589 participants out of 4438 subjects (mean age 73.4 \pm 3.8 years, 51% women) developed HF. In the patient cohort 25059 patients at risk for cardiovascular disease were included (mean age 65.9 \pm 9.2 years, 30% women) of which 526 developed HF. Sex (male), higher age, higher body mass index, higher systolic and lower diastolic blood pressure (only in the population cohort), higher heart rate, lower estimated glomerular filtration rate (eGFR), smoking, history of CV disease and use of antihypertensive medication were detected as significant predictors of incident HF. The 5-year HF risk associated with each point total, derived from the Cox model risk estimates of the population cohort, ranged from less than 1% risk for a point total of ≤ 0 , to more than 30% risk for point totals above 13. In the patient cohort, a point total of 1 or less corresponds to a 5-year HF risk of $<1\%$, while the risk amounts to 30% or more for a point total of ≥ 15 . To estimate HF risk in a general and patient population, two risk score models were developed from clinically relevant parameters to aid in risk stratification and contribute to future prevention.

P453

Did the incidence of chronic heart failure among patients attending cardiovascular rehabilitation program change in last 7 years

S Slavica Stevovic¹; T Vidakovic¹; M Moraca¹; I Burazor¹

¹Institute for Rehabilitation, Belgrade, Serbia

Introduction: Many trials have shown that $>70\%$ of patients with heart failure had an ischaemic heart disease. Medical therapy with or without myocardial revascularisation (coronary angioplasty or bypass surgery) apparently does not provide maximum benefit for these group of patients.

Purpose: To review experience of our institution in incidence of chronic heart failure /CHF/ among patients who were referred to in hospital cardiovascular /CV/ rehabilitation program after cardiac /bypass/ surgery or after myocardial infarction.

Methods and Results: We analyzed our clinical database from 2007-2015 and compared data. In the period of 2007-2015 we admitted 4373 patients after myocardial infarction and 3421 patients after bypass surgery for in hospital cardiac rehabilitation. The age structure over time has not changed. Mostly patients were in two age groups: from 55-64 year (31.15%) and from 65-74 year (33.18%). There were 6149 /78, 9%/ men and 1645 /21,1%/ women. Rehabilitation program lasted for 21 days and includes a physical examination of patients (blood pressure measurement, control of heart rate, recording an electrocardiogram), blood was sampled for analysis, risk factors were noted, education (about risk factors and dietary measures) and aerobic training with telemetric monitoring. We analyzed the data every 4 years /at 2007, at 2011 and at 2015/. During 2007, in our institute, we rehabilitated 1446 (92.57%) patients after myocardial infarction /MI/ and 116 (7.42%) patients after aortocoronary bypass surgery /ACB/. At 2011, there were 570 (57.1%) patients after MI and 546 (48.9%) after ACB. At 2015 rehabilitation after MI included 488 (52.75%) patients and 437 (47.25%) patients after ACB. Heart failure is defined as a reduction in global ejection fraction less than 40% /EF $<40\%$ /. At 2007 most patients attending CV rehabilitation were patients after myocardial infarction. Over the years, the number of patients after myocardial infarction and after cardiac bypass surgery is almost equalized with approximately the same representation of heart failure. There were 26.5% of patients with chronic heart failure on cardiovascular rehabilitation in 2007, 25.9% patients with CHF in 2011 and 27.83% patients with CHF in 2015. There were no significant differences in incidence in CHF among groups ($t=0.760$; $p>0.05$).

Conclusion: new developments in diagnostics and treatment of patients with ischemic heart disease, despite efforts, did not have significant effect on reducing the incidence of chronic heart failure in patients with ischemic heart disease who attended the cardiovascular rehabilitation program in our institute.

P454

"Recovered" left ventricular ejection fraction: a different class of heart failure based on clinical characteristics?

C Diez-Lopez¹; J Lupon¹; M De Antonio¹; M Domingo¹; E Zamora¹;

J Santestanes¹; MI Troya¹; C Diez-Quevedo¹; S Altimir¹; A Bayes-Genis¹

¹Germans Trias i Pujol University Hospital, Badalona, Spain

Background: Advances in pharmacological therapy, devices and surgery are responsible for a non-negligible number of patients with heart failure (HF) and reduced left ventricular ejection fraction (LVEF) whose systolic function improve significantly, even sometimes to normal or almost-normal values. The existence of a third class of HF beyond reduced- and preserved- LVEF HF has already been proposed.

Objective: To analyse the proportion, clinical characteristics and magnitude of improvement of patients with LVEF below 45% at baseline that increase it to a LVEF $\geq 45\%$, after one year of follow-up at a multidisciplinary HF Unit.

Patients and Method: LVEF at first visit and at one-year follow-up were assessed by echocardiography in 1063 patients (72.7% men; mean age 65.6 \pm 11.9 years,

range 30-96 years). Aetiology of HF was mainly ischemic heart disease (52.2%), followed by dilated cardiomyopathy (14%), valvular disease (8.7%) and hypertensive cardiomyopathy (8.6%). Mean LVEF was $32.8\% \pm 12.6$. Most patients were in NYHA functional class II (68.3%) and III (25%). Patients were classified into three groups: 1) LVEF <45% at baseline and $\geq 45\%$ at one year ("recovered HF", $n=237$); 2) LVEF $\geq 45\%$ at baseline ("preserved HF" [HFpEF], $n=145$); and 3) LVEF <45% both, at first and at one-year visits ("reduced HF" [HFrEF], $n=681$).

Results: As expected, HFpEF patients were older (68.3 ± 13.5 years vs. 65.2 ± 11.6 , $p=0.003$), predominantly female (57.9% vs. 21.8%, $p<0.001$) and of non-ischemic aetiology (76.5% vs. 43.2%), had more atrial fibrillation (43.4% vs. 16.7%, $p<0.001$), and were in worse NYHA functional class (37.2% III/IV vs 24%, $p=0.001$), as compared with all patients with LVEF <45% at baseline. Recovered HF patients (as compared with HFrEF) were younger (63.4 ± 12.4 years vs. 65.8 ± 11.3 , $p=0.007$), with more proportion of female sex (30.4% vs. 16%, $p=0.001$), predominantly of non-ischemic aetiology (64.6% vs. 35.8%, $p<0.001$), non-diabetic (66.7% vs. 59%, $p=0.04$), had more atrial fibrillation (21.1% vs. 15.1%, $p=0.03$), had less LBBB (7.6% vs. 16%, $p=0.001$), had shorter HF duration (median 3 months [IQR 1-18] vs. 12 months [IQR 2-56], $p<0.001$), and were in better NYHA functional class (19% III/IV vs. 26%, $p=0.04$). Mean LVEF increase in patients with recovered HF was 20.6 ± 10.3 points vs. 3.4 ± 10.3 in HFrEF, $p<0.001$. Recovered HF patients also significantly differed from patients with HFpEF in age ($p<0.001$), sex ($p<0.001$), ischemic aetiology ($p=0.01$), prevalence of atrial fibrillation ($p<0.001$), duration of HF ($p<0.001$), and NYHA functional class ($p=0.001$).

Conclusion: Almost one quarter of ambulatory patients with HF showed LVEF "recovery" at one year of follow-up. Clinical characteristics of recovered HF patients significantly differed from HFrEF and HFpEF.

P455

Trends in epidemiology, clinical presentation and management of acute heart failure: insights from romanian cohorts of ESC-HF Pilot survey and ESC-HF-LT registry

O Ovidiu Chioncel¹; D Vinereanu²; R Christodorescu³; C Macarie¹; G Tatu-Chitioiu⁴

¹Institute of Cardiovascular Diseases "Prof. Dr. CC Iliescu", Bucharest, Romania;

²University Emergency Hospital of Bucharest, Bucharest, Romania; ³University of Medicine Victor Babes, Timisoara, Romania; ⁴Emergency Hospital Bucharest, Bucharest, Romania

Aim: Temporal trends of epidemiological data on acute heart failure (AHF) are limited. We sought to assess changes in epidemiology, clinical presentation and management of AHF in Romania using data from two European registries conducted 3 years apart.

Methods: The European Society of Cardiology-Heart Failure Pilot study (ESC-HF pilot) and the European Society of Cardiology Long-Term Registry (ESC-HF-LT registry) were conducted during 2009-2010 and 2011-2013, respectively. Both registries were prospective, multicentric, observational surveys with 1-year follow-up and were largely representative for cardiologic European community.

Results: Romanian sites have recruited a total number of 687 AHF patients in the two registries (358 in ESC-HF pilot and 329 in ESC-HF-LT registry). Median age of recruited patients increased from 69 (60-75) years in ESC-HF pilot to 71 (61-78) years in ESC-HF-LT registry, and proportion of patients with HF and EF > 45% increased over time from 31% to 35%, trends similar to those reported by other European countries. 70% of AHF patients in both registries presented with chronic worsening HF and 30% with de novo HF. The use of life-prolonging, guideline-recommended medical therapies (GRMTs) increased over time (pre-admission use of ACE inhibitors/ARBs from 42% to 54%, beta-blockers from 34% to 45%, aldosterone antagonists from 25% to 34%). GRMTs increased substantially during hospitalization in both registries, and minimal variations were noticed during 1-year follow-up. The main intravenous therapies in both registries were diuretics (92% and 85%), followed by vasodilators (21.9% and 17.4%) and inotropes (7.6% and 17.2%), proportions similar to other European countries. While in-hospital mortality increased from 4.3% in ESC-HF pilot to 4.9% in ESC-HF-LT registry, 1-year all cause mortality remained similar, 24.3% vs 24.4%. 1-year HF related hospitalizations dropped from 18.8% in ESC-HF pilot to 15.2% in HF-LT registry. Furthermore, the composite outcome, 1-year all cause mortality and/or HF hospitalizations declined over time, from 39.1% to 35.8%.

Conclusions: Clinical profiles, in-hospital management and outcome of AHF patients in Romania were similar to other European countries, despite regional differences in healthcare systems. A temporal increase in the utilization of life-prolonging GRMTs therapies along with an improvement of 1-year outcome was observed.

Background: In clinical practice lung ultrasound (LUS) is becoming an easy and reliable non-invasive tool for the evaluation of dyspnea. The aim of this study was to assess the accuracy of nurse-performed LUS, in particular, in the diagnosis of acute cardiogenic pulmonary congestion.

Material and Methods: We prospectively evaluated all the consecutive patients admitted for dyspnea in our Medicine Department between April and December 2015. At admission, serum BNP levels and LUS was performed by trained nurses blinded to clinical and laboratory data. The accuracy of nurse-performed LUS alone and combined with BNP for the diagnosis of acute cardiogenic dyspnea was calculated.

Results: 508 patients (41.6% men, mean age 78.7 ± 12.7 years) were included in the study. Nurse-performed LUS alone had a sensitivity of 95.3% (95%CI 92.6-98.1%), a specificity of 88.2% (95%CI 84.0-92.4%), a positive predictive value of 87.9% (95%CI 83.7-92.2%) and a negative predictive value of 95.5% (95%CI 92.7-98.2%). The combination of nurse-performed LUS with BNP level (cut-off 400 pg/mL) resulted in a higher sensitivity (98.9%, 95%CI 97.4-100%), negative predictive value (98.8%, 95%CI 97.2-100%) and corresponding negative likelihood ratio (0.01, 95%CI 0.0, 0.07).

Conclusion: Nurse-performed LUS had a good accuracy in the diagnosis of acute cardiogenic dyspnea. Use of this technique in combination with BNP seems to be useful in ruling out cardiogenic dyspnea. Other studies are warranted to confirm our preliminary findings and to establish the role of this tool in other settings.

Very low levels of circulating B-type natriuretic peptide constitute a risk for heart failure: a prospective population based cohort study

Y Matsuura¹; R Komi¹; F Tanaka¹; Y Yonekura¹; T Onoda¹; K Sakata¹; T Sakai²; M Motoyuki Nakamura¹

¹Iwate Medical University, Morioka, Japan; ²Iwate Prefecture Ninohe Hospital, Ninohe, Japan

Background: The endogenous natriuretic peptide (NP) system plays an important role in enhancing renal sodium excretion and lowering cardiac afterload through its natriuretic and vasodilatory properties. Recent studies have suggested that chronic augmentation of the protective NP system in early stages of heart failure (HF) may ultimately prevent the progression of HF. However, no studies have demonstrated the risk of attenuation of the NP system for development of HF.

Methods: Subjects of this study were recruited from our general population. Baseline data including plasma B-type natriuretic peptide (BNP) levels were determined in 13,637 participants (mean age=64 yrs). Subjects were divided into quartiles (Qs) according to their baseline plasma BNP levels. Event free survival for HF events from entry into the study was estimated using the Kaplan-Meier method. A multivariate Cox regression analysis was performed to determine hazard ratios of plasma BNP quartiles for the onset of HF.

Results: During follow up (mean 9.0 years), 171 cases in the cohort had confirmed onset of HF (Framingham criteria). Although the follow up period was the same for all Qs, the event free rate in the second quartile (Q2) was the lowest (Q1 = 0.62%, Q2 = 0.26%, Q3 = 0.73%, Q4 = 3.41%). After adjustment for traditional cardiovascular risk factors (sex, age, body mass index, hypertension, diabetes, hypercholesterolemia, smoking, eGFR and atrial fibrillation), hazard ratios (HRs) for HF development among BNP quartiles revealed a J shaped pattern (Figure). The lowest Q1 (IQR 1.8 – 6.5 pg/ml) had a higher HR (2.43; 95% CI = 1.10 - 5.34) compared to the reference group (Q2; $p<0.05$).

Conclusion: This cohort study suggests that very low levels of circulating BNP generate risk for future onset of HF in the general population. An impaired endogenous bioactive NPs system may be involved in the etiology of HF in certain subjects at risk.

Multivariate HR among BNP quartiles

EXERCISE TESTING & TRAINING

P458

Exercise training heart failure rehabilitation program in Federal Almazov Medical Research Centre in RussiaT Tatiana Lelyavina¹; MYU Sitnikova¹; EV Shlyakhto¹; VL Galenko¹¹Almazov Federal Center of Heart Blood & Endocrinology, Saint Petersburg, Russian Federation

In 2010 cardiologists of a Medical Research Centre in Russia proposed a new method for determination of exercise intensity for heart failure rehabilitation. We have marked four physiological stages during incremental physical exercise: LACTATE THRESHOLD, pH THRESHOLD, RESPIRATORY COMPENSATION POINT and AEROBIC LIMIT. Lactate threshold was determined when blood lactate level began to increase. pH-threshold was determined when blood pH level began to decrease. Respiratory compensation point (RCP) was determined when ventilation dramatically increase relative to carbon dioxide output (VE/CO₂). By continuous increase of work rate, oxygen consumption, up to a certain point, increases linearly and become stable – it is aerobic limit. This new concept of the division of physical exercises on the physiological phases helped us to develop the more precisely individualized physical rehabilitation program. First three month HF patients trained 40-60 minutes every day on treadmill with exercise intensity observed at LT, every month after control CPET exercise intensity increased gradually. Other three month patients trained 35-50 minutes every day on treadmill with exercise intensity that observed between LT and pH-T, every month after control CPET exercise intensity increased gradually. Before and after training 5 minutes morning exercises made. Since 2012 175 HF pts with III NYHA class participate in new individualized rehabilitation program. There was a significant increase in VO₂ and MLHFQ score after 32 weeks of training. In 15 patients after 32 weeks of aerobic exercises increase VO₂ reached 85-102% of maximum predicted values, which is normal. Such dynamics of oxygen consumption indicates, probably, the increase the number of mitochondria in muscle fibers of lower extremities. The survival rate in 175 HF patients (average age 53.5 ± 0.4, average NYHA class - 3.0, average LVEF - 40.8 ± 0.3%) was 81% in 3 years of follow-up.

Conclusion: Exercise training heart failure rehabilitation program proposed in a Medical Research Centre is safe and effective, increases exercise tolerance in HF patients, improves outcomes.

P459

The benefits of cardiac rehabilitation in coronary artery disease: does the weight matter?M Marta Braga¹; A Rocha¹; H Nascimento¹; M Tavares Silva¹; R Pinto¹; G Pestana¹; J Rodrigues¹; V Araujo¹; F Parada-Pereira¹; M J Maciel¹¹Sao Joao Hospital, Porto, Portugal

Background: Cardiac rehabilitation programs (CRP) are medically supervised exercise-based protocols for patients (pts) who experience a cardiac event. It has been recognized that CRP improved coronary heart disease (CHD) risk factors (RF) and functional capacity. Obesity is a major CHD RF. On the other hand, obese pts may have some difficulties in CRP performance. The aim of this study was to compare obese and non-obese pts regarding their baseline clinical profile and response to a CRP.

Methods: We analysed data from a prospectively collected registry of 433 consecutive pts who underwent CRP after an acute coronary syndrome (ACS) from January 2009 to October 2015. Pts were divided in two groups according to their body mass index (BMI): BMI ≥ 30 kg/m² (obese) and BMI < 30 kg/m² (non-obese). Exercise performance was assessed using both duration and metabolic equivalents (METs) achieved in standard exercise test (ET) using Bruce protocol before and after CRP.

Results: Ninety-nine (22.9%) pts were obese. No differences concerning age (54.1 ± 10.1 vs 54.7 ± 9.6 years) or gender (79.8% vs. 86.7% males) were found between groups. Obese pts had a mean waist circumference 108.4 ± 6.1 cm in males and 102.1 ± 7.6 cm in females, while non-obese pts presented a mean waist circumference of 93.8 ± 5.5 in men and 81.5 ± 7.4 cm in women. Among CHD RF, hypertension and diabetes were more frequent in obese pts (64.6% vs. 40.1%, p < 0.001 and 29.6% vs. 16.3%, p = 0.003, respectively). Obese pts also showed higher levels of depression symptoms at admission (p = 0.005). The index coronary event affected 1 coronary artery in more than half of pts in both groups. Echocardiography showed a mean fractional ejection 55.5 ± 10.8% in obese pts and 51.7 ± 12.0% in other pts (p = 0.012). Baseline functional capacity was lower in obese group both in duration (7.05 ± 2.33 min vs 8.38 ± 2.23 min; p < 0.001) and intensity (7.67 ± 2.32 METs vs 8.91 ± 2.18 METs; p < 0.001). Both groups improved their functional capacity, but obese pts showed better results in duration (+36.7% vs. 28.8%, p = 0.043) and intensity (+32.4% vs. 25.9%, p = 0.079), the last without statistically significance.

Conclusion: Obesity is epidemic in western countries. It is tightly linked to CHD. Overweight should be a main focus in both primary and secondary prevention. CRP showed to improve exercise capacity in obese and can contribute to reduce morbidity and mortality in such important group of pts.

P460

Prediction of peak oxygen consumption in patients with heart failure using classification and regression treesO Oxana Dikur¹; M Poltavskaya¹; YA Ashikhmin¹; M Milkova²; I Giverts¹; A Doletskiy¹¹I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; ²Central Economics and Mathematics Institute of the Russian Academy of Sciences, Moscow, Russian Federation

The aim: to determine factors with most significant impact on peak oxygen consumption (PVO₂) in HF patients and create a model for PVO₂ prediction.

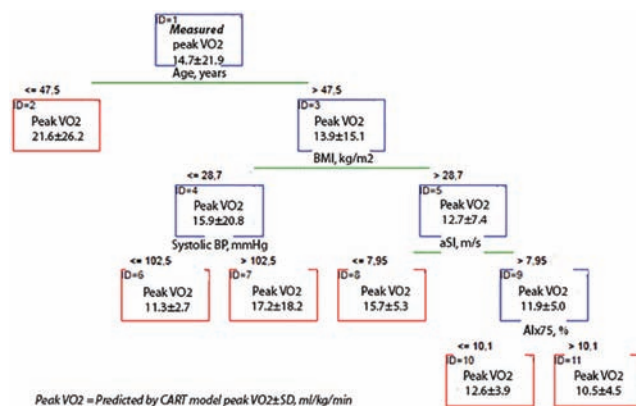

Methods: 91 patients with both reduced and preserved ejection fraction were consequently enrolled in the study (51.6% men; mean age 64.7 years; mean NYHA class 2.2 ± 0.8, mean NT-pro-BNP 563.6 pg/ml). All patients had undergone clinical and laboratory investigation; routine and tissue Doppler echocardiography, cardiopulmonary exercise testing and photoplethysmography arterial stiffness analysis assessing augmentation index, corrected for a heart rate of 75 beats/min (Alx75, %), stiffness index (SI, m/s) and reflection index (RI, %). End-systolic elastance and effective arterial elastance were calculated. Factors with highest impact on peak VO₂ were identified by multivariate discriminant analysis of 49 clinical variables. Then Classification and regression trees (CART) allowing to predict PVO₂ were constructed using STATISTICA 11 software.

Results: relative ranks of different clinical characteristics with strongest influence on PVO₂ were determined by CART (see table). Of note, arterial stiffness characteristics affect PVO₂ more significantly than many "classical" factors. Simplified CART model for PVO₂ prediction is presented on the picture. Model validation in different limited HF patient population shown its affordable accuracy.

Conclusions: we construct CART model for PVO₂ prediction in exercise intolerant that include both classical factors and arterial stiffness characteristics.

Relative factors ranks estimated by CART

Clinical characteristics	Rank of influence on PVO ₂
Age, years	100
Body mass index, kg/m ²	92

Aquatic exercise training is effective in maintaining exercise performance in trained heart failure patients

Heart Foundation of Australia

J Julie Adsett¹; N Morris²; S Kuys³; R Hwang⁴; RM Mullins⁵; M Khatun⁶; JD Paratz¹; AM Mudge¹¹Royal Brisbane and Women's Hospital, Heart Failure Service, Brisbane, Australia;²Griffith University, School of Physiotherapy and Exercise Science, Brisbane,Australia; ³Australian Catholic University, Brisbane, Australia; ⁴Princess AlexandraHospital, Brisbane, Australia; ⁵Queensland University of Technology, Brisbane,Australia; ⁶University Of Queensland, Brisbane, Australia

Background: Exercise training is a standard component of care in the management of all individuals with stable heart failure (HF). Providing flexible models and a variety of exercise options are fundamental to supporting long term exercise participation and maintaining health benefits. In recent years, aquatic exercise has been advocated as a possible alternative to traditional land-based training.

Purpose: The aim of this study was to determine the efficacy of aquatic exercise training to maintain functional performance following heart failure rehabilitation, when compared to land-based training.

Methods: In this 2x2 crossover design trial, individuals who had previously completed HF rehabilitation were randomised into one of two training groups. Participants attended either a land-based or aquatic training programme once per week for six weeks, after which time they changed to the alternative exercise training protocol for an additional six weeks. Six minute walk test (6MWT), grip strength, walk speed and measures of balance were compared for the two training protocols.

Results: Fifty-one participants (43 males, mean age 69.2 yrs), contributed to the analysis. Both groups maintained their function during the follow-up period. Improvements in 6MWT were greater with land-based training compared to the aquatic training protocol ($p = 0.038$, mean difference = 10.8m). For other parameters, no significant difference was observed when the two protocols were compared.

Conclusion: Attending an aquatic exercise programme once per weeks effectively maintains functional performance in patients with stable HF. Aquatic exercise may provide a suitable alternative to traditional training programmes in selected patients.

P462

High-intensity interval training combined with strength exercise effect on aorto-ventricular coupling in patients with chronic heart failure. A randomized phase iii clinical trial.C Christina Chrysohoou¹; G Tsitsinakis¹; A Aggelis¹; E Herouvim¹; D Tsiachris¹; I Vogiatzis¹; C Pitsavos¹; N Koulouris¹; C Stefanadis¹; D Tousoulis¹¹University of Athens, Athens, Greece

It is known that heart failure causes changes in cardiac mechanics, like an unfavorable alteration of ventricular/vascular coupling, which reflects arterial stiffness and has been related with adverse cardiovascular outcomes. Aim of this work was to evaluate the effect of high-intensity interval exercise (i.e. 30 sec at 100% of maximum workload, following by 30 sec at rest, 3 days per week at a 45 minutes working-out schedule, combined with aerobic and muscle strength training, for 12 weeks) on left ventricular function and aortic elastic properties of chronic heart failure patients.

Methods: a phase III clinical trial, that enrolled 100 consecutive eligible patients (NYHA II-IV, ejection fraction <50%) randomly allocated in exercise and control group. Of then 72 patients completed the study (exercise group=33, 63+/- 9 years old, 88% men; control group: n=39, 56+/- 11 years of, 82% men). All patients underwent cardiopulmonary stress test, non-invasive high-fidelity tonometry of the radial artery, pulse pressure measurements by SphygmoCor device and echocardiography before and after the completion of the training program where diastolic indices were measured.

Results: Both groups reported similar medical characteristics and physical activity status. General mixed effects models revealed that the intervention group reduced pulse wave velocity by 9% ($p = 0.05$); Emv/Vp by 14% ($p = 0.06$); E to A ratio by 24% ($p = 0.024$); E to Emv by 8% ($p = 0.05$); quality of life score increased by 66% ($p = 0.003$); depression score decreased by 19% ($p = 0.05$); augmentation index increased by 28% ($p = 0.001$); VTI increased by 4% ($p = 0.05$); 6 minutes walking distance increased by 13% ($p = 0.05$); peak oxygen uptake increased by 28% ($p = 0.001$); and peak power increased by 25% ($p = 0.005$). There were no significant changes in the control group.

Conclusion: Interval high intensity aerobic training, combined with strength exercise seems to benefit aortic dilatation capacity, left ventricular diastolic properties and increases augmentation index which reflects improved cardiac output. Those findings represent a beneficial effect of rehabilitation programs on arterial-ventricular coupling that boosts systolic pressure waveform and improved quality of life in chronic heart failure patients.

P463

Effects of short-time physical training in heart failure patients after surgical revascularizationD Marinkovic¹; M Deljanin-Ilic²; B Ilic¹; D Petrovic¹; D Simonovic¹; S Stojanovic¹; S Ignjatovic¹¹Institute for Treatment and Rehabilitation Niska Banja, Nis, Serbia; ²University of Nis, Medical Faculty, Institute of Cardiology Niska Banja, Nis, Serbia

Aim: To evaluate the effects of short-term physical training on physical exercise tolerance and level of markers of inflammation, neuro-humoral activation and endothelial function, in CHF patients after surgical revascularization.

Methods: The study involved 43 patients (32 males); mean age 60.3 ± 5.7 years, mean EF $34.75 \pm 3.34\%$, NYHA II and III, after surgical revascularization procedures. All patients were included in three-weeks rehabilitation program in the residential center, based on strictly controlled and individually prescribed physical training. Before and after rehabilitation, all patients were underwent exercise stress test, and from the veins blood samples, biochemical markers of inflammation, atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP) an endothelin (ET) were determined.

Results: At the end of the study the hs-CRP and fibrinogen level were showed a decreasing trend (ns). After cardiovascular rehabilitation a significant reduction in white blood cells count was recorded ($p = 0.028$). Erythrocyte sedimentation rate after rehabilitation was higher, but not significant. In all pts, the concentration of ANP and BNP was higher after 3 weeks compared to baseline values ($p = 0.043$; $p = 0.015$). In contrast, the value of endothelin after rehabilitation was lower than baseline value ($p = 0.112$), but not significant. At end of this study, significantly higher serum HDL-cholesterol in CHF patients was found ($p = 0.001$). Exercise tolerance was improved, as well as quality of life assessed by Minnesota Living With Heart Failure Questionnaire.

Conclusion: CHF patients after surgical revascularization residential short-term training decreased the level of inflammatory status and ET and transitory increase ANP and BNP. Those positive effects are associated in significant increases of exercise tolerance and improve of quality of life.

P464

Monitoring of end-tidal pressure of carbon dioxide in patients with chronic heart failure and chronic obstructive pulmonary disease during walk testKA Kira Ageeva¹; VN Abrosimov¹¹Ryazan State Academician Medical University, Therapy Department, Ryazan, Russian Federation

Background: Exercise tests are used to determine exercise tolerance in patients with chronic heart failure (CHF) and in patients with chronic obstructive pulmonary disease (COPD). Breathlessness of is one of the most common reason patients who stopped during 6-minute walk test (6MWT). Dyspnea is combined with changes of pulmonary ventilation and gas exchange of CO₂. Significance of end-tidal CO₂ (PETCO₂) is a constant, which shows the activity of respiratory system.

Methods: We studied 52 patients with CHF in New York Heart Association (NYHA), age 58 ± 3.24 years (25 patients (48,1%) in NYHA class II, 22 patients (4,3%) in NYHA class III, 5 patients (9,6%) in NYHA class IV). Also we studied 42 patients with COPD II-III, age 60 ± 3.48 years (1st group - 22 patients (52,4%) with COPD II, 2nd group - 20 patients (47,6%) with COPD III). Control group 30 patients, age 48 ± 3.42 years. Standard 6MWT was performed. Dyspnea was evaluated on a scale of Borg, MRS and VAS. We recorded capnogram before, during, after the 6MWT and in the recovery period.

Results: Significance of PETCO₂ in patients with CHF in NYHA class II was $38,2 \pm 2,13$ mm Hg, in patients in NYHA class III was $34,4 \pm 2,22$ mm Hg, in patients in NYHA class IV was $32,4 \pm 1,14$ mm mm Hg. Significance of PETCO₂ in 1st group patients with COPD was $36,2 \pm 2,43$ mm Hg, in 2nd group patients was $34,1 \pm 1,22$ mm Hg. All patients performed 6MWT. The 6MWT distance in patients with CHF in NYHA class II was $384 \pm 10,56$ m, in NYHA class III was $290 \pm 17,24$ m, in NYHA class IV was $142 \pm 3,51$ m. The 6MWT distance in 1st group patients with COPD was $440 \pm 15,48$ m, in 2nd group was $384 \pm 15,42$ m. There is reduction PETCO₂ in all patients with CHF during the 6MWT. PETCO₂ in patients with CHF in NYHA class II was $33,34 \pm 2,51$ mm Hg, in NYHA class III was $31,75 \pm 2,89$ mm Hg, in NYHA class IV was $28,8 \pm 1,32$ mm Hg. 69,2% patients reported dyspnea as the main reason for a stop during the 6MWT. There is increase PETCO₂ in all patients with COPD during the 6MWT. After the 6MWT the significance of PETCO₂ in 1st group was $43,21 \pm 2,81$ mm Hg, in 2nd group was $45,05 \pm 3,26$ mm Hg. All patients reported dyspnea as the main reason for a stop during the execution 6MWT. When we analyzed the trend of PETCO₂ we found that these patients showed signs of periodic breathing than control group.

Conclusion: Thus, capnography increases the diagnostic value of the 6MWT, helps to make interpretation of dyspnea in patients with CHF and COPD.

P465

Comparing exercise modalities in heart failure: a systematic review and meta-analysis

J Justien Cornelis¹; P Beckers²; J Taeymans³; C Vrints²; D Vissers¹¹University of Antwerp, Department of Physiotherapy (REVAKI), Antwerp, Belgium;²University of Antwerp Hospital (Edegem), Department of Cardiology, Antwerp, Belgium; ³Bern University of Applied Sciences, Health, Bern, Switzerland

Background: Several exercise modalities are suggested to improve exercise capacity and therefore prognosis in patients with heart failure (HF). Moreover, quality of life (QOL) and the functional modifications of the heart seem to be changeable with training. However, it is not clear which mode of physical activity is superior.

Purpose: In order to assess effect sizes of different exercise modalities, a systematic review and meta-analysis was performed according the PRISMA statement.

Methods: Randomized clinical trials in PubMed, Cochrane Library and Web of Science were selected. Primary outcome data were cardiorespiratory parameters i.e. peak oxygen uptake (peakVO₂), ventilation over carbon dioxide slope (VE/CO₂slope), oxygen uptake efficiency slope (OUES), exercise oscillatory ventilation (EOV), rest and peak pulmonary end-tidal CO₂ (PETCO₂). Secondary variables were QOL, left ventricular ejection fraction (LVEF) and left ventricular end-diastolic diameter (LVEDD). Extracted data were pooled using random or fixed effects meta-analysis, if appropriate.

Results: Twenty RCTs (n=811) met the a-priori stated inclusion criteria. Studies were categorized into four different groups i.e. "interval training (IT1) versus IT and strength (IT1-S)" (n=156), "continuous training (CT1) versus CT and strength (CT1-S)" (n=130), "IT2 versus CT2" (n=501) and "CT3 versus strength (S3)" (n=24). No significant random effects of exercise modality were revealed assessing VE/CO₂slope. However, a trend was seen towards IT2 for peakVO₂ (P=0.099). Insufficient data were reported to assess the other primary parameters. There was a significant improvement in QOL with IT1-S (P<0.001). Comparing IT2 versus CT2, LVEDD and LVEF were significantly improved when applying IT2 (P<0.001).

Conclusions: There is some evidence to support high intensity interval training as effective to improve QOL, LVEF and LVEDD. Towards cardiorespiratory prognostic parameters however, it is not clear which training modality is outstanding. The fact that patients with HF are actively involved in whatever kind of exercise training seems to be enough to improve prognostic parameters, QOL and anatomic function.

P466

Effect of cardiac rehabilitation on glucose metabolism in patients with ischaemic heart failure

G Marazzi¹; R Massaro¹; A Tulli¹; G Caminiti¹; B Sposato¹; C Vitale¹; G M C Giuseppe M C Rosano¹; M Volterrani¹¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Aim: Patients (pts) with cardiovascular diseases frequently have alterations in glucose metabolism (GM). Cardiac rehabilitation (CR) is effective in improving GM in diabetic pts. Our study aims to evaluate the effect of a CR program on GM of non-diabetic pts with schematic heart failure.

Methods: The study population included 524 consecutive patients admitted to our Cardiac Rehabilitation Unit with the diagnosis of heart failure and found to be diabetics. The gluco-metabolic state was evaluated by means of oral glucose tolerance test (OGTT) and HOMA index, the functional capacity was measured through the distance walked at six minute walking test (6mwt) both at baseline and before discharge.

Results: At baseline 85% of pts had Body Mass Index (BMI) of 25 or greater and 61% pts had normal fasting glucose (NFG). At baseline OGTT 17 pts (28,3%) had normal glucose tolerance, 25 (41,6%) had impaired glucose tolerance (IGT), and 18/60 (30,1%) were diabetic (DM). At the end of the CR program a significant reduction in BMI (29.8 ± 3.4 vs 29.0 ± 3.8 p 0.001) and waist circumference (81.0 ± 34.1 vs 79.1 ± 33.4 cm p 0.006) were observed. At discharge OGTT 64,7% of IGT pts had normal glucose tolerance (p 0.04), and 77% of DM pts resulted IGT. Overall there was a significant improvement in 2h glucose levels (170.2 ± 56.2 vs 146.8 ± 54.8; p 0.002), HOMA-R (2.6 ± 1.4 vs 1.8 ± 0.8, p 0.002) and distance walked at 6MWT (287 ± 107.9 vs 482 ± 117.8, p 0.001). IGT pts had a worst performance than pts with normal GM at baseline and discharge 6MWT (291.1 ± 83.4 vs 344.4 ± 87.1; p < 0.04; and 444.9 ± 102.3 vs 510.7 ± 84.7, p < 0.02 respectively). No difference was found between IGT and DM pts at baseline (291.1 ± 83.4 vs 264.7 ± 86.3 mts p > 0.05) and discharge 6MWT (444.9 ± 102.3 vs 457.8 ± 100 mts, p > 0.05). **Conclusion:** OGTT test is usefully to identify gluco-metabolic state in cardiac pts with NFG. Amongst non diabetic pts with heart failure those with IGT have a worse functional capacity than normal-glycemic ones. Cardiac rehabilitation programs improve GM and insulin resistance in cardiac pts with impaired OGTT.

P467

The relation between left atrial function and cardiac output during exercise in left heart disease patients: insights by combining cardiopulmonary exercise testing with stress echo

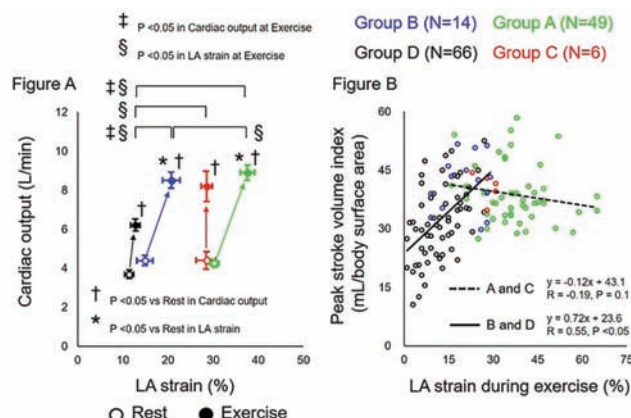

T Sugimoto¹; F Bandera¹; G Generati¹; E Alfonzetti¹; V Tufaro¹; M Guazzi¹¹IRCCS Policlinico San Donato, Heart Failure Unit, Milan, Italy

Background: The hemodynamic response to exercise in left heart disease in relation to left atrial mechanics has never been studied. We aimed at investigating the link between left atrial function and cardiac output response during exercise.

Methods: 69 heart failure patients with reduced (n=46, HFrEF) and preserved (n=20, HFpEF) ejection fraction, 34 aortic stenosis (AS) patients, and 32 control subjects underwent cardiopulmonary exercise testing evaluation combined with Echo-Doppler with assessment of left atrial strain (LAS), measured at a similar stage of percent predicted VO₂, and were divided into 4 groups according to LA volume index (LAVI) and LAS at rest.

Results: In group A (LAVI <34 ml/m², LAS >23%, n=49) and B (LAVI <34 ml/m², LAS ≤23%, n=14), LAS significantly increased during exercise (30.2 ± 5.7 vs 37.7 ± 10.9 and 14.8 ± 6.7 vs 20.6 ± 7.2%, P < 0.05, respectively) but no significant difference was observed in group C (LAVI ≥34 ml/m², LAS >23%, n=6) and D (LAVI ≥34 ml/m², LAS ≤23%, n=66) (28.5 ± 5.3 vs 28.5 ± 3 and 11.4 ± 5.7 vs 12.6 ± 7%). Looking at the two groups (B and D) with worse LAS, average LAS was the similar and no significant differences were observed in cardiac output at rest (3.7 ± 1.3 vs 4.4 ± 0.8 L/min) (Figure A). Nonetheless, in group D (36 HFrEF, 15 HFpEF, and 15 AS patients) compared to group B (1 HFrEF, 3 HFpEF, and 10 AS patients), LAS during exercise (P < 0.05) and cardiac output at peak exercise (6.2 ± 2.4 vs 8.5 ± 1.5 L/min, P < 0.05) were significantly lower (Figure A). LAS during exercise significantly correlated with peak stroke volume index in group B and D (R = 0.55, P < 0.05) and not in Group A and C (R = -0.19, P = 0.1) (Figure B).

Conclusions: In left heart disease patients, irrespective of etiology, an impaired LAS performance at rest is associated with a leftward shifted LAS vs CO response during exercise. Among this group of patients a dilated LA chamber defines the worse LAS vs CO relationship phenotype during exercise.

P468

Exercise intolerance can explain the obesity paradox in patients with systolic heart failure. Data from the Meckl Score Research Group

GQ Villani¹; P Agostoni²; U Corra³; C Passino⁴; E Salvioni²; G Cattadori²; A Verde¹; S Binno¹; M F Massimo Francesco Piepoli¹¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy;²Cardiology Center Monzino IRCCS, Cardiology, Milan, Italy; ³Salvatore Maugeri Foundation IRCCS, Pavia, Italy; ⁴Gabriele Monasterio Foundation, Pisa, Italy

Background: Obesity has been found to be protective in heart failure (HF), a finding leading to the concept of an obesity paradox. We hypothesised that a preserved cardiorespiratory fitness in obese HF patients may affect the relationship between survival and body mass index (BMI) and explain the obesity paradox in HF.

Methods: 4623 systolic HF patients (Left ventricular ejection fraction, [LVEF], 31.5 ± 9.5%, body mass index [BMI] 26.2 ± 3.6 kg/m²) were recruited and prospectively followed in 24 Italian HF centres belonging to MECKI Score Research Group. Besides full clinical examination, patients underwent maximal cardiopulmonary exercise test at study enrolment. Median follow-up was 1113 (553-1803) days. Study population was divided according to BMI (<25, 25-30, 30-35 kg/m²) and predicted peak oxygen consumption (peak VO₂, <50%, 50-80%, >80%) [14]. Study endpoints were all-cause death and cardiovascular deaths including urgent cardiac transplant.

Results: All-cause and cardiovascular deaths occurred in 951 (28.6%, 57.4 per 1000 person/year) and 802 cases (17.4%, 48.4 per 1000 person/year), respectively. In the high BMI groups, several prognostic parameters presented better values [LVEF, peak VO₂, ventilation/carbon-dioxide slope, renal function, haemoglobin ($P < 0.01$)] with respect to the lower BMI groups. Both BMI and peak VO₂ were significant positive predictors of longer survival: both higher BMI and peak VO₂ groups presented lower mortality ($p < 0.001$). At multivariable analysis and using a matching procedure (age, gender, LVEF and peak VO₂), the protective role of BMI disappeared.

Conclusion: Exercise tolerance affects the relationship between BMI and survival. The cardiorespiratory fitness mitigates the obesity paradox, observed in HF sub-jects.

P469

Heart failure as a factor of unfavorable prognosis for women with myocardial infarction

I A Leonova¹; N Tretyakova¹; N Trostyaneskaya¹; S Boldueva¹

¹North-Western State Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation

The study included 385 women with myocardial infarction (MI). Hospital mortality rate was 17.93%, 24-h mortality was 76.9 %. The most frequent cause of death according to autopsy studies was cardiac arrest 95.65 %. In 26.08 % of the cases patients had myocardial rupture and hemotamponade. Multivariate regression analysis identified quantitative and qualitative factors affecting mortality in women. Factors affecting the men's risk of death in the hospital were congestive heart failure (CHF) (RR 17.7 $p = 0.0001$), VT / VF in the first day of MI (RR 13 $p = 0.01$), the SA and AV block (RR 8.1 $p = 0.05$), creatinin > 117 mmol / l (RR 5.5 $p = 0.0005$), potassium < 4.15 mmol / l (RR 3.8 $p = 0.0005$), sodium < 136.5 mmol / l (RR 3.37 $p = 0.0001$), glucose > 9 mmol / l (RR 3.27 $p = 0.003$). All survived women were divided into age groups: young till 44 years, middle age of 45-59 years, elderly - 60 years are more senior. During correlation analysis ($p < 0.0001$) it was found link between heart failure with the presence and duration of a history of CHD, both stable angina and previous MI, also found significant ($p < 0.001$) CHF with the presence and duration of diabetes. No significant differences according to age for NT-proBNP, determined on the 5th day of MI, was found, however, drew the attention of higher average value of this indicator in all age groups: a group of young women in 1036 9 ± 15.1 pg / ml, medium - 1053.9 ± 8.1 pg / ml and the elderly - 1082.3 ± 12.9 pg / ml, respectively. In all age groups was detected significantly higher levels of neutrophils in the development of CHF (Killip's I 4.55 $\pm 0.2 \times 10^9$ / l Killip's IV 7.74 $\pm 0.5 \times 10^9$ / l). NT-proBNP level was significantly higher ($p = 0.03$) in patients with angina before MI. It was found a positive relationship between the level of NT-proBNP and CK MB ($r = 0.64$ $p = 0.03$), the absolute number of monocytes in the first day of MI ($r = 0.46$ $p = 0.02$), CRP levels ($p = 0.01$), as well as the development of left ventricular aneurysms ($p = 0.02$) and a negative - the level of erythrocytes on the first day of MI ($r = -0.58$ $p = 0.02$). Development of acute HF was associated with higher levels of glucose ($p = 0.02$) and creatinine ($p = 0.01$) in the first day of the MI, and the presence of anemia ($p = 0.003$). The findings suggest that NT-proBNP, hyperglycemia and anemia is directly related to the vastness of myocardial lesion, one adverse remodeling in the development of MI and CHF, which are more common in older women with MI. In women the highest predictive value had acute heart failure and rhythm and conduction disturbances.

P470

Serum markers of endothelial dysfunction and long-term prognosis in patients, hospitalized with acute decompensated chronic heart failure

IV Shevchenko¹; AA Shavarov¹; GK Kiyakbaev¹; VS Moiseev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: to estimate the link between serum endothelial dysfunction (ED) markers and poor outcomes in acute decompensated chronic heart failure (ADCHF) patients after discharge

Materials and Methods: The study included 60 ADCHF patients with sinus rhythm, mean age 69 ± 10 years, 35 women (58%), treated with standard ADCHF therapy. The control group included 20 patients with compensated CHF (NYHA class II or III), compatible in age, gender, heart failure functional class, without being hospitalized within 3 months before enrollment. On admission, besides standard clinical examination, echocardiography, brachial artery diameter was measured during postocclusion reactive hyperemia (FMD), using a noninvasive echo-Doppler method. Endothelial dysfunction was considered as brachial artery (BA) FMD ratio (artery diameter before/after compression) of less than 10%. Plasma vWF:Ag and serum levels of E-1, sICAM, sVCAM and -reactive protein (CRP) were also estimated at baseline. Follow-up period was 12 months. All ADCHF patients were contacted by phone for end-points (rehospitalization and/or death) 12 months after discharge.

Results: All ADCHF patients had severe endothelial dysfunction ED, compared with controls, with baseline FMD ratio of $-2.15 \pm 2.86\%$ and $9.00 \pm 1.47\%$ (< 0.001), respectively. Also levels of vWF:Ag, -1, sICAM-1, sVCAM-1 and CRP were significantly higher in ADCHF patients than in the control group: vWF:Ag 1.82 ± 0.40 vs. 0.99 ± 0.22 U/ml ($= 0.002$), E-1 3.1 ± 0.5 vs 1.3 ± 0.4 fmol/ml ($= 0.005$), sICAM-1 - 430 ± 81 vs 224 ± 16 ng/ml ($= 0.004$), sVCAM-1 1999 ± 192 vs 789 ± 62 ng/ml ($= 0.001$), and CRP - 9 ± 7 3 ± 1 mg/dl (< 0.001), respectively. Despite the received treatment, within 12 months after hospitalization due to ADCHF, 38(63%) patients had combined end points, 13(22%) of them died. Multiple regression analysis showed significant correlation between low baseline FMD ratio ($\beta = -0.29$, $p = 0.021$), high levels of ET-1 ($\beta = 0.32$, $p = 0.015$), sVCAM-1 ($\beta = 0.41$, $p < 0.001$) and CRP ($\beta = 0.35$, $p = 0.005$) and poor long-term prognosis.

Conclusion: In ADCHF patients and sinus rhythm low FMD ratio and high levels of ET-1, sVCAM-1 and RPat baseline is connected with poor prognosis after discharge

P471

Cancer patients and the extended follow-up analysis in electrocardiograms

MS Anker¹; B Hildebrandt²; N Ebner³; J Springer³; H Riess²; W Haverkamp⁴; SD Anker³; U Landmesser¹; S Von Haehling³

¹Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany;

²Charite - Campus Virchow-Klinikum (CVK), Department of Hematology and

Oncology, Berlin, Germany; ³University Medical Center Gottingen (UMG),

Department of Cardiology and Pneumology, Gottingen, Germany; ⁴Charite -

Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany

Background: Cardiovascular impairment frequently occurs in patients with advanced cancer and has been shown to lead to reduced exercise capacity and quality of life. Before we showed that using patient's electrocardiograms, the resting heart rate had significant prognostic value. This is the two-year extended follow-up.

Methods: We enrolled 145 patients with histologically confirmed cancer (age 59 ± 10 yrs, 56% men, body mass index [BMI] 24 ± 5 kg/m², tumor stage I/II/III/IV 11/10/32/46%) from 2005 through to 2010, and 59 healthy controls (age 60 ± 11 yrs, 54% men, BMI 26 ± 4 kg/m²). The cancer group consisted of 72 patients with pancreatic, 36 with colorectal, and 37 with non-small cell lung cancer. At baseline, a thorough cardiology assessment was performed including a resting ECG. Patients were followed through hospital record and telephone interviews in January 2016. Of 63 patients that were alive when our study was censored in February 2014, 37 patients could be reached in January 2015 and detailed information was acquired. Of those, 13 patients had passed away which raised the all-cause mortality to 95 (66%) during a mean follow-up of 33 months.

Results: The cancer patient's mean resting heart rate at baseline was 79 ± 14 beats per minute (bpm), that of control subjects' was 70 ± 13 bpm ($p < 0.0001$). In total, 60% of all cancer patients presented with a resting heart rate ≥ 75 bpm, compared to 27% of healthy controls ($p < 0.0001$). As a sensitivity analysis, we excluded control subjects who were taking a beta-blocker. Resting heart rate remained increased in cancer patients versus controls ($p < 0.0001$). We found that resting heart rate, cancer diagnosis, BMI, surgical intervention, hemoglobin, serum potassium, and medication with anticoagulants all predicted survival in univariable analyses (all $p < 0.05$). Cancer patients with heart rate ≥ 75 bpm had increased mortality compared to patients with heart rate < 75 (HR 1.69 [1.10-2.60], $p = 0.016$). Resting heart rate remained an independent predictor of survival in a multivariate model adjusting for all univariate significant parameters deemed clinically relevant including diagnosis, use of anticoagulation, surgery, BMI, hemoglobin, and serum potassium (HR 1.62 [1.04-2.52], $p = 0.032$). In a second model we additionally included sex and age of the patients and the effect stayed significant (HR 1.62 [1.04-2.52], $p = 0.035$).

Conclusion: The strong predictive value of the resting heart rate in advanced pancreatic, colorectal and non-small cell lung-cancer cancer is underlined by our long time follow-up.

P472

Abnormal liver function predicts death and readmissions after acute decompensated cardiac failure

M L Talavera¹; L Battioni²; I Chillik²; MS Trivi²; M Diez²

¹Cardiovascular Institute of Buenos Aires (ICBA), Heart Failure, Buenos Aires,

Argentina; ²Cardiovascular Institute of Buenos Aires (ICBA), Cardiology, Buenos Aires, Argentina

Background: there are several risk factors and scores to predict outcomes after acute decompensated heart failure (ADHF). Regarding blood biomarkers, high sensitive troponin and impairment renal function are one of the most widely studied. Nevertheless, abnormal liver function tests (LFT) during hospitalization could help to identify high risk patient after ADHF admission and may be added as a tool to conventional and well known biomarkers.

Objective: to evaluate the association between abnormal LFT and death/heart transplantation and hospital readmission due ADHF in patients (pts) with ADHF at

180 days of follow up.

Methods: 223 consecutive pts admitted with ADHF between January-2013 and August-2014 were selected; Patients' basic characteristic data including sex, age, past medical history, medications, as well as blood exam results, were analyzed. Renal function impairment was defined by a >0.3 mg/dl in creatinin value and abnormal liver function as an any upper limit increment in alanine aminotransferase, aspartyl aminotransferase, total bilirubin and/or alkaline phosphatase. The primary endpoint was death/heart transplantation and hospital readmission due ADHF at 180 days. Logistic regression analysis was used to evaluate factors associated to death. $P < 0.05$ was considered statistically significant.

Results: mean age was 79 years old (DS \pm 11) and 60% (134 pts) were male, mean left ventricle ejection fraction was 40% (IQR25-75: 29-59) and 43% (97 pts) had an ischemic etiology; abnormal LFT was present in 62% (138 pts) at admission and previous renal failure was recorded in 37% (83 pts); during in-hospital, 68% (153 pts) and 46% (104 pts) developed any liver enzyme enchainment or renal function impairment, respectively. There were 77 events (34%) during follow up. Regression analysis showed that highest bilirubin levels (OR 1.87, CI95%: 1.22-2.85, $p = 0.004$) was the only variable associated to events among others LFT variations and factors like high sensitive troponin levels or renal impairment function.

Conclusions: high bilirubin levels were associated to death/heart transplantation and hospital readmission due heart failure in patients (pts) with ADHF. This easy variable may help to identify a high risk population and therefore to make a closer follow up.

P473

Comparative prognostic role of 3C-HF score across different age and ejection fraction in community-based HF population.

A Iorio¹; M Senni¹; A Gavazzi¹; C Concetta Di Nora²; C Mazzone³; G Russo³; G Cioffi⁴; G Sinagra²; A Di Lenarda³

¹Ospedale Papa Giovanni XXIII, Bergamo, Italy; ²University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ³Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy; ⁴Villa Bianca Hospital, Trento, Italy

Background: The estimates of 3C-HF score across different age range, and EF- HF groups (LVEF $< 50\%$ - HFREF, LVEF $\geq 50\%$ - HFpEF) is unknown. Aim: We investigate the predictive role of 3C-HF score in an epidemiological setting of community-based population according to age and HF phenotypes.

Methods: From October 2009 to December 2013 we studied consecutive ambulatory patients with HF whose ejection fraction had been assessed. We examined and compared the performance of 3C-HF score with Receiver Operating Characteristic for 1 year mortality and overall hospitalizations according to age categories (years): < 65 ($n = 203$), 65-74 ($n = 519$), and 75-84 ($n = 1012$), ≥ 85 ($n = 570$).

Results: A total 2,321 HF patients (mean age 78 ± 8 , 57% men) were included. Of these: 914 (41 %) patients were identified as HFREF and 1,380 (59%) patients as HFpEF. At a follow-up of 28 ± 14 months, 179 (10%) patients died. Of these 87 (11%) had HFREF, and 89 (7%) had HFpEF ($p = 0.01$). There was a high burden of morbidity with 1030 (49%) patients presenting overall hospitalizations (441, 53% HFREF vs 589, 47% HFpEF; $p < 0.001$). Older patients (75-84 years and ≥ 85 years) had higher prevalence of comorbidities (4.2 ± 2.5) with higher frequency of severe functional impairment (NYHA III-IV, 56%). Overall, the 3C-HF score showed a good 1-year mortality prediction irrespective of EF-HF groups (AUC 0.73-HFREF, AUC 0.72-HFpEF). The 3C-HF score prediction increased across age subgroups, and achieved its best prediction in elderly patients (aged 75-84 years-AUC 0.81; aged ≥ 85 years-AUC 0.83). However, 3C-HF score performed a lower prediction in HF patients young adult (aged < 65 years) (ROC curve 0.56). This trend was maintained unchanged both in HFREF and in HFpEF. Similar results were confirmed for 1 - year overall hospitalizations.

Conclusion: The 3C-HF score prediction increased according to age, achieving the best prognostic prediction in HF older patients irrespective of HF phenotypes. The best estimate of 1-year mortality and morbidity of 3C-HF score in elderly population could be related to the sensitivity of this score to comorbidity burden typical of elderly population.

P474

MELD-XI score is associated with high risk clinical profile and outcome in acute heart failure

L Battioni¹; G Daquarti¹; M L Talavera²; C Ametrano¹; MS Trivi¹; M Diez¹

¹Cardiovascular Institute of Buenos Aires (ICBA), Cardiology, Buenos Aires, Argentina; ²Cardiovascular Institute of Buenos Aires (ICBA), Heart Failure, Buenos Aires, Argentina

Background: liver and renal abnormalities may be found in patients (pts) with advanced heart failure. The Model of End-Stage Liver Disease Excluding INR (MELD-XI) score allows functional risk stratification of HF pts on and off anti-coagulation awaiting heart transplantation and/or with left ventricular assist device. However, the impact of MELD-XI on the prognosis of HF pts with a less severe disease remains unclear.

Objective: to evaluate the value of MELD-XI for identifying high-risk pts and to evaluate the prognostic value for predicting mortality during hospitalization and death/hospital readmission due to acute decompensated heart failure (ADHF) at 180 days in pts hospitalized with ADHF.

Methods: 224 consecutive pts admitted with ADHF between January-2013 and August-2014 were selected. A MELD-XI score ($5.116 \log(\text{total bilirubin}) + 11.766 \log(\text{creatinine}) + 9.44$) was graded and pts were stratified by MELD-XI quartiles (Q1 to Q4). Patients' basic characteristic data including sex, age, past medical history, medications, as well as blood exam results, were analyzed. Complex therapy was defined as the needing of intra-aortic balloon pump, mechanical ventilation or hemodialysis; $P < 0.05$ was considered statistically significant.

Results: mean age was 79 years old (DS \pm 11) and 60% (134 pts) were male, mean left ventricle ejection fraction was 40% (IQR25-75: 29-59) and 43% (97 pts) had an ischemic etiology; median MELD-XI was 12.2 (IQR 25-75: 8.1-16). There were 16 (7.1%) deaths during hospitalization and 77 (34%) events (death/rehospitalization due to ADHF) during follow up. The highest MELD-XI quartile was associated with a lower left ventricle ejection fraction: Q4 median 34% (IQR25-75: 21-50%) versus 53% (IQR 37-60), $p > 0.001$. At admission, the highest MELD-XI quartile was associated with more prevalence of cardiogenic shock: Q4: 21% versus Q1: 0%, $p < 0.001$. During hospitalization, the MELD-XI score was associated with more inotropic use: Q4: 21% versus Q1: 0%, $p < 0.001$, more complex therapy use: Q4: 17% versus Q1: 0% $p = 0.001$ and longer length of hospital stay: Q4: 7 days (IQR25-75: 4-15) versus Q1: 5 days (IQR25-75: 4-8) $p = 0.02$. Hospital mortality was higher in the highest MELD-XI quartile: Q4: 14% versus Q1: 1.8%, $p = 0.03$ and death/hospital readmission due to DAHF at 180 days: Q4 56% versus Q1: 24%, $p = 0.001$.

Conclusions: the MELD-XI scoring system, a marker of liver and renal function, can identify high-risk pts at admission. The use of MELD-XI score for risk stratification may help to identify populations with poor outcome during hospitalization and higher risk of death or rehospitalizations during follow-up who will require rapid implementation of an aggressive treatment.

P475

Association of right bundle branch block with ST-elevation myocardial infarction and need for ventricular assist device and cardiac transplantation

EC Tong¹; D Isaac¹; J Wong¹; A Bizios¹; PD Galbraith¹; M Zhang¹; ML Knudtson¹; V Kuriachan¹; SB Wilton¹; B Bryan Har¹

¹Libin Heart Institute, University of Calgary, Calgary, Canada

Background/Introduction: Right bundle branch block (RBBB) at the time of acute myocardial infarction is associated with increased mortality. Ventricular assist devices and/or cardiac transplantation are used for treatment in left ventricular dysfunction following myocardial infarction and may prevent death.

Purpose: To evaluate the relationship between right bundle branch block at ST-elevation myocardial infarction (STEMI) and subsequent left ventricular assist device (LVAD) therapy and/or cardiac transplantation.

Methods: We use a prospective cohort of 3900 STEMI cases treated with primary percutaneous coronary intervention (PCI) from 2002-2012. We excluded 71 repeat primary PCI cases and 55 patients with LBBB. We used multivariate logistic regression to determine if RBBB was associated with subsequent LVAD therapy, cardiac transplantation, and death at or before 1 year.

Results: On the initial presenting ECG with STEMI, normal QRS conduction was present in 3515 patients and RBBB in 259 patients. 6 patients received LVAD: 5 patients subsequently undergoing cardiac transplantation, and 1 patient died following LVAD. A total of 12 patients underwent cardiac transplantation. Following primary PCI for STEMI, 7 of 3515 patients (0.20%) with initial normal QRS and 6 of 259 patients (2.3%) with RBBB underwent LVAD and/or cardiac transplantation. Compared with normal QRS, RBBB was associated with LVAD and/or cardiac transplantation at 1 year (OR 9.86, 95%CI 3.11-31.29). RBBB was associated with the composite outcome of LVAD and/or cardiac transplantation or death at 1 year (adjusted OR 4.62, 95%CI 3.28-6.52).

Conclusion: The presence of RBBB at the time of STEMI diagnosis was associated with the subsequent need for treatment with LVAD or cardiac transplantation, but the absolute number of events was low.

P476

Low body mass index with acute heart failure is independently associated with high in-hospital mortality in community-based registry; KICKOFF Registry.

A Ikuta¹; K Takabayasi¹; Y Okazaki¹; R Hujita¹; S Kitaguti¹; R Nohara¹

¹Hirakata, Kohsai, Hospital, Hirakata, Japan

Background: Elevated body mass index (BMI) is a major risk factor for the development of heart failure (HF), but association with low BMI and in-hospital mortality or social backgrounds have not been well documented.

Purpose: The purpose of this study is to identify the association of low BMI with in-hospital mortality and social backgrounds in acute heart failure (AHF) patients (pts).

Methods: We have enrolled 281 inpatients with AHF in the KICKOFF Registry (13

hospitals in Japan). The KICKOFF Registry is a community-based survey of HF pts. We compared the clinical characteristics, in-hospital mortality, and social backgrounds between HF patients (pts) with BMI <18kg/m² (low BMI; n=53) and the other pts (control; n=228).

Results: The low BMI were older and had longer length of hospitalization than control (84.5±9.0 vs. 76.8±11.8 years of age; $p<0.01$, 33.2±28.8 vs. 24.3±22.3 days; $p=0.02$, respectively). There was no significant difference in gender of male (41.5% vs. 49.6%; $p=0.29$). The low BMI had more valvular disease (47.2% vs. 30.7%; $p=0.02$), but less hypertension, diabetes or dyslipidemia (43.4% vs. 75.0%; $p<0.01$, 17.0% vs. 31.6%; $p=0.03$, 18.9% vs. 36.0%; $p=0.01$, respectively). The low BMI were more likely to need support by others; less by living alone (18.9% vs. 30.7%; $p<0.01$), more using long-term care insurance and dementia (71.7% vs. 41.2%; $p<0.01$, 45.2% vs. 25.0%; $p<0.01$, respectively). In the low BMI, there was higher in-hospital mortality than control (32.1% vs. 8.3%; $p<0.01$). After the adjustment by age, gender, history of heart failure, ischemic heart disease, valvular disease, hypertension, diabetes, dyslipidemia, atrial fibrillation and chronic kidney disease in multiple logistic regression models, low BMI was independently associated with high in-hospital mortality (adjusted odds ratio 5.94; 95% confidential interval 2.38-15.43; $p<0.01$).

Conclusion: Low BMI pts with HF were older, and needed more support by other person. There was more social frailty in low BMI pts. Low BMI was independently associated with high in-hospital mortality.

P477

Reasons why patients with chronic heart failure at very low risk for mortality die

G Russo¹; G Cioffi²; G Pulignano³; G Barbati¹; L Tarantini⁴; D Del Sindaco⁵; A Cherubini¹; C Stefanelli⁶; M Senni⁶; A Di Lenarda¹

¹Cardiovascular Center, A.A.S. 1, Trieste, Italy; ²Villa Bianca Hospital, Trento, Italy;

³San Camillo Forlanini Hospital, Rome, Italy; ⁴San Martino Hospital, Belluno, Italy;

⁵Hospital San Giovanni Addolorata, Rome, Italy; ⁶Hospital Riuniti di Bergamo, Bergamo, Italy

Background: A proper prognostic stratification is crucial for organizing an effective clinical management and treatment decision-making in patients with chronic heart failure (CHF). In this study, we selected and characterized a sub-group of CHF patients at very low risk for death with the aim to assess predictors of death in subjects with an expected probability of 1-year mortality near to 5%.

Methods: Among the best accessible models, we used the Cardiac and Comorbid Conditions HF (3C-HF) Score to identify patients with CHF with the best mid-term prognosis. We selected patients belonging to the lowest quartile of 3C-HF score (<9 points).

Results: We recruited 1777 consecutive CHF patients at 3 Italian Cardiology Units. Median age was 76±10 years, 43% were female, 32% had preserved ejection fraction. Subjects belonging to the lowest quartile of 3C-HF score were 609 (34% of total population). During a median follow-up of 21 [12-40] months, 48 of these patients (8%) unexpectedly died, and 561 (92%) survived. The variables that contributed to survival prediction emerged by Cox regression multivariate analysis were older age (HR 1.03[CI 1.00-1.07]; $p=0.04$), male gender (HR 2.93[CI 1.50-5.51]; $p=0.002$) and a higher degree of renal dysfunction (HR 0.96[CI 0.94-0.98]; $p<0.001$).

Conclusions: The prognostic stratification of CHF patients by 3C-HF score allows in daily practice to select patients at different outcome and to identify the factors associated with death in outliers at very low risk who should survive at mid-term follow-up. The reasons why these patients do not outlive the matching part of subjects who expectedly survive are related to the maintenance of a satisfactory renal function together with unmodifiable conditions such as older age and male gender.

P478

Prognostic impact of identification of patients with diffuse aneurysmatic coronary artery disease.

E Ernst Wellnhofer¹; B Pieske¹

¹German Heart Center Berlin, Berlin, Germany

Aim: Diffuse aneurysmatic coronary artery disease (ANCAD) involving both coronary arteries is a rare variant of CAD with limited and controversial data on prognosis and pathophysiology. Micro vessel disease, micro thrombosis and infarction resulting in chronic heart failure are discussed as risks and targets of treatment. The clinical value of novel diagnostic approaches is partly related to prognosis. We evaluated the prognostic impact of ANCAD in a small stratified long-term study cohort comprising two control groups, controls without CAD and patients with significant coronary stenosis without ectasia (SCAD).

Methods: Patients with ANCAD (n=6; age: 50±10 y, 1 f), with CAD ruled out by angiography (controls) (n=8; age: 53±14y, 5 f) and with SCAD (n=9; age: 59±10y, 3 f) were selected by review of coronary angiograms performed between 1990 and 1994. The burden of stenosis was quantified by the Gensini score. Risk factors including total cholesterol and ejection fraction (EF) were collected. The last censoring of survival during follow-up was performed 2013.

Results: Mean follow-up was 18 y. At study inclusion the ANCAD patients had a

lower EF with history of myocardial infarction (47±10%) than controls (65±7%) and CAD patients (58±10%) in spite of younger age. Cholesterol (228±48 mg/dL), body mass index (27±4 kg/m²) and number of risk factors (2±1) were not significantly different between groups. The Gensini score did not differ between ANCAD (33±31) and SCAD (23±28). Survival analysis (fig) demonstrates a significantly reduced lifespan in ANCAD patients compared to SCAD.

Conclusion:

The lifespan of patients with ANCAD appears to be significantly reduced (20 y) as compared with SCAD in spite of a similar risk profile and burden of stenosis. These high risk patients should be identified at young age to initiate early diagnosis and treatment of micro vessel disease and evolving chronic heart failure. Novel diagnostic approaches may be useful for early detection and treatment.

Prediction of mortality for heart failure patients using intelligent machine learning method

N Liu¹; YH Lau²; D Sim²; LL Sim²; M Ong¹; RS Tan²; L Zhong²

¹Singapore General Hospital, Singapore, Singapore; ²National Heart Centre Singapore (NHCS), Singapore, Singapore

Background and objectives: The prediction of prognosis in heart failure remains challenge. Risk stratification is therefore important for individual patient in terms of prognostic estimation and medical regimen planning. We hypothesized that a predictive model by using intelligent machine learning (ML) with medical data, blood test, and echocardiographic imaging would be a sensitive way to predict 1-year mortality in heart failure.

Material and Methods: Prospective longitudinal single-centre study of 526 patients hospitalized for heart failure. All patients underwent standard two-dimensional, Doppler echocardiography, and tissue Doppler echocardiography to characterize left ventricular (LV) dimension, structure, global and regional contractile function. A total of 157 variables were used in model building, including patient demographics, clinical vital signs, lab results, and imaging biomarkers. An ensemble-based ML method was implemented where artificial neural network was chosen as its base learner. Step-wise logistic regression was also used to build a predictive model and compared to the ML model. The outcome was assessed by hierarchical censoring of death.

Results: 526 HF patients [median age (IQR): 70 (60-78) years] were recruited, with 81 (15.4%) meeting the primary outcome. The ML model produced an area under the curve (AUC) of 0.88 (95% confidence interval [CI], 0.83-0.93), and a cutoff score of 55 gave a sensitivity of 82.7% (95% CI, 74.5%-91.0%), specificity of 78.0% (95% CI, 74.1%-81.8%), positive predictive value (PPV) of 40.6% (95% CI, 33.1%-48.1%), and negative predictive value (NPV) of 96.1% (95% CI, 94.1%-98.1%). The logistic regression model achieved an AUC of 0.78 (95% CI, 0.72-0.84), and at the cut-off score of 0.17 a sensitivity of 67.9% (95% CI, 57.7%-78.1%), specificity of 76.4%

(95% CI, 72.5%-80.3%), PPV of 34.4% (95% CI, 27.0%-41.7%), and NPV of 92.9% (95% CI, 90.3%-95.5%) (all $p < 0.05$).

Conclusion: Intelligent ML method demonstrated better performance than logistic regression modeling in prediction of 1-year mortality in heart failure patients.

Clinical implications of new-onset left bundle branch block after transcatheter aortic valve implantation

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; A Ruiz-Salas³; J Fernandez-Pastor³; J Pena³; JM Garcia-Pinilla³; JM Hernandez-Garcia³; J Alzueta-Rodriguez³; E De Teresa-Galvan³

¹Department of Cardiology, Malaga, Spain; ²Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Cardiac conduction disturbances, including a left bundle branch block (LBBB), occur frequently following transcatheter aortic valve replacement (TAVR) and may be associated with adverse clinical events. The impact of new-onset persistent left bundle branch block (N-LBBB) after TAVI remains controversial. The aim of this study was to determine the impact of new-onset persistent left bundle branch block (on late outcomes after transcatheter aortic valve implantation (TAVI)).

Methods: A total of 394 consecutive patients who underwent TAVI with a balloon-expandable valve without pre-existing LBBB or permanent pacemaker implantation (PPI) were included. Electrocardiograms were obtained at baseline, immediately after the procedure, and daily until hospital discharge. Patients were followed at 1, 6, and 12 months and yearly thereafter.

Results: New-onset LBBB occurred in 162 patients (41.1%) immediately after TAVI and persisted at hospital discharge. After follow-up of 2.37 ± 1.9 years, there were no differences in mortality rate between the N-LBBB and no N-LBBB groups (46.4% vs. 39.7%; adjusted-hazard ratio: 1.31 [95% confidence interval (CI): 0.811 to 2.141]; $p = 0.161$). There were no differences between groups regarding cardiovascular mortality HR=0.39 (95% CI 0.140-1.09), $p = 0.071$, rehospitalizations for heart failure HR=0.88 (95% CI 0.336-2.318), $p = 0.800$. Only 4 patients with N-LBBB required PPI during the follow-up period. There were 4 cases of unexpected (sudden or unknown) death was observed in 2 patients with N-LBBB. Patients with N-LBBB not showed a poorer evolution of left ventricular ejection fraction over time (1, 2 and 3 years) than no N-LBBB group: 62.3 ± 9 vs. 64.7 ± 8 , $p = 0.020$; 53.4 ± 25 vs. 55.6 ± 24 , $p = 0.853$ and 61.6 ± 7 vs. 64 ± 8 , $p = 0.214$, respectively). N-LBBB was also not associated with a poorer New York Heart Association functional class at follow-up (1.78 ± 0.6 vs. 1.68 ± 0.6 , $p = 0.199$). Conclusions N-LBBB was a frequent complication of transcatheter aortic valve implantation, but it was not associated with any increase in overall or cardiovascular death or rehospitalization for heart failure after a mean follow-up of 2 years.

P481

Length of hospital stay in acute heart failure and risk of early readmission

M J Bosch Campos¹; A Paya²; I Cardells²; D Escribano²; E Santas²; G Minana²; A Molla²; J Sanchis²; FJ Chorro²; J Nunez²

¹Hospital La Plana, Cardiology, Vila-Real, Spain; ²University Hospital Clinic of Valencia, Cardiology, Valencia, Spain

Background: Optimal length of stay in patients admitted for acute heart failure (AHF) remains controversial. Longer hospitalizations are associated with higher risk of complications, but little is known about the prognostic implication of short hospitalizations.

Purpose: To evaluate the relationship between length of stay (LOS) and risk of 10-day readmission in patients discharged for AHF.

Methods: we included 2361 consecutive patients admitted with AHF diagnosis in a third level hospital (2004-2014). We excluded 119 in-hospital deaths and 132 who were scheduled for cardiac surgery during index admission. Final study sample included 2110 patients. LOS was categorized: LOS1 (≤ 4 days), LOS2 (5-7 days), LOS3 (8-10 days) and LOS4 (> 10 days). Cox regression analysis adapted for competing events (death) was used to evaluate the independent association between LOS and the risk of unplanned 10-day readmission.

Results: Median LOS was 7 days (IQR=5-11). At 10-days, 130 patients (6,16%) were readmitted. Cumulative incidence of readmission among LOS categories showed a U-shaped pattern with lower rates for those in LOS2 (LOS1=6.1%, LOS2=3.2%, LOS3=7.2%, LOS4=9.1%, ($p < 0.001$) as shown in figure 1. In the multivariate analysis, the U-shaped curve remained significant ($p = 0.006$). Compared to LOS2, short LOS (≤ 4 days) showed and increased risk of 10-days readmission (HR=1.94, CI 95%: 1.06-3.54, $p = 0.031$). Similarly, more prolonged admissions (LOS3 and LOS4) also exhibited a higher risk (HR=2.18, CI 95%:1.28-3.71, $p = 0.004$, and HR=2.45, CI 95%: 1.49-4.04, $p < 0.001$, respectively).

Conclusion: LOS in patients with AHF is related to the risk of 10-day readmission. Higher risk was found for both short and prolonged stays.

P482

The CHA2DS2-VASc score as a predictor for high mortality in hospitalised heart failure patients

Y Yasuchika Takeishi¹; S Watanabe¹; A Yoshihisa¹

¹Fukushima Medical University, Fukushima, Japan

Objective: Atrial fibrillation (AF) is common in patients with heart failure (HF). CHA2DS2-VASc score was originally employed as a risk assessment tool for stroke in patients with AF; however, it has recently been used to predict not only stroke but also various cardiovascular diseases beyond the original AF field. We aimed to verify the CHA2DS2-VASc score as a risk assessment tool to predict mortality in patients with HF.

Methods: Consecutive 1,011 patients admitted for treatment of HF were divided into three groups based on their CHA2DS2-VASc scores: a low score group (CHA2DS2-VASc score 1-3, $n = 317$), moderate score group (CHA2DS2-VASc score 4-6, $n = 549$) and high score group (CHA2DS2-VASc score 7-9, $n = 145$). Of the 1,011 HF patients, 387 (38.3%) had AF. We compared patient characteristics among the three groups and prospectively followed for all-cause mortality.

Results: Although left ventricular ejection fraction was similar among all three groups, all-cause mortality was higher in the high and moderate score groups than in the low score group (37.9% and 29.3% vs. 15.1%, log-rank $P < 0.001$). Furthermore, all-cause mortalities were significantly higher in the moderate and high score groups than in the low score groups ($P < 0.001$) in the HF patients, irrespective of the presence or absence of AF ($P < 0.01$, respectively). In the multivariable Cox proportional hazard analysis, the CHA2DS2-VASc score was an independent predictor of all-cause mortality (all HF patients: hazard ratio (HR) 1.203, $P < 0.001$; HF patients with AF: HR 1.152, $P = 0.009$; HF patients without AF: HR 1.228, $P < 0.001$).

Conclusion: The CHA2DS2-VASc score was an independent predictor of all-cause mortality in HF patients with or without AF. This comprehensive risk assessment score may help identify HF patients who are at high risk for mortality and optimize risk reducing treatment in HF patient.

P483

Prognostic importance of heart rate, and effect of sacubitril/valsartan according to heart rate, in PARADIGM-HF

Novartis Pharmaceuticals

D Castagno¹; P Jhund¹; JL Rouleau²; K Swedberg³; MR Zile⁴; MP Lefkowitz⁵; VC Shi⁵; SD Solomon⁶; M Packer⁷; JVV McMurray¹

¹University of Glasgow, Glasgow, United Kingdom; ²University of Montreal, Montreal, Canada; ³University of Gothenburg, Gothenburg, Sweden; ⁴Medical University of South Carolina, Charleston, United States of America; ⁵Novartis Pharmaceutical Corporation, East Hanover, United States of America; ⁶Brigham and Women's Hospital, Boston, United States of America; ⁷Baylor University Medical Center, Dallas, United States of America

Background: Heart rate (HR) has emerged as an important prognostic marker in heart failure with reduced ejection fraction (HF-REF). Whether it is independently predictive of natriuretic peptides is unknown. We evaluated the prognostic importance of HR in the Prospective comparison of ARNI with ACEI to Determine Impact on Global Mortality and morbidity in Heart Failure trial (PARADIGM-HF) and examined the effect of sacubitril/valsartan (LCZ696), compared with enalapril, according to HR in this trial.

Purpose: To examine the prognostic importance of HR in conjunction with natriuretic peptides in HF-REF and the effect of sacubitril/valsartan compared with enalapril according to baseline HR in patients with HF-REF.

Methods: Baseline HR was added to a multivariable predictive model including age, sex, renal function, LVEF, prior myocardial infarction and HF hospitalization, as well as NT pro BNP. We estimated the risk of the primary composite endpoint (cardiovascular death or heart failure hospitalization) and all-cause death according to HR considered as either a categorical or continuous variable. We also examined the effect of randomized treatment according to HR.

Results: HR data were available in 8399 PARADIGM-HF patients. HR was not an independent predictor of outcome in patients with atrial fibrillation ($n=2223$). The relationship between HR (tertiles) and outcome in patients with sinus rhythm is shown in the table. In these patients, each 10 bpm increase in HR was associated with an 8 (3-14)% increase in adjusted risk of death from any cause and 8 (3-12)% increase risk of the primary composite endpoint. The effect of sacubitril/valsartan compared with enalapril was consistent for all outcomes across HR tertiles and when HR was considered as a continuous variable. In patients with a HR ≥ 70 bpm in sinus rhythm, the sacubitril/valsartan vs. enalapril hazard ratios for the primary endpoint and all-cause mortality were 0.79 (0.69-0.90) and 0.82 (0.70-0.95), respectively.

Conclusions: HR is adds incremental prognostic information to other prognostic variables, including NT proBNP. LCZ696 is equally effective, irrespective of HR (and whether the rhythm is sinus or atrial fibrillation/flutter).

	Adjusted hazard ratio		
	Tertile 1 - reference group (≤ 66 bpm)	Tertile 2 (67-76 bpm)	Tertile 3 (≥ 77 bpm)
Primary endpoint	1.00	1.19 (1.05, 1.35)	1.24 (1.09, 1.43)
CV death	1.00	1.19 (1.01, 1.40)	1.24 (1.04, 1.47)
HF hospitalization	1.00	1.18 (0.99, 1.39)	1.37 (1.15, 1.63)
All-cause mortality	1.00	1.23 (1.07, 1.42)	1.27 (1.08, 1.48)

Association between heart rate and outcome (tertile analysis)

A new tissue Doppler index to predict malignant ventricular arrhythmic events in patients with heart failure

C Mornos¹; L Petrescu¹; A Ionac¹; S Crisan¹; A Mornos²; M Lazar²; D Cozma¹
¹University of Medicine & Pharmacy Victor Babes, Clinic of Cardiology, Timisoara, Romania; ²Institute of Cardiovascular Diseases, Timisoara, Romania

Background: Recent studies demonstrated that a new tissue Doppler index, $E/(E' \times S')$, including the ratio between early diastolic transmitral and mitral annular velocity (E/E'), and the systolic mitral annular velocity (S'), is a good echocardiographic predictor of cardiovascular events (atrial fibrillation, hospital readmission and cardiac death).

Purpose: We investigated the value of $E/(E' \times S')$ ratio to predict malignant ventricular arrhythmic events in patients with heart failure (HF).

Methods: In this prospective study, 300 consecutive outpatients with HF, in sinus rhythm, with optimal medical treatment, were analysed. Echocardiography was performed at 1.6 ± 0.4 months after hospital discharge and $E/(E' \times S')$ ratio was determined. The average of the velocities from the septal and lateral site of the mitral annulus was used for the analysis. Patients with inadequate echocardiographic images, significant primary valvular heart disease, acute coronary syndrome in the last 40 days, coronary artery by-pass graft before baseline echocardiographic examination, congenital heart disease, and patients undergoing ventricular pacing were excluded. The end point included sudden cardiac death, ventricular fibrillation and sustained ventricular tachycardia (VA/SCD).

Results: Mean left ventricular ejection fraction of our patients was $39 \pm 14\%$. During follow-up period (36 ± 9 months) VA/SCD occurred in 48 patients (16%). Mean $E/(E' \times S')$ was 3.85 ± 1.49 in those patients, while it was 2.04 ± 0.92 in the rest ($p < 0.001$). The area under the Receiver Operating Characteristic curve for $E/(E' \times S')$ to predict VA/SCD was 0.82 (95% confidence interval = 0.74-0.91, $p < 0.001$). The optimal $E/(E' \times S')$ cut-off was 2.84 (79% sensitivity, 80% specificity). Of our patients, 87 (29%) presented $E/(E' \times S') > 2.84$ and 213 (71%) presented $E/(E' \times S') \leq 2.84$. VA/SCD was significantly higher in the group of patients with $E/(E' \times S') > 2.84$ than in the group with $E/(E' \times S') \leq 2.84$: 38 events (43.7%) versus 10 events (4.7%), $p < 0.001$. Kaplan-Meier analysis (Figure 1) showed that the event-free survival rate during follow-up was significantly higher in the group of patients with $E/(E' \times S') \leq 2.84$ (log rank, $p < 0.001$).

Conclusions: In patients with HF, $E/(E' \times S')$ ratio is an important predictor of malignant ventricular arrhythmic events and may improve cardiovascular risk stratification.

Figure 1. Kaplan-Meier analysis.

⁶Severance Hospital, Seoul, Korea Republic of; ⁷Chungbuk National University

Hospital, Cheongju, Korea Republic of; ⁸Seoul National University Hospital, Seoul, Korea Republic of

Background: Prior studies have suggested that low serum cholesterol level is associated with increased mortality in patients with heart failure, but there still have been controversies on the relationship between lipid levels and the outcomes of acute decompensated heart failure (ADHF). Therefore, the aim of this study was to evaluate the impact of baseline lipid levels on mortality in a nationwide cohort study of ADHF patients.

Methods: A total of 5,625 ADHF patients enrolled in the present registry were divided into 4 groups according to the quartile distribution of total cholesterol (TC), serum low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and triglyceride (TG) level; the lowest quartile (Q1), second quartile (Q2), third quartile (Q3), the highest quartile (Q4). TC: Q1 < 121, Q2 121-147, Q3 147-178, Q4 > 178 mg/dL, LDL-C: Q1 < 66.7, Q2: 66.7-90.1, Q3 90.1-115.6, Q4 > 115.6 mg/dL, HDL-C: Q1 < 32, Q2 32-40, Q3 40-49, Q4 > 48 mg/dL, TG: Q1 < 64, Q2 64-85, Q3 85-117, Q4 > 117 mg/dL. In-hospital death and 1-year mortality were compared among the quartile groups of each lipid profile.

Results: In-hospital death was highest in the lowest quartile and gradually decreased as the quartile increasing for TC (Q1 6.8% vs. Q2 4.2% vs. Q3 4.4% vs. Q4 3.5%, linear $p < 0.0001$) and for HDL-C (Q1 7.7% vs. Q2 3.6% vs. Q3 2.8% vs. Q4 2.3%, linear $p < 0.0001$), but LDL-C and TG quartile were not associated with in-hospital death. One year mortality was highest in the lowest quartile and gradually decreased as the quartile increasing for TC (Q1 21.4% vs. Q2 18.0% vs. Q3 14.8% vs. Q4 13.3%, linear $p < 0.0001$), LDL-C (Q1 18.6% vs. Q2 15.5% vs. Q3 15.0% vs. Q4 12.8%, linear $p = 0.003$), and TG (Q1 19.3% vs. Q2 16.7% vs. Q3 14.6% vs. Q4 11.7%, linear $p < 0.0001$). Although HDL-C quartile did not show significant linear association on 1-year mortality, the lowest quartile of HDL-C showed significantly higher 1-year mortality than other quartiles on Kaplan-Meier survival analysis ($p = 0.032$ by log-rank test).

Conclusion: Low serum TC and HDL-C are significantly associated with in-hospital death and low serum TC, LDL-C, HDL-C, and TG are significant predictor of 1-year mortality in patients with ADHF. The results of the present study suggested that

the measurement of baseline lipid levels would be simple and useful for predicting adverse clinical outcomes in patients with ADHF.

PULMONARY HYPERTENSION

P486

Severe pulmonary artery hypertension in stenosis of left main coronary artery with left ventricular dysfunction: a case report

W Serra¹; MAC Cattabiani¹; IT Taddonio¹; DA Ardissoni¹; LV Vignali¹

¹Cardiology Division AOU Parma, Parma, Italy

This case report describes a man 78 year old, who presented a rapidly progressive dyspnea in patient with dyslipidemia, obesity, obstructive sleep apnea syndrome by being treated with C-PAP at night. Since about 2 months complained progressive worsening dyspnea for minimal effort and a few episodes of breathlessness at rest with nocturnal paroxysms. Echocardiographic exam showed left ventricle hypokinetic (FE 38%) with akinesia of posterior wall; right atrial dilatation; mild mitral regurgitation; TAPSE 18 mm and signs of severe pulmonary hypertension (PAPs 90 mmHg; actpo 77msc). CT chest: no signs of TEP, not evident parenchymal lesions or interstitial lung disease, expansion of trunk pulmonary artery. Work up for the common other secondary causes of pulmonary hypertension was negative. Blood tests (CBC, liver function, renal profile, coagulation) all substantially within the limits. Coronary angiography and right catheterization was performed and showed severe atherosclerosis of left main trunk, the right coronary artery and circumflex with the absence of significant stenosis. At the right catheterization: severe pulmonary hypertension (mPAP 42 mmHg; PVR 4.8 U.W) with postcapillary component (PCW 17 mmHg) and the systolic gradient (GTP) was 25mm/hg Fig. Excluded from the surgery option, was placed indication to perform Echo-stress to evaluate indication to a revascularization procedure. This examination revealed: Akinesia (Basic) rear, anterolateral hypokinesia and basal inferior; after infusion of the stressor is reduced coronary reserve observed in absence of ischemic induction. It was placed a medicated stent in the trunk of left main coronary artery with excellent result. After 6 months, right heart catheterization highlighted a PCW reduction and indication to specific therapy. Ambrisentan tablets 5mg /die was started with benefit (NYHA II) The right heart catheterization is necessary to confirm the diagnosis and to measure the systolic (GTP) and diastolic transpulmonary gradient (DPG); these could target patients who can benefit from specific treatment. Although not included in the vast majority of PAH vasodilator therapy clinical trials, vasodilator therapy may be of clinical benefit in a few carefully selected patients with left-sided cardiac disease. In patients over 55 years we recommend coronary angiography for the possibility of coexistence of coronary heart disease.

P487

The advanced functional class and the variables of poor prognosis in pulmonary hypertension

A Lescano¹; L Talavera¹; J Mazzei²; E Barimboim²; V Saurit³; B Varela²; D Haag⁴; C Botta⁵; V Rios⁵; G Giacomi⁵

¹Sociedad Argentina de Cardiología, Buenos Aires, Argentina; ²SOCIEDAD ARGENTINA DE MEDICINA RESPIRATORIA, Buenos Aires, Argentina;

³SOCIEDAD ARGENTINA DE REUMATOLOGIA, BUENOS AIRES, Argentina;

⁴Sociedad Argentina de Pediatría, Buenos Aires, Argentina; ⁵Federación Argentina de Cardiología, Buenos Aires, Argentina

Introduction: Pulmonary arterial hypertension (PAH) is a multifactorial disease associated with high morbidity and mortality. However, the diagnosis and therapeutics strategies used in most of the Argentinean regions are poorly known. The advanced functional class (FC) is an indicator of poor prognosis and one of the therapeutic goals.

Aims: 1-To determine the impact of advanced FC in patients with PAH on established markers of poor prognosis, such as clinical, biomarker, hemodynamic, and echocardiographic parameter 2-To compare treatment strategies between an advanced and non advanced FC

Method: Between July 2014 and May 2015, 170 patients with confirmed PAH were prospectively included in a multicenter, collaborative, observational registry by 60 investigators from 20 provinces in Argentina. Inclusion criteria were as follows: 1-patients over three months of age; 2-mean pulmonary arterial pressure (mPAP) at rest ≥ 25 mmHg by right heart catheterization (RHC) and 3 - clinical stability in the absence of hospitalization in last month. WHO FC III or IV at diagnosis was defined as advanced (AFC) whereas WHO FC I or II were considered as non advanced (NAFC)

Results: Mean age was 50.5 years (SD 18) and 79% were female. According with the Nice classification, the distribution was: idiopathic 51.6%, inherited 1.6%, drugs

2.4%, connective tissue disease 15.3%, portal hypertension 1.6% and congenital heart disease 27.4%. WHO FC at initial diagnosis was: I: 3%; II: 27%; III: 45% and IV: 25% and during follow-up was: I: 19%, II 54%, III 21% and IV 6% ($p < 0.001$). AFC at initial diagnosis was 70% and during follow up 27% ($p < 0.001$). Clinical manifestations in AFC compared with NAFC was: syncope 11 vs 13% (NS); heart failure 30 vs 4% ($p < 0.001$); BNP 372 vs 158 pg/ml (0.02), NT-proBNP 1595 vs 668 pg/ml (0.012), TAPSE 17.2 vs 19.3 mm (0.032), pericardial effusion 18 vs 10% ($p = 0.020$); 6MWT 367 vs 373 (NS); CI 2.6 vs 2.8 (NS); RAP 12.3 vs 10 mm Hg (NS). PAH targeted drugs in AFC was = None in 26.7%, Monotherapy in 31.4% and Combined therapy in 41.9%.

Conclusion: In our registry of PAH, we observed a high percentage of patients with AFC (70%) at initial diagnosis and a significant decrease during follow-up (27%). Advanced FC at initial diagnosis was significantly associated with other variables of poor prognosis. These findings emphasize the need for strategies for early detection and therapy.

Functional capacity is predicted by right atrial volume in patients with pulmonary arterial hypertension. A cardiac magnetic resonance study

S A Sophia Anastasia Mouratoglou¹; G Giannakoulas¹; A Kallifatidis²;

T Panagiotidis¹; G Pitsiou³; I Stanopoulos³; S Hadjimiliadis¹; H Karvounis¹

¹Aristotle University of Thessaloniki, AHEPA University Hospital, 1st Department of Cardiology, Thessaloniki, Greece; ²Agios Loukas Hospital, Department of Radiology, Thessaloniki, Greece; ³Aristotle University of Thessaloniki, Respiratory Failure Unit, "G. Papanikolaou" Hospital, Thessaloniki, Greece

Background: Right heart function is of clinical importance in patients with pulmonary arterial hypertension (PAH). There is however scarce data on the role of right atrial (RA) indices in the evaluation of functional capacity of PAH patients. The aim of our study was to investigate the relationship of RA size and volume as assessed by cardiac magnetic resonance (CMR) with exercise capacity assessed by 6-minute walk test (6MWT) distance in adult patients with PAH.

Materials and methods: This was a cross sectional study including patients with PAH. All patients underwent CMR (Avanto Siemens 1.5T) and 6MWT at the same day. RA volumes were assessed in end-systole (RAESV) and end-diastole (RAEDV) according to Simpson's rule. 4-chamber view was used for the determination of RA area.

Results: Our study included 21 patients with PAH (9 with idiopathic PAH, 10 with PAH associated with connective tissue disease and 2 with portopulmonary arterial hypertension, mean age 54.5 ± 12.9 years) that walked 449.0 ± 104.4 m. After controlling for confounding parameters, a direct linear correlation between distance walked in 6MWT and RAESV, RAEDV, RA area in end-systole and end-diastole (Table). Multivariate regression analysis showed that RAESV was an independent predictor of distance walked in 6MWT.

Conclusion: RAESV is a predictor of functional capacity in PAH.

Predictors of functional capacity in PAH

		Univariate regression	Multivariable regression	
		r	p	B p

Pulmonary hypertension role in hospitalizations in Spain: (2005-2013)

M Mendez¹; R Barba²; E Botella¹; B Calvo¹; M Farid¹; N Munoz-Rivas³; JF Martin¹; M Varas¹; A Zapatero⁴; J Marco¹

¹Hospital Clinic San Carlos, Madrid, Spain; ²Hospital Rey Juan Carlos I, Madrid, Spain; ³Hospital Infanta Leonor, Madrid, Spain; ⁴Hospital de Fuenlabrada, Madrid, Spain

Objective: The aim of this study was to assess clinical characteristics, in-hospital admission caused by pulmonary hypertension (PH) in internal medicine wards.

Materials and Methods: Data from the Spanish National Minimum Basic Data Set (MBDS) of discharged admissions who were initially diagnosed of PH (from all internal medicine (IM) departments of Spanish National Health Care System hospitals between 2005 and 2013 were analysed (ICD-9: 416.8, 416.0). A descriptive data analysis was conducted comparing the administrative variables of all admissions in internal medicine with and without PH. A multivariate logistic regression analysis was performed, taking hospital mortality and hospital readmissions as dependent variables, and age, gender, comorbidity according to the Charlson comorbidity index (CHCI) and PH as independent variables.

Results: A total of 5,258,542 admissions in internal medicine were identified, of whom 205,038 were coded with PH. PH were more common in >75 years old patients (77.79 ± 10 vs 72.03 ± 17); p < 0.0001) and women (60% vs 47%; p < 0.0001). Among the comorbidities assessed, PH was more associated to the diagnosis of heart failure (64% vs 22%; p < 0.0001), atrial fibrillation (53% vs 21%; p < 0.0001), obesity (13% vs 8%; p < 0.0001), COPD (51% vs 36%; p < 0.0001) anaemia (24% vs 17%; p < 0.0001) and chronic renal dysfunction (20% vs 11%; p < 0.0001). Hospital readmissions due to any cause in patients with PH was 18% vs 14% in non-PH patients (p < 0.0001). PH maintained statistical significance in the regression model for readmissions: OR 1.336 (95% CI 1.282-1.393; p < 0.0001) after adjusting for gender, age, and CHCI.

Conclusions: In Spain, PH is an independent risk factor for hospital re-admission in internal medicine wards. In hospitalization, PH was mostly coded in elderly patients with comorbidities such as chronic heart failure, atrial fibrillation and pulmonary disease.

P490

S TWEAK content in platelets is lowered in patients with pulmonary arterial hypertension

R Remigiusz Kazimierzczuk¹; M Jasiewicz¹; K Kowal¹; B Sobkowicz¹; E Waszkiewicz¹; WJ Musial¹; KA Kaminski¹

¹Medical University of Białystok, Department of Cardiology, Białystok, Poland

Background: Pulmonary arterial hypertension (PAH) is a progressive disease characterized by proliferative changes in pulmonary arteries, which lead to deterioration in cardiopulmonary function. There is growing evidence suggesting that soluble tumor necrosis factor-like weak inducer of apoptosis (sTWEAK) could be involved in PAH development and progression. We hypothesized that circulating platelets may be an important source of sTWEAK and patients with PAH may present altered amount of TWEAK in platelets.

Methods: We enrolled 11 stable patients (48 ± 20 years old, 7 females) with confirmed diagnosis of PAH and 15 healthy controls matched for age and sex (46 ± 15 years old, 8 females). We obtained total blood sTWEAK capacity (serum) and sTWEAK present in circulating plasma (EDTA as anticoagulant). Platelets were isolated from citrate plasma by repeated centrifugation and homogenized in PBS for analysis of sTWEAK content.

Results: Most PAH patients had WHO class III (81.8%, n=9). Mean pulmonary artery pressure obtained during right heart catheterization was 60.4 ± 26 mmHg. Maximal exercise capacity was significantly limited with the average peak V_{O2} of 16.46 ± 7 ml/kg/min in PAH vs 30.8 ± 8.3 ml/kg/min in the control cohort, p < 0.0001. PAH group also manifested significant ventilatory inefficiency characterized by elevated VE/VCO₂ slope (48.48 ± 12.8 vs 24.6 ± 3.9, p < 0.0001). Patients with PAH presented significantly lower serum sTWEAK levels comparing to control subjects (184.8 ± 58 vs 257 ± 86 pg/ml, p = 0.027). Furthermore, there were no significant differences in sTWEAK concentrations in EDTA plasma samples (86.2 ± 36 pg/ml in PAH vs 90.3 ± 27.8 pg/ml in controls). The concentration of sTWEAK content in platelets was significantly lower in PAH group than in platelets of patients from control group (141.43 ± 16.76 vs 346.86 ± 54.73, p = 0.0008). PAH group presented lower number of platelets (182 ± 58 vs 242.6 ± 57.8 *1000/mcl, p = 0.008), however sTWEAK concentration in platelet lysates did not correlate with thrombocytes levels neither in PAH nor control groups, suggesting diminished platelet storage capacity in PAH patients. Difference between concentration of sTWEAK in serum and in EDTA plasma (released sTWEAK during clotting) was lower in PAH group (88 ± 61.6 vs 166.6 ± 86.1 pg/ml, p = 0.02). Interestingly, in combined PAH and healthy controls group (n=26) sTWEAK levels in platelets correlated positively with sTWEAK concentrations in EDTA plasma samples (r = 0.4, p = 0.04). Conclusions Patients diagnosed with pulmonary arterial hypertension present diminished storage capacity in platelets as well as lower serum sTWEAK concentrations. Platelets seem to be a major source of sTWEAK and could have an impact on pathophysiology of PAH, however the exact role of this phenomenon remains to be established.

Incremental benefit of echocardiographic imaging and cardiopulmonary exercise test in prognostic evaluation of idiopathic pulmonary arterial hypertension

R Badagliacca¹; S Papa¹; G Valli¹; B Pezzuto¹; R Poscia¹; G Manzi¹; S Sciomer¹; F Fedele¹; CD Vizza¹

¹Sapienza University of Rome, Dept. of Cardiovascular and Respiratory Science, Rome, Italy

Background: In idiopathic pulmonary arterial hypertension (IPAH) survival is strongly associated to right ventricle (RV) function.

Purpose: The aim of the study was to evaluate the incremental prognostic value of echocardiographic and cardiopulmonary exercise testing (CPET) on long-term prognosis compared to traditional clinical and hemodynamic parameters. Methods. One hundred-thirty naïve IPAH patients were enrolled in our centre and prospectively followed-up for the presence of clinical worsening (CW). Baseline evaluation included clinical, hemodynamic, echocardiographic and CPET parameters. Cox regression modeling with c-statistic evaluation was realized and internal validation of the Cox analysis based on bootstrapping was considered.

Results: During a mean period of 528 ± 304 days, 54 patients presented CW (53%). Among demographic, clinical and hemodynamic parameters, WHO functional class and cardiac index remained independent predictors of CW (Model-1). Adding echocardiographic and CPET variables (model-2) peak O₂ pulse and RV fractional area change (RVFAC) resulted the only independent factors, significantly improving the power of the prognostic model (AUC: 0.81 vs 0.66, respectively; p = 0.005). Combining together the ROC cut-off values of O₂ pulse and RVFAC, patients with high RVFAC/high O₂ pulse had significantly a better prognosis compared with the others. Patients with low RVFAC/low O₂ pulse and high RVFAC/low O₂ pulse showed 99.8 and 29.4 increase in the hazard ratio, respectively, compared with high RVFAC/high O₂ pulse (p = 0.0001).

Conclusions: RVFAC and O₂ pulse evaluation are able to increase the power of the prognostic model, allowing clinicians to identify at an early stage patients with normal RV systolic function at higher risk of right heart failure before hemodynamic instability appearing.

RIGHT VENTRICULAR FUNCTION

P492

Characteristics and outcome of patients with isolated right heart failure in acute heart failure syndrome

HS Hee-Sun Lee¹; SE Lee¹; W Choe¹; CH Kim¹; HJ Cho¹; HY Lee¹; ES Jeon²; SH Baek³; MC Cho⁴; BH Oh¹

¹Seoul National University Hospital, Department of Internal Medicine, Division of Cardiology, Seoul, Korea Republic of; ²Samsung Medical Center, Seoul, Korea Republic of; ³Seoul St. Mary's Hospital, Seoul, Korea Republic of; ⁴Chungbuk National University Hospital, Cheongju, Korea Republic of

Background: Though dysfunction of right ventricle itself can lead to heart failure (HF) with typical symptoms and signs, right HF has been out of picture till lately under the presumption that right heart is a secondary player in the interaction of HF where left ventricle has taken the initiative. Yet, the significance of right HF in determining clinical outcomes has recently become the subject of increasing interest. Purpose We sought to assess the prevalence, clinical characteristics, and outcome of isolated right HF in patients hospitalized for acute heart failure syndrome (AHFS).

Methods: We prospectively enrolled 5,625 consecutive patients hospitalized for AHFS in Korea from 2011 to 2014 (the Korean Acute Heart Failure [KorAHF] registry). They were classified by the ESC guidelines and patients with isolated right HF were compared to those with left heart failure with reduced ejection fraction (HFrEF) to describe their unique features and outcomes.

Results: In KorAHF registry, 131 patients (2.3%) were hospitalized for isolated right HF. Compared with heart failure and reduced LV ejection fraction group (HFrEF group, n = 2,270), isolated right HF group was younger (64.0 vs. 66.5 years, p = 0.008) and female dominant (55.0 % vs. 38.6%, p < 0.001). Cor pulmonale (12.2%) and pulmonary thromboembolism (11.5%) were two major causes of isolated right HF, while ischemia was the leading cause of HFrEF (41.2%). At admission, isolated right HF group had significantly lower blood pressure (systolic 118.8 vs. 126.9 mmHg, p < 0.001, diastolic 71.7 vs. 78.9 mmHg, p = 0.014), hemoglobin (12.4 vs. 12.9 g/dL, p < 0.001), and serum sodium level (132.6 vs. 137.4 mmol/L, p = 0.008). There was no significant difference in intensive medical care between the groups during admission. In-hospital mortality was twice as high in isolated right HF group than in HFrEF group (8.1% vs. 3.7%, p = 0.041). Pump failure was the leading cause of in-hospital death in both group. The post-discharge 1-year mortality was significantly higher in isolated right HF group (31.3% vs. 21.6%, p = 0.008). Systolic blood pressure <90 mmHg (adjusted HR 3.18, 95% CI 1.03 – 9.82, p = 0.044), serum albumin <3.5 g/dL (adjusted HR 3.24, 95% CI 1.51 – 6.95, p = 0.003) and serum sodium <135 mmol/L (adjusted HR 3.63, 95% CI 1.73 – 7.62,

$p=0.001$) on admission, and hemodialysis during admission (adjusted HR 7.72, 95% CI 2.23 – 26.66, $p<0.001$) were independent predictors for 1-year mortality in isolated right HF group.

Conclusions: Our analysis reveals that patients with isolated right HF admitted for acute symptoms aggravation have worse clinical prognosis and several unique features, including lower blood pressure and serum sodium levels compared to those with left heart failure. This result provides a new insight for isolated right HF, which may make a step forward to develop its proper management strategy.

Discordance of right atrial pressure and pulmonary capillary wedge pressure correlate significantly with impaired exercise tolerance and predict refractory heart failure

W Wataru Fujimoto¹; S Oishi¹; H Kawai¹; Y Tasaka¹; Y Taniguchi¹; K Okajima¹; A Shimane¹; S Kobayashi¹; T Onishi¹; T Sawada¹

¹Himeji Cardiovascular Center, Cardiology, Himeji, Japan

Background: Right atrial pressure (RAP) is usually correlated to pulmonary capillary wedge pressure (PCWP). On the other hand, higher RAP/PCWP ratio was known as a risk of adverse outcomes. However, it is not clear whether higher RAP/PCWP ratio is associated with impaired exercise tolerance.

Methods: We investigated consecutive 35 patients with chronic heart failure due to dilated cardiomyopathy who received right heart catheterization (RHC) and cardiopulmonary exercise testing (CPET) at in-patient setting (around the same time as RHC) and out-patient setting (around 3 months after first CPET). We defined patients as discordant group (Group D) whose mean RAP (mRAP) was over 5mmHg and RAP/PCWP ratio was over 0.5, and the rest as concordant group (Group C). We compared patients characteristics, background, parameters obtained from right heart catheterization (PCWP, RAP, and cardiac index), echocardiogram, and CPET ((peak VO₂/W, VE/VO₂ slope, and work rate (VO₂-WR relationship)) at in-patient and out-patient setting between groups.

Results: Six patients were divided into Group D. There were no significant differences in age, gender, LVEF, estimated GFR between two groups. NYHA functional class ($p=0.0009$) and BNP level were higher ($p=0.025$) in Group D. Exercise tolerance was significantly lower ($p=0.036$) in Group D, and work rate was tended to be impaired in Group D ($p=0.069$). And also exercise tolerance remained impaired at chronic phase in Group D ($p=0.016$).

Conclusion: This study indicated that patients with higher RAP/PCWP ratio show lower exercise tolerance and predict refractory heart failure. We have to investigate more and make sure of this fact.

The Tei index: a possible tool in assessing pulmonary embolism severity

This work was supported by CREDO Project - ID: 49182

M Dorobantu¹; A I Alexandru Ioan Deaconu¹; A Radu¹; S Iancovici¹

¹Clinical Emergency Hospital, Department of Cardiology, Bucharest, Romania

Introduction: The right ventricular (RV) myocardial performance (Tei) index is a global estimate of both systolic and diastolic function of the right ventricle. However, the value of the Tei index as a tool in the evaluation of the severity of pulmonary embolism (PE) has not been well investigated.

Objective: The objective of this observational retrospective study was to investigate the possible correlation between the RV Tei index and the early mortality risk of PE, as evaluated by validated clinical risk scores, imaging tests and cardiac laboratory biomarkers.

Methods: 50 patients diagnosed with acute PE by computed spiral tomography pulmonary angiography and classified as being at high, intermediate or low risk of early mortality were included in our study. All study population underwent a comprehensive echocardiographic study including tissue Doppler imaging (TDI) within first 12 hours of admission, with focus on different RV signs of pressure overload. The Tei index was measured by means of TDI, using the formula: (Tricuspid Valve Closure to Opening Time (ms) - RV Ejection time (ms)) / RV Ejection time (ms). Patients with concomitant cardiac or respiratory disease that could present signs of RV overload or dysfunction due to comorbidities were excluded from the study.

Results: In our study group, the patient risk categories were as follows: 21 patients were in the low early mortality risk category, 24 patients were in the intermediate risk category, and 5 patients in the high risk category. In this population, Tei index values of > 0.5 were powerful indicators of non-low risk category ($p<0.005$). However, in the > 0.5 category, Tei index values were unable to discriminate between intermediate and high risk of early mortality (no statistical significance).

Conclusion: Tei index accurately predicted patients that were at non-low early mortality risk, with a cut-off value of > 0.5, thus with a possible clinical impact in the process of decision making of whether to admit or discharge the patient. However, in our study group, it was unable to differentiate between intermediate and high risk patients, probably due to the low number of high risk patients.

P495

Use of ivabradine in patients with chronic cor pulmonale and right heart failure.

G Ganna Tytova¹; O Liepieieva¹; A S Al-Karawi¹; PG Kravchun¹

¹Kharkiv National Medical University, Kharkiv, Ukraine

Cor pulmonale is associated with development of right heart failure and tachycardia. Heart rate more than 70 beats per minute increases myocardial oxygen demand so it provokes myocardial ischemia. Prescription of beta-blockers in order to decrease heart rate is limited in patients with cor pulmonale due to their influence on hyperresponsiveness of airways.

Purpose : To investigate the influence of ivabradine on hemodynamics and HR in patients with chronic cor pulmonale.

Material and methods: 72 patients (38 men and 34 women, 41.3 ± 3.8 years of age) with chronic cor pulmonale on a background of COPD and bronchial asthma (non severe clinical course) without ischemic heart disease were examined. Patients were divided into 2 groups according to prescription of ivabradine in addition to basic treatment. The 1st group-36 patients with basic treatment of chronic cor pulmonale – Ca channel blockers (diltiazem), ACE inhibitors, low doses of loop diuretics; 2nd group-36 patients that were prescribed ivabradine 7.5 mg BD in addition to the basic treatment. All patients underwent a transthoracic echocardiography in A4C in dynamics of treatment within 12 weeks.

Results: Results of investigation are shown in the Table 1. It was found that patients of the second group that were taking ivabradine had statistically more significant tendency to normalization of structure-functional data of the right heart chambers due to significant decreasing of the heart rate.

Conclusion: Heart rate control has a big influence on the processes of heart remodeling. Thus, early prescription of ivabradine in patients with cor pulmonale could prevent worsening of right heart failure.

Comparison of echocardiography and cardiac magnetic resonance imaging in the evaluation of the right ventricle

S Soufia Naccache¹; W Sdiri¹; R Tlili¹; S Longo¹; A Mokaddem¹; Y Ben Ameur¹; MR Boujnah¹

¹Mongi Slim Teaching Hospital, La Marsa, Tunisia

Introduction: The physiological impact of the right ventricle has long been underestimated. Thus, the RV maintains adequate pulmonary perfusion and ensure low systemic blood pressure to prevent organ's congestion. However, the RV dysfunction may affect the left ventricular function, not only through direct mechanical interactions but also, by limiting the left ventricular pre-filling volumes. In our study, we aimed to compare echocardiography and cardiac magnetic resonance (CMR) imaging in the assessment of the RV during heart failure.

Patients and results: Thirty patients were collected, consecutively, during their hospitalization for heart failure in our department. CMR and echocardiography were realized during hospitalization. The right ventricular function was assessed by echocardiography using the tricuspid annular plane systolic excursion (TAPSE) and the pulsed wave doppler tissue imaging systolic velocity (S'), and by CMR using the measures of the right ventricular volumes and ejection fraction. Finally, 43% of patients had RV dilation in bi-dimensional echocardiography versus 13% in CMR with poor correlation between the 2 exams ($r=0.20$, $p=0.18$). We found also, a poor correlation between echocardiography and CMR for the assessment of the right ventricular function ($r=0.17$). Indeed, 36.7% of the patients had impaired right ventricular function on echocardiography versus 26% on cardiac magnetic resonance.

Conclusion: Right ventricular dilation and dysfunction are independent risk factors of mortality and cardiovascular events, this is particularly, important in case of heart failure. The assessment of the RV should be considered in the evaluation of the prognosis of cardiomyopathies. CMR imaging represents a good alternative, if the RV cannot be well studied by echocardiography.

Percutaneous stenting for aortic coarctation in children and adults: is it a valid option?

J C Joana Catarina Duarte Rodrigues¹; FS Saraiva²; MTS Tavares Silva²; SL Leite²; GP Pestana²; JCS Carlos Silva²; JM Moreira³; MC Campelo¹; JCA Carlos Areias³; MJM Julia Maciel¹

¹Sao Joao Hospital, Department of Cardiology, Porto, Portugal; ²Faculty of Medicine University of Porto, Physiology and Cardiothoracic Surgery, Porto, Portugal; ³Sao Joao Hospital, Pediatric Cardiology, Porto, Portugal

Background: Coarctation of the aorta (COA) accounts for 5-8% of all congenital heart defects. Traditionally, treatment for this condition is surgical. However, stenting for native or recurrent COA has become an important therapeutic strategy. The aim of this study was to evaluate the procedural safety and efficacy along with immediate and midterm results of stent implantation for either native or recurrent COA in children and adults.

Methods: We retrospectively reviewed the medical records of patients aged > 5 years who were submitted to endovascular treatment of COA in a tertiary care center between April 2009 and November 2015. Clinical, demographic and catheterization data were collected. Diagnosis of COA was based upon a combination of clinical signs, noninvasive imaging or invasive gradients measurements. Successful outcome was defined as peak systolic pressure gradient after stent implantation <20 mmHg.

Results: Forty-one patients underwent percutaneous repair of COA, 24% were associated with bicuspid aortic valve. The procedure was successful in 40 patients, all using femoral approach. Median age was 20 years (6 - 54), 73.2% were men, 73% had a native COA and 22% had a previous surgical repair of COA. Isolated balloon angioplasty was performed in one patient and one stent was inserted in the remaining cases, 93% were covered stents. The mean pre-procedural pressure gradient was 49 ± 15 mmHg and the mean post procedural pressure gradient was 11 ± 8 mmHg ($p < 0.001$). Acute complications were found in 28% of the procedures and included: 4 stent migrations, 1 sub-optimal stent expansion (but with no significant systolic gradient) and 5 complications related with femoral access vessel, 3 of whom required vascular surgery. Mean follow-up time was 35 ± 25 months. All patients were symptom free except one, who required reintervention with balloon angioplasty 20 months after the initial procedure. Comparing with pre-procedure antihypertensive therapy, the intervention led to discontinuation or reduction of therapy in 52% of cases ($p = 0.002$). Recurrent post-surgical COA was significantly associated with maintenance of antihypertensive medications ($p = 0.004$) and no other associations were found, namely age at intervention, gender or body mass index.

Conclusions: Stent implantation of native or recurrent COA is safe and effective in children and adult patients. Abnormal blood pressure values are not unusual, and blood pressure monitoring is mandatory after the procedure. Midterm follow-up suggests that the treatment is durable and may be considered an alternative to surgical repair, although a longer follow up is needed.

P498

Silent hypertension in normotensive subjects is a major risk factor for LVH

M El Shahawy¹; A Antonella Sabatini²

¹Cardiovascular Center of Sarasota, Cardiovascular Health Assessment Center, Sarasota, FL, United States of America; ²Careggi University Hospital (AOUC), School of Medicine and Surgery, Florence, Italy

Purpose: Elevated BP is a well-known risk factor for left ventricular hypertrophy (LVH), which might lead to heart failure. We have reported, previously, that abnormal

Table 60827

	526 (22%), no Medications, no Comorbidities regardless of BP					
	NT	Pre-HTN	HTN	A	B	C
	SBP <120 DBP <80	SBP 120-139 or DBP 80-89	SBP ≥140 or DBP ≥90	SBP 120-129 DBP <80	SBP 130-139 DBP <80	SBP 140+ DBP <80
	281 (53%)	179 (34%)	66 (13%)	81 (15%)	25 (5%)	12 (2%)
Abnormal BPrisePME	29 (10%)	45 (25%)	40 (61%)	19 (23%)	10 (40%)	5 (42%)
LVH	17 (6%)	19 (11%)	15 (23%)	5 (6%)	5 (20%)	5 (42%)
Abnormal BPrisePME and LVH	2 (7%)	8 (18%)	12 (30%)	3 (16%)	2 (20%)	3 (60%)

rise in BP post mild exercise (BPrisePME) is associated with structural and functional abnormalities. The purpose of this study was to assess whether abnormal rise in BPrisePME in normotensive subjects is associated with LVH, which ultimately might lead to heart failure.

Methods: We screened 2406 asymptomatic subjects, age 20-79, for CVD risk using ECVDRS, which consists of 10 tests: large (C1) and small (C2) artery stiffness, blood pressure (BP) at rest and post mild exercise (PME), Carotid Intima Media Thickness (CIMT), abdominal aorta and left ventricle ultrasound (LVUS), retinal photography, microalbuminuria, ECG, and pro-BNP. Abnormal blood pressure rise post mild exercise (BPrisePME) was defined as systolic BP rise >30mmHg post 3-min-walk at 7% elevation, 2.5mph. Normotension (NT), pre-hypertension (pre-HTN), and hypertension (HTN) were defined according to JCN7 criteria.

Results: Among the 2406 subjects (1258 Female and 1148 Male), 1679 were not taking any CV medication. Among these, 526 subjects had no comorbidities, regardless of BP values. These subjects were divided into 6 groups, NT, Pre-HTN, HTN, and according to their systolic BP values (SBP), in groups A, B and C respectively. Results are shown in Table.

Conclusions: Based on our data,

1. LVH is present even in asymptomatic normotensive subjects with no CV comorbidities and not taking any medications.

2. 7% of normotensive subjects who have abnormal BPrisePME, have LVH.

Accordingly, we recommend screening for abnormal rise in BP post mild exercise in all subjects and initiating appropriate treatment to avoid progression to LVH with well-known deleterious consequences, including heart failure.

Longitudinal and orthostatic changes of blood pressure predict dementia

HH Holm¹; K Nagga²; E Nilsson²; E Bachus¹; O Mellander¹; A Fedorowski³; M Magnusson³

¹Skane University Hospital, Department of Clinical Sciences, Lund University, Malmö, Sweden; ²Skane University Hospital, Clinical Memory Research Unit, Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden, Malmö, Sweden; ³Skane University Hospital, Department of Cardiology, Skane University Hospital, Malmö, Malmö, Sweden

Background: The role of blood pressure (BP) variability in dementia is arguable. The aim of this study was to analyse how resting and orthostatic BP changes relate to incident dementia over a long-term follow-up.

Methods: In a prospective population-based project, 18,240 study participants (mean age: 45±7 years, 63 % male) were examined with resting and orthostatic BP measurement at baseline (1974-92) and re-examined after 23±4 years (mean age: 68±6 years) with resting BP (2002-2006). A total of 428 participants (2.3%) were diagnosed with dementia through Dec 31, 2009. The association of resting and orthostatic BP changes with the risk of dementia was studied using multivariable-adjusted Cox regression models controlling for traditional risk factors.

Results: At baseline diastolic BP (DBP) decrease on standing was predictive of dementia (Hazard ratio (HR) per 10 mmHg: 1.22; 95% confidence interval (CI), 1.01-1.44, p=0.036). At re-examination, higher SBP and DBP lowered risk of dementia (HR per 10 mmHg: 0.94; 95% CI, 0.89-0.99, p=0.011; and 0.87; 0.78-0.96, p=0.006, respectively). SBP decrease between baseline and re-examination (4th quartile; -7±12mmHg) indicated increased risk of dementia (HR: 1.46; 95%CI, 1.11-1.93, p=0.008) compared with reference group (1st quartile; +44±13mmHg), as also did pronounced DBP decrease (4th quartile; -15±7mmHg,) compared with reference group (1st quartile; +15±7mmHg); HR: 1.54; 95%CI, 1.14-2.08, p=0.005.

Conclusion: Diastolic BP decrease on standing in the middle age, decline in BP between middle-and advanced age, and lower BP in advanced age are independent risk factors of developing dementia.

Abnormal rise in BP is associated with increased prevalence of LVH even in asymptomatic pre-hypertensive subjects

A Antonella Sabatini¹; M El Shahawy²

¹Careggi University Hospital (AOUC), School of Medicine and Surgery, Florence, Italy; ²Cardiovascular Center of Sarasota, Cardiovascular Health Assessment Center, Sarasota, FL, United States of America

Purpose: The purpose of this study was to assert whether abnormal rise in BP post mild exercise (BPrisePME) in pre-hypertension and hypertension is associated with increased prevalence in left ventricular hypertrophy (LVH).

Methods: We screened 2406 asymptomatic subjects, age 20-79, for CVD risk using ECVDRS, which consists of 10 tests: large (C1) and small (C2) artery stiffness, blood pressure (BP) at rest and post mild exercise (PME), Carotid Intima Media Thickness (CIMT), abdominal aorta and left ventricle ultrasound (LVUS), retinal photography, microalbuminuria, ECG, and pro-BNP. Abnormal blood pressure rise post mild exercise (BPrisePME) was defined as systolic BP rise >30mmHg post 3-min-walk at 7% elevation, 2.5mph. Normotension (NT), pre-hypertension (pre-HTN), and hypertension (HTN) were defined according to JCN7 criteria.

Results: Among the 2406 subjects (1258 Female and 1148 Male), 1679 were not taking any CV medication. Among these, 526 subjects had no comorbidities, regardless of BP values. These subjects were divided into 6 groups, NT, Pre-HTN, HTN, and according to their systolic BP values (SBP), in groups A, B and C respectively. Prevalence of abnormal structural and functional abnormalities are shown in Table.

Conclusions: Based on our data, abnormal rise in BP post mild exercise in pre-hypertension and hypertension is associated with increased prevalence in LVH as compared with normal control. Accordingly, we advocate screening for abnormal rise in BP post mild exercise in all subjects for identification of those at high risk for developing LVH with well-known grave consequences. Early detection and implication of appropriate treatment is better than late cure.

P501

Inter-arm blood pressure difference: the prevalence and characteristics in Korean general population

J-H Ju-Hee Lee¹; M-Y Rhee²; M-C Cho¹

¹Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of; ²Dongkuk University Ilsan Hospital, Cardiology, Goyang, Korea Republic of

Background: An increased inter-arm systolic blood pressure difference (IBPD) is an easily determined physical examination finding and a significant IBPD has recently been associated with worse cardiovascular outcome. But the prevalence of IBPD in Asian population is unknown and the relationship between IBPD and blood pressure (BP) variability is not yet determined. Method A representative population was selected by list-assisted random-digit dialing method from a city. The BP of two arms was simultaneously measured using validated automatic BP measurement devices for 3 times and an increased IBPD was defined as ≥10mmHg using the average of 3 BP differences obtained simultaneously in both arms.

Results: We recruited 497 subjects in this study, and 10 subjects were excluded because of inadequate ABPM measurements. Mean age was 46.9±9.4 years and 309 participants were female (63.4%). Overall systolic BP and diastolic BP were 118.5±13.4 mmHg and 75.1±10.3 mmHg and mean systolic IBPD was 5.7±4.0mmHg. Of the 487 subjects, 66 subjects (13.6%) had an increased systolic IBPD. Compared with those with normal IBPD, subjects with increased systolic IBPD showed higher clinic BP (127.2±13.7 vs. 117.2±12.8 mmHg in systolic BP, P<0.001; 78.7±11.2 vs. 74.6±10.1 mmHg in diastolic BP, P=0.002), higher

24-hour systolic BP (118.5 ± 12.0 vs. 115.6 ± 10.8 mmHg, $P=0.045$) and higher 24-hour pulse pressure (42.4 ± 7.4 vs. 40.2 ± 6.5 mmHg, $P=0.012$). The subjects with increased systolic IBPD showed higher 24-hour BP variability; increased standard deviation of daytime BPs, increased weighted standard deviation of BPs, increased coefficient of variation of daytime BPs and increased average real variability of both 24-hour BPs and daytime BPs (Table). There was no significant difference in nighttime dipping pattern of increased IBPD subjects.

Conclusion: In this community-based cohort, an increased IBPD is common and associated with an increased short-term BP variability.

Incremental rise in blood pressure from normotensive to hypertensive is a major risk factor for LVH

M El Shahawy¹; A Antonella Sabatini²

¹Cardiovascular Center of Sarasota, Cardiovascular Health Assessment Center, Sarasota, FL, United States of America; ²Careggi University Hospital (AOUC), School of Medicine and Surgery, Florence, Italy

Purpose: Hypertension is a major CV risk factor for left ventricular hypertrophy (LVH) and heart failure. The purpose of this study was to assess whether abnormal rise in BP post mild exercise (BPrisePME) might be the culprit and the clue for early detection of LVH in pre-hypertensive and hypertensive subjects.

Methods: We screened 2406 asymptomatic subjects, age 20-79, for CVD risk using ECVDRS, which consists of 10 tests: large (C1) and small (C2) artery stiffness, blood pressure (BP) at rest and post mild exercise (PME), Carotid Intima Media Thickness ? (C1MT), abdominal aorta and left ventricle ultrasound (LVUS), retinal photography, microalbuminuria, ECG, and pro-BNP. Abnormal blood pressure rise post mild exercise (BPrisePME) was defined as systolic BP rise >30mmHg post 3-min-walk at 7% elevation, 2.5mph. Normotension (NT), pre-hypertension (pre-HTN), and hypertension (HTN) were defined according to JCN7 criteria.

Results: Among the 2406 subjects (1258 Female and 1148 Male), 1679 were not taking any CV medication. Among these, 526 subjects had no comorbidities, regardless of BP values. These subjects were divided into 6 groups, NT, Pre-HTN, HTN, and according to their systolic BP values (SBP), in groups A, B and C respectively. Prevalence of abnormal structural and functional abnormalities are shown in Table.

HFPEF - HEART FAILURE WITH PRESERVED EJECTION FRACTION

P504

Hidden under metabolic syndrome: do many patients already have unrecognised HFpEF?

AM Jakstaite¹; J Celutkienė²

¹Vilnius University, Vilnius, Lithuania; ²University Hospital Santariskiu Klinikos, Vilnius, Lithuania

Background: Heart failure with preserved ejection fraction (HFpEF) is an epidemic problem associated with high morbidity and mortality rates. The importance of metabolic syndrome (MetS) in patients who already have diagnosed heart failure is widely discussed. However, there is a lack of knowledge on early development and diagnosis of HFpEF in metabolic syndrome.

Purpose: We hypothesised that a significant number of patients with MetS already have occult, undiagnosed HFpEF.

Methods: We evaluated 153 patients (mean age 57.59 ± 8.69 , 46.15% males, 53.85% females) with MetS: 115 patients were enrolled from the Lithuanian High Cardiovascular Risk primary prevention programme prospectively, and 38 patients retrospectively. Retrospective patients with HFpEF were referred to cardiopulmonary stress testing for differential diagnosis of dyspnea, and were enrolled as they satisfied MetS criteria and had left ventricle ejection fraction >55%. Subjects were classified as having MetS if they met three or more criteria of the National Cholesterol Education Program. Patients were only included if they had satisfactory cardiac ultrasound, cardiopulmonary stress assessments and required laboratory tests. We considered patients as having HFpEF if during cardiopulmonary test the peak VO₂ was ≤90% of predicted or/and BNP was 35 pmol/l or more. The t-test was used for comparison.

Results: Number of patients with reduced predicted VO₂ n=116 (75.82%), with increased BNP n=95 (62.09%), with both reduced predicted VO₂ and increased BNP n=76 (49.67%).

Conclusions: A significant number of metabolic syndrome patients have undiagnosed HFpEF. Therefore, there is a need for comprehensive future researches on this topic. BNP was better discriminator for the presence of HFpEF than VO₂ in MetS patients.

Gender disparity in heart failure patients with preserved ejection fraction

J-H Ju-Hee Lee¹; H-R Kang¹; D-H Bae¹; S-M Kim¹; S-Y Lee¹; J-W Bae¹; K-K Hwang¹; D-W Kim¹; M-C Cho¹

¹Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of

Background: Because relatively little attention has focused on the gender related differences in heart failure (HF), women have been underrepresented in HF clinical trials. And there are few data regarding the gender disparity in HF especially in patients with HF with preserved ejection fraction (HFpEF). **METHODS** We evaluated the HFpEF patients hospitalized for ADHF in ten regionally-representative tertiary university hospitals who registered in the Korean Acute Heart Failure (KorAHF) Registry from March 2011 to February 2014. HFpEF defined as EF ≥45%.

Results: A total of 5,625 patients were recruited and 1,769 patients (31.4%) were classified as HFpEF. Mean age was 72.0 ± 13.3 and 1,052 patients (59.5%) were male. Mean follow up duration was 787 ± 400 days. Women were older and showed higher prevalence of hypertension, valvular heart disease and atrial fibrillation and lower prevalence of previous MI and coronary revascularization. At baseline echocardiography, women showed higher LV EF, but they showed higher LA volume index, E/e' ratio and RV systolic pressure. Despite the higher EF, mean NYHA functional class of women was worse at baseline and NYHA functional class III and IV patients were more prevalent in women. But the improvement in mean NYHA functional class after treatment was significant in both genders. The use of ACE inhibitor, ARB, beta blocker and aldosterone antagonist was equal in both genders. Although the unadjusted in-hospital mortality and overall mortality were comparable, the adjusted in-hospital mortality and overall mortality were significantly higher in male.

Conclusions: There were significant gender disparity in baseline characteristics, clinical presentation and co-morbidity in HFpEF patients. The differences of gender can affect the prognosis variously, so we emphasize the importance of the approach concerning these differences.

P506

Which measurement of blood pressure is more associated with ejection fraction preserved heart failure without hypertension: central blood pressure or peripheral blood pressure?

G Kim¹; GM Kim¹; DM Moon¹; SN Lee¹; JH Kim¹; KW Moon¹; KD Yoo¹

¹The Catholic University of Korea, Seoul, Korea Republic of

Background: Peripheral systolic blood pressure (pSBP) has been used to predict ejection fraction preserved heart failure (HFpEF). However, the assessment of superiority between pSBP and central SBP (SBP2) to predict ASCVD in patients without hypertension (HTN) has not been fully established.

Methods: Two hundred and twenty patients (male:female ratio 115:105, mean age 54.2 ± 14.7 years) without HTN were enrolled from subjects who simultaneously received transthoracic echocardiography and non-invasively semiautomated radial artery applanation tonometry in the Department of Internal Medicine of our Hospital, from July 2011 to May 2015. Moreover, the area under the receiver operating characteristic curve (AUC) of SBP2 was compared with that of SBP to identify HFpEF.

Results: Thirty nine subjects (male:female ratio 20:19, mean age 65.9 ± 11.3 years) were diagnosed as HFpEF according to ESC guidelines for diagnosis and treatment of heart failure 2012. HFpEF patients had significantly higher pSBP (131 ± 20mmHg vs 126 ± 14mmHg), SBP2 (125 ± 21mmHg vs 116 ± 16mmHg) and pulse pressure (54 ± 19mmHg vs 49 ± 11mmHg) than the patients without HFpEF. After multivariate analysis after adjusted for age, gender, body mass index, fasting plasma glucose, diabetes, lipid profiles, antihypertensive medication and lipid-lowering medication, SBP2 (β = 0.231, 95% CI 1.036 to 1.289, p = 0.010) or pSBP (β = 0.887, 95% CI 0.800 to 0.982, p = 0.021) were associated with HFpEF. In addition, AUC (0.639) of pSBP was significantly greater than that of SBP2 to identify HFpEF. (P = 0.007).

Conclusions: Central blood pressure is superior to pSBP in identifying HFpEF, although both peripheral and central SBP are associated with HFpEF in patients without hypertension.

P507

Heart rate response and functional capacity in patients with advanced heart failure with preserved ejection fraction

E Dominguez Mafe¹; P Palau Sampo²; E Nunez Botero³; JM Ramon Ferrandis³; R Heredia³; J Gonzalez³; L Lopez⁴; J Melero Lloret¹; FJ Chorro Gasco³; J Nunez Villota³

Universitat Jaume I, Castellón, Spain; ³Cardiology Department. Hospital Clínico Universitario, INCLIVA. Universitat de València, Valencia, Spain; ⁴Facultat de Fisioteràpia. Universitat de València, Valencia, Spain

Background: The mechanisms of exercise intolerance in heart failure with preserved ejection fraction (HFpEF) are not yet elucidated. Chronotropic incompetence has emerged as a potential mechanism.

Purpose: We aimed to evaluate the relationship between heart rate (HR) response to exercise and functional capacity in advanced HFpEF patients.

Methods: We prospectively studied 40 HFpEF patients [50% NYHA III, 55% female, age (mean ± SD) 71.6 ± 8.6 years and 40% atrial fibrillation]. Functional performance was assessed by peak oxygen consumption (peak VO₂).

Results: The mean (SD) peak VO₂ was 10.2 ± 3.1 mL/min/kg. Following chronotropic parameters were calculated: Delta-HR (HR at peak exercise-HR at rest), chronotropic index (CI) = (HR at peak exercise-resting HR) / [(220-age)-resting HR] and CI according to the equation developed by Keteyian (CIK) as HR at peak exercise-HR at rest / [(119 + (HR at rest/2) - (age/2) - 5 - HR at

rest)]. In a bivariate setting, peak VO₂ was positively and significantly correlated with Delta-HR ($r = 0.33$, $p = 0.037$) and borderline with CI and CIK ($r = 0.30$, $p = 0.055$ and $r = 0.31$, $p = 0.050$, respectively). In a multivariable linear regression analysis chronotropic parameters were associated with peak VO₂. For increase in 10 bpm in Delta-HR and 0.1-unit increase in CI and CIK there was an associated increase in the mean of peak VO₂ of 0.32 mL/kg/min ($p = 0.040$), 0.27 mL/kg/min ($p = 0.015$) and 0.15 mL/kg/min ($p = 0.016$), respectively.

Conclusion: In patients with advanced HFpEF, the HR response to exercise was positively associated to patient's functional capacity.

See Figure 1. Functional form of the adjusted association among different chronotropic indexes and peak oxygen consumption. Variables modeled with fractional polynomials. Delta-HR, absolute difference between heart rate (HR) at peak exercise and HR at baseline; CI, chronotropic index, a measure of chronotropic response based on the Astrand formula; CIK, chronotropic index according to the equation of Keteyian; peak VO₂, peak oxygen consumption.

Evidence of pericardial abnormalities with potential haemodynamic significance is frequent in HFpEF patients: causality or causality?

B Benjamin Munoz Calvo¹; E De La Calle De La Villa¹; A Villa-Martinez¹; F Roman Garcia¹; V Nadador Patino¹

¹Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

Background: Due to obvious practical difficulties for invasive haemodynamic assessment the frequency of cardiac chamber compression from concomitant pericardial disease contributing to diastolic dysfunction (DD) in HFpEF patients is unknown.

Purpose: To evaluate by means of non-invasive methods how often patients with stage C HFpEF exhibit evidence of anatomical pericardial involvement and/or ultrasound functional abnormalities that, although not diagnostic of a definite cardiac compressive syndrome, may suppose a superimposed compromise of the myocardial diastolic function.

Methods: 207 patients with stage C HFpEF were retrospectively studied. Their clinical and ultrasound parameters and results of thoracic CT and cardiac MRI were recorded. Study subgroups were designed according to classical patterns of DD (I, II, III and IV). Categorical variables included the following signs of probable cardiac compression (SPCC): 1. Jugular veins distension and/or Kussmaul sign, if not serious pulmonary hypertension present (<40 mm Hg), 2. Moderate to severe pericardial effusion (> 10 mm) accompanied by RA collapse or paradoxical pulse; 3. Calcification or thickening (> 3 mm) of the pericardium with corresponding heart wall flattening, interventricular septal bounce or pericardial knock sound; 4. Respiratory variation of early transmitral flow > 25%; and 5. Estimated RA pressure > 15 mmHg (providing PSP <40 mmHg) along with typical abnormalities of the venous inflow (non collapse of IVC on inspiration ± hepatic veins expiratory reversal). Clinical outcome was analyzed by means of logistic regression.

Results: At least one SPCC was found in 28 cases (13.5%). Remarkably, while 21 out of 101 patients with types III/IV DD (20.7%) showed some SPCC, only 7 of the remaining (6.6%) evinced SPCC suggesting diastolic compromise of pericardial origin. Detection of 2 or more SPCC independently increased the risk of death or hospitalization from HF decompensation.

Conclusion: Significant pericardial involvement with possible haemodynamic transcendence is frequently seen in HFpEF patients with types II and IV DD, and it may represent an important independent risk factor. SPCC could be being underestimated in clinical practice thus avoiding the implementation of specific decompressive therapies in HFpEF.

P509

Defining the phenotype of stage B HFPEF progressers

M D Mark David Wilkinson¹; S James¹; C Watson²; E O'Connell¹; C Kenny¹; MD Ledwidge²; K McDonald¹

¹St Vincent's University Hospital, Cardiology, Dublin, Ireland; ²Conway Institute, Dublin, Ireland

Intro: Asymptomatic Left Ventricular Diastolic Dysfunction (LVDD) is defined as evidence of diastolic dysfunction, but normal systolic function, in the absence of the signs and symptoms of the clinical syndrome of heart failure (HF). The ACC/AHA define this clinical entity as Stage B Heart Failure. Our understanding of who is at greatest risk of progressing from Stage B HFPEF remains limited. We report a longitudinal analysis of progression from Stage B to identify a higher risk phenotype.

Methods: The STOP-HF Screening Service recruits patients at risk of developing heart failure. Criteria requires age > 40 and at least one of the following: (1) hypertension medicated for > 1 month; (2) dyslipidaemia (TC>5.0mmol/l and/or LDL>3.0mmol/l); (3) BMI>30; (4) vascular disease; (5) diabetes; (6) arrhythmia requiring therapy; (7) moderate to severe valvular disease. Those with established HF or left ventricular systolic dysfunction are not recruited.

We include 609 individuals with Stage B HFPEF in this analysis. Individuals who progressed from Stage B HFPEF to heart failure were classified as Stage B Progressers. Median follow-up for Progressers from time of baseline BNP to diagnosis of HF was 5.5 years. We define Stage B HFPEF as patients who are asymptomatic with Doppler-echocardiographic evidence of significant LVDD (LAVI>34ml/m² and septal E prime < 10mm). We define HFPEF as the presence of typical clinical signs and symptoms of the HF syndrome in the presence of a raised BNP with the aforementioned echocardiographic features. Baseline demography, medical and clinical parameters were recorded along with echocardiographic parameters, and biomarkers (including BNP). Comparison between subgroup was calculated according to appropriate statistical analysis.

Results: 28 of 609 were Stage B Progressers (4.6% over a Median of 5.5years). 40.8% of the Stage B cohort compared with 60.7% of Stage B Progressers were female. Median BNP at baseline was 28.3 pg/ml in the Stage B group compared with 102 pg/ml in Stage B Progressers. Median Age in the Stage B group was 66.7 at baseline, and 71.0 in the Stage B Progressers.

Conclusion: Our data suggests a high risk Stage B phenotype for the development of HF, comprising older age, female gender and higher baseline BNP. This higher risk cohort may be best suited to intervention strategies directed at prevention of HFPEF.

P510

Predictors of mortality in acute de novo heart failure with preserved ejection fraction in long-term follow-up

D-G Dae-Gyun Park¹; WW Seo¹; SE Kim¹; JH Lee¹; KR Han¹; DJ Oh¹; SH Kim²; JJ Park³; DJ Choi³

¹Hallym University Kangdong Sacred Heart Hospital, Seoul, Korea Republic of;

²Borame Hospital, Seoul, Korea Republic of; ³Bundang SNUH hospital, Sungnam, Korea Republic of

Background: Chronic heart failure with preserved ejection fraction (HFpEF) is reported to have a similar prognosis to heart failure with reduced ejection fraction. However, studies about acute de novo HFpEF have not been established.

Purpose: We sought to determine risk factors for all-causes mortality in patients with acute de novo HFpEF, including echocardiographic parameters, especially, left atrial size and pulmonary hypertension, which reflect chronic hemodynamic status of left ventricular diastolic dysfunction.

Methods: We enrolled consecutively 495 patients (mean age, 72 ± 13 years; 65% female) with acute de novo HFpEF, who were admitted to our hospital. Patient underwent echocardiography and assay of biomarkers (B-type natriuretic peptide, myoglobin etc.). Cox proportional-hazards model was used to assess risk factors for all-causes mortality.

Results: All-causes mortality was 43% over a median follow-up of 4.4 years. On univariate analysis, old age, female, diabetes mellitus, low body mass index, high TR pressure gradient, high inferior vena cava size, high BNP, low sodium level and high myoglobin were associated with all-causes mortality. After adjustment for covariates, Cox regression analysis revealed that old age ($P < 0.001$), low BMI ($P < 0.001$), high BNP ($P = 0.003$), low sodium ($P = 0.01$) and high myoglobin ($P = 0.001$) were independently associated with all-causes mortality. But, echocardiographic parameters such as left atrial size, TR pressure gradient and IVC size were not related to mortality.

Conclusions: Our study confirmed that age, BMI, BNP, sodium and myoglobin level were independent risk factors for all-cause mortality of acute de novo HFpEF. But, echocardiographic parameters reflecting left ventricular diastolic dysfunction failed to show clinical relevance.

P511

Body mass index and adverse outcomes in heart failure patients with preserved ejection fractionJ-H Ju-Hee Lee¹; H-R Kang¹; D-H Bae¹; S-M Kim¹; S-Y Lee¹; J-W Bae¹; K-K Hwang¹; D-W Kim¹; M-C Cho¹¹Chungbuk National University Hospital, Cardiology, Cheongju, Korea Republic of

Background: Obesity is a major risk factor for incident heart failure (HF). Paradoxically, in HF with reduced ejection fraction (HFrEF), a high body mass index (BMI) appears to be beneficial. However, there are few data regarding the relationship between BMI and outcomes in HF with preserved ejection fraction (HFpEF). Method We evaluated the HFpEF patients hospitalized for ADHF in ten regionally-representative tertiary university hospitals who registered in the Korean Acute Heart Failure (KorAHF) Registry from March 2011 to February 2014. HFpEF defined as EF $\geq 45\%$ and BMI were categorized according to WHO criteria for Asian (<18.5, 18.5 to 22.9, 23 to 24.9, and ≥ 25 Kg/m²).

Results: Among the 5,625 patients who were registered at KorAHF Registry, 1,769 patients (31.4%) were classified as HFpEF. Mean age was 72.0 ± 13.3 and 717 patients (40.5%) were male. Mean follow up duration was 787 ± 400 days. The patients were categorized to underweight (BMI <18.5 Kg/m², 207 patients, 11.8%), normal (18.5 \leq BMI <23 Kg/m², 731 patients, 41.6%), overweight (23 \leq BMI <25 Kg/m², 355 patients, 20.2%) and obese (BMI ≥ 25 Kg/m², 466 patients, 26.5%). Patients with higher BMI were younger, more often men, and more likely to have hypertension and diabetes. Obese patients showed the lowest mortality. In multi-variate analysis adjustment for 14 risk variables including age, sex, and N-terminal pro-brain natriuretic peptide, the hazard ratio for the mortality was increased in patients with lower BMI. (Figure).

Conclusion: Obesity is common in HFpEF patients and is accompanied by multiple differences in clinical characteristics. Independent of other key prognostic variables, there was a significant obesity-paradox in relationship between BMI and mortality in HFpEF.

Gender specific treatment effects of Spironolactone in Diastolic Heart Failure: Insight from ALDO-DHF

Federal Ministry of Education and Research Grant 01GI0205 (clinical trial program Aldo-DHF [FKZ 01KG0506])

TD Trippel¹; V Regitz-Zagrosek²; G Gelbrich³; L Mueller-Scholden³; R Wachter⁴; HD Dungen¹; X Taylor⁴; BM Pieske¹; F Edelmann¹

¹Charite - Campus Virchow-Klinikum, Department of Internal Medicine-Cardiology, Berlin, Germany; ²Charite - Campus Mitte (CCM), Gender Medicine, Berlin, Germany; ³University Hospital of Wurzburg, Institute for Clinical Epidemiology and Biometry, Wurzburg, Germany; ⁴University Medical Center Gottingen (UMG), Department for Cardiology and Pneumology, Gottingen, Germany

Background: Women are approximately two times more likely than men to develop HFpEF, a common condition without established therapy. Aldosterone stimulation may contribute to the progression of HFpEF. Long-term aldosterone receptor blockade in the randomized controlled ALDO-DHF trial improved left ventricular diastolic function in these patients. We aimed to assess differences in baseline

characteristics, cardiovascular structure and function and gender specific treatment effects of spironolactone in HFpEF.

Methods: This is a secondary, post-hoc analysis of the ALDO-DHF. Subjects were stratified according to sex. Clinical characteristics and cardiac structure and function were compared between men and women. Efficacy endpoints that reached significance in the comparison of Spironolactone vs. Placebo in ALDO-DHF were assessed in ANCOVA models for interaction of sex, treatment.

Results: 422 subjects (221 female) were studied. Mean age was 67 years. At baseline male vs female subjects differed significantly ($p < 0.001$), e.g. in NYHA class, Maximal workload, Peak VO₂, 6MWT distance, LV diameter, LV mass index, LAVI and SF 36 physical functioning score. Also, RR systolic ($p = 0.015$) and Mean arterial pressure ($p = 0.005$) differed significantly between subjects at baseline. In regard to effect of spironolactone vs. placebo, Systolic RR and Mean arterial pressure changed significantly from baseline to follow-up in both sex ($p < 0.001$, respectively), with no significant difference between both sex (ANCOVA $p = 0.079$ and $p = 0.93$ respectively). Change in pulse pressure was -0.8 (95% CI -4.4 to 2.6 , $p = 0.64$) in men and -8.2 (95% CI -11.6 to -4.9 , $p < 0.001$) in women, $p = 0.003$ for interaction of sex and treatment, $p = 0.043$ after Bonferroni-adjustment.

Conclusion: We observe distinct sex-differences in baseline clinical characteristics, structure and function in the ALDO-DHF population. A marked decrease of pulse pressure in women was documented. This finding may bear notable medical consequences.

Heart failure in women and their pathophysiological factorO Oswald Londono Sanchez¹; L Torres²; G Prior¹

¹Medical and Cardiology Centre, Dr. Londono, Barcelona, Spain; ²Barcelona Hospital Clinic, Barcelona, Spain

Abstract: Heart failure can occur in any age, no depend on sex, but in men and women the mechanism, even if is the same, the fact is that the compromise on pumping function is different. AIM We realized a follow-up with 100 female patients during hospitalization with heart failure as a mean diagnostic. These are patient between 60 and 75 years old, with different pathologies: diabetes mellitus, arterial hypertension, obesity, atrial fibrillation, and hypothyroidism. We observed their treatment comparing with a control group (100 men in heart failure) by administering vasodilator and diuretic drugs. Performed echocardiography doppler control, daily renal function, NT pro BNP levels control, oxide nitric response.

Results: We observed that ventricular dilation, hypertrophy as tachycardia is more typical in men. Our group demonstrated very fast response to beta blockers and diuretics. The ejection fraction increased in 10-15% faster than in control group. Oxide nitric had not the result we expected. But in men the effect is very high. NT pro BNP levels no were increased as a control group. Recovering renal function in women during heart failure depends on risk factors as diabetes mellitus, obesity, more characteristics for women.

Conclusions: In women heart failure has the same mechanism that in men, but more of the cardiac compensatory mechanisms during heart failure as Frank-Starling mechanism, ventricular dilation or hypertrophy and tachycardia present more complications in men; women recover sinus rhythm faster than men, hypertrophy is not characteristic and dilation recovers EF as pumping function is near normal. We do not observed increased sympathetic adrenergic activity in our patients and increased vagal activity to heart. Renin-angiotensin-aldosterone and antidiuretic hormone systems in women is compensated by vasoconstriction improving ventricular stroke volume by reducing afterload on the ventricle.

Table 3. NT-pro BN characteristics

NT-proBNP cutoff value of 125 pg/mL had the best sensitivity-to-specificity ratio and NPV to rule out asymptomatic LV moderate to severe diastolic or systolic dysfunction in patients at risk for heart failure:

1. Men younger than 60 years (sensitivity, 87.5%; specificity, 92.7%; NPV, 99.5%; positive predictive value [PPV], 33.3%)
2. Women younger than 60 years (sensitivity, 100%; specificity, 84.1%; NPV, 100%; PPV, 33.3%)
3. Men at least age 60 years (sensitivity, 100%; specificity, 77.1%; NPV, 100%; PPV, 32.5%)
4. Women at least age 60 years (sensitivity, 100%; specificity, 69.9%; NPV, 100%; PPV, 21%)

Cardiorenal effects of intravenous thrx-215409, a novel neprilysin inhibitor, in a canine model of acute heart failure

Funded by Theravance Biopharma
S S Hegde¹; R M Baldwin¹; D L Bourdet¹; A D Hughes¹; A J Alexander
Mcnamara¹

¹Theravance Biopharma, Discovery Biology, South San Francisco, United States of America

Introduction: Acute heart failure (AHF) episodes are associated with unacceptably high mortality and rehospitalisation rates despite treatment with conventional therapies including furosemide (FUR). Adverse consequences of AHF may be related to inadequate compensation by protective endogenous neurohormonal systems including natriuretic peptides (NP) such as atrial NP, brain NP and C-type NP which are degraded by the enzyme neprilysin (NEP). Acute NEP inhibition elevates the levels of endogenous NP which could offer short and long-term therapeutic benefit by exerting protective cardiorenal effects, neurohormonal inhibition and end-organ protection.

Purpose: To assess the haemodynamic, renal and neurohormonal effects of intravenous (IV) THRX-215409 (THRX), a potent and selective NEP inhibitor, when co-administered with FUR in a canine model of AHF.

Methods: Mongrel dogs, paced 10 days at 240 beats per min, were anaesthetised and instrumented for assessment of hemodynamic and renal function. After a 30-min baseline, dogs were treated IV with vehicle (V), FUR (0.1 mg/kg/hr) or THRX (3 mg/kg/hr) + FUR (0.1 mg/kg/hr) for two 30 min treatment periods, followed by a 30 min recovery.

Results: THRX + FUR increased urinary cGMP output to a significantly greater magnitude than FUR (47711 ± 13519 vs 25481 ± 3382 moles/30 min; $p < 0.01$), which was consistent with NEP target engagement. THRX + FUR reduced left ventricular end-diastolic pressure to a significantly greater extent than FUR alone (change from baseline: -8 ± 2 vs -5 ± 1 mmHg, $p < 0.05$) without altering mean arterial pressure (MAP; -3 ± 3 vs 4 ± 6 mmHg). THRX + FUR produced a significant increase in glomerular filtration rate (GFR) relative to FUR (20 ± 13 vs -1 ± 7 mL/min, $p < 0.05$). THRX + FUR and FUR produced similar diuretic (38 ± 10 vs 39 ± 10 mL/30 min) and natriuretic (4.8 ± 1.6 vs 5.2 ± 1.5 moles/30min) effects. THRX + FUR, compared to FUR, produced significantly greater decreases in plasma renin activity (change from baseline: -3 ± 1 vs 2 ± 1 ng/mL/hr, $p < 0.005$) and plasma angiotensin II levels (-48 ± 20 vs 41 ± 15 pg/mL, $p < 0.005$). FUR and THRX + FUR had similar effects on renal blood flow, cardiac output, plasma norepinephrine and aldosterone levels.

Conclusion: In a canine model of AHF, THRX + FUR is more effective than FUR alone at reducing ventricular filling pressures, suppressing renin-angiotensin system activity and improving GFR. The salutary cardiorenal effects of THRX were accompanied by preservation of the renal effects of FUR and had no impact on MAP. These preclinical findings support clinical investigation of the efficacy of THRX-215409 in AHF.

Short and long-term prognostic Impact of QRS duration at baseline in acute heart failure population: insight from HEARTS

AH Ahmad Hersi¹; N Alfuraih¹; K Alhabib¹; H Alfaleh¹; W Alhabib¹; T Kashour¹; A Alasfar¹; F Alshaer¹

¹King Khalid University Hospital (KKUH), Riyadh, Saudi Arabia

Objective: Predictors of mortality in heart failure (HF) are widely studied and examined in order to utilize therapeutics and interventions preventing undesired outcomes. Interventricular conduction delays, defined as prolonged QRS duration (> 120 ms), have been shown to affect outcomes in HF population, however, there is limited data with wider QRS during in HF patients. Therefore, we evaluated the association between QRS duration of (≥ 150 ms) and short and long term outcomes in HF cohort.

Methods & Results: Data was gathered from the HEart function Assessment Registry Trial in Saudi Arabia (HEARTS). A national multicenter project, studying clinical features, management, short- and long-term outcomes, and mortality predictors in patients admitted with acute decompensated heart failure (ADHF). The registry enrolled 2609 ADHF patients admitted to 18 hospitals in Saudi Arabia between October 2009 and December 2010, and followed mortality rates until January 2013. Registering 2609 patients with diagnosed and de novo HF. The cohort was divided into two groups. Group 1 were patients with a QRS duration of ≥ 150 ms at baseline. Group 2 were patients with QRS duration < 150 ms in duration. The first group (QRS duration ≥ 150 ms $n = 116$) showed an independent association with worse clinical outcomes and higher adjusted in-hospital, 1-year, 2-year and 3-year mortality rates 15.52%, 37.93%, 43.97% and 44.83% respectively. Compared to the second group (QRS duration < 150 ms $n = 2489$) 6.11%, 18.64%, 22.62 and 23.38% respectively ($p < 0.001$). These findings were independent of the morphology of the QRS at baseline.

Conclusion: QRS duration wider than 150ms at baseline is strongly associated with increased short and long-term mortality in HF population. Moreover, greater QRS width proportionately increases the association with worse outcomes.

Suppressive effect of epigallocatechin 3-O-gallate on endoglin molecular regulation in myocardial fibrosis in vitro and in vivo

Shin Kong Wu Ho-Su Memorial Hospital (Taipei, Taiwan) to Lin, CM (grant number: SKH-8302-102-0501)

CM Chiu-Mei Lin¹; KG Shyu²; BW Wang³; H Chang¹; SK Chua²

¹Shin Kong Wu Ho-Su Memorial Hospital, Emergency Medicine, Taipei, Taiwan

ROC; ²Shin Kong Wu Ho-Su Memorial Hospital, Cardiology, Taipei, Taiwan ROC;

³Shin Kong Wu Ho-Su Memorial Hospital, Central Laboratory, Taipei, Taiwan ROC

Background: Epigallocatechin-3-O-gallate (EGCG), derived from green tea, has been studied extensively because of its diverse physiological and pharmacological properties.

Purpose: This study evaluates the protective effect of EGCG on angiotensin II (Ang II)-induced endoglin expression in vitro and in vivo.

Materials and Methods: Cardiac fibroblasts (CFs) from the thoracic aorta of adult Wistar rats were cultured and induced with Ang II. Western blotting, Northern blotting, real-time PCR, and promoter activity assay were performed. Through in vivo AMI-related myocardial fibrosis study, immunohistochemical and confocal analyses were performed, and hemodynamic monitoring data were measured.

Results: Ang II increased endoglin expression significantly as compared with control cells. The specific extracellular signal-regulated kinase inhibitor SP600125 (JNK inhibitor), EGCG (100 mM), and c-Jun N-terminal kinase (JNK) siRNA attenuated endoglin proteins following Ang II induction. In addition, pretreated Ang II-induced endoglin with EGCG diminished the binding activity of AP-1 by EMSA. Moreover, the luciferase assay results revealed that EGCG suppressed the endoglin promoter activity in Ang II-induced CFs by AP-1 binding. Finally, EGCG and the JNK inhibitor (SP600125) were found to have attenuated endoglin expression significantly in Ang II-induced CFs, as determined through confocal microscopy. Following in vivo AMI-related myocardial fibrosis study, as well as immunohistochemical and confocal analyses, after treatment with endoglin siRNA and EGCG (50 mg/kg), the area of myocardial fibrosis reduced by 53.4% and 64.5%, and attenuated the left ventricular end-diastolic and systolic dimensions, friction shortening in hemodynamic monitor.

Conclusions: Epigallocatechin-3-O-gallate (EGCG) attenuated the endoglin expression and myocardial fibrosis in vitro and in vivo, the novel suppressive effect was mediated through JNK/ AP-1 pathway.

Family support and self-care behaviors in individuals with heart failure: an integrative review

M Dakhteh Harouni¹

¹Sciences Nursing Department, university of Welfare and Rehabilitation. Iran, Tehran., Nursing, Tehran, Iran (Islamic Republic of)

Objective: The purpose of this review is examine and synthesize recent literature regarding the relationship between social support and self-care behaviors in individuals with heart failure(HF).

Background: self-care is an important factor in maintaining health and well-being for individuals with heart failure. self-care behaviors are an integral component of self-care, and maybe impacted by the disease process of heart failure. However, family support may positively influence an individual's self-care behaviors by associated with activities associated with maintaining heart failure-related treatment regimens. This review will synthesize the current knowledge related to the influence of social support on heart failure self-care behaviors.

Design: Using and integrative review method, a review of current empirical literature was conducted utilizing CINAHL, Science Direct, and PubMed computerized databases for a period of January 2004 to December 2014.

Results: Family support appears to have a positive relationship on heart failure self-care behaviors, can also provide a variety of real and perceived resources including emotional support, instrumental support or tangible. Family plays an important role in helping people to maintain positive self-care behaviors. Despite the multidimensionality of the concept, should be focus on a support and often emotional support for self-care behaviors in heart failure patients.

conclusion: Family support is effective in engaging and decision- making related to self care behaviors in HF patients and self-confidence is a potential mediator of this relationship.

Predictive model for in-hospital outcome in ST elevated myocardial infarction complicated with acute heart failure

M Sladojevic¹; S Sladojevic²; J Dejanovic¹; A Redzek¹; S Susak¹;

M Golubovic¹; N Gocic-Peric¹; J Rajic¹

¹Institute of Cardiovascular Diseases Vojvodina, Novi Sad, Serbia; ²Faculty of technical sciences, University of Novi Sad, Novi Sad, Serbia

Introduction: Acute ST elevated myocardial infarction (STEMI) represents often the underlying condition for the development of acute heart failure (AHF). The aim of this

study was to develop predictive model for in-hospital outcome in patients presenting with acute STEMI and AHF, after primary percutaneous coronary intervention (pPCI).

Methods: A total of 1495 patients with STEMI were admitted to our hospital and treated with pPCI during 36 months. In this study we analyzed 45 (3.01%) of them, which were presented with symptoms and clinical signs of AHF. Each patient was initially described using 386 attributes (clinical and demographic characteristics, biochemical analysis of blood parameters, echocardiographic parameters, and diagnosis codes). Model induction and evaluation was conducted within the widely used Waikato Environment for Knowledge Discovery.

Results: The in-hospital mortality was 26.67%. Mean age was 65.87 ± 10.84 . Survivors were younger (64 ± 10.88 vs. 68.33 ± 10.81 , $p=0.363$). Most subjects were male, 60.00%. Regarding to gender there wasn't statistically significant difference in those with in-hospital mortality (male 18.5% vs. female 38.9%, $p=0.175$). There was 68.9% with previously hypertension, 53.4% diabetics and 46.63% with preserved left ventricular ejection fraction ($\geq 45\%$). Model for predicting in-hospital mortality was developed by boosting the Decision Stumps machine learning algorithm (accuracy 82.2%, AUC=0.856). It is one of the simplest weak classifiers, which is a one-level decision tree. Boosting trained an army of Decision Stumps which each focus on one part of the characteristics of the data. Features selected as most important were: Left Ventricular Internal Diameter at end diastole (in survivors 5.29 ± 0.34 vs. in those with lethal outcome 5.49 ± 0.578 ; $p=0.373$), Right Ventricular Systolic Pressure (lower values in survivors 36.83 ± 2.18 vs. 39.28 ± 10.06 ; $p=0.566$), Fibrinogen (lower values in survivors 3.44 ± 0.722 vs. 4.94 ± 1.62 ; $p<0.005$), Sedimentation (higher in those with lethal outcome 10 vs. 34.83 ± 22.79 ; $p=0.304$), time elapsed from pain occurrence to admission to hospital (334.29 ± 283.25 in survivors vs. 223.89 ± 153.70 in those with lethal outcome; $p=0.169$), Mitral Regurgitation (MR) (severe MR in 11.1% of patients) and present QS complexes (in 34.2% of patients).

Conclusion: Although selected features are not all statistically significant as standalone predictors, machine learning algorithm utilized their combination, so predictive model for in-hospital outcome with good predictive performances has been made and ready for usage in clinical practice.

P520

Predicting the development of cardiogenic shock in myocardial infarction

I Irina Sukmanova¹; OST Olga Tanana¹

¹Altay region cardiologist hospital, acute infarction, Barnaul, Russian Federation

Purpose: To develop a mathematical formula to calculate the risk of developing cardiogenic shock in patients with AMI.

Methods: We examined 55 patients with mi aged 56-85 years. The first group consisted of 29 patients (14 men and 15 women) at the age of 66.8 ± 1.2 years, complicated by cardiogenic shock, second - 26 patients (15 men and 11 women) at the age of 66.4 ± 1.0 years without cardiogenic shock. All admission underwent standard laboratory tests with dynamic assessment of the level of troponin I, D-dimer. Repeatedly recorded 12-lead ECG was performed the echocardiography, the coronary angiography on the unit of General Electric, was measured central hemodynamic parameters. The

Results: Patients in compared groups were matched for age, both groups were dominated by men. In the first and second groups of more than 60% of patients with IMPT (at 65.5% and 61.5%, respectively, $p<0.05$). Patients with back, they were almost 2 times more in the 1st group (CABG) than in the second (10 (34.4%), against 5(19.2%), with 2/3 of them involved the right ventricle. More than 60% (62.2%) patients in the CABG group and 61.5% in the group without CABG was performed revascularization ISA. The "symptom-balloon" in the group with CABG when INT was 2 times longer and amounted to 420 minutes than in those without CABG (210, $p<0.05$), which was an important factor determining the development of complications. Thrombolytic therapy is carried out 10 (52.6%) patients with INT in the 1st group and 6 (37.5%) patients of the second group. PCI completed 18(62%) patients of the first group and 14(53.8 percent) in the second. Pharmacoinvasive strategy (TLT+PCI) due to non-delivery of the patient in the first 120 minutes were used in 5(27.2%) patients of the first group and 4(15.4 %) second. Most patients of the 1st group, they developed in the first day, admission CABG were signs in 8(27.5%) patients. The garden in the first group at admission was less than during the second (96.5 % against 138.4, $p<0.01$). To predict the development of shock on the obtained data was applied stepwise discriminant analysis selected the most important predictors of the development of CABG. For these factors amounted to equations linear discriminating functions for each group. To predict outcome in new patients of the equation 2 is calculated: Shock(+) = $-308,4 + 0,22 \cdot \text{AD}(p) + 4,47 \cdot \text{Sat} + 0,44 \cdot \text{GFR} - 0,32 \cdot \text{Troponin} + 0,61 \cdot \text{Creatinine} - 0,0011 \cdot \text{income} + 6,37 \cdot \text{Potassium} + 0,37 \cdot \text{Glucose} + 0,32 \cdot \text{Hemoglobin}$; Shock(-) = $-288,0 + 0,16 \cdot \text{AD}(p) + 4,21 \cdot \text{Sat} + 0,49 \cdot \text{GFR} - 0,22 \cdot \text{Troponin} + 0,66 \cdot \text{Creatinine} - 0,0014 \cdot \text{income} + 7,66 \cdot \text{Potassium} + 0,28 \cdot \text{Glucose} + 0,29 \cdot \text{Hemoglobin}$. Each patient can be assigned to the group corresponding to the maximum value of the function, with a probability of 83.6 per cent.

Conclusions: Thus, a multivariate mathematical model based on the method of discriminant analysis to predict the development of shock.

Endothelial leptin receptor signalling contributes to the development of cardiac hypertrophy and fibrosis following chronic pressure overload in mice

Deutsche Forschungsgemeinschaft

R Gogiraju¹; A Hubert²; T Muenzel¹; G Hasenfuss¹; K Schaefer²

¹Department of Cardiology and Pulmonary Medicine, Goettingen, Germany;

²University Medical Center of Mainz, Center for Cardiology, Cardiology I, Mainz, Germany

Background: The adipokine leptin and its receptors are expressed in the heart, and leptin has been shown to promote cardiomyocyte hypertrophy and collagen production in fibroblasts. Leptin expression in cardiomyocytes increases after mechanical stretch, and heart failure in humans is associated with elevated serum leptin levels. In the past, it has been difficult to dissect any direct effects of leptin on the heart from those associated with its role in body weight regulation. Endothelial cells play an important role during cardiac remodelling processes, among others via secretion of paracrine factors acting on cardiomyocytes and other cells in the heart.

Purpose: To determine the role of endothelial leptin signalling for the cardiac remodelling in response to chronically increased pressure overload.

Methods: Cardiac hypertrophy was induced by transverse aortic constriction (TAC) in mice with inducible, endothelial-specific deletion of leptin receptors (End.LepR-KO) and controls (End.LepR-WT).

Results: Western blot analysis confirmed reduced leptin receptor expression in endothelial cells isolated from End.LepR-KO mice ($24 \pm 5.1\%$ of controls). Survival after TAC did not differ between genotypes: i.e. 17 out of 37 (46%) End.LepR-WT and 14 out of 30 (47%) End.LepR-KO mice died within the observation period of 20 weeks ($P=0.304$). Echocardiography revealed that endothelial leptin receptor deletion improved LV function ($P<0.01$) and was associated with reduced LV dilation ($P<0.01$) and cardiac hypertrophy ($P<0.001$). Histological analysis demonstrated a significantly greater mean cardiomyocyte cross-sectional area in banded hearts from End.LepR-WT compared to End.LepR-KO mice ($P<0.05$) as well as increased cardiac fibrosis, as determined by Masson trichrome ($P<0.05$) and sirius red ($P<0.01$) staining, whereas the number of CD31-positive endothelial cells was reduced ($P=0.056$). Western blot analysis confirmed elevated leptin protein levels in banded hearts of WT mice (1.3-fold increase vs. sham), however, activated LepR signalling was observed only in End.LepR-WT mice and blunted in their End.LepR-KO counterparts, as indicated by reduced levels of phosphorylated STAT3 and total SOCS3 expression. Moreover, significantly increased cardiac levels of VCAM1 in End.LepR-WT, but not in End.LepR-KO mice suggested that endothelial leptin receptor deletion protects against the development of endothelial dysfunction. In line with the more pronounced cardiac hypertrophy observed echocardiographically and histologically in End.LepR-WT mice, cardiac levels of mTOR were significantly increased (2.4 ± 0.6 -fold change vs. sham), but not in End.LepR-KO mice (0.9 ± 0.1 -fold change vs. sham; $P<0.05$).

Conclusions: Our findings suggest that activation of leptin signalling in endothelial cells, for example by elevated leptin produced in hypertrophic cardiomyocytes, contributes to pathological cardiac remodelling following chronic pressure overload.

P522

Histologic and histometric characterization of myocardial fibrosis in end-stage hypertrophic cardiomyopathy: a clinical-pathological study of 30 explanted hearts

G Galati¹; O Leone²; F Pasquale¹; E Biagini¹; F Grigioni¹; E Pilato³; C Rapezzi¹

¹Institute of Cardiology, Department of Experimental, Diagnostic and Specialty

Pathology, Department of Experimental, Diagnostic and Specialty Medicine,

S.Orsola-Malpighi University Hospital, Bologna, Italy; ³Cardiac Surgery,

Department of Experimental, Diagnostic and Specialty Medicine, S.Orsola-Malpighi University Hospital, Bologna, Italy

Background: Myocardial fibrosis is frequently found by cardiovascular magnetic resonance (CMR) in hypertrophic cardiomyopathy (HCM), particularly in End-Stage HCM (ES-HCM) and showed to carry an ominous prognosis. Nonetheless, extent and distribution of fibrosis were never pathologically characterized.

Objectives: To assess overall amount, base-to-apex, circumferential and epicardial/endocardial distribution, pattern and type of myocardial fibrosis in a group of transplanted ES-HCM. To evaluate quantitative relationship between CMR and histometric assessment of fibrosis (subgroup analysis).

Methods: For each heart, a whole midventricular short-axis section (subdivided into 10 samples), three samples from basal and three from apical level were considered. Histomorphometric analysis was carried out.

Results: Thirty hearts examined. Overall Fibrosis: 37.3%. Left-Ventricular (LV) base-to-apex distribution (% of assessed myocardium): 31.9% basal, 43% medium and 46.2% apical level. Midventricular short-axis section: circumferential distribution (% of overall fibrosis within the section): anterior, anterolateral, inferolateral, inferior LV walls (11.9%; 15.8%; 7.0%; 24.3% respectively); anterior, medium and posterior septum (11%, 10.7%, 11.4% respectively); anterior and inferior Right-Ventricular walls (3.4%, 4.5% respectively). Midventricular short-axis section: epicardial-endocardial distribution (% of overall fibrosis within the section): trabecular 26.1%; subendocardial 20.2%; midwall 33.4%; subepicardial 20.3%. Main patterns identified: midwall 33.3%, transmural 23.3%, midwall and subepicardial 23.3%, midwall and subendocardial 20%. Fibrosis Type: replacement 53.3%, mixed 33.3% and perimycocyte interstitial fibrosis 13.3%. Comparison LGE-histological quantification of fibrosis: mean difference = 11%.

Conclusions: In hearts of ES-HCM undergoing heart transplantation the amount of myocardial fibrosis was very marked; there was a clear growing base-to-apex gradient. The most represented pattern was midwall, while subendocardium and subepicardium were never exclusively involved. The LV inferior and anterior walls and the entire septum are maximally affected, whereas the inferolateral wall was significantly spared. Replacement fibrosis was the predominant type and it was marked and typical of older patients. There was a good correlation between LGE-CMR and histometric quantification of fibrosis. These observations have numerous potential implications on the understanding of the HCM pathophysiology and on interpretation of imaging techniques.

miR-181a mediates the effects of the CB1 inhibition on cardiac remodelling

A E Foinquinos Marin¹; J Fiedler¹; S Thanscheid¹; A Zimmer²; C Nozaqui²; K Xiao¹; R Geffers³; A Just¹; S Batkai¹; T Thum¹

¹Hannover Medical School, Institute for Molecular and Translational Therapeutic Strategies, Hannover, Germany; ²University of Bonn, Institute of Molecular Psychiatry, Bonn, Germany; ³Helmholtz-Zentrum für Infektionsforschung GmbH, Genomanalytik, Braunschweig, Germany

Purpose: The endocannabinoid system is increasingly studied in the cardiac field due to its role in fibrosis, inflammation and cell fate modulation. The deregulation of this system has been implicated in myocardial infarction (MI) and consequent heart failure development. A recent study suggests cannabinoid receptor 1 (CB1) inhibition to improve cardiac function and to reduce adverse remodelling in response to cardiac stress, but the exact underlying molecular mechanisms of these beneficial effects remain unknown. MicroRNAs (miRNAs, miRs) provide a complex layer of post-transcriptional regulation modulating key biological processes such as tissue remodelling in heart failure. The aim of the present study was to explore microRNA pathways in the chronic effect of CB1 receptor inhibition after angiotensin-fibrosis induction and left ventricular remodelling.

Methods and Results: Adverse cardiac remodelling was induced in mice by chronic administration of Angiotensin II (AngII, 1.5 mg/kg/day) with osmotic minipumps for 14 days. Treatment with CB1 antagonist, or vehicle was delivered every second day during the AngII administration period. Hemodynamic parameters were measured by echocardiography and cardiac pressure-volume catheter and tissue samples were taken for molecular and histological analysis. After two weeks of AngII infusion, left ventricular dysfunction was prevented by CB1 antagonist treatment. This was shown by significantly improvements of the myocardial performance index and end-diastolic pressure values. At the tissue level, anti-fibrotic effects of CB1 antagonist treatment were confirmed histologically and by expression analysis of pro-fibrotic genes. These beneficial effects were also observed in CB1 KO mice and in an aging mouse model. The particular role of tissue fibroblast in AngII-induced cardiac fibrosis was further explored. Primary cardiac fibroblasts (CF) from each experimental group were isolated and analysed by next generation deep RNA sequencing to identify differentially regulated microRNAs. MicroRNA-181a was downregulated by in vivo AngII delivery and vice versa upregulated after CB1 antagonist treatment. Foxb1 (a direct target of miR-181a) was differentially regulated, suggesting a possible mechanism of action for the benefits of CB1 receptor inhibition. Mir-181a KO mice confirm these results on a functional and molecular level.

Conclusion: We found that in AngII-induced cardiac remodelling, LV function is preserved by chronic CB1 antagonist treatment and that cardiac fibrosis is reduced with concomitant downregulation of pro-fibrotic genes. Also, CF-enriched miR-181a seems to be sensitive to CB1 antagonist treatment, thereby affecting cardiac fibrosis. The current study employs a novel concept regarding chronic CB1 inhibitor treatment and may provide important details and novel targets for anti-fibrotic approaches in heart failure.

Pharmacological inhibition of sphingosine 1-phosphate receptor 2 (S1pr2) ameliorates pressure overload-induced cardiac hypertrophy and fibrosis in mice

National Natural Science Foundation of China 81470472

L Lin Zhang¹; LUER Bao¹; HUIMIN Fan¹

¹Tongji University School of Medicine, 1. Research Center for Translational Medicine, Shanghai East Hospital, Shanghai, China People's Republic of

Background: S1P, a bioactive sphingolipid metabolite, tightly regulates cardiovascular functions via its receptors. It has been shown that S1P/S1Pr2 signaling regulated heart and vascular development. However, it is unknown whether S1pr2 regulates cardiac remodeling in pressure overload-induced heart failure. We aimed to investigate the effect of pharmacological inhibition of S1pr2 by JTE013 in a mouse model of pressure overloaded-induced cardiac hypertrophy.

Methods: We performed transverse aortic constriction (TAC) to induce pressure overload-induced cardiac remodeling in mice. We treated operated mice with 5 mg/kg/day S1pr2 antagonist, JTE013, or placebo (DMSO) i.p., respectively. We performed echocardiography to investigate cardiac hypertrophy and cardiac function. We also carried out histological analysis to study cardiac remodeling in TAC model.

Results: Echocardiography showed obvious myocardial hypertrophy in the TAC mice following 8 weeks of pressure overload of the heart (corrected LV Mass (AW): 71.83 ± 10.32 Sham group vs. 124.98 ± 10.81 TAC-DMSO group. $P < 0.05$), which is confirmed by measurement of heart weight (heart weight/body weight: 0.0059 ± 0.0002 Sham group vs. 0.0099 ± 0.0007 TAC-DMSO group. $P < 0.05$) and histological analysis of cardiomyocyte cross-sectional area (114 ± 3.1 square micrometer Sham group vs. 393 ± 12.2 square micrometer TAC-DMSO group. $P < 0.05$). Cardiac function was significantly reduced in TAC mice (ejection fraction (EF%): 75.23 ± 1.84 Sham group vs. 41.16 ± 5.33 TAC-DMSO group. $P < 0.05$). S1pr2 antagonist, JTE013, significantly attenuated cardiac hypertrophy (corrected LV Mass (AW): 124.98 ± 10.81 TAC-DMSO group vs. 91.98 ± 8.06 TAC-JTE013 group. $P < 0.05$), which was verified by post mortem analysis (heart weight/body weight: 0.0099 ± 0.0007 TAC-DMSO group vs. 0.0079 ± 0.0003 TAC-JTE013 group. $P < 0.05$; cardiomyocyte cross-sectional area: 393 ± 12.2 square micrometer TAC-DMSO group vs. 245 ± 15.6 square micrometer TAC-JTE013 group. $P < 0.05$), while JTE013 moderately improved cardiac function in pressure overloaded heart failure (ejection fraction (EF%): 41.16 ± 5.33 TAC-DMSO group vs. 49.01 ± 0.47 TAC-JTE013 group. $P > 0.05$). Our further Masson's Trichrome staining and Picro Sirius Red staining showed that cardiac fibrosis and collagen deposition in myocardium were significantly reduce in TAC-JTE013 group compared to TAC-DMSO group.

Conclusions: Our results demonstrate that inhibition of S1pr2 ameliorates cardiac hypertrophy and cardiac fibrosis in pressure overload-induced heart failure, suggesting that S1pr2 negatively regulates cardiac remodeling in chronic heart failure.

Association of angiotensin-converting enzyme polymorphism with phenotype of hypertrophic cardiomyopathy

Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ)

A Freitas Pereira Gondar¹; ALF Sales¹; TCP Gil¹; MI Bittencourt¹; MB Castier¹; DA Da Silva²; R Mourilhe-Rocha¹

¹State University of Rio de Janeiro, Cardiology, Rio de Janeiro, Brazil; ²State University of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil

Introduction: The factors that determine the morphological characteristics and the clinical course of patients with hypertrophic cardiomyopathy (HCM) are still unclear. Genetic polymorphisms may have influence on the different phenotypes found in these patients. The angiotensin-converting enzyme (ACE) gene deletion/insertion polymorphism, which has three distinct genotypes (II, ID, and DD) have been associated with differences phenotypic in HCM.

Objectives: The aim of this study was to determine the frequency of ACE genetic polymorphism in the population of patients of our University Hospital and to correlate with the types of hypertrophic cardiomyopathy.

Methods: We selected 43 consecutive patients with HCM from the Cardiomyopathy Unit, our University Hospital, and a State University. Echocardiographic 2D studies were performed according to the recommendations of the American Society of Echocardiography and DNA was extracted from blood samples for the polymerase chain reaction.

Results: We analyzed 43 patients with HCM (53.4% males and 46.6% females). ACE genotype DD was found in 23.2%, 16.2% ACE genotype II and 60.4% ACE genotype ID. Among the patients, 51.1% have non-obstructive asymmetric septal hypertrophy (NOASH), 27.9% obstructive asymmetric septal hypertrophy (OASH), 11.6% apical hypertrophic form and 9.3% other forms of HCM. Among patients with ACE genotype DD 40% have OASH, 30% NOASH, 20% apical form and 10% others types of hypertrophy. Patients with ACE genotype DI, 23% have OASH, 57.6% NOASH, 7.6% apical form and 11.5% others types. And with ACE genotype II, 28.5% have OASH, 57.1% NOASH, 14.2% apical form and none have another form of hypertrophy.

Conclusion: We observed that the ACE genotype DI was more frequent in HCM patients, followed by ACE genotype DD and ACE genotype II. These results are similar to the current available medical literature. The ACE genotype DI is more related to non-obstructive asymmetric septal hypertrophy. The ACE genotypes DD and II do not have any predominant form of hypertrophy.

Study of a mouse with proximal titin A-band truncation reveals disease mechanisms and modifiers of titin dilated cardiomyopathy

I G Lunde¹; H Wakimoto²; J Jiang²; MA Burke²; V Soukoulis²; A Unger³; G Christensen¹; WA Linke³; JG Seidman²; CE Seidman²

¹Oslo University Hospital & University of Oslo, Oslo, Norway; ²Harvard Medical School, Department of Genetics, Boston, United States of America; ³Ruhr University Bochum (RUB), Bochum, Germany

Purpose: 20% of dilated cardiomyopathy (DCM) patients carry heterozygous truncating mutations in the giant protein titin (TTNΔ). Titin spans the cardiomyocyte sarcomere from Z-disc to M-line and regulates sarcomere assembly, contraction, relaxation and signaling. Truncating mutations are overrepresented in the A-band. We engineered mice with titin A-band truncation (TTNΔA) and assessed cardiac phenotype and transcriptional profile.

Results: TTNΔA mice were generated by introducing lox-P sites flanking exons 276-277 and crossing with Ella-Cre mice, causing a frameshift and a premature stop codon in the TTN proximal A-band. 28 heterozygous intercrosses produced 120 pups: none were homozygous TTNΔA. Genotyping (n = 125) revealed homozygous embryos at E8.5 - E10.5, with fetal demise at E10.5. Heterozygous male and female mice (age 6-80 weeks) were viable, fertile and not different from wild type (WT) in appearance, activity, or echocardiographic phenotype. Pregnant heterozygous females showed no echocardiographic phenotype and produced similar litter size as WT. Transcriptional changes (RNA sequencing) and local sarcomere lesions (electron microscopy) at baseline (age 6-8 weeks, males) suggested that TTNΔA pre-disposed to disease. Voluntary cage-wheel running (two months) (n = 5-8 per study, males), angiotensin II or isoproterenol infusion (two weeks) evoked no echocardiographic differences in TTNΔA compared to WT. Double heterozygous TTNΔA LMNA knock-out, TTNΔA MYH6 F764L knock-in and TTNΔA PLN R9C transgenic mutation mice showed no exacerbation of DCM. Interestingly, upon thoracic aortic constriction (TAC, four weeks) TTNΔA mice showed exacerbated DCM and congestive heart failure. RNA sequencing of TTNΔA vs. WT TAC hearts showed differential expression (fold change > 1.5 / < 0.67, p < 0.001) of 1465 transcripts. Total TTN transcripts were reduced and mutant transcripts half that of WT transcripts (digital PCR) in TTNΔA TAC hearts, with no detection of mutant protein (titin gels and titin immunoblotting). rAAV9 delivery to WT pups in vivo (n = 12-15) of TTN RNAi targeting the TTN exon 276-277 junction, reduced TTN mRNA and protein to 30% and resulted in mortality and severe DCM, with degradation of myofibrils (electron microscopy). Pathway analyses of differentially expressed transcripts in TTNΔA TAC and TTN RNAi, i.e. titin DCM, implicated cardiotoxic pathways. Calcineurin-NFAT and TGFβ/Smad signaling were identified as central players in titin DCM, along with titin-associated mechanosensors FHL1 and ANKRD1 (pathway analyses and immunoblotting).

Conclusions: Homozygous TTNΔA mutation is embryonically lethal, while heterozygous mice show overt DCM upon pressure overload. TTNΔA transcripts are expressed but do not yield detectable mutant protein, suggesting haploinsufficiency as disease mechanism. Reduced titin level is sufficient to cause DCM.

P527

Lack of growth differentiation factor 15 aggravates adverse cardiac remodeling upon pressure-overload in mice

J J Judith Jeanette De Haan¹; L Bosch¹; MAD Brans¹; SM Van Der Weg¹; JC Deddens¹; SJ Lee²; JPG Sluiter¹; G Pasterkamp¹; SCA De Jager¹

¹University Medical Center Utrecht, experimental cardiology, Utrecht, Netherlands;

²Johns Hopkins University of Baltimore, Molecular biology and genetics, Baltimore, United States of America

Background/introduction: Growth differentiation factor 15 (GDF15) is a distant member of the TGF-β family. Under homeostatic conditions GDF15 is not highly expressed, however, upon injury GDF15 levels robustly increase. GDF15 influences many processes including inflammation, apoptosis and fibrosis. In a mouse model of myocardial infarction, GDF15 deficiency results in increased incidence of cardiac rupture. This detrimental effect on the healing process is most likely related to an exacerbated inflammatory response. In heart failure (HF) patients, GDF15 plasma levels are increased and high GDF15 levels are associated with a higher mortality. Despite this association, a causal role of GDF15 in adverse cardiac remodeling leading to HF is currently not very well established. We therefore aimed to study the role of GDF15 in a mouse model of non-ischemic HF development.

Methods: GDF15 knock-out (KO) mice and wild type (WT) mice underwent trans aortic constriction (TAC) with a 27 gauge needle. Correct placement of the TAC was confirmed by Doppler measurements of the carotid flow ratios. Cardiac function

and geometry was assessed using echo at baseline, 7, 28 and 42 days after TAC. At day 42 immunohistochemistry was performed to study cardiomyocyte hypertrophy (WGA) and influx of different leukocyte subtypes. Flow cytometry was performed at 42 days after TAC on cardiac lymph nodes (LN), blood and spleen to study the effect of GDF15 deficiency on leukocyte subtypes.

Results: GDF15 KO mice have significantly increased end diastolic volume (EDV) and end systolic volume (ESV) after 6 weeks of TAC compared to WT mice (EDV: 93 μl versus 64 μl, ESV: 72 μl versus 38 μl, p < 0.05). The increase of ESV is already present 7 days after TAC. GDF15 KO mice show increased heart weight/body weight ratios after 42 days of TAC compared to WT mice. (7.0 mg/g versus 9.2 mg/g, p < 0.01) Though this observation implies increased cardiac hypertrophy in GDF15 KO mice, we did not observe a difference in cardiomyocyte hypertrophy. Flow cytometry did not show any alterations in the amount or activation status of leukocytes in the blood, LN or spleen after 42 days of TAC. Conclusions GDF15 deficiency aggravates adverse cardiac remodeling upon pressure-overload. Volume increase, both EDV and ESV is accelerated in GDF15 KO mice compared to WT mice. These changes are already present after 7 days of TAC. Increased heart weight/body weight ratio in GDF15 KO mice is not related to an increased volume of individual cardiomyocytes. More in depth analyses are needed to provide a mechanistic explanation for the worsening of cardiac function in GDF15 KO mice.

³Magna Graecia University of Catanzaro, IRC-FSH Institute of Research for Food Safety and Health, Catanzaro, Italy

Background: Doxorubicin (DOXO) is one of the most widely used antineoplastic drugs. Despite its highly beneficial effects against several neoplasias, the clinical use of DOXO has the serious drawback of cardiotoxicity, which over time causes a cardiomyopathy that leads to congestive heart failure. The molecular pathogenesis of anthracycline cardiotoxicity remains highly controversial, although the oxidative stress-based hypothesis involving intramitochondrial production of reactive oxygen species (ROS) has obtained great interest. In this regard, dietary polyphenols, in particular flavonoids, play a cardiovascular protecting role due to their pleiotropic anti-oxidative and anti-inflammatory effects.

Purpose: Thus, we have investigated whether a rich mixture of flavonoids extracted from Bergamot (Citrus Bergamia Risso et Poiteau), the bergamot-derived polyphenolic fraction (BPF), could attenuate DOXO-induced cardiomyopathy in vivo.

Results: Here we show that BPF was able to prevent DOXO-induced LV impairment and myocardial strain dysfunction. Indeed, echocardiographic assessment demonstrated that BPF administration in DOXO+BPF group significantly reduced LV end-systolic diameter (LVESd), LV end-diastolic diameter (LVEDd), improving both ejection fraction (EF) and fractional shortening (FS) compared to DOXO-treated rats. BPF was also able to prevent time-to-Peak (TPK) delay of cardiac strain and strain rate and dyssynchrony of radial motion in short axis when compared to DOXO group.

Histological analysis of DOXO+BPF-treated rats revealed a significant reduction of myocyte apoptosis, accompanied by a decrease in reactive myocyte hypertrophy and myocardial fibrosis compared to DOXO-treated rats. Moreover, cardiomyocytes isolated from DOXO-treated rats showed a slight increase in Akt phosphorylation which was associated with a strikingly increase in p38 phosphorylation compared to control rats. Importantly, phospho-Akt was significantly increased by BPF co-treatment, which, at the same time, reduced p38 phosphorylation compared to DOXO-treated rats.

Finally, we found that BPF significantly prevent 8-OHdG (marker of oxidative damage of DNA) nuclear accumulation in cardiac tissue and counteracts the increase in lipid peroxidation, tyrosine nitration of cardiomyocytes isolated from DOXO-treated rats.

Conclusion: BPF reduces DOXO-induced cardiotoxicity by decreasing ROS production and myocyte apoptosis that lead to a significant improvement of cardiac function. These data suggest that BPF may be used as a promising cardioprotective agent in patients undergoing anthracycline chemotherapy.

Programmed cell death-1 antigen as a potential mechanism of the pathogenesis of idiopathic dilated cardiomyopathy

D Stettner¹; E Grywalska²; J Rolinski²; A Wysokinski¹

¹Medical University of Lublin, Department of Cardiology, Lublin, Poland; ²Medical

University of Lublin, Department of Clinical Immunology and Immunotherapy, Lublin, Poland

Introduction: Programmed cell death-1 (PD-1), is expressed on activated T cells, and delivers inhibitory signals. Little is known about the role of cellular immunity in the pathogenesis in idiopathic dilated cardiomyopathy (IDCM). The aim of the study was to assess an expression of PD-1 on CD4+ T and CD8+ T lymphocytes in patients with IDCM.

Material and methods: We studied 50 IDCM patients and 20 healthy persons. Mononuclear cells were isolated from peripheral blood, incubated with appropriate fluorochrome-conjugated monoclonal antibodies and analyzed with a flow cytometer.

Results: Increased proportion of PD-1+ cells was detected from CD4+ T cells in patients than in controls ($6.98 \pm 3.29\%$ vs. $4.82 \pm 1.37\%$, $p < 0.001$). Similarly, the expression of PD-1 in CD8+ T cells was also significantly upregulated in IDCM patients compared with controls ($7.02 \pm 1.03\%$ vs. $3.99 \pm 1.32\%$, $p < 0.001$). Patients with ejection fraction lower than 30% had higher frequencies of both PD-1+ lymphocyte subsets than other patients ($13.06 \pm 4.92\%$ vs. $5.93 \pm 1.75\%$, $p < 0.001$).

Conclusions: The study identified that expression of PD-1 was upregulated on CD4+ T and CD8+ T cells from IDCM patients. Moreover the percentage of PD-1+ cells was extremely high in patients with low ejection fraction. Our data suggest a potential mechanism of the pathogenesis of IDCM.

CaMKII beta isoform induced dilated cardiomyopathy and heart failure

CIHR

B Balwant Tuana¹; Y Fanous¹; M Sonoda¹; F Gaisler Da Silva¹; M Ramos¹; J Major¹; M Salih¹

¹University of Ottawa, Ottawa, Canada

The calcium calmodulin dependent protein kinase II β 4 isoform (CaMKII β 4) is a muscle specific isoform of the CaMKII family of protein kinases which is also expressed at low levels in myocardium. CaMKII δ isoform is the most abundant and its activation is implicated in cardiac hypertrophy/failure. We generated transgenic (tg) mice lines with specific expression of CaMKII β 4 in postnatal myocardium to examine its impact on structure and function. Echocardiography indicated a dose and time dependent depression of fractional shortening, ejection fraction and cardiac output in tg mice. In high CaMKII β 4 expressers a marked increase in left ventricular internal diameter and a decrease in wall thickness with a ~70% decrease in cardiac function was noted at 6 weeks post birth. The level of CaMKII β 4 activation (phosphoThr-287) impacted the severity and temporal appearance of myocardial dysfunction in tg mice. qPCR analysis indicated that the fetal gene program was activated and Western blot analysis indicated that the expression of proteins involved in calcium transport at the SR were significantly depressed in Tg myocardium. CaMKII β 4 also inhibited the activity of CaMKII δ and resulted in a unique dilated cardiomyopathy. These data suggest that a cross talk between specific CaMKII isoforms induces distinct cardiomyopathies.

P531

Assessment of peripheral blood T, NK and NKT-like cells in patients with idiopathic dilated cardiomyopathy

D Diana Izabela Stettner¹; E Grywalska²; J Rolinski²; A Wysokinski¹

¹Medical University of Lublin, Department of Cardiology, Lublin, Poland; ²Medical University of Lublin, Department of Clinical Immunology and Immunotherapy, Lublin, Poland

Introduction: Although chronic myocardial inflammatory process mediated by viral/bacterial and autoimmune factors has been postulated in the pathogenesis of idiopathic dilated cardiomyopathy (IDCM), the role of immune mechanisms still remains unclear.

The aim of the study was to assess the frequencies of peripheral blood T, NK and NKT-like cells in patients with IDCM.

Material and methods: We studied 50 IDCM patients and 20 healthy persons. Percentages of NK and NKT-like cells were evaluated with flow cytometry using monoclonal antibodies: anti-CD3/FITC, CD16/CD56/PE, CD45/PerCP (BD Biosciences), which allowed for simultaneous assessment of CD3+ T lymphocytes and NK (CD16+CD56+) cells. During analysis, the CD3+CD16+CD56+ population was also determined. Immunofluorescence studies on T cell subsets were performed using a combination of the following mAbs: CD3/FITC, CD19/PE, CD8/FITC, CD4/PE, purchased from R&D Systems. Statistical analysis of the results was conducted using Statistica 9.0. A value p less than 0.05 was considered statistically significant.

Results: The mean frequency of CD3+CD56+CD16+ NKT-like cells in the peripheral blood of patients with IDCM was $10.93\% \pm 11.02\%$ and this value was significantly lower in comparison to the control group ($21.15\% \pm 9.08\%$, $p = 0.0005$). The mean percentage of CD56+CD16+ NK cells in the group of patients was $14.67\% \pm 6.89\%$, and was significantly higher compared to the healthy controls ($4.71\% \pm 2.99\%$, $p = 0.000002$). The mean percentage of CD3+ T lymphocytes in the peripheral blood of patients with IDCM was $67.91\% \pm 16.56\%$ and was significantly higher in comparison to the control group ($51.7\% \pm 24.12\%$, $p = 0.02$). The mean percentage

of CD8+ T lymphocytes in the study group was $28.89\% \pm 11.68\%$ and was significantly higher in comparison to the healthy controls ($18.72\% \pm 6.86\%$, $p = 0.001$).

Conclusions: Our findings of the abnormalities in immune cells distribution in peripheral blood of IDCM patients suggest that IDCM development and progression is related to the dysregulation of the immune system.

P532

Patients with diabetes mellitus subjected to PCI during hospitalisation.

O Olga Stoiko¹; SV Shalae¹

¹Tyumen state medical university, Tyumen, Russian Federation

The aim of investigation was to reveal clinical - demographic characteristics of patients (pts) with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) and diabetes mellitus (DM) subjected to PCI during hospitalization in 2014 - 2015.

Methods: We observed 120 pts with NSTEMI-ACS, among them DM in 27 (23%) pts. Monitoring of patients continued 6-18 months.

Results: Among 27 pts with NSTEMI-ACS and DM prevailed aged group 60-69 years, 59% (16) males. Smoking was registered in 4 (15%) pts with NSTEMI-ACS and DM (less than in non-diabetic NSTEMI-ACS pts, $p = 0.002$). The following risk factors were observed: arterial hypertension - 93% (25) pts, BMI ≥ 25 - 93% (25) pts, family history of cardiovascular disease - 19 (70%) pts (more frequent than in non-diabetic NSTEMI-ACS pts, $p = 0.002$). Previous myocardial infarction was in 37% (10) of pts, 10 pts (37%) had previous PCI. Pts received oral hypoglycemic drugs (80.0%), insulin (20%). Ischemic changes of ECG were determined in 56% (15) pts. The level of troponin T at admission > 0.05 ng/ml was detected in 56% of pts. The level of glucose at admission was 9.3 ± 0.7 mmol/l (in pts without DM - 5.7 ± 0.14 mmol/l). Average LDL-C level was 3.0 ± 0.2 mmol/l, LDL > 1.8 mmol/l was registered in 78% (21) of pts. All admitted pts received anticoagulants and dual antiplatelet therapy (aspirin in conjunction with either clopidogrel or ticagrelor), β -blockers, statins. In pts with NSTEMI-ACS and type 2 DM risk of adverse cardiovascular events during hospitalization (GRACE) was higher ($p = 0.038$) than in those without DM. Coronary stenosis $> 55\%$ revealed in 100% of patients, multivessel disease in 81% (22) pts, in 6 (22%) pts was determined stent stenosis de novo. One-vessel coronary disease was revealed in 7.5% of pts, two-vessel disease - 15.8% pts. Balloon angioplasty with stenting was performed in all pts. In pts with NSTEMI-ACS unstable angina was diagnosed in 60 pts, myocardial infarction was revealed in 60 pts. During hospitalization there were no lethal outcomes, one case of non-fatal ischemic stroke was observed on the 2-d day of hospitalization, in 2 pts was registered non-fatal myocardial infarction, in 1 patient - early postmyocardial angina. In 3 non-diabetic NSTEMI-ACS pts unstable angina was observed, in 2 pts - early postmyocardial angina. The development of combined end point (death from myocardial infarction, unstable angina, myocardial infarction) in pts with NSTEMI-ACS and DM was significantly earlier than in non-diabetic NSTEMI-ACS pts ($p < 0.008$). Thus, risk of cardiovascular events during hospitalization and observation (6-18 months) in pts with NSTEMI-ACS and DM was significantly higher than in non-diabetic NSTEMI-ACS pts. So, DM is considered to be an important risk factor of ischemic heart disease progression.

Microrna-155 promotes myocardial microvascular endothelial activation in septic cardiomyopathy

F Francisco Vasques-Novoa¹; T Laundos²; C Quina-Rodrigues¹; R Cerqueira¹; F Baganha¹; DS Nascimento²; P Pinto-Do-O²; AF Leite-Moreira¹; R Roberto-Roncon Jr¹

¹University of Porto, Faculty of Medicine, Porto, Portugal; ²University of Porto, i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal

Purpose: Septic cardiomyopathy remains a leading cause of death in critically ill patients and its pathophysiology remains poorly understood. Myocardial edema and inflammatory cell recruitment to interstitial space are proposed mechanisms underlying sepsis-induced contractile dysfunction. In previous experiments we have localized miR-155 expression in septic myocardium mainly to the microvascular (MV) endothelial cells. The aim of this work was to evaluate the role of miR-155 in myocardial endothelial activation.

Methods: 1) Experimental sepsis was induced using LPS injection in WT ($n = 20$) and miR-155-/- (KO; $n = 20$) male mice. Cardiac function was evaluated through echocardiography. Myocardial expression of NOS, PKG activity and cGMP and NOx content was evaluated. Cardiac MV permeability was assessed with Evans blue-albumin leaking and myocardial water content. Mouse cardiac MV endothelial cells (MCMVEC) were isolated with FACS. Quantification of miR-155, cytokine mRNA profile and adhesion molecules was performed. 2) Human cardiac MV endothelial cells (HCMVEC) were transfected with anti-miR-155 or scramble LNA probe and incubated with LPS (100ng/mL) or vehicle for 24h. Evaluation of cytokine mRNA profile, NOS expression, NOx and adhesion molecules was performed. Monocyte adhesion assay was performed using DiI-stained THP1 cells. 3) MiR-155 expression, inflammatory cell infiltration and interstitial space area were assessed in post-mortem myocardial samples from septic shock patients ($n = 28$).

P537

Blocking the N-terminal domain of midkine attenuates acute inflammation and prevents pathological remodelling and heart failure in experimental autoimmune myocarditisS Stefan Brunner¹; L Weckbach¹; A Uhl¹; U Grabmaier¹¹University Hospital Grosshadern, Munich, Germany

Rationale: Midkine plays a critical role for the recruitment of polymorphonuclear cells. Nevertheless, its role in acute myocarditis and progression to inflammatory dilated cardiomyopathy (IDCM) has not been clearly defined.

Objective: To investigate the effect of an antibody against midkine on inflammatory cell recruitment and disease progression in the mouse model of Experimental Autoimmune Myocarditis (EAM).

Methods and Results: EAM was induced by immunization of BALB/c mice with heart-specific myosin- α heavy chain peptide together with Complete Freund's adjuvant. An antibody directed versus the N-terminal domain of midkine was administered from day 0 until day 21. As evidenced by histopathology, EAM severity scores at peak of inflammation were significantly reduced in antibody-treated mice. Accordingly, flow cytometry revealed reduction of CD45+ cells as well as distinct subsets such as monocytes/macrophages, polymorphonuclear cells and T cells. Further, antibody-treatment protected mice from progressive cardiac fibrosis and heart failure at later stages. Interestingly, treatment with an antibody directed versus the C-terminal domain of midkine did not attenuate acute inflammation during EAM. **Conclusion:** Our findings provide in vivo evidence, that blocking the N-terminal but not the C-terminal midkine domain attenuates acute inflammation and prevents pathological remodelling and heart failure progression after acute myocarditis.

The role of autophagy in alcoholic cardiomyopathy

PON03PE_00078_1; PON03PE_00078_2

J Jessica Maiuolo¹; A Maretta²; M Gliozzi²; F Oppedisano¹; C Carresi³; V Musolino³; F Scarano²; A Scarcella¹; C Muscoli³; V Mollace¹

¹Institute of Research for Food Safety & Health (IRC-FSH), University of Catanzaro, Italy; Catanzaro, Italy; ²Consortium Nutramed, SCARL, Catanzaro, Italy; Catanzaro, Italy; ³Centre for Clinical and Basic Research, IRCCS San Raffaele Pisana, via della Pisana, 235, 00163 Rome, Italy

Alcoholic cardiomyopathy represents one of the major clinical complications in chronic alcoholics being accompanied by significant impairment of the myocardial structure, cardiac remodeling and cardiomyocyte hypertrophy. On the other hand, chronic alcohol consumption, leads to alterations of mitochondrial structure and function in cardiac cells, decreased protein synthesis, impairment of the myofibrillar architecture, myocardial contractile dysfunctions and dilatation of the sarcoplasmic reticulum. Besides these evidences, the pathophysiological mechanism underlying cardiomyocyte alterations subsequent to chronic exposure to ethanol still remains to be elucidated. An exaggerated, ROS-dependent autophagic response has been suggested at the early stages of alcoholic cardiomyopathy, though the mechanism is still unclear. Here we investigated on the potential role of overproduction of ROS and autophagy in rat cultured cardiomyocytes undergoing chronic alcohol exposure. Chronic exposure of H9c2 cardiomyocytes to ethanol (500 and 1000 μ M) failed to produce direct impairment of cell viability as detected by trypan blue and MTT assay, thus confirming previous data showing that ethanol exposure leads to cell death at higher concentrations. However, the effect of ethanol was accompanied by significant dose-dependent increase of ROS generation in cardiomyocytes. Moreover, immunoblot experiments indicated that a 500 and 1000 μ M ethanol exposure for 12 days caused a statistically significant dose-dependent increase of Beclin 1 expression compared to the control, thus indicating that autophagic response occurs early in the development of ethanol-induced cardiomyopathy at sublethal ethanol concentrations. The relationship between ROS overproduction and the occurrence of autophagy due to ethanol exposure was confirmed by experiments carried out in the presence of the peroxynitrite decomposition catalyst MnTBAP. Indeed pre-treatment of H9c2 cells with MnTBAP decreased ROS levels as well as ethanol-induced autophagy is expressed by the decrease of Beclin 1 expression.

Thus, our data showed that chronic ethanol exposure of cultured cardiomyocytes causes ROS accumulation which supports protective autophagy. This effect occurs in the absence of cardiomyocyte death, suggesting a reversible stage of the disease. Exhausting protective autophagy leads to further oxidative stress and finally, apoptotic death of cardiomyocytes, thereby generating alcoholic cardiomyopathy and the subsequent heart failure.

catanzaro, Italy; ³Centre for Clinical and Basic Research, IRCCS, San Raffaele Pisana, Rome, Italy, Rome, Italy

Methylmercury is the most common and toxic form of organic mercury. In particular, fish products are the main source of methylmercury in the diet. For decades, the toxic effects of mercury were associated mainly with neurological disorders and nephropathy. Recent studies have suggested that methylmercury exposure leads to an increased risk of cardiovascular disease, increased vascular resistance alongside with an elevation of blood pressure.

The mechanism of mercury-induced cardiotoxicity is not fully elucidated. However, an increased oxidative stress via NADPH oxidase activation has been suggested to play a role.

Here, we investigated on the toxic effects subsequent to acute exposure to methylmercury in cardiomyocytes. In particular we found that exposure of the cell line H9c2 to methylmercury (0.5, 1, 5, 10, 25, 50, 75 and 100 μ M) for 24 hours produced a dose-dependent cell death. Flow cytometric analysis showed that the treatment with methylmercury at lower concentration (25 μ M) determined early apoptotic death; higher concentrations (75 and 100 μ M) of methylmercury produced a late apoptosis. This was confirmed by detection of caspase 3, a biomarker of apoptotic cell death, which was overexpressed after exposure of cardiomyocytes methylmercury, (25 e 50 μ M). Moreover, methylmercury 10 and 25 μ M produced an arrest in phase S/G2M of cardiomyocyte cell cycle, thus confirming heavy metal-related cardiomyocytes to undergo apoptotic cell death.

Thus, methylmercury leads to apoptotic cell death accompanied by oxidative stress and this may represent the basis for a better understanding and treatment of heavy metal-related cardiomyopathy.

Peripartum cardiomyopathy : clinical pictures and prognosis about 10 casesH Habiba Drissa¹; MERIEM Drissa¹; MERIEM Drissa¹; MERIEM Drissa¹; MERIEM Drissa¹; MERIEM Drissa¹; MEHDI Cheour¹; MEHDI Cheour¹; MEHDI Cheour¹; MEHDI Cheour¹; MEHDI Cheour¹; HAJER Malek¹; HAJER Malek¹; HAJER Malek¹; HAJER Malek¹¹La Rabta University Hospital, adults cardiology, Tunis, Tunisia

Introduction: Peripartum Cardiomyopathy (PPCM) is a rare type of heart failure of unknown cause occurring late in pregnancy or in the postpartum period.. Unfortunately, PPCM is a disease whose underlying etiology and natural history remain completely understood. only a few case series have been published to date **Purpose:** is to describe the clinical pictures and prognosis of PPCM Results we reported a cases of 10 women hospitalized in a department hospital , the mean age was 32 years ,7 patients were multiparous. Caesarean section was performed in 6 cases , 2 patients had severe preeclampsia. The main presenting symptom was congestive heart failure with acute pulmonary edema. Only in one case. Electrocardiogram (ECG) showed tachycardia ; Furthermore, in all the ten cases, cardiac ultrasound showed a left ventricular diastolic diameter of more than 58 mm and a shortening fraction of or less than 25 %(25-40%). The treatment administered to these patients included bed rest, oxygen ,Intravenous diuretics , than converting enzyme inhibitors. In one case, circulatory support for hemodynamic instability in spite of inotropic therapy was required. Six patients got well with clinical recovery and echocardiography normalization of left ventricular parameters but 3 women had persistent signs of chronic heart failure and ultrasound signs of left ventricular dysfunction. We reported one case of death due to a refractory heart failure.

Conclusion: PPCM is an uncommon complication of pregnancy with unknown cause and potentially life-threatening complications. Echocardiography appears to be extremely valuable in diagnosing PPCM, formulating prognosis of recovery and following the course of the disease which is still a mystery.

Role of S100A8 and S100A9 alarmins in Cocksackievirus B3-induced myocarditisI Mueller¹; S Van Linthout¹; T Vogl²; B Pieske³; C Tschoepe³

¹Berlin-Brandenburg Center for Regenerative Therapies, Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²University of Munster, Department for Immunology, Munster, Germany; ³Charite - Campus Virchow-Klinikum (CVK), Department for Cardiology and Pulmonology, Berlin, Germany

Background: The alarmins S100A8 and S100A9 are danger-associated molecular pattern molecules and have been shown to be of importance in several cardiovascular disorders. Their role in myocarditis has not been explored yet.

Purpose: The aim of the present study was to investigate the role of S100A8/S100A9 in biopsy-proven myocarditis patients and in experimental CVB3-induced myocarditis.

Methods: S100A8/A9 serum concentrations (ng/ml) were evaluated in myocarditis (n=8) and control (n=11) patients. S100A8 and S100A9 mRNA expression was analyzed in endomyocardial biopsies (EMBs) of CVB3+ patients (n=5), who eliminated the virus over time. S100A9 knock down (–/–) and wild-type (wt) C57BL/6

mice were i.p. infected with 5×10^5 and 5×10^6 p.f.u. of CVB3. A subgroup of S100A9 $^{-/-}$ CVB3 mice was additionally i.p. injected with S100A8 every 2 days. Seven days after infection, mice were hemodynamically characterized and left ventricles (LV) were isolated. To further assess the role of both alarmins, CVB3-infected HL-1 cardiomyocytes and cardiac fibroblasts were supplemented with S100A8 or S100A9.

Results: S100A8/9 serum concentrations were 2.2-fold ($p < 0.05$) higher in myocarditis versus control patients. S100A8 and S100A9 mRNA expression in EMBs dropped over time in CVB3+ patients who spontaneously healed, whereas LV S100A8 and S100A9 mRNA expression was 13.4-fold and 12.1-fold higher in CVB3-infected vs control mice ($p < 0.0005$). S100A9 $^{-/-}$ CVB3 mice exhibited an improved LV function compared to CVB3 wt mice. CVB3 copy number was 2.3-fold ($p < 0.05$) lower in S100A9 $^{-/-}$ CVB3 mice compared to their wt CVB3 littermates. S100A9 $^{-/-}$ CVB3 mice further displayed 2.9-fold and 2.1-fold lower LV myeloperoxidase activity and Ly6G mRNA levels versus CVB3 wt mice ($p < 0.05$), as well as 2.2-fold and 1.3-fold lower LV Ly6c mRNA expression and CD68+ cells in S100A9 $^{-/-}$ CVB3 vs CVB3 wt mice, respectively ($p < 0.05$). LV NOX1 and RAGE mRNA levels were 3.3-fold and 2.2-fold decreased in S100A9 $^{-/-}$ CVB3 vs wt CVB3 mice ($p < 0.05$). I.p. application of S100A8 in S100A9 $^{-/-}$ CVB3 mice induced the CVB3 copy number by 5.0-fold ($p < 0.05$) vs S100A9 $^{-/-}$ CVB3 mice. S100A8 and S100A9 supplementation led to a 1.8-fold and 1.7-fold ($p < 0.0005$) increase in CVB3 copy number in HL-1 cells, respectively, and both to a 1.2-fold ($p < 0.05$) induction in CVB3 mRNA expression in cardiac fibroblasts.

Conclusions: The cardiac S100A8/A9 system is upregulated in human and murine myocarditis, thereby increasing oxidative stress and reducing anti-viral mechanisms. We conclude that S100A8/A9 could be an important therapeutic target for the treatment of myocarditis.

NOD2 knock down improves left ventricular function and attenuates NLRP3 inflammasome activity in experimental Coxsackievirus B3-induced myocarditis

C Tschoepe¹; I Mueller²; Y Xia²; K Savvatis²; D Lassner³; H-P Schultheiss³; B Pieske¹; U Kuehl¹; S Sophie Van Linthout²

¹Charité - Universitätsmedizin Berlin, Campus Virchow-Klinikum (CVK) Kardiologie, Berlin, Germany; ²Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany; ³Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany

Introduction: The cytoplasmatic pattern recognition receptor, nucleotide binding oligomerization domain 2 (NOD2), belongs to the innate immune system and is among others responsible for the recognition of single stranded (ss) RNA.

Purpose: With Coxsackievirus B3 (CVB3) being a ssRNA virus and the recent evidence that the NOD2 target, NLRP3 is of importance in the pathogenesis of CVB3-induced myocarditis, we wanted to unravel the role of NOD2 in CVB3-induced myocarditis.

Methods: Gene expression was analyzed on endomyocardial biopsies taken from CVB3+ patients who spontaneously eliminated CVB3 ($n=6$). NOD2 knockdown ($-/-$) mice and wild-type (wt) C57BL/6 mice were i.p. infected with 5×10^5 p.f.u. of CVB3. Seven days after infection, mice were hemodynamically characterized and left ventricles (LV) were isolated. NOD2 was knocked down in HL-1 cells via NOD2 siRNA. HL-1 cells transfected with scrambled (scr) siRNA served as controls.

Results: Endomyocardial biopsy NOD2 and NLRP3 mRNA expression decreased by 2.5-fold and 2.2-fold over time in patients, which spontaneously eliminated CVB3, respectively ($p < 0.05$). Furthermore, LV NOD2 mRNA expression was 2.3-fold ($p < 0.0005$) increased in CVB3-infected versus control mice. NOD2 $^{-/-}$ mice were rescued from the detrimental CVB3-mediated effects as shown by a reduced cardiac inflammation (less cardiac infiltrates, suppression of pro-inflammatory cytokines and TLR4 signaling), cardiac fibrosis, apoptosis, 12.5-fold ($p < 0.05$) lower CVB3 copy number, and an improved LV function in NOD2 $^{-/-}$ CVB3 compared to wt CVB3 mice. In agreement, the CVB3-induced inflammatory response, CVB3 copy number and apoptosis were less pronounced in CVB3-infected NOD2 siRNA versus CVB3 scr siRNA HL-1 cardiomyocytes. Both in vivo and in vitro, NOD2 $^{-/-}$ was associated with a decrease in CVB3-induced NLRP3 expression and activity as evidenced by lower ASC expression, caspase 1 activity and/or IL-1 expression in CVB3 NOD2 $^{-/-}$ versus CVB3 wt mice and CVB3 NOD2 siRNA versus CVB3 scr siRNA HL-1 cells.

Conclusions: NOD2 is involved in the pathology of acute CVB3 myocarditis. Its inhibition exerts cardioprotective effects, indicating that modulation of NOD2 represents a promising therapeutic strategy to treat viral myocarditis.

Cannabidiol is a novel treatment for autoimmune myocarditis

Intramural Program of NIH/NIAAA

C Matyas¹; L Wen-Shin¹; K Erdelyi¹; ZV Varga¹; P Mukhopadhyay¹; T Radovits²; B Merkely²; P Pacher¹

¹National Institutes of Health, National Institute on Alcohol Abuse and Alcoholism, Bethesda, United States of America; ²Semmelweis University, Heart and Vascular Center, Budapest, Hungary

Introduction: Myocarditis is a major cause of heart failure and sudden cardiac death in young adults and adolescents. Many cases of myocarditis are associated with autoimmune processes in which cardiac myosin is a major autoantigen. Conventional immunosuppressive therapies often provide unsatisfactory results and are associated with adverse toxicities during the treatment of autoimmune myocarditis. Cannabidiol (CBD) is a non-psychoactive constituent of Marijuana which exerts anti-inflammatory effects independent from classical cannabinoid receptors. Recently 80 clinical trials have been reported investigating the effects of CBD in various diseases from inflammatory bowel disease to graft-versus-host disease. CBD-based formulations are used for the management of multiple sclerosis in numerous countries, and CBD also received FDA approval for the treatment of refractory childhood epilepsy and glioblastoma multiforme.

Purpose: Herein, using a well-established mouse model of experimental autoimmune myocarditis (EAM), we studied the potential beneficial effects of CBD on T cell-mediated inflammation, cardiomyocyte cell death, fibrosis and myocardial dysfunction.

Methods: EAM was induced by immunization with cardiac myosin emulsified in adjuvant in our mice. Fibrotic remodeling and cardiac inflammation were investigated by qRT-PCR, histological and immunohistochemical tools. Detailed myocardial systolic and diastolic function were examined by invasive hemodynamic measurements by using pressure-volume conductance microtip catheter system.

Results: EAM was characterized by marked myocardial T cell-infiltration, profound inflammatory response, fibrosis (Sirius Red staining: 5.33 ± 0.59 vs. 1.00 ± 0.15 in controls; fold change) and oxidative stress (4-hydroxynonenal (4-HNE) content: 4.29 ± 0.78 vs. 1.00 ± 0.28 in controls; fold change) accompanied by marked attenuation of both systolic (end systolic pressure-volume relationship (ESPVR): 1.78 ± 0.19 vs. 8.39 ± 1.21 in controls) and diastolic (end diastolic PVR (EDPVR): 0.27 ± 0.05 vs. 0.09 ± 0.02 in controls) cardiac functions. Chronic treatment with CBD largely attenuated the CD3+ and CD4+ mediated inflammatory response and injury, myocardial fibrosis (Sirius Red staining: 2.07 ± 0.97), oxidative stress (4-HNE: 2.54 ± 0.12) and cardiac dysfunction in mice (ESPVR: 3.33 ± 0.54 ; EDPVR: 0.16 ± 0.02).

Conclusion: CBD may represent a promising novel treatment for management of autoimmune myocarditis and possibly other autoimmune disorders, and organ transplantation.

Intracoronary infusion of allogeneic cardiosphere-derived cells attenuates myocardial inflammation and prevents depression of systolic function in rats with autoimmune myocarditis

E Leventaki¹; M Nana¹; N Pouliantis¹; CJ Kapelios¹; S Vakrou¹; D Rontogianni²; D Perrea³; J John Nanas³; K Malliaras¹

¹University of Athens, School of Medicine, 3rd Cardiology Dept., Athens, Greece;

²Evangelismos Hospital, Athens, Greece; ³University of Athens, Athens, Greece

Background: Myocarditis is a potentially lethal inflammatory cardiomyopathy without effective treatment. Cardiosphere-derived cells (CDCs) have been shown to exert cardioprotective, regenerative and immunomodulatory effects in ischemic cardiomyopathy. However, the effect of CDC administration in hearts with myocarditis is unknown.

Purpose: To investigate the effects of intracoronary infusion of allogeneic CDCs in rats with autoimmune myocarditis.

Methods: Allogeneic CDCs were grown from hearts explanted from healthy Lewis rats. Autoimmune myocarditis was induced in Lewis rats by subcutaneous footpad injection of purified porcine cardiac myosin mixed with complete Freund's adjuvant on days 1 and 7. On day 10, rats with autoimmune myocarditis underwent lateral thoracotomy and were subsequently randomized to undergo global intracoronary infusion of 500,000 allogeneic CDCs ($n=6$) or vehicle solution ($n=8$). Global intracoronary infusion was achieved through infusion of cells or vehicle solution into the left ventricular cavity during brief aortic clamping. Rats were followed for 3 weeks post-infusion and underwent cardiac echocardiography on day 1, day 10 (prior to infusion) and day 28 (3 weeks post-infusion). Afterwards, rats were euthanized, hearts were explanted and underwent histology. Myocardial lymphomononuclear infiltration was assessed by whole-field microscopy after hematoxylin eosin staining.

Results: Subcutaneous footpad injection of purified porcine cardiac myosin mixed with complete Freund's adjuvant induced histologically-confirmed autoimmune myocarditis in 14/14 rats. Left ventricular ejection fraction was comparable on day 1 ($83.4 \pm 1.5\%$ vs $83.3 \pm 4.2\%$, $p=0.95$) and on day 10 ($81.1 \pm 5.8\%$ vs $78.7 \pm 5.8\%$, $p=0.57$) between the 2 groups. Intracoronary infusion of allogeneic CDCs prevented myocarditis-induced functional depression and resulted in significantly higher left ventricular ejection fraction at 3 weeks post-infusion compared to control animals ($84.9\% \pm 0.9\%$ vs $61.3 \pm 8.4\%$, $p=0.02$). Allogeneic CDC therapy resulted in dramatic attenuation of lymphomononuclear infiltration at 3 weeks post-infusion compared to control animals ($8.1\% \pm 7.2\%$ vs $21.5 \pm 3.8\%$ of the myocardium infiltrated by inflammatory cells, $p=0.03$).

Conclusions: Global intracoronary infusion of allogeneic CDCs dramatically attenuates myocardial inflammation and prevents depression of systolic function in rats with autoimmune myocarditis.

Enalapril, eplerenone or their combination: finding the best paradigm to protect against Doxorubicin-Induced Cardiotoxicity

Swiss Heart Foundation, Pfizer

D David Martin¹; M Metrich¹; R Van Heeswijk²; M Stuber²; R Hullin¹

¹University Hospital Centre Vaudois (CHUV), Cardiology, Lausanne, Switzerland;

²Center for Biomedical Imaging (CIBM), Lausanne, Switzerland

Introduction: Anticancer therapy with anthracyclines such as Doxorubicin (Dox) is complicated by the generation of reactive oxygen species (ROS) in cardiomyocytes, causing early and late cardiac dysfunction. Dox treatment is associated with activation of the renin-angiotensin-aldosterone system which may further increase ROS load and fibrosis upon activation of the mineralocorticoid receptor (MR) by aldosterone.

Purpose: Using mice, we assessed the ability of MR blockade, ACE inhibition or their combination to protect against Dox-induced cardiotoxicity (DIC).

Methods: Acute and chronic DIC were induced in C57Bl6 male wild type (WT) mice by a single injection of Dox (15 mg/kg) or five weekly injections of Dox (4 mg/kg), respectively. MR blockade was achieved in WT mice with an Eplerenone-enriched diet and in transgenic mice by deleting the MR gene specifically in cardiomyocytes (MR KO). ACE inhibition was provided by adding Enalapril in drinking water. Left ventricular (LV) systolic function was assessed by 2D echocardiography and magnetic resonance imaging and diastolic function by Doppler imaging. Changes in gene expression levels were assessed by qPCR and activation of stress-sensing pathways assessed by western blot. Plasma aldosterone levels were measured by LC-MS and radio-immunoassay.

Results: Acute and chronic models of DIC both triggered body weight loss as well as cardiac atrophy, which was associated with reduced cardiomyocyte cell size and decreased activation of mTOR and Rps6. DIC was further characterized in both models by cardiac diastolic and systolic dysfunction, as shown by decreased mitral inflow velocities and decreased cardiac output, respectively. MR blockade with Eplerenone was not sufficient to prevent cardiac dysfunction. It drastically increased plasma aldosterone levels and was associated with an increased expression of CTGF and of angiotensin II (AngII) receptor type I, suggesting that an interplay between aldosterone and AngII signaling diverts the effect of MR blockade. Enalapril treatment, however, decreased the severity of both diastolic and systolic dysfunction in the chronic model of DIC. Combination of Enalapril and Eplerenone lowered cardiac dysfunction and further decreased aldosterone and CTGF levels.

Conclusions: Our data show that blocking MR with Eplerenone does not prevent DIC in mice. However, blocking AngII production with Enalapril limits the severity of cardiac dysfunction in a clinically relevant model of chronic DIC. Our results suggest that Enalapril or Enalapril and Eplerenone combination in human may protect against DIC.

Ranolazine protects from trastuzumab cardiomyopathy

C Coppola¹; G Piscopo¹; A Barbieri²; G Riccio¹; D Fiore³; G Condorelli³; E Esposito⁴; C Arra²; N Maurea¹

¹Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Division of Cardiology, Naples, Italy; ²Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Animal Facility, Naples, Italy; ³University 'Federico II', Department of Molecular Medicine and Medical Biotechnology, Naples, Italy; ⁴Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale - IRCCS, Department of Breast Surgery and Cancer Prevention, Naples, Italy

Purpose: The anti-cancer anti-ErbB2 Trastuzumab (T) is used to treat HER2 positive breast cancer, but unfortunately can produce cardiac dysfunction. The mechanisms of cardiotoxicity have not been fully elucidated, but oxidative stress may play an important role. The late INa inhibitor Ranolazine (R) protects from doxorubicin-induced oxidative stress and cardiac dysfunction as we have previously described. Here, we hypothesize that treatment with R reduces T cardiotoxicity.

Methods: To assess toxicity in vitro, rat H9C2 cardiomyoblasts and human fetal cardiomyocytes were pretreated with R (1 and 10 μ M) for 72 hours and then treated with T (200 nM) for additional 72 hours. Cell viability was determined by cell counts and MTT assays. To evaluate cardiac function in vivo, fractional shortening (FS) and ejection fraction (EF) were measured by M-mode echocardiography and radial and longitudinal strain (RS and LS) were measured using 2D speckle-tracking echocardiography in C57BL6 mice, 2-4 months old, pretreated with R (305 mg/kg/day, a

dose comparable with that used clinically in humans of 750 mg twice daily) per os for 3 days. R was then administered for additional 7 days, alone and in combination with T (2.25 mg/kg/day ip), according to our well established protocol. We have evaluated tissue expression of BNP (brain natriuretic peptide) and MMP2 (matrix metalloproteinase 2) by reverse transcription-polymerase chain reaction (RT-PCR) analysis on heart tissue.

Results: R reduced T toxicity in H9C2 cardiomyoblasts and human fetal cardiomyocytes as evidenced by higher viability rate of cells treated with R+T than cells treated with T alone ($p < 0.01$). In our in vivo studies, after 7 days with T, FS, EF, RS and LS decreased. Interestingly, in mice treated with R+T, the reduction in cardiac function was milder: FS was $59 \pm 3\%$, EF was $90 \pm 2\%$, RS was 39.6 ± 2 , LS was -20.5 ± 0.9 $p < 0.05$ respectively, vs T alone. R prevents the increased expression of BNP and MMP2 ($p < 0.05$) on heart tissue.

Conclusions: In our mouse model, T produces LV dysfunction and R reduces T cardiotoxic effects. We plan to test R as a cardioprotective agent with other antineoplastic cardiotoxic drugs in our experimental models and to define the mechanisms of cardioprotection.

Sildenafil treatment in a rat model of cancer cachexia

Piano di azione e coesione PONricerca e competitività
V Vincenzo Musolino¹; C Carresi¹; C Giannotta¹; S Nucera¹; F Bosco¹; M Scicchitano¹; J Maiuolo¹; C Muscoli¹; M Gliozzi¹; V Mollace¹

¹Institute of Research for Food Safety & Health (IRC-FSH), University of Catanzaro "Magna Graecia", C, Catanzaro, Italy

Background: Cachexia, or wasting syndrome, is a complex metabolic disorder which has been shown to occur in late stages of chronic disease including end-stage cancer characterized by involuntary weight loss caused by an ongoing wasting of skeletal muscle and depletion of adipose tissue. Cachexia affects 50-80% of cancer patients and is responsible for 30% of their death. Given that, brown adipose tissue (BAT) plays a key role in thermogenesis and energy balance, increased thermogenesis in brown fat during cancer cachexia indicates that metabolically active adipose tissue contributes to the imbalanced energy homeostasis involved in catabolic wasting. Cachexia also affects the cardiac muscle, indeed, the atrophy of the heart and impairment of cardiac function consequently increases mortality. Anti-cachectic therapy in patients with cancer cachexia is, so far, limited to nutritional support. Sildenafil, a selective inhibitor of the the enzyme phosphodiesterase-5 (PDE5), responsible for the breakdown of cGMP has been shown to induce myocardial protective effects and to improve energy balance in a variety of experimental models. We hypothesized that sildenafil ameliorates the wasting process and the heart function in the Yoshida hepatoma tumor model.

Methods: In this study the effects of sildenafil were tested in cachectic tumour-bearing rats (Yoshida AH-130 ascites hepatoma). Rats were treated daily with 30mg/kg/d of sildenafil or vehicle starting one day after tumor-inoculation, and for a period of 16 days. Body weight and body composition were assessed at baseline and at the end of the study. Cardiac function was analyzed by echocardiography at baseline and at day 11.

Results: Treatment with 30mg/kg/d of sildenafil attenuated the loss of body weight and the wasting of fat mass. Administration of 30mg/kg/d of sildenafil protected the heart from general atrophy. Tumor-bearing rats displayed cardiac dysfunction, as indicated by the significant impairment of the left ventricular ejection fraction (LVEF) as well as the left ventricular fractional shortening (LVFS). In contrast, sildenafil improved cardiac dysfunction. Although sildenafil did not reduce the loss of lean body mass, it was able to protect from adipose tissue depletion.

Conclusions: The animals carrying the ascites hepatoma AH-130, treated with Sildenafil showed, an attenuation of fat adipose tissue. In addition, the drug showed an improvement of the cardiac function probably due to an antagonism of cardiac atrophy subsequent to cancer-induced cachexia. Larger studies, with longer follow-up and molecular analysis, are required in order to get better insight of the pathophysiological mechanisms underlying sildenafil related cardioprotection.

Enhanced-autophagy by exenatide mitigates doxorubicin-induced cardiotoxicity in vitro and in vivo

W Weon Kim¹; KH Lee¹; HN Cho¹; SR Lee¹; JS Woo¹; WS Kim¹

¹Kyung Hee University Hospital, Seoul, Korea Republic of

Background: Exenatide, glucagon-like peptide-1 analogue, mitigates myocardial injury caused by ischemia/reperfusion injury via survival signaling pathway. We investigated that exenatide would also provide a protective effect in doxorubicin-induced cardiotoxicity.

Methods: H9c2 cardiomyocytes were incubated after treatment with doxorubicin (DOX, 1, 10 μ M) or pre-treatment with exenatide (3, 30 nM) followed by DOX in vitro. Incubated cells were measured with cell viability and autophagosome staining. In vivo, SD rat was treated with exenatide (10 μ g/kg, subcutaneous injection) or

control saline 1 hour prior to every DOX (accumulative dose, 20 mg/kg) intraperitoneal injection, and left ventricular (LV) function and performance were assessed by echocardiography. Western blot, TUNEL staining and ROS study to determine the intracellular changes. Autophagic process was visualized by Cyto-ID staining in H9c2.

Results: In vivo, echocardiography shows that reduced LV function by DOX treatment was significantly improved by pre-treatment of exenatide. Doxorubicin significantly increased myocyte apoptosis by TUNEL and ratio of activated caspase-3, which also decreased by pre-treatment exenatide. However, the oxidative stress in cardiac tissue and serum did not significant differ between each groups. Autophagic markers, LC3 II, Beclin, and ATG5 signal increased in exenatide combination group. Also, number of autophagosomes increased appreciably with more exenatide pre-treated H9c2 cells than DOX treated cells. When suppress the formation of autophagosome by Bafilomycin A1, apoptosis regulated under the exenatide-mediated autophagy inhibition in H9c2.

Conclusion: Exenatide reduces DOX-induced cardiomyocytes apoptosis by upregulating autophagy and improves cardiac function. These novel results highlight the therapeutic potential of exenatide to prevent doxorubicin cardiotoxicity.

TLR4 and TLR2 detection method from peripheral human blood for early detection of doxorubicin induced cardiotoxicity

AL Pop-Moldovan¹; M Trofenciu¹; M Puschita¹; DA Darabantiu¹; R Cristodorescu¹; V Leordean¹; LA Velcean²

¹"Vasile Goldis" Western University of Arad, Faculty of Medicine, County Emergency Clinical Hospital, Arad, Romania; ²County Emergency Clinical Hospital, Arad, Romania

Background/introduction: -Reducing mortality and morbidity in cancer patients with current therapies is a major breakthrough in the treatment of cancer patients. Through their mechanisms of action, cancer treatments can have significant cardiovascular adverse effects that can cause cardiomyopathy and heart failure with reduced survival benefit and considerable decrease in the use of antineoplastic therapy.

Purpose: The purpose of this study is to assess the role of TLR2 and TLR 4 gene expression as an early marker for the risk of doxorubicin induced cardiomyopathy in correlation with early diastolic dysfunction in patients treated with doxorubicin.

Methods: Our study included 25 consecutive patients who received treatment with doxorubicin for hematological malignancies (leukemia, lymphomas or multiple myeloma), aged 18-65 years old, with a survival probability > 6 months and with left ventricular ejection fraction > 50% who expressed their informed consent. Exclusion criteria consisted of previous anthracycline therapy, previous radiotherapy, history of heart failure or chronic renal failure, atrial fibrillation or other significant arrhythmias, pregnancy. In all patients, in fasting state, a blood sample was drawn for the assessment of TLR2 and TLR4 gene expression. Gene expression was assessed by qRT PCR using the following steps: blood collection (3 ml of blood), RNA isolation, cDNA reverse transcription, qRT PCR and quantification of the relative expression. Patient's blood was drawn directly in TempusTM Blood RNA Tube (4342792 Applied Biosystems). At enrolment all patients were evaluated clinically, an ECG and an echocardiography were performed. Echocardiographic parameters recorded (determined on a Siemens Acuson X300 machine) were those of left ventricular diastolic and systolic function (ventricular volumes, ejection fraction, pulsed and tissue Doppler analysis).

Results: - The average amount of gene expression units was 0.113 for TLR4 (range 0.059-0.753) and 0.218 for TLR2 (range 0.046-0.269). The mean mRNA extracted quantity was 113,571 ng/μl. As for the diastolic function parameters, criteria for diastolic dysfunction were present after 6 months in 16 patients (64%). In these patients the mean values for TLR4 were 0,1198625 and for TLR2 0,16454 gene expression units. As for the diastolic function parameters, criteria for diastolic dysfunction were present after 6 months in 16 patients (64%). In these patients the mean value for TLR2 was 0.30 ± 0.19 and for TLR4 0.15 ± 0.04. The corresponding values for the patients who did not develop diastolic dysfunction were 0.16 ± 0.07 for TLR2 (p = 0.01) and 0.11 ± 0.10 for TLR4 (p = 0.2).

Conclusion: - Our study suggests that TLR4 and TLR2 expression is higher in patients under doxorubicin therapy which develop diastolic dysfunction. This may suggest a predisposition to myocardial involvement, a higher sensitivity to doxorubicin cardiac effects.

Modulation of cardiac structure by epicardial adipose tissue

G Gloria Conceicao¹; J Matos²; N Goncalves¹; D Fontoura¹; S Leite¹; AP Lourenco¹; R Vitorino²; AF Leite-Moreira¹; I Falcao-Pires¹

¹Faculty of Medicine University of Porto, Department of Physiology and Cardiothoracic Surgery, Porto, Portugal; ²University of Aveiro, QOPNA, Department of Chemistry, Aveiro, Portugal

Introduction: Diastolic heart failure (DHF) is recognized an important cause of cardiovascular mortality and morbidity reaching approximately 50% of heart failure cases. Several risk factors, such as obesity, are associated with its development. Adipose tissue is now considered an 'endocrine organ' that secretes numerous bioactive peptides, termed adipokines. In obesity, due to adipocyte hypertrophy and dysfunction, there is an increased secretion of proinflammatory adipokines. These adipokines produced by epicardial adipose tissue (EAT) can act in a paracrine manner directly on the myocardium and influence their structure and function. In this work we aim to characterize the profile of EAT under conditions of DHF and to evaluate their possible changes in cardiac structure.

Methods: EAT of 20-weeks-old lean and obese ZSF1 rats was collected for: 1) separation of proteins to mass spectrometry (MS) identification, 2) adipokines' expression, 3) adipocytes fibrosis and cross-sectional area assessment and 4) for 24h DMEM incubation to obtain conditioned medium. Successively, organotypic cultures were prepared from 7 day-old Wistar Kyoto cardiac explants and incubated for 24h with the conditioned media previously obtained from both groups. After incubation, cross-section area of cardiomyocytes and fibrosis were evaluated.

Results: In EAT of the obese ZSF1, MS-results presents decreased levels of 3-ketoacyl-CoA thiolase protein enzyme as a compensatory mechanism in order to inhibit fatty acid oxidation and increase lumican and collagen-alpha-1(I) proteins suggesting a link between inflammation caused by obesity and increases of adipose tissue extracellular matrix. The histological and molecular studies of EAT revealed hypertrophy of adipocytes in obese animals (1505 ± 80.01 μm² vs. 7595 ± 265.5 μm², p < 0.0001) without fibrosis, as well as a significantly increase in expression of several adipokines. Among these overexpressed adipokines are visfatin (0.42 ± 0.18 AU vs. 1.4 ± 0.33 AU, p < 0.05), leptin (0.12 ± 0.032 AU vs. 0.93 ± 0.18 AU, p < 0.0001), apelin (0.08 ± 0.03 AU vs. 0.24 ± 0.04 AU, p < 0.05) and chemerin (0.33 ± 0.096 AU vs. 0.90 ± 0.16 AU, p < 0.05) that are involved in fibrosis and hypertrophic pathways. In organotypic cultures, conditioned media from obese ZSF1 EAT rats triggered a significant increase in the cross-sectional area of cardiomyocytes (100.7 ± 18.98 μm² vs. 111.25 ± 24.02 μm², p < 0.05) and in fibrosis (3.48 ± 1.51 % vs. 4.79 ± 1.53 %, p < 0.05) compared to the conditioned medium from lean rats ZSF1.

Conclusions: Obesity promotes significant alterations in EAT which alter the myocardial structure, inducing collagen deposition and cardiomyocyte hypertrophy.

Insulin signaling exacerbates heart failure via an IRS1-Akt1 signaling module that is independent of IRS2

C Christian Riehle¹; AR Wende²; ED Abel³

¹Hannover Medical School, Hannover, Germany; ²University of Alabama Birmingham, Birmingham, United States of America; ³University of Iowa, Iowa City, United States of America

Background: Generalized insulin resistance exacerbates heart failure, and heart failure is an insulin resistant state. We recently reported that pressure overload cardiac hypertrophy (POH) leads to activation of Insulin Receptor (IR) tyrosine kinase activity in cardiomyocytes and that reducing cardiomyocyte insulin signaling prevented heart failure in a mouse model of POH.

Objectives: To further explore the signaling mechanisms responsible for this phenomenon we generated mice with cardiomyocyte-restricted deficiency of IRS1 and IRS2 respectively and induced POH using transverse aortic constriction (TAC). Results Following TAC, wildtype (WT) controls developed POH and heart failure characterized by hyperactivation of Akt1 (2.01fold, p < 0.05) but not Akt2, which was accompanied by increased myocardial fibrosis (+46.0% vs. WT Sham, p < 0.05). Remarkably, following TAC, IRS1 deficient hearts were completely resistant to cardiac hypertrophy and maintained normal left ventricular (LV) function. Akt1 activation and increased fibrosis were also absent. In contrast, IRS2 KO hearts developed an exacerbation of the WT phenotype, which was prevented by haploinsufficiency of Akt1. We then examined LV tissue from failing human hearts, obtained at the time of implantation of a left ventricular assist device, and compared insulin signaling with LV tissue obtained from normal donor hearts. Failing human hearts exhibited increased IRS1 (+73.7%, p < 0.05) but not increased IRS2 phosphorylation. Hyperactivation of Akt1 (+84.4% p < 0.05), was observed in failing human hearts, but Akt2 phosphorylation was normal. Conclusion Taken together these data define a critical

role for an IR-IRS1-Akt1 signaling module in exacerbating LV remodeling in the failing heart and provides a molecular mechanism linking insulin resistance and heart failure.

MR antagonists protect against diet induced obesity and cardiac inflammation in mice, through browning of the adipose tissue and modulation of autophagy

A Andrea Armani¹; V Marzolla¹; A Feraco¹; C Mammi¹; W Malorni²; G Rosano¹; M Caprio¹

¹IRCCS San Raffaele Pisana, Rome, Italy; ²Superior Institute of Health, Department of Drug Research and Evaluation, Rome, Italy

Background: Obesity is a key factor in the development of insulin resistance (IR), cardiovascular disease, hypertension, type 2 diabetes etc. Given the near epidemic incidence of obesity in western society there is a clear need for effective treatment options. Mineralocorticoid receptor (MR) blockade has shown significant promise in transgenic mouse models of obesity in limiting IR and adipocyte dysfunction, a disease that is independent of classical MR actions (renal).

Purpose: Metabolic effects of MR antagonists were investigated on adipose tissue and heart in mice fed a high fat diet (HFD).

Methods: Female 10-week-old C57Bl6 mice were fed with normal chow or a HFD for 12 weeks. Mice fed HFD were concomitantly treated for 12 weeks with drospirenone (DRSP, 6 mg/Kg/day), a potent MR antagonist with antiadipogenic activity, or spironolactone (SPIRO, 20 mg/kg/day). Magnetic Resonance Imaging (MRI) and PET/CT imaging were used to analyse fat tissue mass and metabolic activity. Gene expression analysis was performed by real time RT-PCR. Autophagy was investigated by western blot for LC3.

Results: DRSP and SPIRO prevented weight gain and white fat mass expansion induced by HFD in parametrial, perivisceral, and inguinal depots without affecting interscapular fat pad weight. Mice fed HFD showed no increase in heart or kidney weight and tissue fibrosis. Cardiac macrophage recruitment and osteopontin staining was increased in hearts of HFD-fed mice and reversed by both MR antagonists. Moreover, both DRSP and SPIRO prevented the impaired glucose tolerance in mice fed HFD, and countered HFD-induced up-regulation of WAT markers transcripts and adipocyte hypertrophy. Importantly, MR antagonists increased uncoupling protein 1 (UCP-1) positive brown-like adipocyte content in WAT, and improved metabolic activity of adipose tissue, as indicated by PET/CT imaging. In keeping with this, MR antagonism significantly increased expression of brown-like adipocyte marker genes (PRDM16, CIDEA, ADRB3, UCP-1) in all WAT depots analysed. In exploring the mechanism, we demonstrated that MR antagonism induced brown adipose tissue (BAT) markers, and reduced the autophagic rate, a key remodelling process in adipocyte differentiation, in WAT depots in vivo as well as in primary cultured adipocytes.

Conclusions: We conclude that adipocyte MR regulates BAT-like remodeling of WAT through modulation of autophagy. MR blockade therefore has promise as a novel therapeutic option for the prevention of metabolic dysfunctions and the cardiac consequences of obesity.

Obesity, mainly its abdominal form, is considered a relevant risk factor not only in type 2 diabetes, lipid disorders and hypertension but also in the development of coronary artery disease. During the past decade, evidence has been collected showing that among patients with type 2 diabetes and cardiovascular comorbidity, overweight and obese patients had a lower mortality compared with normal-weight subjects. These paradoxical findings are known as the "obesity paradox". In our experimental model, rats were fed with a normocaloric diet (NPD group) or with a high fat diet (HFD group), respectively. One month later, streptozocin (STZ, 35 mg/Kg, i.p.) was administered in a subgroup of both NPD and HFD rats to induce diabetes and the sacrifice was carried out after sixty days. Our results revealed that diabetic rats fed with a normocaloric diet (NPD+STZ) showed a significant loss of muscle tissue compared to the corresponding controls (NPD). On the other hand, hyperlipidemic diabetic rats (HFD+STZ) as well as HFD rats, didn't show any significant difference in lean mass composition. In addition, the impairment of body mass observed in hyperglycemic rats was associated with a decreased cardiac function, less pronounced in HFD+STZ rats. This effect was accompanied by a down-expression of mitochondrial Translocator Protein (TSPO) in hyperlipidemic

diabetic rats as compared with controls. TSPO plays a central role in the regulation of mitochondrial function modulating the crosstalk between Inner Membrane Anion Channel (IMAC) and Permeability Transition Pore (PTP) in the mitochondrion. To date, the role of TSPO in preventing mitochondrial dysfunction and apoptosis is unclear. In response to oxidative stress and impairment of intracellular antioxidant systems, TSPO down-regulation might represent a defensive mechanism of cardiomyocyte aimed to prevent the opening of PTP. TSPO has also been associated with cholesterol import into mitochondria, a key step in steroidogenesis; as a consequence, its down-regulation can further reduce PTP opening induced by mitochondrial cholesterol accumulation and oxysterol overproduction. Despite of TSPO down-expression, in HFD+STZ rats we observed an increase in plasmatic levels of cholesterol derived- allopregnanolone probably involved in the protection of heart and skeletal muscle tissues by oxidative damage. The discussion over the molecular mechanisms underlying the obesity paradox cannot lead to an underestimation of obesity as a crucial risk factor for the development of cardiovascular and metabolic diseases; however, the preservation of cardiac and muscle tissues from mitochondrial-induced oxidative damage observed in HFD+STZ rats suggests the need of further investigations aimed to identify new therapeutic strategies in cardiovascular diseases.

Diabetes is a metabolic, heterogeneous disorder caused by obesity, sedentary lifestyle and hypercaloric dietary supply and frequently related to genetic susceptibility. Hyperglycaemia and hyperlipidemia represent the most important risk factors for cardiovascular diseases which are the leading cause of death among people with diabetes. Despite this evidence, to date, the exact role of hyperglycaemia and hyperlipidemia in diabetic cardiomyopathy is not well established. To better clarify this aspect, rats were fed with a normocaloric diet (NPD group) or with a high fat diet (HFD group), respectively. One month later, streptozocin (STZ, 35 mg/Kg, i.p.) was administered in a subgroup of both NPD and HFD rats to induce diabetes. After a period of 60 days, we observed that hyperglycaemia or hypercholesterolemia significantly increased the diameter of the left ventricular chamber in diastole (LVEDd) and in systole (LVESd) and these pathological conditions reduced ejection fraction (EF) and fractional shortening (FS) compared to control (NPD). Unexpectedly, cardiac dysfunction was less marked in diabetic rats fed with an hyperlipidemic diet (HFD+STZ) suggesting an adaptive response to injury of diabetic heart in the presence of hyperlipidemia. This response was characterized by a modulation of matrix metalloproteinases (MMPs), a family of zinc-dependent endopeptidases responsible for both physiological and pathophysiological tissue remodeling. In particular, we observed an activation of all myocardial MMP-2 isoforms (intracellular full-length-MMP-2, N-terminal truncated intracellular MMP-2 and extracellular MMP-2) in NPD as well as in HFD and HFD+STZ rats as paragoned with diabetic rats not affected by hyperlipidemia. On the other hand, N-terminal truncated intracellular MMP-2 (NT-MMP-2) and MMP-9 activities appeared comparable in NPD and in diabetic hyperlipidemic rats. Recent evidence shows that NTT-MMP-2 activity impairs heart muscle function reducing calcium transients without affecting the structure of myofilaments, as occurred after full-length-MMP-2 activation. As a consequence, in HFD+STZ rats, the enhanced activity of NTT-MMP-2 among all MMP-2 isoforms and restored MMP-9 activity suggest their involvement in a myocardial remodeling to preserve cardiac function and integrity in response to oxidative stress induced by diabetes. In conclusion, our results highlight the importance of MMPs as a potential pharmacological target in order to counteract myocardial oxidative damage in diabetes.

Diabetes is a metabolic, heterogeneous disorder characterized by a complex pathogenesis which can be related to genetic susceptibility, obesity, sedentary lifestyle and hypercaloric dietary supply. Hyperglycaemia and hyperlipidaemia are the most

important risk factors for cardiovascular diseases which are the leading cause of death among people with diabetes. Despite this evidence, to date, the exact role of hyperglycaemia and hyperlipidaemia in the onset of cardiovascular diseases is not well established.

To better clarify mechanisms underlying these metabolic dysfunctions, rats were fed with a normocaloric diet (NPD group) or with a high fat diet (HFD group), respectively. One month later, streptozocin (STZ, 35 mg/Kg, i.p.) was administered in a subgroup of both NPD and HFD rats to induce diabetes. After a period of 60 days, we observed that hyperglycaemia or hypercholesterolemia significantly increased the diameter of the left ventricular chamber in diastole (LVEDd) and in systole (LVESd) and these pathological conditions reduced ejection fraction (EF) and fractional shortening (FS) compared to control (NPD). Unexpectedly, cardiac dysfunction was less marked in diabetic rats fed with an hyperlipidemic diet (HFD+STZ) suggesting an adaptative response to injury of diabetic heart in the presence of hyperlipidaemia.

Growing evidence shows that the development of left ventricular dysfunction in diabetes is induced by myocardial injury which is characterized by mitochondrial dysfunction and altered myocardial metabolism. In particular, oxidative stress appears to play a very important role in tissue damage as we observed in diabetic rats fed with normocaloric diet (NPD+STZ) showing an overexpression of myocardial NADPH oxidase compared to control. On the other hand, the concomitant presence of both pathological conditions in HFD+STZ rats induced a down-expression of myocardial NADPH oxidase compared to NPD+STZ animals as well as an increased expression of Bcl-2 suggesting an improved mitochondrial function and a down-regulation of apoptosis. However, we also revealed an enhancement of cytosolic cytochrome c levels in HFD+STZ rats as compared with other groups. As a consequence, here we hypothesize that cytochrome c release from mitochondria to cytosol represents an early event caused by free radicals overproduction in cardiomyocytes of HFD rats. This detrimental event is probably compensated by enhanced Bcl-2 levels in response to later STZ-induced hyperglycaemia, suggesting a role for Bcl-2 in promoting cell survival after release of cytochrome c.

In conclusion, our results highlight the importance to prevent free radicals-induced diabetic cardiomyopathy and represent a new insight in order to counteract oxidative damage and to improve cardiac dysfunction in diabetes.

New interesting targets for heart failure therapy in the natriuretic peptide clearance system- could type c natriuretic peptide receptor be as promising as neprilysin?

Institute of Cardiology Research Grant

K Katarzyna Kodziszewska¹; P Leszek¹; B Sochanowicz²; W Piotrowski¹; T Zieliński¹

¹Institute of Cardiology, Warsaw, Poland; ²Institute of Nuclear Chemistry and Technology, Centre for Radiobiology and Biological Dosimetry, Warsaw, Poland

Background: Since the introduction of new molecules targeting neprilysin (NEP) and natriuretic peptide (NP) receptors for the treatment of heart failure the interest in molecular mechanisms governing clearance of natriuretic peptides has also increased. NEP, a membrane-bound metallo-endoropeptidase, degrades a variety of peptide hormones, including natriuretic peptides, while type C natriuretic peptide receptor (NPR-C) is a clearance receptor for NPs with some signalling properties of its own associated with adenylyl cyclase and phospholipase C transduction pathways. It binds NPs on the cell surface, internalizes them and delivers to lysosomes for degradation.

Goal: This study aimed to demonstrate the changes in natriuretic peptide clearance system (NEP and NPR-C) taking place in a failing human heart.

Methods: NEP and NPR-C levels were measured using ELISA in cardiac tissues of 43 heart failure patients referred for heart transplantation and 12 healthy donor hearts not allotted to transplantation. Cardiac NPR-C expression was also assessed with rtPCR for mRNA expression. NEP activity was assayed using fluorimetry.

Results: In failing hearts the levels of NPR-C mRNA were significantly increased (fold change: 2.93; $p=0.0000131$) in the presence of significantly reduced NPR-C protein levels (7.5 vs. 4.8 ng/mg of protein; $p=0.0014$). NEP levels did not differ between healthy and failing heart tissues (respectively: 205.7 vs. 218.5 ng/mg of protein; $p=0.4181$). However, neprilysin activity was significantly increased in cardiac tissues obtained from heart failure patients (1951.8 vs. 5424.1 F/10 µg of protein/30 min; $p<0.0002$).

Conclusions: Augmented production of natriuretic peptides in heart failure induces changes to their clearance system through a positive feedback loop, leading to increased transcription of NPR-C mRNA in cardiac cells. Lower levels of NPR-C protein in heart failure reflect its increased activity as a clearance receptor (binding the molecules, internalization and lysosomal fusion) since the receptor is removed from the cell surface and degraded together with its ligand. The neprilysin system also adapts to increased concentrations of NPs. While NEP expression remains unchanged, the activity of neprilysin appears to be significantly increased in failing

hearts. Both of these mechanisms contribute to reduction of antifibrotic and anti-hypertrophic activity of NPs. While neprilysin inhibitors are extensively investigated and their anti-remodeling properties were already demonstrated, NPR-C remains a potential therapeutic target of heart failure treatment that has been somewhat neglected to date.

A preliminary study on carbon-based nanotubes gelatin scaffold for cardiac tissue regeneration

M Cabiati¹; F Vozzi¹; F Gemma¹; F Montemurro²; C De Maria²; G Vozzi²; C Domenici²; S Del Ry¹

¹Institute of Clinical Physiology of CNR, Pisa, Italy; ²University of Pisa, Research Centre "E. Piaggio, Pisa, Italy

Introduction: A realistic goal for cardiac muscle engineering is the design of a scaffold able to mimic both the tissue-specific architecture and mechanical properties as well as the main physiological functions.

Purpose: Aim of this study was the set up of gelatin and carbon nanotubes (CNT) scaffolds for cardiac tissue engineering applications.

Methods: Gelatin-based scaffolds (Sc) and CNT in percentage of 0.3% and 0.9% ($n=12$), cross-linked with genepin 0.2%, were prepared. H9c2 cell line was cultured for 10 days in DMEM, supplemented with 10% of FBS (C10%, $n=10$). Myoblast differentiation was induced by adding 1% FBS (C1%, $n=6$), while cardiac phenotype by 10 nM all trans-retinoic acid (CRA, $n=6$). Cell viability, cytotoxicity, phenotype differentiation and immunohistochemical assay were performed. After 10 days cells and Sc were collected in tri-reagent and RNA was extracted for Real-Time PCR analysis (CFX-96 Real-Time PCR detection systems, Bio-Rad). In order to evaluate cardiac phenotype, the natriuretic peptide (NP) and endothelin (ET) system were studied. To confirm cellular interaction by gap junction formation, connexin (CX)-43 was measured.

Results: Immunohistochemistry study revealed that C1% showed the presence of elongated myotubes, typical of skeletal phenotype and dissimilar from myoblast of control condition. CRA was induced to cardiac phenotype showing round and multinucleated nuclei. Data were also confirmed by a significantly increased expression of NP system in CRA with respect to C10% and C1% except for NP receptor-C that significantly decreased in CRA. Furthermore, CRA revealed an increased of both ET-A and ET-B receptors in parallel with a decreased ET-1 expression with respect to C10% and C1%. In CNT Sc cell viability was similar both at 0.3% than and 0.9% and resulted decreased at 3 days probably for adapting at the Sc. NP and ET system expression decreased in CNT0.3% and CNT0.9% with respect to C10% ,as well as CX43 mRNA ($p<0.01$), mainly due to a lacking of complete differentiation in cardiac phenotype during these few days.

Conclusions: In this study the addition of retinoic acid during serum reduction favours a cardiac phenotype at the expense of skeletal muscle trans-differentiation, confirmed by NP and ET system expression. Moreover, the lacking of a complete differentiation of cells on CNT-Sc highlights the need of more day of culture to realize this process. Nevertheless further analysis on novel biomaterials to enhance cell growth/proliferation and to support the damaged heart will be needed to bring heart tissue engineering into clinical application, these results are an useful starting point to develop new Sc-based biomaterials.

Cardioprotective effects of sitagliptin against doxorubicin-induced cardiotoxicity in rats

DINA S El-Agamy¹; H Hany Haded²; M A Elkablawy³

¹ Faculty of Pharmacy, Mansoura University, Department of Pharmacology and Toxicology, Mansoura, Egypt; ² Mansoura University Children hospital (MUCH), Mansoura, Egypt; ³ Taibah University, pediatric departement, madinah, Saudi Arabia

Background: There is a large body of evidence suggesting that inhibitors of dipeptidyl peptidase-4 (DPP-4), such as sitagliptin, may exhibit beneficial effects against different inflammatory disorders.

Purpose: This investigation was conducted to elucidate the potential ability of sitagliptin to counteract the injurious effects of doxorubicin (DOX) in cardiac tissue.

Methods: Male Wistar rats were pretreated with sitagliptin for 10 days then treated with a single dose of DOX (20 mg/kg, i.p). Electrocardiography, biochemical estimation of serum and tissue markers, histo- and immunopathological examinations were done.

Results: have shown that supplementation with sitagliptin resulted in significant improvement of cardiac function with contaminant decrease in serum markers of DOX-induced cardiotoxicity. These results were supported by the histopathological **Results:** Furthermore, a marked protection against oxidative stress was evident through reduction of lipid peroxidation and prevention of reduced glutathione content depletion and superoxide dismutase activity reduction in cardiac tissue of rats pretreated with sitagliptin in combination with DOX. Moreover, sitagliptin ameliorated the activation of in nuclear factor kappa-B and the release of inflammatory cytokines tumour necrosis factor-alpha and nitric oxide. Finally, sitagliptin

attenuated DOX-induced increase in the expression of pro-apoptotic protein Bax and in the apoptotic marker, caspase-3.

Conclusions: these data indicate that sitagliptin pretreatment could alleviate DOX-induced cardiotoxicity via reducing oxidative damage and its subsequent inflammation and apoptosis.

Nitric oxide forms a paramagnetic compound with hemoglobin in venous erythrocytes that reflects vascular no bioavailability in vivo and is quantifiable by electron paramagnetic resonance spectroscopy

FNRS-FRIA

F Flavia Dei Zotti¹; I Lobyshva¹; C Beauloye¹; J-L Balligand¹

¹Institute of Experimental and Clinical Research (IREC), Brussels, Belgium

Nitric oxide bioavailability reflects severity of endothelial dysfunction in metabolic and cardiovascular diseases, but its quantification in circulating blood remains a challenge. NO can form paramagnetic iron-nitrosyl complexes with hemoglobin (5-coordinate- α -HbNO) in erythrocytes (RBCs) representing bioavailability of vascular endothelial function and NO in vivo. We observed the HbNO complex in RBCs from mouse, rat and human venous blood and we developed a modified subtraction method using EPR spectroscopy to quantify it. The HbNO circulating concentration is ~425nM in rodents and ~92nM in human venous blood. RBCs contain endothelial nitric oxide synthase (eNOS) protein. We measured, using NOS and arginase inhibitors, nitrite/nitrate production and HbNO formation in human, eNOS(+/+) and eNOS(-/-) mice RBCs. Nitrite and HbNO signals increased after arginase inhibition and were abrogated after NOS inhibition in human and eNOS(+/+) RBCs but insensitive to modulators in eNOS(-/-). However, HbNO signal from freshly drawn venous RBCs was minimally sensitive to NOS inhibitors ex vivo suggesting a minor contribution of erythrocytic NOS to HbNO complex compared with vascular endothelial NOS or other NO sources. Next, we determined that HbNO signal is influenced by physico-chemical determinants. The HbNO formation, upon exogenous NO donor exposure, was significantly higher in hypoxic condition (1% O₂: 0.018 ± 0.002 μ M compared to room air 0.0036 ± 0.0004 μ M HbNO/NO donor μ M). The stability of pre-formed HbNO was higher after 30min under hypoxia (17 ± 0.4% degradation vs 49 ± 0.2% at room air), at 20°C (16 ± 0.3% degradation vs 30 ± 0.1% at 37°C) and under acidic pH (32 ± 1% vs 62 ± 0.7% at physiological pH). HbNO signal is significantly preserved by RBCs incubation with catalase (2 μ M HbNO/L vs 0.5 μ M HbNO/L in untreated controls) whereas superoxide dismutase had minimal effect. Conversely, catalase inhibition highly increased ROS formation. This suggested that HbNO formation is sensitive to oxidative degradation, possibly by H₂O₂. Finally, we compared circulating HbNO levels in venous RBCs from healthy volunteers or patients with cardiovascular diseases and found decreased HbNO in patients

(0.141 ± 0.11 μ M/L vs 0.22 ± 0.12 μ M/L in volunteers; n = 38 and 48). HbNO was significantly correlated with endothelial function (ENDO-PAT) and (inversely) correlated with major cardiovascular risk factors. We conclude that HbNO reflects exposure of RBCs to NO in vivo and is sensitive to oxidative degradation by H₂O₂. HbNO could be developed as a biomarker of NO bioavailability and/or oxidative stress ex vivo.

P560

Circular RNAs in heart failure: identification of MICRA as a novel biomarker of left ventricular dysfunction

M Vausort¹; L Zhang¹; P Leszek²; A Salgado-Somoza¹; D Wagner³; Y Devaux¹

¹Luxembourg Institute of Health, CVRU, Strassen, Luxembourg; ²National Institute of Cardiology, Heart Failure and Transplantation Department, Warsaw, Poland;

³Hospital Centre, Luxembourg, Luxembourg

Background/Introduction: Prediction of the development of left ventricular (LV) dysfunction after acute myocardial infarction (AMI) is challenging. Existing biomarkers such as brain natriuretic peptides have serious limitations due to lack of specificity and stability in the few hours following AMI. Therefore, novel biomarkers are needed to improve the identification of patients at risk of LV dysfunction after AMI. Both microRNAs and long noncoding RNAs circulating in the bloodstream have shown some potential to predict outcome after AMI. Whether circular RNAs (circRNAs), a novel class of long noncoding RNAs formed by back splicing, constitute a reservoir of cardiac biomarkers is unknown.

Purpose: To address the ability of circRNAs to predict outcome after AMI.

Methods: Expression levels of a circRNA called MICRA for Myocardial Infarction-associated Circular RnA were measured by quantitative PCR in peripheral blood cells obtained at reperfusion in a test cohort of 409 AMI patients and a validation cohort of 145 additional AMI patients. The capacity of MICRA to predict LV dysfunction (4-month LV ejection fraction <40%) was determined using univariate and multivariable analyses. Blood samples from 87 healthy volunteers and human LV biopsies from 22 failing hearts and 5 control hearts were also used. Results— In the test cohort, MICRA was down-regulated in AMI patients compared to healthy volunteers (P = 0.003) and was mostly expressed by lymphocytes. MICRA was a univariate predictor of 4-month LV dysfunction (P < 0.001). In multivariable analyses, MICRA was the strongest predictor of LV dysfunction (P = 0.0001; Figure). Patients with low levels of MICRA were at high risk of LV dysfunction (odds ratio 0.09 [95% confidence interval (CI) 0.03-0.31]). MICRA provided an additive predictive value, as demonstrated by a decrease in model deviance (P < 0.001) and an integrated discrimination improvement of 7%, 95% CI [2-12]. The predictive value of MICRA was confirmed in the validation cohort (odds ratio 0.03 [0.001-0.96]). Finally, MICRA was detected in the left ventricles of failing human hearts (P < 0.01).

Conclusions: We identified MICRA, a novel circRNA predicting LV dysfunction after AMI. This finding motivates further investigation of the biomarker and therapeutic value of circRNAs.

P561

Circulating miR-122-5p and miR-124a-3p predict outcome after out-of-hospital cardiac arrest. a sub-study of the target temperature management (TTM) trial

A Salgado-Somoza¹; Y Devaux¹; P Stammet²; O Collignon¹; C Hassager³; MP Wise⁴; M Kuiper⁵; H Friberg⁶; D Erlinge⁷; N Nielsen⁸

¹Luxembourg Institute of Health, CVRU, Strassen, Luxembourg; ²Hospital Centre, Luxembourg, Luxembourg; ³Rigshospitalet University Hospital, Department of Cardiology B, Copenhagen, Denmark; ⁴University Hospital of Wales, Department of Intensive Care, Cardiff, United Kingdom; ⁵Leeuwarden Medical Centrum, Department of Intensive Care, Leeuwarden, Netherlands; ⁶Skane University Hospital, Department of Anesthesia and Intensive Care, Lund, Sweden; ⁷Lund University, Department of Cardiology, Lund, Sweden; ⁸Helsingborg Hospital, Department of Anesthesia and Intensive Care, Helsingborg, Sweden

Background: Heart failure is a frequent underlying cause of cardiac arrest. MicroRNAs (miRNAs) are small nucleotides with biomarker value in various cardiovascular contexts. Previous small-scale studies suggested that miRNAs might be useful indicators of outcome after cardiac arrest.

Purpose: To determine the prognostic value of miRNAs in a large cohort of comatose survivors of out-of-hospital cardiac arrest (OHCA).

Methods: The Target Temperature Management (TTM) trial addressed the potential benefit of TTM at 33°C vs. 36°C on outcome after OHCA. In this sub-study, circulating levels of 5 miRNAs (Table) were measured in serum samples from 579 TTM patients, 48h after return of spontaneous circulation. The primary and secondary end-points were poor neurological outcome at 6 months and survival at the end of the trial, respectively.

Results: Forty-eight percent of the patients had a poor neurological outcome or were dead at 6 months, presenting lower miR-122-5p and higher miR-124a-3p levels compared to good outcome patients (both $p < 0.001$). This was independent of targeted temperature management regimen. Both miRNAs were significant univariable predictors of neurological outcome (odds ratios 0.68 [0.54-0.86] for miR-122-5p and 5.75 [3.97-8.34] for miR-124a-3p). In multivariable analyses including neuron-specific enolase, miR-122-5p and miR-124a-3p were independent predictors of neurological outcome (Table) and generated an integrated discrimination improvement of 0.03 ($p < 0.001$). In Cox proportional hazards models, miR-122-5p and miR-124a-3p were significant predictors of death (hazards ratios 0.67 [0.52-0.86] and 2.53 [1.94-3.28]).

Conclusion: Low levels of miR-122-5p and high levels of miR-124a-3p predict poor neurological outcome and mortality after OHCA.

Odds ratio of poor neurological outcome

Parameter	OR	95% CI	p-value
Neuron-specific enolase	1.04	1.01-1.07	0.003
Log miR-21-5p	1.43	0.84-2.43	0.19
Log miR-122-5p	0.38	0.22-0.65	< 0.001
Log miR-124a-3p	4.94	2.63-9.29	< 0.001
Log miR-181a-5p	0.66	0.37-1.18	0.16
Log miR-221-3p	0.69	0.41-1.18	0.17

Other variables in the model: age, gender, time from cardiac arrest to return of spontaneous circulation, bystander cardiopulmonary resuscitation, first monitored rhythm, shock on admission, lactate levels and targeted temperature management regimen.

P562

Galectin 3 plasma levels at baseline correlate with poor clinical outcome in patients with peripartum cardiomyopathy

F Feriel Azibani¹; W Dowling¹; O Briton¹; T Adam¹; S Kraus¹; J Anthony²; K Sliwa¹

¹University of Cape Town, Medicine, Cape Town, South Africa; ²University of Cape Town, Obstetrics & Gynaecology, Cape Town, South Africa

Background: and objective: Peripartum cardiomyopathy (PPCM) is characterized by new onset of heart failure in late pregnancy and up to the first six months postpartum. Galectin 3 is a β -galactoside-binding lectin protein that is required for transforming growth factor (TGF)- β pathway-mediated myofibroblast activation leading to cardiac fibrosis. This matricellular protein was described as a prognostic biomarker in heart failure patients. We aimed to determine whether galectin 3 and cardiac fibrosis are associated with poor outcome in PPCM patients.

Methods and Results: In this single centre prospective study, we enrolled 37 PPCM patients and 10 age-matched healthy subjects. All patients received ACE inhibitors and beta-adrenergic blocking agents. Plasma NT-proBNP and Galectin 3 levels were measured at baseline. Echocardiograms were performed at baseline and six months postpartum. Poor outcome in PPCM patients was defined by NYHA ≥ 3 or death.

At baseline, PPCM patients had significantly higher NT-proBNP and Galectin 3 levels than healthy controls ($p < 0.001$ and $p < 0.05$, respectively). Six months postpartum, four patients did not improve their cardiac function (EF, $26.7 \pm 7.4\%$) and seven died. Baseline NT-proBNP (3865.6 ± 1039 vs. 1730.1 ± 245 pmol/l, $p = 0.035$) and Galectin 3 (15.72 ± 0.91 vs. 8.75 ± 0.69 ng/ml, $p = 0.02$) levels were significantly higher in patients with poor outcome compared to patients that improved their cardiac function (EF, $45.7 \pm 11.3\%$).

Conclusion: NT-proBNP and Galectin 3 levels were increased in the plasma of PPCM subjects who had poor outcome 6 months after delivery. Galectin 3 may be a clinically useful biomarker that identifies a subset of PPCM patients at highest risk of myocardial dysfunction due to fibrosis. These findings should be confirmed in a larger cohort and could lead to specific therapeutic intervention.

P563

Role of galectin-3 and plasma B-type natriuretic peptide in predicting prognosis in discharged heart failure patients

M Mauro Feola¹; M Testa²; L Leto²; M Cardone³; M Sola³; GL Rosso⁴

¹Cardiovascular Rehabilitation-Heart Failure Unit, Fossano, Italy; ²School of Geriatric University of Turin, Turin, Italy; ³Ospedale Regina Montis Regalis, Laboratory Service, Mondovì, Italy; ⁴ASL CN1, Emergency Service 118, Cuneo, Italy

In discharged HF patients the combination of galectin-3 and NT-proBNP seemed to be the best predictor for short-term (60-day) mortality. Furthermore, galectin-3 demonstrated to be a robust independent marker of cardiovascular mid-term (18-month) outcome in HF patients. The objective of this study was to analyse the value of a single, pre-discharge determination of plasma galectin-3 alone and in correlation with plasma BNP in predicting mid-term clinical outcome in HF patients discharged after an acute decompensated heart failure (ADHF) episode.

Methods: all HF subjects discharged alive after an ADHF episode were enrolled in an out-patient clinic follow-up. All patients underwent a determination of BNP and galectin-3, a 6-minute walk test (6MWT) and a transthoracic echocardiogram within 48 hours upon hospital discharge. Death by any cause, cardiac transplantation and worsening heart failure requiring readmission to the hospital were considered cardiovascular events. Data regarding the occurrence of cardiovascular events were collected from multiple sources in all patients.

Results: eighty-three patients (67 males, age 73 ys old) were analysed (mean follow-up 11.6 ± 5.2 months; range 3-22 months). During the follow-up 38 events (45.7%) were scheduled (13 cardiac deaths, 35 re-hospitalisation for ADHF). Main differences between the events group vs no-events group are described in Table 1. CHF patients who suffered an event are more impaired in renal function and showed an higher plasma BNP and Gal-3 at pre-discharge evaluation. Choosing adequate cut-off points (BNP ≥ 500 pg/ml and Gal-3 ≥ 17.6 ng/ml), the Kaplan-Meier curves depicted the powerful stratification using BNP+Gal-3 in predicting clinical course at mid-term follow-up (Fig 1) (log rank 5.65; $p = 0.017$).

Conclusion: adding Gal-3 to BNP, a single pre-discharge strategy testing seemed to obtain a satisfactorily predictive value in alive HF patients discharged after an ADHF episode.

Tab 1

	No-event group (45pts)	Event group (38 pts)	p
Age	72.6 \pm 11.6	74 \pm 7.4	0.5
Galectin-3 (pg/ml)	19.1 \pm 10.5	24.4 \pm 10.9	0.03
LVEF (%)	40.7 \pm 15.8	33.8 \pm 16.4	0.07
Creatinine	1.3 \pm 0.9	1.4 \pm 0.7	0.5
6MinWalkingTest (m)	374.4 \pm 186.2	287.2 \pm 102.2	0.01
Glomerular Filtration Rate	70.3 \pm 17.3	58.8 \pm 22.6	0.05
Haemoglobin (gr/dl)	13.2 \pm 2.4	12.7 \pm 2.1	0.6
BNP (pg/ml)	681.5 \pm 569.5	1357.5 \pm 1229.2	0.003

LVEF = left ventricular ejection fraction; BNP = brain natriuretic peptide.

Osteopontin could be a predictor of severity in patients with cor pulmonale and patients with left sided heart failure?

M Mahmoud Soliman¹; W A Ebraheem¹; A E El Shkaa¹; A A Reda¹

¹Menoufiya University, Faculty of Medicine, Shebin El-kom, Egypt

Objectives: to measure osteopontin levels in patients with cor pulmonale and patients with left sided heart failure and correlate these levels with pulmonary artery systolic pressure and ejection fraction respectively.

Background: Many biomarkers were recently investigated as possible diagnostic and prognostic makers in left sided and right sided heart failure.

Methods: The study included 75 subjects, divided in three groups : 20 patient in group 1 suffering from left sided heart failure, 23 patients in group 2 suffering from right sided heart failure and cor pulmonale ,20 healthy persons in control group and 12 patients were excluded. All individuals were subjected to thorough history taking, clinical examination, conventional transthoracic echocardiography , osteopontin and brain natriuretic peptide plasma levels measurement.

Results: osteopontine and BNP plasma levels were significantly higher in left sided heart failure patients as well as in patients with cor pulmonale compared with control group (patients with cor pulmonale have the highest values). There was significant negative correlation between osteopontine and EF($r = -0.681, p = 0.001$) and significant positive relationship between osteopontine and NYHA class in patients with left sided heart failure($r = 0.605, p = 0.002$). In patients with cor pulmonale, there was insignificant positive correlation between osteopontin and PASP ($r = 0.311, p = 0.148$).

Conclusion: osteopontin levels were significantly increased in patients with left sided heart failure and correlated with ejection fraction and NYHA class. Also increased significantly in patients with cor pulmonale and right sided failure but the correlation with pulmonary artery systolic pressure was non significant.

P565

Prevention of rehospitalization for heart failure through site visits on Italy territory using an equipped vehicle with POCT brain natriuretic peptide(BNP) + bioimpedance vector analysis (BIVA)

CR Christopher Bartoli¹; RO Marino¹; LA Magrini¹; SI Navarin¹; OB Vitali¹; MR Di Somma¹; SA Di Somma¹

¹Sant' Andrea Hospital, Department of Medical-Surgery Sciences and Translational Medicine, Rome, Italy

Background: Prevention of rehospitalization for Heart failure is a major worldwide issue. The objective of this study was to evaluate if outside hospital medical visits in several Italian areas using an itinerant vehicle equipped with BNP and BIVA would be helpful in identifying patients at risk for rehospitalization for HF.

Methods: This was an observational study by using a medicalized vehicle traveling through 11 cities in Italy during the heart failure ESCHEFA awareness week of 2015. All studied patients underwent into the vehicle: 1.Health questionnaire to test the presence of symptoms of heart failure; 2.Physical examination with vital signs assessment; 3. POCT BNP Test measurement (pg/ml) (AlereTM Heart Check) and 4.BIVA(EFG)assessment. Patients were followed up by phone call 90 and 180 days after in order to check the occurrence of events (death, rehospitalization and needs for Cardiology urgent visit).

Results: 100 patients (M/F 56/44), mean age 67.69 ± 13.13 years were enrolled. On the basis of recorded data patients were divided into four groups: group 1, patients without heart failure (36%); group 2, patients with unrecognized heart failure (21%); group 3, patients with controlled chronic heart failure (19.4%); group 4, patients with heart failure not controlled by therapy (23.6%). In group 1,2,3 and 4 : median values of [IQR] of BIVA and BNP were:73.7%[73.-73.9] and 52.0[35.0-91.0]; 79%[76.3-81.5]

and 270[189.7-383]; 73.7%[73.5-73.8] and 132.5[73-221]; and 80.9%[77.6-84.9] and 241[151.7-460.2] respectively. There was a significant difference within the groups both for BIVA and for BNP: group1 vs group2 ($p < 0.0001$); group1 vs group4 ($p < 0.0001$); group2 vs group3 ($p < 0.0001$); group 3 vs group4 ($p < 0.0001$). A direct correlation was found between BNP and Hydration% ($r = 0.34, p < 0.003$), and a significant inverse correlation between BNP and reactance ($r = -0.38, p < 0.001$). In all studied population the combination of BNP+BIVA showed to have good prognostic power for future events with an AUC 0.78 ($p < 0.001$). In the group 4: the value of the BNP (with a cut-off > 211 pg/ml) showed to be as a prognostic factor for future events with an AUC 0.90 ($p < 0.0001$); while at BIVA analysis: hydration percentage (with a cut-off $> 82\%$) and reactance (with a cut-off < 29.2 ohm) resulted to be have prognostic role for future events with AUCs of 0.82 ($p < 0.001$) and 0.78 ($p < 0.006$) respectively.

Conclusion: In patients with HF, on site preventive, examination using POCT BNP+BIVA seems to be useful to identify those subjects apparently asymptomatic and in stable condition but at risk for future events. This initiative could be useful for primary heart failure prevention and better management in order to avoid rehospitalizations for worsening heart failure.

P566

Diagnostic and prognostic value of BNP, NGAL, ST2 AND TnIhs in patients with hypertensive crisis in the emergency department

F Cristofano¹; V Amadoro¹; I Lalle¹; L Magrini¹; G Salerno¹; P Cardelli¹; S Di Somma¹

¹Sant' Andrea Hospital, Emergency Medicine, Rome, Italy

Introduction: Hypertensive Crisis are one of the most common and frequent cause of visits for patients referring to Emergency Department (ED). There are few studies in literature investigating the diagnostic and prognostic role of biomarkers in patients with hypertensive crisis.

Purpose: Aim of this study was to investigate the diagnostic and prognostic role of Brain Natriuretic Peptide (BNP), Neutrophil Gelatinase-Associated Lipocaline (NGAL), suppression of tumorigenicity 2 (ST2) and high sensitive Troponin I (TnIhs) in patients with hypertensive crisis, and to evaluate their possible role in the differential diagnosis between hypertensive emergencies or urgencies.

Methods: This was a prospective observational study in hypertensive crisis patients (Systolic Blood Pressure > 180 mmHg and/or Diastolic Blood Pressure > 120 mmHg), presenting to the ED of Sant'Andrea University Hospital of Rome from August 2014 to February 2015. At ED arrival BNP, NGAL, ST2 and TnIhs blood values were measured.

Results: 73 patients (M/F 40/35; mean age 66.39 ± 14.05 years) with hypertensive crisis (34 hypertensive emergencies; 39 hypertensive urgencies) were enrolled. In hypertensive emergencies the final diagnosis were: acute ischemic coronary disease (8/34, 24%), acute pulmonary edema (8/34, 24%), acute cerebrovascular disease (13/34, 38%), acute renal failure (5/34, 14%). Compared to patients with hypertensive urgencies, patients with hypertensive emergencies showed significantly higher levels of biomarkers (BNP 358.36 ± 504.68 vs 43.80 ± 36.94 pg/ml ($p = 0.001$); NGAL 85.55 ± 75.33 vs 53.40 ± 22.23 ng/ml ($p = 0.04$); TnIhs $11.80 [3.34 - 3.67]$ pg/ml vs $3.75 [2.2 - 8]$ pg/ml ($p < 0.0007$). ST2 levels were not different in the two subgroups of patients: ST2 $31.55 [21.5 - 51.7]$ ng/ml e $31.5 [19.42 - 51.07]$ ng/ml ($p = 0.66$). We analyzed biomarkers prognostic value in terms of probability of rehospitalization: BNP showed a significant prognostic value (AUC 0.744, $p < 0.0001$), similar to the combination of the three biomarkers (AUC 0.672, $p < 0.03$)

Conclusions: BNP, NGAL and TnIhs seem to be potential useful biomarkers in distinguishing hypertensive emergencies from urgencies in Emergency Department. Moreover, BNP seems to have a good prognostic value for rehospitalization in patients with hypertensive emergencies from the ED.

P567

Features of N-terminal of the prohormone brain natriuretic peptide plasma level in patients with arterial hypertension and chronic heart failure with a preserved left ventricular ejection fraction

E JU Gubareva¹; IV Gubareva¹; NN Kryukov¹

¹Samara State Medical University, Internal diseases, Samara, Russian Federation

Purpose of research is to study the characteristics of N-terminal of the prohormone brain natriuretic peptide plasma level (NT-proBNP) in patients with arterial hypertension (AH) and heart failure with a preserved left ventricular ejection fraction (HFpEF).

Research methods: 346 men, average age 46.68 ± 10.44 year were surveyed and divided into groups: group 1 - patients with hypertension without HF ($n = 180$); group 2 - patients with AH and HFpEF ($n = 86$). Healthy men with normal blood pressure, without CH ($n = 80$) representative by age were included in a control group. All patients underwent echocardiography, daily monitoring of arterial pressure, NT-proBNP plasma level was determined with enzyme-linked immunosorbent assay (ELISA method).

Results: the highest NT-proBNP was in the patients of the first group with 1 degree of hypertension in comparison with patients with 2 and 3 degree of

AH, the control and the second group of patients. Correlation analysis of the data in group 1 showed an inverse correlation between NT-proBNP and the degree of hypertension ($r=-0.624$; $p=0.023$). In group 2 this correlation was not established ($r=0.151$; $p=0.294$). NT-proBNP in group 2 correlated with functional class of chronic heart failure ($r=0.215$; $p=0.049$) and diastolic filling: E ($r=0.252$, $p=0.05$), E/A ($r=0.347$, $p=0.018$). The level of natriuretic peptides was highest in the group "non-dipper", "night-peaker" and statistically significantly different from patients with an unchanged circadian blood pressure profile and the profile of the "over-dipper" as for systolic blood pressure, and the circadian profile of diastolic blood pressure.

Conclusions: The determination of natriuretic peptides in patients with arterial hypertension and chronic heart failure personifies the diagnosis of disease and prediction of cardiovascular events: a decrease in plasma levels of NT-proBNP in patients with arterial hypertension without HF is associated with higher degree of hypertension and the risk of defeat of target organs; in patients with chronic heart failure, regardless of the degree of hypertension, increased levels of natriuretic peptides indicates the severity of myocardial dysfunction and severity of chronic heart failure.

P568

Exhaled breath analysis in diagnostics of heart failure with preserved ejection fraction

This study was supported by Russian Academy of Science

A A Alexandra Bykova¹; L K Malinovsky¹; PH YU Kopylov¹; P SH Chomahidze¹; A L Syrkina¹; V B Betelin²; YU R Shaltaeva³; V S Pershenkov³; N N Samotaev³

¹I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; ²Scientific Research Institute of System Development, Moscow, Russian Federation; ³National Research Nuclear University "MEPhI", Moscow, Russian Federation

Background:

Heart failure (HF) is a leading cause of cardiovascular morbidity and mortality. The 5-year survival rate for all patients with heart failure, regardless of ejection fraction (EF), is less than 50%. Data from epidemiologic studies of heart failure with preserved EF (HF-PEF) find that the annual mortality is approximately 10%. The diagnosis of HF-PEF is more difficult than the diagnosis of HF with reduced EF (HF-REF). In our previous studies we found out that concentration of certain voluntary organic compounds (VOCs) in exhaled breath in patients (pts) with and without HF is differ.

Purpose:

The purpose of this study was to investigate exhaled breath in patient with HF-PEF. METHODS From October 2013 to September 2015 we enrolled 21 pts with HF-PEF in heart failure group and 16 pts without HF in control group. HF-PEF was diagnosed according ESC active guidelines. We collected fasting exhaled breath samples of all patients in 1L Tedlar bags. Exhaled breath was analyzed using PTR-MS (Compact PTR-MS, Ionicon, Austria).

Results: The baseline characteristics of pts are in the Table 1. In compare with control group several biomarkers were significantly higher in HF-PEF group. They are acetone, acetic aldehyde, ethanol, propylene. The median (interquartile range) concentration of acetone in HF-PEF group when compared to control group was 934 ppb [324-2432] vs 322 ppb [280-368], $p=0.002$; acetic aldehyde 297 [213-441] vs 193 [177-231], $p=0.004$; ethanol 18 [14-28] vs 10.6 [9-21], $p=0.018$; propylene 343 [122-873] vs 124 [94-141], $p=0.04$ respectively.

Conclusion: There are significant difference in exhaled breath between patients with HF-PEF and without heart failure. Further investigation is necessary to determine the correlation between these biomarkers and levels of natriuretic peptides.

Baseline characteristics.

Cardiac expression of NGAL is up-regulated in experimental cancer cachexia

Piano di azione e coesione ricerca e competitività PON 2007-2013

V Vincenzo Musolino¹; C Carresi¹; M Gliozzi¹; C Drescher¹; C Latouche²; F Jaisser²; SD Anker³; V Mollace¹; J Springer¹

¹Institute of Research for Food Safety & Health (IRC-FSH), University of Catanzaro "Magna Graecia", C, Catanzaro, Italy; ²Institut National de la Santé et de la Recherche Médicale UMR 872 Team 1, Centre de Recherche des C, Paris, France; ³Division of Innovative Clinical Trials, Department of Cardiology, University Medical Center Göttinge, Berlin, Germany

Introduction: NGAL is commonly seen as a marker of kidney injury; however, it has also been associated with critically ill patients (heart failure, sepsis, multi-organ failure) and is thought to play a role in cancer cell motility.

Study design and methods: Here we compared the mRNA expression of NGAL in the heart of cachectic rats bearing the Yoshida hepatoma ($n=16$) to that of the aldosterone antagonist spironolactone-treated (5 or 50 mg/kg/d, $n=11$ and 9, respectively) rats as well as healthy controls ($n=10$). Plasma levels of NGAL and aldosterone were assessed by ELISA. Tumor bearing rats lost 45 ± 4 g body weight, while controls gain 61 ± 3 g ($p<0.001$) after 16 days. Five mg/kg/d spironolactone reduced wasting (-25 ± 10 g) and 50mg/kg/d stopped weight loss ($+0.5 \pm 16$ g, $p<0.05$). Cardiac NGAL mRNA expression was up-regulated by 93% compared to controls ($p<0.05$) and was reduced to control levels by 50 mg/kg/d spironolactone ($p>0.05$), while the 5mg/kg/d dose was not effective. Aldosterone was up-regulated from 337 ± 7 pg/mL in controls to 591 ± 31 pg/mL in the placebo group ($p<0.001$) and reduced to 396 ± 22 pg/mL in animals treated with 50mg/kg/d spironolactone ($p<0.01$). Plasma levels of NGAL were increased in tumor-bearing rats (1462 ± 360 g/L) compared to controls (93 ± 6 g/L, $p<0.001$). High dose spironolactone reduced NGAL levels to 530 ± 77 g/L ($p<0.05$ vs placebo). Cardiac function assessed by echocardiography was markedly improved by high dose spironolactone. Cardiac output on day 11 was decreased in the placebo group compared to control 49 ± 7 mL/min vs 80 ± 7 mL/min, respectively $p<0.01$). This functional impairment was reduced by high dose spironolactone (79 ± 7 mL/min, $p<0.01$ vs placebo), which may functionally reflect the reduction of NGAL mRNA in the heart and protein in plasma.

Conclusion: NGAL could potentially be used as a biomarker to assess cardiac impairment in cancer cachexia. However, more studies are needed to confirm our results.

P570

Dependence of concentrations of heart failure biomarkers on ultrasound indicators of remodeling in subjects with myocardial infarction

N Natalya Fedorova¹; ON Hryachkova¹; OM Poliklutina¹; OL Barbarash¹

¹Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation

Purpose: To estimate the content of galectin-3 and its relationship with ultrasound indicators of remodeling in comparative aspect with N-terminal natriuretic propeptide (Nt-proBNP).

Materials and methods: We examined 87 subjects admitted with the diagnosis of ST-elevated myocardial infarction (STEMI). All the subjects underwent standard diagnostic methods in MI, including coronary angiography (CAG). On the 10th - 14th days of MI all the subjects underwent echocardiography under standard modes with left ventricle (LV) ejection fraction (EF) estimation and remodeling parameters such as LV end-diastolic dimension (EDD), LV end-systolic dimension (ESD). Galectin-3 was estimated by immunoenzyme method in blood serum in all the subjects on the 1st - 2nd days of the disease and in 81 subjects it was estimated in dynamics on the 10th - 14th days. The allowed values of this biomarker in blood serum are 0.0-2.28 ng/ml. Nt-proBNP level was estimated in 81 subjects on the 1st - 2nd days of MI and in 78 subjects on the 10th - 14th days of the disease. Reference range of this indicator in subjects younger than 75 years old is up to 125 pg/ml, older than 75 years old - up to 450 pg/ml. We used standard statistical methods of data processing.

Results: Evaluation of instrumental indicators showed that subjects with LV dilatation are characterized by higher ($=0.01$) values of galectin-3 estimated on the 10th - 14th days of the disease ($26.1 [11.9;42.9]$ ng/ml and $10.6 [9.1;28.9]$ ng/ml respectively). These data were also confirmed by conducting a correlation analysis, thus we noted a positive correlation of galectin-3 estimated on the 10th - 14th days of MI with the values of LVEDD ($r=0.39$; $p=0.01$) and LVESD ($r=0.4$; $p<0.01$). The presence in subjects of a reduced LVEF less than 40% was associated ($=0.01$) with the increased value of galectin-3 on the 10th - 14th days of MI which was $45.6 [44.8;52.8]$ ng/ml as compared to subjects with the preserved LVEF - $15.5 [9.9;35.9]$ ng/ml. Nt-proBNP level didn't show any significant association with echocardiographic parameters.

Conclusions: Galectin-3 is more sensitive to ultrasound markers of acute myocardial remodeling as opposed to Nt-proBNP.

Purpose: Induced therapeutic hypothermia is documented to be organ-protective including neuro- and cardiac protection. In contrast, spontaneously occurring hypothermia provokes several negative effects that rise concerns regarding potential detrimental effect of induced hypothermia, particularly during inflammation. Whereas septic patients with hypothermia suffer from higher incidence of organ dysfunction and increased mortality, underlying molecular mechanisms are barely elaborated.

Methods: Mice were acclimatized either to neutral ambient temperature of 30°C (normal ambient temperature group, NORM) or reduced ambient temperature of 26°C (reduced ambient temperature group, COOL). Thereafter, mice received LPS (10mg/g bw i.p.) and effects on survival, cardiac autonomic regulation (ANS, telemetry), left ventricle performance (Pressure-Volume-conductance) and stress-associated tissue injury and cell death in heart were studied at control, 3h, 24h, 3days & 7days post injection.

Results: Intriguingly, an enhanced sympathetic tone verified by heart rate (HR), HRV (heart rate variability), sympathetic tone activity and cardiac catecholamine release was found in mice kept at 26°C. Mortality rate of the COOL group was significantly increased (> 50%) after LPS-induced SIRS, compared to the NORM group (mortality rate < 10%). The evaluation of body temperature revealed a LPS-dependent induction of hypothermia in both groups, which was more pronounced in the COOL group by about 4°C. We further revealed that the cardiac contractility was transiently impaired in mice kept at 30°C with complete recovery after 7days, whereas animals of the COOL group developed a pronounced and prolonged myocardial dysfunction with reduced contractility compared to the NORM group. The reduced contractility of the COOL group was further confirmed by a reduced beta adrenergic pathway activity of heart tissue. Surprisingly, the level of inflammation in cardiac tissue from both groups was comparable, whereas the stress maker (HSP90) for tissue and organ injury known to be upregulated under catecholamine overstimulation was abundantly increased in COOL group. In addition, further evaluation of cardiac tissue revealed a higher level of stress-related inflammatory response (iNOS expression with enhanced nitrotyrosine formation), stress-induced damage (PARP) and cell death (Tunel positive) in mice from the COOL group.

Conclusion: Enhanced sympathetic activation induced by unsuitable ambient temperature provokes in LPS-induced SIRS mice significant effects including mortality rate and sustained heart failure.

Effects of GRK5 gene removal in stress induced cardiomyopathy

M Ciccarello¹; M De Rosa²; L Napolitano²; D Sorriento³; J Gambardella¹; B Trimarco²; G Iaccarino¹

¹University of Salerno, Salerno, Italy; ²"Federico II" University of Naples - Dept of Advanced Biomedical Sciences, Naples, Italy; ³Institute of Genetics Biophysics CNR, Naples, Italy

Background: G protein coupled receptor kinase 5 (GRK5) is a ser/thr kinase involved in the regulation of the beta adrenergic receptors (β ARs) signaling and cardiac function. A genetic variant of GRK5 gene (L41Q polymorphism) is strongly associated with Stress Induced Cardiomyopathy, in which catecholaminergic stress plays a central role. We can induce SIC like regional akinesia in mice by intraperitoneal (i.p.) injection of a single dose (400 mg/kg) of isoprenaline (ISO), a non-selective beta adrenergic agonist.

Purpose: To evaluate the role of GRK5 in the pathogenesis of SIC.

Methods: In order to assess the effects of ISO on global and regional cardiac contractility we performed echocardiography (Vevo 770) in mice with gen deletion for GRK5 (GRK5KO) and C57BL/6J (WT) used as control. We calculated Ejection Fraction (EF) and Fractional Wall Thickening (FWT), defined as the ratio between wall thickness in systole and diastole, in basal condition and after stimulation with ISO. FWT was calculated in 18 different cardiac segments. Results were represented as variation of EF and FWT (Δ EF% and Δ FWT) respect to basal. At last, hearts were collected for biochemical analysis.

Results: In WT group after 2 hrs stimulation we observed a Δ 25% \pm 2% for EF, while the analysis of Δ FWT evidenced a regional contractile impairment in 13/18 cardiac segments. In GRK5KO group after 2 hours stimulation we observed an higher Δ EF% respect to WT (Δ 52% \pm 4%) while the analysis of Δ FWT evidenced an impairment of contractility in only 9/18 cardiac segments. In particular, contractility impairment

was significantly higher in apical segments in WT group in comparison to GRK5KO group (6/6 in WT vs 3/6 in GRK5KO). To identify the role of regional β AR signaling we explored the localization to cardiac membranes of another GRKs classically associated to desensitization, GRK2. In membrane extracts from basal and apical sections of myocardium, in basal condition, GRK2 levels are higher in the apex of WT mice and ISO reduced such accumulation. Opposite, in GRK5 KO mice, GRK2 levels are lower in the apex in basal condition, compared with WT, and are recovered in response to ISO.

Conclusion: This data confirm the role played by catecholaminergic stress in SIC. GRK5 removal preserve left ventricular function in this condition, suggesting that β AR desensitization is involved in the pathogenesis of SIC. Moreover, SIC specific cardiac phenotype may be due to the different pattern of distribution of GRKs and β ARs.

A-B crystallin reverses high titin-based stiffness in failing human cardiomyocytes

FP7-Health-2010; MEDIA-261409

C Constantijn Franssen¹; N Hamdani¹; WJ Paulus¹

¹VU University Medical Center, Department of Physiology, Amsterdam, Netherlands

Background: Increased diastolic stiffness is present in almost every heart failure patient and is caused by fibrotic changes of the extracellular matrix (ECM) and changes in the cardiomyocyte protein titin. Purpose: The purpose of this study was to determine the relative contributions of the ECM collagen and the cardiomyocyte titin to diastolic stiffness in failing human hearts. Moreover, different contributors to titin-based stiffness were explored.

Methods: Left ventricular tissue was procured during aortic valve replacement in patients with severe aortic stenosis (AS, n=7) or during cardiac catheterization in patients with dilated cardiomyopathy (DCM, n=3). Explanted donor hearts (n=8) served as controls. Myocardial strips were dissected and attached between a force transducer and a length motor to measure passive stiffness (Fpassive) caused by titin and collagen over a range of muscle stretches. After detaching all cardiomyocyte filaments with KCl and KI, stretches were repeated and the remaining Fpassive was collagen-based. In isolated, single cardiomyocytes, similar experiments were performed to further explore titin-based Fpassive. Cardiomyocytes subsequently underwent incubation with alkaline phosphatase to dephosphorylate titin, a prestretch in an acidic environment (to mimic failing myocardium) and, finally, incubated in α -B crystallin. After each step, muscle stretches were repeated and Fpassive was determined. Also, another series of experiments were performed in AS samples to determine the effect of each individual step in the single cardiomyocyte experiments.

Results: Cardiomyocyte Fpassive was increased over the whole range of stretches in AS and DCM, whereas ECM Fpassive was only higher in failing hearts at higher muscle lengthening. Fpassive in donor samples increased after dephosphorylation, but not to levels observed in failing cardiomyocytes. Acidity and prestretch increased Fpassive in donor to reach levels observed in failing cardiomyocytes and this was normalized by α -B crystallin. In single AS cardiomyocytes, prestretch was the key mechanism to increase Fpassive. In failing cardiomyocytes, irrespective of pretreatment, α -B crystallin normalized Fpassive.

Conclusion: The ECM contributed to increased diastolic stiffness in failing myocardium, but only at higher muscle lengthening or at an advanced stage. Cardiomyocyte Fpassive was increased over a whole range of muscle stretches in failing myocardium. Changes in titin phosphorylation status were insufficient to explain the increased Fpassive in failing cardiomyocytes. These findings suggest that structural changes, such as titin aggregation under conditions of wear and tear lead to increased cardiomyocyte Fpassive and this was normalized by administration of α -B crystallin.

Cardiac dysfunction induced by ionizing radiation exposure: the mitochondrial side

M Michele Ciccarello¹; L Napolitano²; A Franco²; D Sorriento³; M De Rosa²; A Flordelis²; B Trimarco²; G Iaccarino⁴

¹University of Naples Federico II, Dpt of Clinical Medicine, Cardiovascular & Immunological Science, Naples, Italy; ²"Federico II" University of Naples - Dept of Advanced Biomedical Sciences, Naples, Italy; ³Institute of Genetics Biophysics CNR, Naples, Italy; ⁴University of Salerno, Salerno, Italy

Background: Exposure to ionizing radiation (IR) is a cause of cardiac dysfunction whose severity relates among other factors to the increased reactive oxygen species production (ROS). Mitochondria, being the primary source of radical oxygen species (ROS) and of energetic substrates for the myocardium, are the possible mechanisms of IR related cardiac dysfunction.

Purpose: To evaluate the possible involvement of mitochondria to mediate the effects of IR exposure on cardiac function.

Methods: In C57BL/6 mice subjected to IR exposure by X-ray (4 Gy), we performed

echocardiography at basal, and 3 and 24 hours post IR exposure. Mice were sacrificed and heart samples collected at each time point for analysis of mitochondria morphology by transmission electron microscopy (TEM) and biochemistry.

Results: At 3 h post-IR, we observed increased left ventricle diastolic diameter (LVDd: 39.5 ± 0.3 vs 35 ± 0.15 mm; $p < 0.05$ vs Basal) with reduced ejection fraction (EF: $45\% \pm 2$ vs $66\% \pm 4$; $p < 0.05$ vs Basal). At 24h post-MI, we found a recovered LVDd (36.2 ± 0.4 vs 35 ± 0.15 mm; ns) and ameliorated cardiac contractile function (EF: $60\% \pm 3$ vs $66\% \pm 4$; ns). Morphological analysis by TEM (Fig 1) revealed that, at 3 hours post IR exposure, mitochondria were reduced in number, showing cristae disarrangement with intra-vacuolization and fragmentation. At 24 h post-IR mitochondria number and morphology are recovered with normal cristae and absence of vacuolization. Morphological changes were accompanied by molecular modifications involved in mitochondria induced apoptosis (Cyt C), mitophagy (p62) and mitochondrial mass (SOD). In particular, Cyt C release was dramatically increased into cytosolic fraction at 3 h post IR and reduced at 24 h. Similarly, p62 was increased in response to stress at 3 h with a partial reduction at 24 h. Inversely, SOD level was reduced at 3h but normalized at 24h as compared to basal, indicating recovering of mitochondrial mass. Mitochondria damage was also evaluated by expression of the different complexes (I to IV) composing the mitochondria respiratory chain through RT-PCR. At 3 h post-IR complex I,II,III and IV are all reduced as well ATPase expression. At 24 hours post-IR, complexes expression and ATPase were recovered.

Conclusions: IR induces an acute cardiomyopathy that is associated to an altered mitochondrial morphology and function.

Mito post IR

Biventricular remodelling in pressure overload: the role of adipose tissue and inflammation

NG Nadia Goncalves¹; AF Silva¹; G Almeida¹; M Santos¹; CM Moura¹; MJ Mendes¹; R Roncon-Albuquerque Jr¹; AF Leite-Moreira¹; I Falcao-Pires¹

¹University of Porto, Faculty of Medicine, Department of Physiology and Cardiothoracic Surgery, Porto, Portugal

Purpose: Evaluate the impact of left ventricle chronic pressure overload in both ventricles and the contribution of inflammatory mediators produced by the adipose tissues in the cardiac adaptations.

Methods: Wistar rats (65-85g) were randomly divided and submitted to ascending aortic constriction (AC group) or sham procedure (Sh group). Echocardiographic and hemodynamic evaluations were performed after 8 weeks and samples of myocardium, skeletal muscle and adipose tissue obtained for morpho-histological and molecular assessment.

Results: (Figure): As expected the AC group developed increased heart weight, left ventricle (LV) wall thickness, cardiomyocyte hypertrophy and elevated fibrosis content compared with the Sh group. The AC also promoted increased systolic pressure (Psyst), reduced contractile reserve (Pisovol) and myocardial stiffness (EDPVR) of LV. Interestingly the same structural adaptations were observed in the right ventricle (RV) of the animals with AC: cellular hypertrophy and fibrosis deposition. At the functional level these animal presented elevated Psyst beside increased TEI index and time of constant of isovolumetric relaxation (Tau) in the RV. Furthermore, although similar body weight in the 2 groups, the AC animals presented adipose tissue and skeletal muscle atrophy at cellular level. These structural alterations in the adipose tissue resulted in altered secretory profile with increased synthesis of pro-inflammatory molecules such as TNFα.

Conclusions: We observed that LV overload affect both ventricles before impairment of the systolic function. This condition also impacts other tissues at an early stage, stimulating skeletal muscle and adipose tissue atrophy. Mediating the bi-ventricular cardiac remodeling might be the pro-inflammatory environment promoted by the dysfunctional adipose tissue.

Recombinant factor Xa activates murine primary cardiac fibroblasts in vitro.

M Schwarzl¹; D Lindner¹; K Giese¹; S Blankenberg¹; D Westermann¹

¹University Heart Center Hamburg, Dept. of General and Interventional Cardiology, Hamburg, Germany

Background: Clinical data suggest that heart failure patients with coronary artery disease may benefit from pharmacological factor Xa-inhibition. A potential pathophysiological mechanism relates to protease activated receptor (PAR) mediated processes leading to adverse cardiac remodeling, as PARs are stimulated by a number of proteases including factors Xa and IIa. We aimed to investigate the contribution of cardiac fibroblasts and tested, whether they are activated by recombinant factors Xa and IIa.

Methods and Results: Using TaqMan-PCR we found PAR-1 highest expressed in primary murine cardiac fibroblasts, whereas PAR-2 was lower expressed and PAR-3 as well as PAR-4 expression was almost not detectable (Fig. A). When primary murine cardiac fibroblasts were incubated with recombinant factor Xa (1 U/ml, 24 hours), connective tissue growth factor (CTGF) expression (Fig. B, normalized to CDKN1b expression) increased significantly, while the inactive factor X did not alter CTGF expression. Similar results were found for the recombinant factor IIa (1 U/ml).

Conclusion: PAR-1, a receptor potentially sensitive for factor Xa and IIa, is highly expressed on primary murine cardiac fibroblasts. Stimulation with recombinant factors Xa and IIa resulted in activation of these cells, indicating that cardiac fibroblasts may contribute to PAR mediated adverse cardiac remodeling in heart failure. This and a potential protective effect of pharmacological factor Xa-inhibition will be clarified in further mechanistic studies and animal models.

Exercise preconditioning increases endothelium-dependent dilatation of isolated pulmonary vessels in rats with hypoxic pulmonary hypertension

N Pankova¹; M Artemieva¹; N Boiko¹; A Terentyev¹; E Lagereva¹; N Medvedeva¹

¹M.V. Lomonosov Moscow State University, Biological, Moscow, Russian Federation

Introduction: One of the reason of pulmonary hypertension is an imbalance between vasodilators and vasoconstrictors. The increase of endothelium-derived vasoconstrictors causes vessels wall thickening, increases pulmonary resistance and right ventricular systolic pressure. Exercise was shown to improve endothelial function (Mereles, 2006). The aim of the study was to test the hypothesis that exercise training will increase endothelium-dependent dilation of pulmonary vessels and reduce the degree of pulmonary hypertension.

Methods and design: Male Wistar rats were used. The procedures followed the FELASA/ICLAS for use of the laboratory animals (Guide for use of the laboratory animals, National Academy Press, Washington, D.C.1996). hPAH was induced by exposure to hypobaric hypoxia. Rats were housed in a hypobaric chamber at simulated altitude of 5000 m, 10 h a day, 2 wk. (O2 concentration reduced to 10%). The rats were divided into two groups: hPAH control (CPAH) and trained hPAH (TPAH). Rats underwent exercise training (aerobic swimming during 30 min.) for a period of

2 weeks to hypoxia. Right ventricular (RV) hypertrophy was calculated as RV weight /rat b. w. Systolic right ventricle pressure (RVSP) was measured. Perfusion pressure of isolated pulmonary and systemic (popliteal) artery to vasoconstrictor serotonin (10-9 – 10-5) was measured. Endothelium-dependent dilatation of isolated blood vessels caused by estradiol (10-9 – 10-5). Endothelium-independent vasodilatation caused by sodium nitroprusside (10-9 – 10-5M).

Results: Two weeks after hypoxia exposure all rats developed hPH and RVSP was higher by 26% in group TRAH compared with group CRAH. Pulmonary vessels of rats, which had exercise preconditioning demonstrated elevated vasodilation to estradiol (106M, -58% vs. control -28% $p < 0.05$) without changing responses to sodium nitroprusside (-91% vs 81%) and serotonin perfusion. In the arteries of the systemic circulation differences between groups were not found.

Conclusions: Aerobic exercise preconditioning (30 min. swimming) causes an increase in endothelium-dependent vasodilatation of isolated pulmonary vessels in rats with hypoxic pulmonary hypertension. However, this does not reduce the extent of the disease.

P578

Effects of aerobic exercise training on hypoxia-induced pulmonary hypertension and platelet count in male rats

N Natalia Medvedeva¹; N Pankova¹; A Andreev-Andrievskiy¹; A Popova¹

¹M.V. Lomonosov Moscow State University, Biology Department, Moscow, Russian Federation

Introduction: Analysis of the influence of exercise training on the development of pulmonary hypertension has been for 40 years. However, the answer has not been received. It is shown that physical exercise can both positively and negatively influence on the disease. The result depends on the type of pulmonary hypertension, hemodynamic, age and others. Aim. We analyzed the role aerobic exercise training on the systolic right ventricle pressure, and platelet count in the male rats with hypoxia pulmonary hypertension (hPAH).

Methods and design: Male Wistar rats were used. The procedures followed the FELASA/ICLAS for use of the laboratory animals (Guide for use of the laboratory animals, National Academy Press, Washington, D.C.1996). hPAH was induced by exposure to hypobaric hypoxia. Rats were housed in a hypobaric chamber at simulated altitude of 5000 m, 10 h a day, 2 wk. (O₂ concentration reduced to 10%). The rats were divided into two groups: hPAN control (CPAH) and trained hPAH (TPAH). Rats underwent exercise training (aerobic swimming during 30 min.) for a period of 2 weeks to hypoxia. Right ventricular (RV) hypertrophy was calculated as RV weight /rat b. w. Systolic right ventricle pressure (SAP) was measured. Blood hematocrit (Hmt), hemoglobin (Hb) and platelet (PLT) were measured using a blood analyser Gemalait 1280 (Dikson Russia).

Results: Two weeks after hypoxia exposure both groups of male rats developed hPAH. However the degree of disease was different: the magnitude of RV hypertrophy was significantly greater in TRAH rats than in CPAH (7,02 ± 0,29 vs. 5,86 ± 0,30 $p < 0.05$). The degree of systolic right ventricle pressure in TRAH groups as the indicator of hPAH was high than in CPAH rats (74,8 ± 5,25 vs 59,3 ± 4,9 mm Hg; $p < 0.05$). Hmt and Hb were similar in both groups. But PLT was higher in TRAH group than in CPAH group (449 vs 562 × 10⁹/L).

Conclusions: The two-week aerobic exercise training to hypoxia leads to an increase in the level of development of hypoxic pulmonary hypertension. It can be assumed that platelet activation and pulmonary vascular thrombosis plays a role in this effect.

Effects of asthma severity on remodeling of right ventricular in patients with arterial hypertension

AA Odegova¹; EI Tarlovskaya²

¹Kirov State Medical Academy, Internal medicine, Kirov, Russian Federation;

²Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation

Background: Bronchial asthma (BA) is a serious medical problem. It was found that the frequency of arterial hypertension (AH) detection in patients with asthma is about 30 %. Purpose of the study. The article analyzes peculiarities of progression of changes in the right ventricle (RV) in cases of different degrees of severity of BA at the background of AH.

Material and methods: 91 patients were involved in a study of 2008-2015 years with varying BA severity in the step of controllability associated with AH 1, 2 severity. Of these, 26 patients (29%) with mild BA (BAMAH), 34 (37%) with an average severity of BA (BAAAH), 31 (34%) - severity of severe BA (BASAH). A group of 30 patients with AH 1.2 degrees and a group of 32 people with BA were taken for a comparative analysis. All examined patients were outpatients and were taken adequately matched basic therapy on BA with inhaled corticosteroids (ICS). The patients used a β_2 -agonists (β_2 -AM) short action on demand. A group of patients with AH 1.2 degrees, n = 30, and a group with different degrees of BA in the stage of

control n = 32, were taken for comparative analysis. The diagnosis of AH and extent of increase the blood pressure (BP) - on the basis of criteria of WHO 2013. In groups of comparison there were no statistically significant distinctions of an average the BP, groups were comparable on age, sex and an experience of AH ($p > 0.05$). All patients were performed the echocardiography on Acuson 128XP \ 10c (USA).

Results: Changes in the RV in patients with BA accompanied by AH and without it were similar. There were more unfavorable situations in case of combined pathology. The number of hypertrophy of the RV in patients with combined BA and AH was reliably higher. BA-1,9 ± 0,07cm, H-1,94 ± 0,05cm, BAMAH-3,83 ± 0,16cm, =0,01, BAAAH-5,2 ± 0,12cm, =0,002, =0,005, BASAH-10,45 ± 0,49cm, =0,0015, =0,0001.

Conclusion: Remodeling of the right parts of the heart in patients with BA with AH was similar. With isolated BA hypertrophy of the RV was revealed in several patients included in the group with severe BA. In cases of combined pathology hypertrophy of the RV was already revealed in mild degrees of bronchial obstruction. Obvious hypertrophy of the RV increased with increase of the severity of bronchial obstruction in patients with combined AH and BA.

Cartilage oligomeric matrix protein (COMP) is a potential adaptive mechanism to the pressure overload in the right ventricle

LB1 LVR

B Bakytbek Egemnazarov¹; S Crnkovic¹; H Olschewski²; A Olschewski¹; LM Marsh¹; G Kwapiszewska¹

¹Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria; ²Medical University of Graz, Graz, Austria

Objective: Right ventricle (RV) is subjected to pressure overload in many clinical situations like pulmonary embolization and pulmonary arterial hypertension. The functional status of RV predicts survival of those patients. However, the mechanisms of RV adaptation to pressure overload are not fully investigated. The aim of our study was to investigate the role of COMP in the RV pressure overload model.

Methods: RV pressure overload was induced in wild-type (WT) or COMP knockout (KO) mice by pulmonary artery banding (PAB). Three weeks post-operation, mice were investigated by echocardiography and invasive hemodynamics. Subsequently, histology and gene expression analysis were performed on RV tissue samples. Cultured cardiac fibroblasts were stimulated by TGF β and PDGF and COMP expression was analyzed by RT-PCR.

Results: PAB generated a significant pressure overload in WT mice (RV systolic pressure (RVSP) in PAB=48 ± 11 mm Hg vs. sham29 ± 5 mm Hg, $p = 0.001$). Echocardiography showed thickened RV free wall, enlarged RV and reduced cardiac. Invasive hemodynamics revealed reduced contractility index, prolonged tau, and elevated EDP. Elevated expression of ANP, BNP and collagens was measured in RV tissue samples. Histologic examination revealed RV fibrosis. Elevated COMP expression was detected in RV tissue, which was localized to vimentin and DDR2 positive cells. PAB operation in COMP KO mice caused RVSP elevation comparable with RVSP in WT mice (COMP KO RVSP=50 ± 4 mm Hg, $p = 0.15$ vs. WT PAB). However, COMP KO mice demonstrated worse survival after PAB operation. They demonstrated worsening of diastolic function compared to WT mice as evidenced by prolonged Tau ($p = 0.012$ vs. WT PAB) and elevated RV EDP ($p = 0.005$ vs. WT PAB). Higher degree of RV fibrosis was revealed by Masson's Trichrome staining in RV of COMP KO PAB operated mice. In the isolated cultured cardiac fibroblasts, stimulation by TGF β but not PDGF caused increase in COMP expression.

Summary: RV in pressure overload model is characterized by systolic and diastolic dysfunction. Absence of COMP led to worse survival, deterioration of RV diastolic function and more pronounced RV fibrosis. Thus, COMP appears as an adaptive mechanism to pressure overload.

Urocortin(UCN)-2 is highly expressed in the cardiovascular system and has shown promising therapeutic effects in several studies in human and experimental heart failure. This study analysed the levels of UCN-2 in human and experimental pulmonary arterial hypertension (PAH), and the effects of UCN-2 treatment in an animal model of right ventricular (RV) failure, secondary to PAH.

Rats were submitted to monocrotaline (MCT, n=35)/vehicle (CTRL, n=27) administration, or pulmonary artery banding (PAB, n=13)/Sham (n=5). After 14 days, animals were randomly assigned to receive either UCN-2(5 μ g/Kg/day) or vehicle. Functional measurements were performed 23-25days after MCT or PAB, and

after euthanasia tissue was collected. Moreover, RV, lung and blood samples were collected from PAH patients ($n=7$) and non-PAH controls ($n=6$). Only significant data (mean \pm SEM, $p < 0.05$) are given. Functional studies revealed that MCT group developed PAH, as shown by increased RV end-systolic pressure (MCT vs CTRL: 60 ± 3 vs 22 ± 1 mmHg), end-diastolic pressure (6.0 ± 0.7 vs 3.7 ± 0.3 mmHg), and decreased ejection fraction (32 ± 4 vs $75 \pm 3\%$) and pulmonary artery acceleration time (13.6 ± 0.57 vs 25.7 ± 2.61 ms). UCN-2 treatment attenuated these changes (48 ± 4 ; 4.3 ± 0.3 mmHg; $60 \pm 3\%$ and 20.0 ± 1.11 ms, respectively). Also, UCN-2 treated rats had higher survival rate (76 vs 44%) and exercise capacity (MCT vs CTRL vs MCT+UCN-2: 219 ± 88 vs 749 ± 71 vs 573 ± 88 m). PAH rats presented RV hypertrophy as shown by the morpho-histological analysis (RV weight/tibia length ratio, MCT vs CTRL: 0.08 ± 0.00 vs 0.04 ± 0.00 g/cm; cardiomyocyte cross-sectional area: 353 ± 25 vs $234 \pm 25 \mu\text{m}^2$). UCN-2 therapy attenuated RV remodelling (0.06 ± 0.00 g/cm and $283 \pm 22 \text{mm}^2$, respectively). MCT-group isolated cardiomyocytes developed higher passive force compared to CTRL-group at the sarcomere lengths of 2.2 (MCT vs CTRL: 5.09 ± 1.14 vs 2.48 ± 0.56 N/m 2) and 2.3 μm (8.10 ± 1.77 vs 4.02 ± 0.82 N/m 2). UCN-2 restored passive force development (3.44 ± 0.70 and 5.36 ± 0.97 N/m 2 , respectively). Plasmatic levels of UCN-2 were increased in MCT rats with decompensated RV function, compared to compensated RV ($p = 0.0338$). PAB rats treated with UCN-2, showed RV-specific decrease in cardiomyocyte hypertrophy (PAB vs SHAM vs PAB+UCN-2: 534 ± 46 vs 280 ± 29 vs $387 \pm 31 \mu\text{m}^2$) and fibrosis (11.96 ± 1.2 vs 2.23 ± 0.3 vs $2.66 \pm 0.2\%$). Moreover, UCN-2 levels in the buffy coat from blood of human PAH patients were higher than in controls ($p = 0.035$), while a trend toward an up regulation was seen in the RV and Lung of PAH patients ($p = 0.0663$ and $p = 0.0734$, respectively). UCN-2 levels are altered in human and experimental PAH. UCN-2 treatment attenuates PAH and RV dysfunction and increases survival in MCT-induced PAH, and has direct anti-remodelling effects on the pressure-overloaded RV. UCN-2 has a relevant role in the pathophysiology of PAH, and might be a new treatment option in this condition.

Pulmonary hypertension induced right ventricular stiffness predicted by spectral transfer function analysis: an experimental study

M Alaa¹; M Abdellatif²; AF Leite-Moreira¹; AP Lourenco¹

¹Faculty of Medicine University of Porto, Department of Physiology and Cardiothoracic Surgery, Porto, Portugal; ²Medical University of Graz, Division of Cardiology, Graz, Austria

Recent clinical studies suggest right ventricular (RV) diastolic stiffness is an important prognosis determinant in pulmonary hypertension (PH). Impaired stroke volume (SV) variation induced by fluctuating RV end-diastolic pressure (EDP) during ventilation as assessed by spectral transfer function (STF) gain may enable detection of RV stiffness without the need for invasive pressure-volume (PV) recordings with inferior vena cava (IVC) occlusions.

Our aim was to evaluate the role of RV stiffness in disease progression in Monocrotaline-induced pulmonary hypertension (MCT) and to validate STF gain

between EDP and SV as a marker of RV stiffness. Seven-week old Wistar-Kyoto (WKY) randomly injected with 60 mg/Kg monocrotaline (MCT) or placebo were divided into three groups (12 rats each) according to their cardiac index (CI). Placebo-injected controls (Ctrl), MCT preserved CI (MCTpCI), and MCT reduced CI (MCTrCI). All underwent RV open-chest PV hemodynamic evaluation on the 24-34th day after MCT injection, under halogenate anesthesia and positive-pressure ventilation at constant inspiratory pressure. Beat-to-beat fluctuation in hemodynamic parameters during ventilation was assessed by STF. End diastolic stiffness (β_i) and end-systolic elastance (Ees) for indexed volumes were obtained from IVC occlusion. Additionally, indexed ventricular-vascular coupling (VVCi), indexed arterial elastance (Eai), and preload-recruitable stroke work (PRSW) were calculated and correlated to CI to establish determinants of RV failure progression.

Eai was found to be the strongest determinant of reduced CI, alongside with β_i ($P < 0.001$) but not PRSW. MCTrCI showed higher β_i and Ees compared with both Ctrl and MCTpCI ($P < 0.05$), along with impaired RV STF gain between EDP and SVi, denoting impaired dynamic Frank-Starling mechanism. On multivariate analysis and analysis of covariance with group as dummy variable β_i and not Ees or PRSW correlated with impaired STF gain from EDP to SVi ($P < 0.001$). Receiver-Operating Characteristics curve analysis of STF gain between EDP and SVi showed an area under curve of 0.84 for higher β_i prediction ($P < 0.001$).

Afterload and RV stiffness and not RV contractile function are the major players in RV failure progression. RV diastolic stiffness can be reasonably assessed by STF analysis between EDP and SV variation with respiration. Results suggest right heart catheterization-derived EDP and SVi or noninvasive surrogate variation with respiration as a prognostic tool to assess RV stiffness in PH.

Correlations of STF gains

Mid-upper arm circumference is a better predictor of mortality than calf circumference in patients with heart failure.K Kentaro Kamiya¹; T Masuda²; Y Matsue³; N Hamazaki²; R Matsuzawa⁴; S Tanaka²; K Nozaki⁴; E Maekawa⁵; T Inomata⁵; J Ako⁵¹Kitasato University Hospital, Sagami-hara, Japan; ²Department of Cardiovascular Medicine, Kitasato University Graduate School of Medical Sciences, Sagami-hara, Japan; ³Department of Cardiology, Kameda Medical Center, Chiba, Japan;⁴Department of Rehabilitation, Kitasato University Hospital, Sagami-hara, Japan;⁵Department of Cardiovascular Medicine, Kitasato University School of Medicine, Sagami-hara, Japan

Background: Sarcopenia is one of the most powerful prognostic factors of heart failure (HF). Although decreased mid-upper arm circumference (MUAC) and calf circumference (CC) are known to reflect muscle mass and nutritional status, direct comparison remains to be elucidated. The purpose of this study was to investigate prognostic significance of MUAC and CC, and to compare their predict ability in patients with HF.

Methods: MUAC and CC were measured at the time of discharge in 570 admitted heart failure patients. Prognostic predictive ability of MUAC and CC were compared for all-cause mortality. C-indices were compared between 3 models: Seattle Heart Failure Model (SHFM) only, SHFM plus MUAC, and SHFM plus CC.

Results: Patients were mean age of 67.4 years old and 398 (70%) were male. During the mean follow-up period of 1.8 years, 70 deaths were observed. In the univariate analysis, MUAC and CC were significant predictors of mortality. After adjustment for other prognostic factors, MUAC (adjusted HR per SD increase: 0.47, 95% CI: 0.31 – 0.73; $p < 0.01$) but not CC (adjusted HR per SD increase: 0.74, 95% CI: 0.49 – 1.11; $p = 0.15$) predicted mortality. Likewise, MUAC but not CC showed complementary prognostic predictive capability to SHFM [C-index: SHFM only = 0.63, SHFM + MUAC = 0.71 ($p = 0.008$ vs SHFM only), SHFM + CC = 0.67 ($p = 0.133$ vs SHFM only)] (Figure).

Conclusion: The evaluation of MUAC could be used for risk stratification in patients with heart failure.

Fig. Comparison of C-index for all-cause mortality

Utility and potential impact of a structured telephone support tool to facilitate a seamless program of composite nurse-led, face-to-face and structured telephone support management for heart failure.

National Health and Medical Research Council of Australia

NA Emanuele¹; Y Ahamed¹; MJ Carrington¹; D Thompson¹; S Stewart¹¹Australian Catholic University, Mary MacKillop Institute for Health Research, Victoria, Australia

Background: Structured Telephone Support (STS) in the management of chronic heart failure (CHF) is associated with improved health outcomes relative to standard care, but has been mainly applied as a substitute rather than adjunctive strategy in the management of the syndrome.

Purpose: To evaluate the utility and potential impact of the Green Amber Red Delineation of risk And Need in CHF (GARDIAN-CHF) and an integrated system of STS management (GARDIAN-Angel) as part of a multicentre, randomised trial of standard versus intensified management of recently hospitalised patients with CHF (the WHICH? II Trial).

Methods: Baseline profiling data used to categorise trial participants as low (green), medium (amber) or high (red) risk for recurrent morbidity and mortality via the GARDIAN-HF tool were analysed. The subsequent nature and consequences of initially applied STS via the GARDIAN-Angel surveillance system and team (via a national telephone call centre) were also analysed.

Results: 328 trial participants (aged 74.7 ± 10.8 years), 42% female and 15% living remotely) were studied. The majority (57%) had CHF with reduced LVEF ($31.4 \pm 9.4\%$). Delineation of increased risk was mediated via holistic/socio-demographic factors (22% had self-care deficits, management deficits (46%); and clinical instability at index hospitalisation (91%) then at 7-14 days (48%) indicative of increased surveillance/support with an elevated BNP recorded in 42% of all patients, irrespective of age. GARDIAN-HF profiling indicated that 4.3% (GREEN), 29% (AMBER), and 67% (RED Status) were at a low, medium and high risk of poor event-free survival. Subsequent assessment by the GARDIAN-Angel STS team in 5754 structured calls (62% capture with a mean call time of 12 minutes including 304 initial structured calls lasting a mean of 22 minutes), assessing patients for variation of their self-reported overall health and heart failure symptoms and consequently given an automated GREEN flag (35%), requiring no response, AMBER flag (53%), with issues requiring monitoring, and the remainder a RED flag (12%), indicating new clinical instability requiring immediate action by the home-based team. Calls revealed ongoing fatigue (62.4%), dyspnoea (43.4%) and pedal oedema (27.6%); with a further 12% and 3% reporting angina or any type of fall. The STS team confirmed that 44%, 46%, and 10% of flags were GREEN, AMBER and RED respectively, indicating occasional disagreement with the automated GARDIAN-Angel flag rating. Alternatively, 57 RED/Crisis flag calls (1% of all structured calls and in total of 34 patients) required a high priority response and 13 (22%) of these RED/Crisis calls were re-hospitalised.

Conclusion: These preliminary data demonstrate the utility and potential health impact of an integrated method to modulate STS according to individual need and risk.

Self-care confidence totally mediates the influence of simple attention and working memory on self-care in adults with heart failure

National Institutes of Health, USA

E Ercole Vellone¹; L Pancani²; A Greco²; M D'addario²; P Steca²; B Riegel³¹University Tor Vergata, School of Nursing, Rome, Italy; ²University of Milan-Bicocca, Milan, Italy; ³University of Pennsylvania, School of Nursing, Philadelphia, United States of America

Background: Cognition is impaired in 25-50% of heart failure (HF) patients. Cognitive impairment may affect patients' abilities to perform HF self-care. The situation-specific theory of HF self-care proposes that self-care confidence may

mediate the relationship between cognition and self-care, but little is known about this issue.

Purpose: The purpose of this study was to test the hypothesis that self-care confidence mediates the relationship between specific cognitive domains (simple and complex attention, processing speed, working memory, and short-term memory) and HF self-care.

Methods: This was a secondary analysis of data from a longitudinal cohort comparative study. A sample of 280 adults with chronic HF were enrolled from 3 outpatient settings in the USA. Self-care was measured with the Self-Care of HF Index, which measures self-care maintenance (i.e., monitoring of HF symptoms and adherence to treatments), self-care management (i.e., recognizing and managing symptoms of HF exacerbation), and self-care confidence (i.e., confidence in each of the self-care processes). Cognition was measured with a battery of neuropsychological tests. Sociodemographic characteristics, illness duration, HF type, comorbidity, and NYHA functional class were measured. The mediation model was tested with structural equation modeling using baseline data.

Results: Patients were 62 (SD, 12.5) years old on average, mostly male (64.3%) and functionally compromised (NYHA class III, 58.6%). Most (93.2%) patients had at least 1 test in which they demonstrated impaired cognition. In mediation analysis, self-care confidence totally mediated the relationship between simple attention and self-care (self-care maintenance and management) and between working memory and self-care (self-care maintenance and management). Processing speed, complex attention, and short-term memory were neither mediated by self-care confidence nor had a significant relationship with self-care maintenance and management. However, short-term memory had a significant direct effect on self-care maintenance. The tested models had acceptable fit indices.

Conclusions: Results of this study suggest that self-care confidence might compensate for impaired cognition in HF patients. That is, patients with confidence in their ability to perform self-care may do well in spite of impaired cognition. Because cognitive impairment is so difficult to modify, interventions focused on self-care confidence might successfully improve self-care.

Gait speed provides prognostic capability comparable to 6-min walk test in elderly patients with cardiovascular disease.

K Kamiya¹; T Masuda²; Y Matsue³; N Hamazaki²; R Matsuzawa¹; S Tanaka²; K Nozaki¹; E Maekawa⁴; A Matsunaga²; J Ako⁴

¹Department of Rehabilitation, Kitasato University Hospital, Sagami, Japan;

²Department of Cardiovascular Medicine, Kitasato University Graduate School of Medical Sciences, Sagami, Japan; ³Department of Cardiology, Kameda Medical Center, Chiba, Japan; ⁴Department of Cardiovascular Medicine, Kitasato University School of Medicine, Sagami, Japan

Background: Although gait speed and 6-min walk (6MW) tests are applied as prognostic gauges for elderly cardiovascular disease (CVD) patients, few direct comparison studies have been conducted. The purpose of this study was to compare the prognostic predictive ability of gait speed and 6MW tests in CVD patients.

Methods: Usual gait speed (over a 10 meters) and 6MW were measured at the time of discharge in admitted elderly CVD patients (≥ 65 years old). Prognostic predictive ability of gait speed and 6MW were compared for all-cause mortality.

Results: A total of 599 CVD patients (75 \pm 6 years old, 65% male, 57% heart failure, 37% ischemic heart disease, and 6% others) were included. During the mean follow-up period of 1.9 years, 72 all-cause deaths were observed. After adjustment for confounding factors, both usual gait speed (adjusted hazard ratio per SD increase: 0.67, 95% CI: 0.50 to 0.89, $P = 0.006$) and 6MW (adjusted hazard ratio per SD increase: 0.60, 95% CI: 0.45 to 0.81, $P = 0.001$) were independent predictors of all-cause mortality. C-indexes were 0.64 (95% CI: 0.57 to 0.71) for usual gait speed and 0.65 (95% CI: 0.58 to 0.72) for 6MW. There was no significant difference in c-indexes between groups of gait speed and 6MW ($P = 0.456$).

Conclusion: Gait speed and 6MW test showed similar prognostic predictive ability for all-cause mortality in elderly patients with CVD. Gait speed, which is an easy and non-invasively measurable metric, can be used as a risk stratification tool.

Cost-analysis in the management of cardiac implanted electronic devices with remote monitoring: our experience

A Zanni¹; C Sticozzi¹; A Malagoli¹; L Rossi¹; U Corvi¹; M Piepoli¹; G Villani¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Introduction: The implantation of cardiac electronic devices has increased exponentially over the last decade in response to widening indication. Follow-up of patients with cardiac implantable electronic devices (CIEDs) is challenging due to both their increasing volume and technical complexity. The devices equipped with the remote monitoring (RM) function are capable of providing on daily basis automatic information about the patient cardiac condition as well as the implant status without compromising the safety. New organizational models promote significant efficiencies regarding physician and technician personnel time. Accordingly, the RM is proposed to be a clinical practice for the follow-up.

Purpose: To assess the costs-analysis of the RM compared to standard follow-up of CIEDs.

Methods: In our institution 590 outpatients with chronic HF and single- or dual-chamber CIED implanted are followed through standard outpatient visits (group A, 295 patients) or by the RM (group B, 295 patients). In the group A planned visits are scheduled every 6 months with an increased frequency when the device approaches its end of service or in case of advisories; in the group B instead are scheduled one annual visit, transmissions every six months and alert notification. Each planned visit total cost € 19.16 (including medical equipment, clinical staff and maintenance of the outpatient areas). Physician and technician personnel time-consuming was assessed for both groups.

Results: During 18-months follow-up were performed 806 planned visits in group A compared to 304 in group B. Costs in group A was € 32.37 / patient per year compared to 30.1 € / patient per year in group B. The overall time-consuming by the physician and technician personnel in group A was 18.2 minutes per patient/ per year compared to 12.7 minutes per patient /per year for remote control in group B.

Conclusions: The device's RM allows effective optimization of healthcare resource consumption, allowing a reduction of the cost of follow-up.

The lived experience of adults with heart failure: a phenomenological study

This study was founded by the Centre of Excellence for Nursing Scholarship Rome, Italy

M Marco Paturzo¹; L Berto²; A Petruzzo¹; A Mottola¹; MZ Cohen³; R Alvaro¹; E Vellone¹

¹University of Rome Tor Vergata, Biomedicine and Prevention, Rome, Italy;

²Ospedali Riuniti della Valdichiana Senese, Siena, Italy; ³University of Nebraska Medical Center, Omaha, United States of America

Background: People with heart failure (HF), a major public health problem that continues to grow in Europe and the USA, have significant mortality, decreased quality of life and high hospitalization rates. Although a number of studies have been conducted on patients with HF, they have not given a rigorous comprehensive description of what it is like to live with HF

Purpose: The purpose of this study was to describe the lived experience of adults with heart failure (HF).

Methods: A hermeneutic phenomenological design was used. Thirty patients affected by HF were enrolled between February 2014 and July 2014 from an outpatient cardiovascular clinic in Italy. Phenomenological interviews took place at patients' homes, and the investigators analyzed verbatim transcripts. Data saturation was achieved, and participants to ensure data trustworthiness confirmed all extracted themes.

Results: The patients were mostly male (67%) with a mean age of 71 (SD 9.15) with a range of 48–86. Mostly were in NYHA class I-II (70%) and a mean illness duration in months of 66 (SD 57.72). Seven themes emerged from the phenomenological analysis: 1) important life changes; 2) social isolation caused by the illness; 3) anger and resignation associated with the disease; 4) relief from spirituality; 5) will to live; 6) uncertainty about the future and 7) the inescapability of disease and death.

Conclusions: The findings of this study provide an overview of the lived experiences of patients with HF, give new insights and reinforce the findings of previous research. Thoroughly understanding the lived experiences of patients with HF could play an important role in designing nursing care. The meaning that our patients attribute to their lived experience helps to create their needs, which are important to direct care. Family support and religious beliefs are an important source for HF patients to better manage their fears and cope with the future. Findings of this study provide nurses with a comprehensive description of what it is like to live with HF, which can be useful in helping to meet patients' needs more effectively and in tailoring interventions.

Cardiac magnetic resonance derived extracellular volume fraction estimates myocardial fibrosis in patients with cardiomyopathy without inflammation but not in presence of significant inflammationP Philipp Lurz¹; D Lang¹; C Luecke²; J Lurz¹; K Rommel¹; K Klingel³; M Gutberlet⁴; G Schuler⁴¹University of Leipzig, Heart Center, Department of Internal Medicine and Cardiology, Leipzig, Germany; ²Heart Center of Leipzig, Diagnostic and Interventional Radiology, Leipzig, Germany; ³University Hospital Tuebingen, Department of Molecular Pathology, Tuebingen, Germany; ⁴Heart Center of Leipzig, Department of Paediatric Cardiology, Leipzig, Germany**Background:** The presence of diffuse fibrosis in non-ischemic cardiomyopathy is associated with unfavorable outcome. Endomyocardial biopsy (EMB) is the gold standard in quantifying the extend of fibrotic tissue. Recently, cardiac magnet resonance imaging (CMR) modalities such as T1 mapping and estimation of the extracellular volume fraction (ECV) have been suggested as non-invasive measurement strategies. However, it is uncertain whether ECV provides a valid estimate of diffuse fibrosis in the presence of other pathologies impacting on ECV such as myocardial edema.**Methods:** 107 consecutive patients with suspicion of inflammatory cardiomyopathy underwent CMR. Extracellular volume fraction was calculated from T1 times pre and post contrast. Furthermore, in all patients left ventricular (LV) endomyocardial biopsies (EMB) were taken. Quantification of fibrosis in EMB was realized using Masson-trichrome-stained slides and digital marking of fibrotic areas.**Results:** Significant inflammation was present in 66 patients, 41 exhibited no significant inflammation on EMB. There were no difference in age (45 ± 14 vs. 45 ± 15 years; $p=1.0$) or LV ejection fraction (37 ± 17 vs. $36 \pm 18\%$; $p=0.9$). Although LV collagen volume percentage was similar in both groups (inflammation 12.3 ± 17.8 vs. non-inflammation $11.4 \pm 7.9\%$; $p=0.577$), ECV was significantly higher in patients with inflammation (0.37 ± 0.06) than in patients without inflammation ($0.33 \pm 0.08\%$; $p=0.02$). Importantly, ECV adequately estimated the degree of LV collagen volume percentage only in patients without inflammation ($r=0.72$; $p<0.0001$), but not in those with inflammation ($r=0.24$; $p=0.06$; Figure).**Conclusion:** These findings prove the theoretical concept of ECV as an estimate for diffuse fibrosis only in absence of other pathologies such as myocardial edema. This should be considered when ECV is used as a surrogate for diffuse fibrosis or predictor of outcome in cardiomyopathies.

Survival after first heart failure hospitalization in slovenia between 2004 and 2012D Daniel Omersa¹; J Farkas¹; I Erzen¹; M Lainscak²¹National Institute of Public Health, Ljubljana, Slovenia; ²General Hospital Celje, Department of Cardiology, Celje, Slovenia**Introduction:** Heart failure (HF) is a global health problem with excessive mortality and significant economic burden. There is limited data about post-hospitalization mortality, particularly for central and east European countries. Aim We aimed to evaluate mortality in patients with first heart failure related hospitalization in Slovenia.**Methods:** Slovenian national hospital discharge registry was searched for HF hospitalizations (HF coded in any diagnose fields) in all Slovenian residents ≥ 20 years between 2004 and 2012 and linked with National death registry; follow-up was censored at the end of 2013. First HF hospitalization was defined as the first HF hospitalization of an individual after 4 years of observational period. Trends of standardized mortality rates (in-hospital, 30-day and 1-year) were assessed using ANOVA. The effects of age, sex, admission year and different comorbidities were evaluated with multiple Cox proportional hazards model. Results Overall, 43,636 patients had first HF hospitalization between 2008 and 2012. The in-hospital mortality was 20.1%. In the remaining 34,865 patients, who were discharged alive, the 30-day and 1-year mortality was 3.8% and 18.0%, respectively. Between 2004 and 2012, in-hospital, 30-day and 1-year mortality rates per 100,000 have changed from 116 to 118, 36 to 32 and 181 to 166, respectively, whereas no significant trends were observed. Men, older patients, patients with myocardial infarction, diabetes mellitus, chronic kidney disease, chronic obstructive pulmonary disease and cancer had increased independent hazards for higher mortality. The most important variables in the model were higher age (HR = 1.826 per 10 year increase, $P<0.0001$) and cancer (HR = 2.303, $P<0.0001$).**Conclusion:** In recent years, mortality rates remained high where older patients and those with cancer had the highest mortality.

626

Quantitative contributor of comorbidities in HF patients according to HF phenotypes.A Iorio¹; M Senni¹; A Gavazzi¹; C Concetta Di Nora²; S Poli²; E Zamboni²; G Barbati³; G Cioffi³; G Sinagra²; A Di Lenarda⁴¹Ospedale Papa Giovanni XXIII, Bergamo, Italy; ²University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ³Villa Bianca Hospital, Trento, Italy; ⁴Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy**Background:** Co-morbidities frequently accompany heart failure (HF), contributing to increased mortality and morbidity. However, the prognostic contributor of non cardiac comorbidities in HF according to EF- HF phenotypes is still widely unknown.

Aim: We compare prognostic contributor of co-morbidities in patients with chronic HF according to HF phenotypes (LVEF <50% - HFrEF, LVEF ≥50% - HFpEF) in community population.

Methods: From October 2009 to December 2013 we studied all consecutive HF patients whose ejection fraction (EF) had been assessed. Prognostic impact of 15 non cardiac comorbidity burden on mortality and morbidity was compared between EF-HF phenotypes using population attributable risks (PARs).

Results: A HF population consistent of 2314 patients (mean age 78 ± 8, 57% men), 941 (41%) HFrEF, 1373 (59%) HFpEF. Overall, there was a high rate of comorbidities (Median 3, IQR 2-4), with 1257 (54%) patients presenting ≥ 3 non-cardiac comorbidities. The high comorbidity rates occur similarly between EF-HF phenotypes. At a follow-up of 28 ± 14 months, 472 (20%) patients died, 225 (24%) with HFrEF, and 247 (18%) with HFpEF (p<0.001). When we grouped HF patients for 1,2, ≥3 comorbidities, the latter was associated to a worse outcome (Figure 1). For overall population, prognostic implications of comorbidities (PARs) for mortality were: CKD=40%, anemia=41 %, COPD=30%, diabetes=21%, PAD=20%, and <10% for all other co-morbidities. This trend was maintained unchanged by considering PARs between HF phenotypes for mortality and morbidity (HF, Cardiovascular and Non-Cardiovascular Hospitalizations).

Conclusion: In a community HF population, comorbidity burden contributed to high mortality and morbidity with similar quantitative effect across EF-HF phenotypes. These observations suggest that targeting of comorbidities could have a crucial role on prognosis irrespective of LVEF.

627

Chagas' cardiomyopathy mortality in the 21st century: seven years prospective follow up

GE Germano Emilio Souza¹; JL Vieira¹; AT Casolato¹; LR Moraes¹; GA Braga¹; VS Issa¹; SM Ayub-Ferreira¹; PR Chizzola¹; EA Bocchi¹; LM Pessoa De Melo²
¹Heart Institute -InCor, São Paulo, Brazil; ²Servico de Hematologia e Hemoterapia, Sao Jose dos Campos, Brazil

Background: Chagas' cardiomyopathy is a neglected disease with poor prognosis. Most of prognostic information about this disease was produced through small cohorts or under suboptimal follow-up time.

Purpose: We sought to evaluate systolic heart failure prognosis according to its etiology: Chagas' cardiomyopathy(G1) versus non Chagas' cardiomyopathy(G2) in the 21st century, in a big sample and long term follow-up.

Methods: Cohort study. Non-randomized. Inclusion criteria: Left ventricle ejection fraction <45% and onset of symptoms time > 1 month. Two different serologic tests were performed to allocate patients either for CC group or NCC group. Exclusion criteria: varfarin or heparin anticoagulation, mechanic heart valve prothesis, neoplasia, pregnancy or puerperal state, strogenic therapy, ongoing infection, decompensated thyroid disease, extra-corporeal circulation, dialytic therapy, diagnosed coagulation disorders, congenital heart disease. All patients underwent clinical, eletrocardiographic, laboratorial and echocardiographic evaluation. Primary outcome was transplant-free survival. Secondary outcome was hospitalization-free survival. Sample size calculated for 90%power. P value significative if <0.05. Fischer's exact test for categoric variables; non-paired T-student test for parametric continuous variables and Mann-Whitney test for non-parametric continuous variables. Kaplan-Meier method and log-rank test were used for estimating outcomes and difference between groups, respectively.

Results: From January 2008 to april 2009, 287 patients were prospectively included (138 patients in CC group- G1 - and 149 in NCC group - G2). The mean follow-up time was 7.8years. G1 patients were younger, had lower body mass index, lower blood pressure and LVEF, and higher BNP levels. Hypertension, diabetes, tobacco use and dislipidemia were less frequent in G1. Previous stroke was more prevalent in G1. In G1 and G2, 5.6% and 6.8% of patients were lost for follow-up. Primary outcome was higher in G2 (59,2%) versus G1 (32,2%);log-rank=0,0001. Secondary outcome was also higher in G2 (38,8%) versus G1 (24,5%);log-rank = 0.0001.

Conclusions: Chagas' cardiomyopathy prognosis remains worse than non-Chagas' cardiomyopathy in the 21st century in this large sample after a long term follow-up.

628

Clinical characteristics and long term outcome of peripartum cardiomyopathy in a resource limited setting.

MEPI funding through NIH Grant Number TW008881 and TW008905.

E T Gambahaya¹; JG Hakim¹; DP Kao²; GT Fana¹; JA Matenga¹

¹University of Zimbabwe College of Health Sciences, Medicine, Harare, Zimbabwe;

²University of Colorado Denver, Cardiology, Denver, United States of America

Introduction: Peripartum cardiomyopathy (PPCM), a rare and potentially fatal complication of pregnancy occurs with a relatively high frequency in African women. However, there is limited data about the long term outcome of PPCM in African patients where diagnosis is often delayed with limited access to treatment.

Objectives: The primary objective was to evaluate clinical outcomes and risk factors for adverse outcomes among PPCM patients.

Methods: Patients with a diagnosis of PPCM were recruited prospectively and followed up for 2 years. Assessments included New York Heart Association (NYHA) functional class, clinical examination and echocardiograms at enrolment, at 6 and at 24 months follow-up. Baseline characteristics associated with the primary outcome (a composite of death, left ventricular ejection fraction (LVEF) <50%, NYHA functional class III/IV at 24 months) were identified.

Results: Forty-nine patients with a new diagnosis of PPCM were recruited at a tertiary care centre in Zimbabwe. The mean age was 28.1 ± 5.7 years. Approximately 1/3 were primigravid with a median parity of 2. In total, 17 (34.7%) had a history of pregnancy-induced hypertension and 2 (4%) were HIV positive. Six (12.2%) had left ventricular intramural thrombi at baseline. NYHA class improved from baseline to each time point (p<0.001). Eight (16.3%) patients died within the 2 year follow up period including 7 (14.2%) within 6 months. LVEF improved from 29.3 ± 9.7% at baseline to 43.8 ± 15.4%, after 6 months (p<0.001) and 42.7 ± 14.0% after 24 months (p<0.001). Twenty-four (49.0%) patients fully recovered left ventricular function with 16 patients recovering within 6 months and a further 8 patients after 6 months. Twenty-six patients had an adverse outcome. Factors associated with an adverse outcome were lower maternal age (OR 0.82, 95% CI 0.72-0.95, p=0.006), baseline NYHA class III/IV (OR 8.8, 95% CI 2.08-37.20, p=0.003 and OR 24.0, 95% CI 2.33-247.37, p=0.008 respectively), being primigravid (OR 0.20, 95% CI 0.05-0.72, p=0.014), onset of symptoms after the postpartum period (OR 2.35, 95% CI 1.19-4.62, p=0.014), increased left ventricular end diastolic dimensions (OR 1.11 95% CI 1.00-1.23, p=0.049), and lower LVEF at baseline (OR 0.91 95% CI 0.84-0.98, p=0.012).

Conclusions: A substantial proportion of African PPCM patients fully recovered left ventricular function. However, mortality and adverse outcomes were frequent. Lower maternal age, worse NYHA class, being primigravid, symptom onset after the postpartum period, increased LVDD, and reduced LVEF at baseline were associated with an adverse outcome.

629

Clinical presentation and prognosis of patients with Chagas' cardiomyopathy during episodes of acute decompensated heart failure

L M Lina Marcela Gomez Madronero¹; LR Moraes¹; CB Terhoch¹; HF Moreira¹; SM Ayub-Ferreira¹; MT Oliveira¹; SG Lage¹; VS Issa¹; EA Bocchi¹

¹Heart Institute of the University of Sao Paulo (InCor), heart Failure, Sao Paulo, Brazil

Introduction: Chagas' disease is a major cause of heart failure in Latin America. However, few studies have analyzed the clinical presentation and prognosis of patients with Chagas during acute decompensated heart failure.

Methods: We analyzed a cohort of 409 patients admitted for decompensated heart failure in a tertiary hospital dedicated to cardiology from August 2013 through December 2015; we categorized the patients according to the presence of Chagas' etiology and compared clinical characteristics and prognosis.

Results: Mean age was 55.3 ± 15 years and 254 (62.1%) patients were male; left ventricle ejection fraction was 30 ± 12%; 102 (24.9%) patients had ischemic heart disease, 97 (23.7%) Chagas' cardiomyopathy, 74 (18.1%) idiopathic dilated cardiomyopathy and 48 (11.7%) hypertensive disease. At admission BNP level was 1486 ± 1297pg/dL and creatinine 1.96 ± 1.2mg/dL. During hospital admission 45 (11%) patients were submitted to heart transplant and 128 (31.3%) died.

As compared to other etiologies, patients with Chagas' disease had a smaller proportion of patients with history of hypertension (33% vs 58.7%, P<0.001) and diabetes mellitus (14.4% vs 36.5%, P<0.001), had lower heart rate at admission (75.2 ± 21.9 vs 86.2 ± 25.8, P<0.001), were more hypotensive (systolic pressure of 92.3 ± 22.3 vs 100.8 ± 28.7, P=0.009) and had more frequently ascites (31.3% vs 19.7%, P=0.06) and hypoperfusion (47.4% vs 33.3%, P=0.04). Echocardiographic data showed that Chagas' patients had lower ejection fraction (27 ± 9.1% vs 31 ± 12.6%, P=0.004), larger left ventricle diastolic diameter (68.9 ± 8.8mm vs 65.3 ± 11.9, P=0.008), lower pulmonary systolic pressure (43.9 ± 12.3 vs 48.6 ± 14mmHg, P=0.01) and larger proportion of patients with right ventricular dysfunction (40.5% vs 66.3%, P=0.002). Admission BNP was higher in patients with Chagas' (2033 ± 1574pg/ml vs 1315 ± 1148pg/ml, P<0.001). The degree of organ dysfunction, measured by BUN, creatinine, sodium, bilirubin and hemoglobin was similar between groups. Prognostic data showed that Chagas'

patients received more frequently intraortic balloon pump (IABP) (34% vs 16.7%, $P < 0.001$), were more frequently transplanted (21.6% vs 7.8%) and had lower mortality (27.8 vs 32.7, $P = 0.01$).

Conclusion: Patients with Chagas markedly differ in their clinical and hemodynamic presentation. Despite more severe cardiac dysfunction and similar degree of organ damage, prognosis was better. IABP was effective in bridging patients until heart transplant. These data are important for therapeutic decision involving heart transplant and use of ventricular assist-devices in this setting.

630

Riociguat - new therapeutic option in the management of cardiac amyloidosis

Austrian fellowship grant, KLI 246, KLI 245 and the Austrian Society of Cardiology, the Österreichischer Herzfonds

F Franz Duca¹; C Zotter-Tufaro¹; A Kammerlander¹; S Aschauer¹; B Boerries¹; H Agis²; J Mascherbauer¹; D Bonderman¹

¹Medical University of Vienna, Cardiology, Vienna, Austria; ²Medical University of Vienna, Oncology, Vienna, Austria

Background: Cardiac amyloidosis (CA) is a rare disease and represents the prototype of a restrictive cardiomyopathy. A vast majority of affected patients present with advanced heart failure and face significant morbidity and mortality. However, an effective therapy is still lacking and a diagnosis of CA precludes patients from participation in standard heart failure clinical trials. The soluble guanylate cyclase (sGC) -- stimulator riociguat, already approved for the treatment of precapillary pulmonary hypertension, has also been shown to have favorable hemodynamic effects in heart failure.

Purpose: We aimed to test the safety and efficacy of Riociguat in patients with cardiac amyloidosis.

Methods: CA was diagnosed based on cardiac magnetic resonance imaging and myocardial biopsy. Baseline work-up of patients and re-evaluation under therapy included the assessment of blood pressure, NYHA functional class, exercise capacity as measured by the 6-minute walk test (6MWT), serum NT-proBNP and invasively measured hemodynamic parameters.

Results: Six participants with wild-type transthyretin amyloidosis (83.3% male, 16.7% female, mean age 82.5 (73.0--85.8) years) were included in the named-patient use program. Follow-up was performed after a median of 4.5 months (3.0--7.0). Our preliminary findings indicate that application of riociguat in CA patients is safe. Systolic blood pressure 127 mmHg (116--147) vs. 116 (113--129) mmHg; ($p = 0.345$) and diastolic blood pressure 87.0 mmHg (80.3--90.0) vs. 74.5 mmHg (66.3--80.8); ($p = 0.058$) basically remained unchanged from baseline values. Despite a small patient number, considerable effects could be encountered with respect to outcome measures. At baseline three patients presented with NYHA II (50.0%) and three patients presented with NYHA III (50.0%). Under treatment three patients improved from NYHA III to NYHA II. The other patients remained clinically stable with no change in NYHA class; ($p = 0.083$). 6MWT improved from 340m (210--444) to 392m (298--480); ($p = 0.046$). NT-proBNP levels decreased from 4009pg/ml (1837--8360) to 3250pg/ml (1792--8576); ($p = 0.753$). With regards to invasive hemodynamic parameters, cardiac output increased from 3.7l/min (2.8--4.9) to 4.2l/min (3.6--5.2); ($p = 0.028$), mean pulmonary arterial pressure 33.0mmHg (29.0--39.5) vs. 32.0mmHg (27.5--39.5) and pulmonary artery wedge pressure 25.0mmHg (16.8--30.0) vs. 22.0mmHg (16.8--28.8) did not change under treatment.

Conclusion: Our preliminary data from a named patient use program indicate that riociguat treatment is safe in patients with CA. More information is necessary to support the evidence that riociguat may relieve the burden of disease associated with CA.

631

Manifestation of delay peripartum cardiomyopathy in Taiwan: implications from 925 cases in ten years

T H Tien Hsing Chen¹; VCCWU Wu¹

¹Chang Gung Memorial Hospital, Taipei, Taiwan ROC

Background: Relationship of onset and outcome in peripartum is not clear. **Method:** We identified all women hospitalized with HF 3 months before or 10 months after a delivery between January 1, 1997 and December 31, 2012. HF was initially screened for by International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) codes congestive heart failure (428.0, 428.1, 428.40, 428.41, 428.42, 428.43, 428.9, 425.4, 425.9, 674.5). We further categorized PPCM patients into 3 groups: (1) Early Diagnosis: PPCM diagnosed as early as 1st month till 9th month of pregnancy (2) Traditional Diagnosis: PPCM diagnosed as previously defined between one month prior to and 5th month post-delivery, and (3) Late Diagnosis: PPCM diagnosed from 6th month till 12th month post-delivery. **Result:** A total of 925 patients (30.4 ± 5.7 years old) satisfied our TNHIDB criteria as candidates of PPCM patients and were followed for a mean of 5.4 ± 4.1 years. There were 88 patients in the Early Diagnosis group, 742 patients in the Traditional Diagnosis group, and 95 patients in the Late Diagnosis group. There was significant difference in previous delivery ($p = 0.046$), delivery type (abortion, vaginal delivery, and Cesarean section) at diagnosis of PPCM ($p < 0.001$), multiparity at diagnosis of PPCM ($p = 0.003$) among groups. For long-term outcome, patients in Late Diagnosis had highest all-cause mortality (18.2%), compared with patients in Traditional Diagnosis group (8.7%) and Early Diagnosis group (5.7%), and also highest mortality within 1 year (9.1%), compared with patients in Tradition Diagnosis group (3.8%) and Early Diagnosis group (2.3%). **Conclusion:** Late diagnosis of peripartum cardiomyopathy results in increased morbidity and mortality in pregnancy-associated heart failure.

The presence of a truncating mutation in titin independently associates with arrhythmic burden in patients with dilated cardiomyopathy

Medical Research Council (UK); Jansons Foundation; NIHR Cardiovascular BRU, Royal Brompton Hospital

U Tayal¹; S Newsome²; R Buchan³; N Whiffin³; C Shakespeare⁴; J Ware¹; SA Cook¹; SK Prasad³

¹Imperial College London, London, United Kingdom; ²London School of Hygiene and Tropical Medicine, Statistics, London, United Kingdom; ³Royal Brompton Hospital, London, United Kingdom; ⁴Queen Elizabeth Hospital London, London, United Kingdom

Background: Dilated cardiomyopathy (DCM) can be associated with prognostically adverse arrhythmias at presentation. It is often unclear whether this is a marker of phenotypic severity or whether they reflect an independent pathophysiological process. We sought to establish whether truncating variants in the sarcomeric protein TTN (TTNtv), found in up to 20% of DCM, were associated with the occurrence of arrhythmic DCM at baseline independently of cardiac function.

Methods: 630 prospectively recruited DCM patients underwent cardiac MRI and were sequenced for TTNtv. The presence of confirmed ventricular tachycardia (VT), non-sustained ventricular tachycardia (NSVT) or atrial fibrillation (AF) at baseline was collected on all patients. Continuous and categorical variables were compared using Mann-Whitney/t-tests or Chi-squared tests as appropriate. Univariable and multivariable logistic regression models were used to identify variables that were independently associated with arrhythmic DCM status.

Results: 201 patients (32%) had evidence of AF, VT, or NSVT at baseline. These patients were more likely to be older, male, with worse cardiac function (age 63.4 years \pm 11.6 vs 54.6 years \pm 15.9, $p < 0.0001$; gender male $n = 164$ (81.6%) vs $n = 266$ (62.0%), $p < 0.0001$; baseline left ventricular ejection fraction 36.0% \pm 12.2 vs 40.8% \pm 12.6, $p < 0.0001$; baseline right ventricular ejection fraction 32.3% \pm 13.6 vs 39.8% \pm 13.4, $p < 0.0001$). TTNtv were found in 13.9% ($n = 28$) of patients with arrhythmias compared to 7.9% ($n = 34$) of patients without ($p = 0.03$). Age, gender and baseline left and right ventricular function were each predictive of arrhythmia status in univariate analysis. Adjusting for these variables, the presence of TTNtv was an independent predictor of arrhythmia status (odds ratio 3.01, $p = 0.001$) (Table 1).

Conclusion: Adjusting for age, gender and baseline cardiac function, the presence of a truncating variant in TTN is independently associated with atrial and ventricular arrhythmias. This suggests that arrhythmia status in DCM is not solely a reflection of phenotypic severity, which has implications for guiding patient management.

Table 1

Variable	Unadjusted analysis		Adjusted analysis		OR	P value	95% confidence interval
	OR	P value	OR	P value			
Age	1.04	< 0.0001	1.03	< 0.0001	1.06	< 0.0001	1.04 to 1.08

Cardiology, Roskilde, Denmark; ⁴Rigshospitalet - Copenhagen University Hospital,

Cardiology, Copenhagen, Denmark; ⁵Aalborg University Hospital, Aalborg,

Denmark

Background: Impaired cardiac function is the main predictor of poor outcome in infective endocarditis (IE). 2-dimensional (2D) global longitudinal strain (GLS) has proven superior in prediction of long-term outcome as compared to LVEF in valvular disease and heart failure in general. Whether measurements of cardiac deformation can predict survival in patients with IE has not previously been investigated.

Purpose: To determine whether 2D GLS is associated with long-term outcome and further to investigate whether GLS is superior to LVEF in risk stratification and prognosis of IE.

Methods: The study included consecutive patients with definite IE admitted between January 2006 and January 2014. Log-rank significance testing was applied to determine survival for LVEF and GLS, respectively. Cox models adjusted for surgery and reclassification statistics were applied to identify independent predictors of 1-year mortality.

Results: A cohort of 190 patients met eligibility criteria. LVEF and GLS were both prognostic markers of mortality. Independent predictors of 1-year mortality were s. aureus IE (HR:2.02; 95%CI 1.11–5.72, $p = 0.022$), diabetes (HR:2.05; 95%CI 1.12–3.75, $p = 0.020$), embolic stroke (HR:3.95; 95%CI 1.93–8.10, $p < 0.001$) and GLS $< -15.4\%$ (HR:2.95; 95%CI 1.52–5.72, $p < 0.001$). Adding GLS to known risk factors of IE resulted in significant increase of AUC (AUC = 0.722, $p < 0.001$).

Conclusions: Impairment of both LVEF and GLS was associated with long-term mortality in left-sided IE. GLS was superior to LVEF in both risk prediction and risk discrimination of patients with left-sided IE.

Independent predictors in IE

Palpitations in a young male scheduled for tonsillectomy

AA Constantinescu¹; JH Von Der Thussen²; OC Manintveld¹; SC Yap¹; IM Van De Laar³

¹Erasmus Medical Center, Thoraxcenter, Department of Cardiology, Rotterdam, Netherlands; ²Erasmus Medical Center, Department of Pathology, Rotterdam, Netherlands; ³Erasmus Medical Center, Department of Clinical Genetics, Rotterdam, Netherlands

Introduction and case-report description: A 21-year old male scheduled for tonsillectomy due to recurrent pharyngitis was referred for analysis of an irregular heart rhythm. He had occasionally palpitations. He used a maximum of three units of alcohol weekly, but no drugs. His physical examination was unremarkable. ECG showed sinus rhythm with ventricular extrasystoles. Echocardiography revealed a diffuse hypokinetic left ventricle (LV) with an end-diastolic diameter of 58 mm, normal wall thickness and diastolic filling pressures. There was no valve pathology. The right ventricle (RV) dimensions and function were normal. Computer tomography revealed a normal coronary anatomy. Three months later he was admitted because of palpitations and pre-syncope. Rhythm observation revealed frequent episodes of polymorphic non-sustained ventricular tachycardia. NT-proBNP and high-sensitivity troponin T were moderately increased (59 pmol/l and 584 ng/l, respectively). Thyroid function was normal.

Description of the problem: This young patient had symptomatic ventricular arrhythmias associated with an impaired LV function at normal loading conditions. Questions, problems or possible differential diagnosis: What is the differential diagnosis? What additional investigations should be performed? Should this patient receive an ICD?

Answers and discussion: Differential diagnosis includes infectious or auto-immune myocarditis, sarcoidosis, or arrhythmogenic cardiomyopathy. We performed a MRI that revealed a dilated LV with an ejection fraction of 45%, and linear midwall delayed enhancement in the interventricular septum. Endomyocardial biopsy of RV septum showed no active myocarditis, no granulomas, but extensive fibrosis. All immunologic markers were negative, including the anti-heart antibodies. Genetic testing showed a pathogenic frame-shift mutation in desmoplakin (DSP) gene, that was also found in his mother. He was treated with an angiotensin-converting enzyme inhibitor, a mineralocorticoid receptor antagonist and high dose beta-blocker. An ICD was implanted.

Conclusions and implications for clinical practice: Ventricular arrhythmias associated with impaired LV function at normal loading conditions in a young patient warrant additional examination, including myocardial biopsy and genetic testing. The phenotype associated with the pathogenic mutation of DSP can represent an arrhythmogenic left ventricular cardiomyopathy (ALVC). Cardiac screening of first-degree relatives revealed severely impaired LV function and ventricular arrhythmias in a younger sister. Several studies showed an increased risk for malignant ventricular arrhythmias in male patients with laminar A/C mutations. Whether this increased risk is present for other genetic mutations is unknown. In our patient the decision for ICD implantation was based on the burden of ventricular arrhythmias and the presence of an anatomic substrate, although there are no specific recommendations for this phenotype.

Sudden unexplained death in a young patient

M Juarez Fernandez¹; MA Espinosa Castro¹; I Sousa Casasnovas¹; C Devesa Cordero¹; V Gomez Carrillo¹; M Martinez Selles¹; R Yotti Alvarez¹; F Fernandez Aviles¹

¹University Hospital Gregorio Marañon, cardiology, Madrid, Spain

Introduction and case report: A 22 year old man without medical history or family history of heart disease presented a cardiac arrest. Rhythm was analyzed with a semiautomatic defibrillator that detected a shockable rhythm and delivered electrical defibrillation. The patient recovered with an atrial fibrillation rhythm.

Procedure: The patient was admitted to our Cardiovascular Intensive Care Unit and hypothermia was performed. After completing the hypothermia and rewarming, he awakened without neurological sequelae. Atrial fibrillation persisted since admission so finally successful electrical cardioversion was performed. His electrocardiogram and Holter monitoring showed no other abnormalities. Further investigations (echocardiogram, coronary angiography, cardiac magnetic resonance, exercise stress test, flecainide and epinephrine test) were also normal.

In the absence of diagnosis an implantable cardioverter defibrillator (ICD) was implanted and genetic testing was performed with a NGS panel (76 genes) identifying a missense mutation in KCNQ1 gene, in exon 5 (R231H). Therefore the patient was diagnosed with Long QT Syndrome type I and he started beta blockers. Genetic counseling was given and genetic cascade was recommended to first-degree relatives.

Differential diagnosis: When facing a sudden death in a young patient without structural heart disease inherited channelopathies such as Long QT syndrome (LQTS), Brugada syndrome or catecholaminergic ventricular tachycardia need to be ruled out. Our patient's electrocardiogram showed neither Brugada nor LQTS findings. Provocative testing were normal. A clinical clue in this case was the finding of persistent atrial fibrillation which is rare after defibrillation of ventricular fibrillation in a young patient.

Conclusions and implications for clinical practice: In about a third of young patients with sudden cardiac death the etiology is not identified. In most the cause is an inherited arrhythmogenic disorder and the clinical-genetic study can diagnose up to 40 % of these. It is worth to perform a genetic testing in the unexplained cases in order to minimize the risk of recurrence or shocks after ICD implantation and to identify family members at risk in the case of hereditary diseases. In the case we present here, genetic testing has allowed the diagnosis of LQTS although electrocardiogram, exercise test and epinephrine test were normal. The R231H variant in KCNQ1 is related to LQTS type I and familial AF. This mutation has been described in several families with ventricular arrhythmias and AF, and it is not found in individuals from population databases. This case illustrates the importance of genetics in the management of sudden unexplained death in the young. In such patients genetic testing should be part of our diagnostic workup.

636

Acute myocarditis with prominent epsilon-waves on electrocardiogram

A Kulikov¹; A Bobrov²; V Dvinyadinov²; S Rud²

¹Saint Petersburg Pavlov State Medical University, Saint Petersburg, Russian Federation; ²Military Medical Academy, Saint Petersburg, Russian Federation

A 66-year old male came to our emergency department with signs of arrhythmogenic shock caused by right ventricular tachycardia (190 bpm). Emergency defibrillation restored his sinus rhythm. From the age of 20 he had experienced a few episodes of paroxysmal palpitations. This episode of arrhythmia was accompanied by the loss of consciousness for the first time. After the cardioversion examination detected heart failure signs: acrocyanosis, peripheral oedema, jugular venous distention, mild hypotension (105/60 mm Hg) and hepatomegaly. Laboratory findings were slightly reduced haemoglobin level (120 g/l) and elevated brain natriuretic peptide (650 pg/ml). Sinus bradycardia (50 bpm) and high epsilon-waves in V1-3 leads were detected on ECG. 4 episodes of accelerated ventricular rhythm (up to 4 complex with 70-80 bpm) and frequent premature ventricular contractions (130 per hour) were found on Holter monitoring. Signal-averaged ECG detected late potentials (HF QRS

duration = 222 ms, RMS-40 = 27 mV, LAS40 = 105 ms). Echocardiography revealed enlarged right ventricle (RV) and right atrium (RV diastolic dimension - 45 mm, right atrium diastolic volume - 105 ml) with normal volumes of left chambers; RV wall thickening (up to 10 mm) and prominent trabeculations of middle and apex part of RV; impaired local and global RV contractility ($S' = 6$ cm/s, $FAC = 14\%$) with normal left ventricular systolic function ($EF = 62\%$); signs of both ventricles diastolic dysfunction (left $E/e' = 10$, right $E/e' = 9$). With magnetic resonance imaging of the heart we found thickening of the RV wall up to 8 mm, extensive subtotal wall fibrosis in apical and middle RV segments with small separate areas of fatty wall infiltration in some basal and apical segments. The kinetics of the RV walls was sharply decreased. RV diastolic volume was 190 ml, ejection fraction - 16%. Right ventriculography showed RV enlargement and high cavity trabeculation. Preliminary diagnosis of arrhythmogenic right ventricular dysplasia was made on the basis of 3 major and 3 minor modified McKenna criteria (2010). Meanwhile endomyocardial biopsy discovered degenerative changes of RV cardiomyocytes (vacuole dystrophies) with perivascular lymphocytic infiltration and small areas of granular tissue. The proportion of residual cardiomyocytes was 72%. Thus, we were unable to identify morphological features of arrhythmogenic right ventricular dysplasia. Analysis of biopsy samples showed that the patient has signs of acute healing myocarditis. As a result, possible relationships between myocarditis and arrhythmogenic right ventricular dysplasia are being discussed.

ECG epsilon-waves in V1-3 leads

637

A challenging case of infiltrative cardiomyopathy in a young man with syncope

F Grossi¹; A Giomi¹; F Zeraushek¹; L Fratoni¹; G Mascia¹; L Zampini¹; S Pradella²; M Emdin³; M Giaccardi¹; M Mili¹

¹Hospital of Santa Maria Nuova, Cardiology and Electrophysiology Unit, Florence, Italy; ²University Hospital Careggi, Radiology Department, Firenze, Italy; ³Gabriele Monasterio Foundation, Pisa, Italy

We report the case of a 43 years old man that was admitted to our Cardiac Care Unit - CCU because of syncope. Mild smoker with a family history of myocardial infarction and sudden death in young age. He reported that during the last month when performing moderate-to-intense sport activity his heart rate suddenly halved (he was used to wear a heart rate belt), a finding that he never observed before. The echocardiogram showed an increased thickness of the interventricular septum - IVS (15 mm) and a preserved left ventricular contractility (left ventricular ejection fraction - EF: 0.55). The patient underwent an electrophysiological study - EPS that showed normal intra-cardiac delays and no induction of ventricular arrhythmias. The coronary angiography was normal. An intra-cardiac loop-recorder - ILR was implanted and the patient was discharged. The day after the patient presented palpitations and a non-sustained ventricular tachycardia - NSVT was documented during the device interrogation; a therapy with beta-blocker was started. After few days the patient suffered exertional syncope; the recording from the ILR showed a complete atrioventricular block with 9 seconds of asystole. The patient was admitted to our CCU, underwent cardiac magnetic resonance - CMR and then was implanted with a dual chamber pacemaker-defibrillator - ICD. The CMR showed a late gadolinium enhancement - LGE of the right ventricle and a spotted LGE of the left ventricle. One month later the patient came to our Heart Failure Clinic for clinical follow-up. While he was waiting to be called in the doctor's office he suddenly lost consciousness. The ICD interrogation showed a ventricular fibrillation correctly recognized and treated by a 11 J shock. Amiodarone 200 mg was added to the betablocker. In the suspicion of an infiltrative cardiomyopathy the patient underwent chest computed tomography (CT) and positron emission tomography (PET) that placed the diagnosis of cardiac sarcoidosis. A myocardial biopsy guided by electroanatomical mapping system and targeted on low voltage right ventricular free wall areas showed a histological pattern of cardiac sarcoidosis. A therapy with prednisone was started and the patient rapidly recovered. After a two months follow-up no arrhythmia recurrence was detected by the ICD remote monitoring.

638

A rare acromegalic cardiomyopathy with malignant arrhythmogenic pattern

S Doimo¹; D Miani²; C Nalli²; M Driussi²; N Finato³; G Sinagra¹; U Livi²; A Proclemer²

¹Postgraduate School in Cardiovascular Sciences, Cardiovascular Department, Trieste, Italy; ²University Hospital Santa Maria della Misericordia, Department of Cardiothoracic Science and IRCAB foundation, Udine, Italy; ³University Hospital Santa Maria della Misericordia, Laboratory Department of Medical and Biological Sciences, Udine, Italy

We report a case of 48 years old man, presented in emergency department in October 2011 for chest pain and dyspnea. Systemic examination revealed coarse facial features and signs of heart failure. The electrocardiogram showed sinus rhythm, left bundle branch block and ectopic ventricular beats. Echocardiographic evaluation was suggestive of dilated cardiomyopathy with left ventricular dilatation, posterior wall motion abnormalities, apical thrombosis, severe depressed ejection fraction (EF) and mild mitral regurgitation. Coronary angiography showed normal coronary arteries and cardiac magnetic resonance confirmed the severe left ventricular dilatation (indexed telediastolic volume: 195 ml/mq) and dysfunction (EF 22%), eccentric hypertrophy with apical thrombosis and transmural fibrosis. At the same time, the patient was evaluated for acromegaly. Elevated somatotropin levels (11.5 ng/ml) and cerebral magnetic resonance were compatible with pituitary adenoma. With tailored heart failure therapy, amiodarone, warfarin and somatostatin analog, the patient remained asymptomatic, with improved EF (35%) and only sporadic ventricular extrasystoles at Holter registration. Pituitary adenoma was removed by trans-sphenoidal surgical resection in 2013. Clinical stability was maintained until January 2014, when the patient was admitted to our hospital for sustained ventricular tachycardia (VT), 190 bpm, solved with 50 joule D.C. shock. A dual coil lead ICD defibrillator was implanted and amiodarone was interrupted for iatrogenic hyperthyroidism. After 6 months, the patient was readmitted for repeated ICD interventions due to VT episodes (190 bpm). With introduction of procainamide (1.5 gr/day per os) no recurrence of VT was documented and patient was successfully discharged. Unfortunately, in November the patient was readmitted for refractory VT and ventricular fibrillation storm, which required venous arteriosus ECMO, associated to intra-aortic balloon counterpulsation and urgent placement on the waiting list for heart transplantation. After 19 days, a compatible organ was available and heart transplantation with bicaval anastomoses was performed. At macroscopic analysis of the explanted heart, the severe dilatation and eccentric hypertrophy was confirmed. Histologically, we highlighted sporadic foci of fibro-adipose replacement, interstitial fibrosis and fibrous thickening of the endocardium without inflammation. **Conclusion:** acromegaly is a rare disease in which cardiovascular complication are common. Malignant ventricular tachyarrhythmias are a frequent manifestation of cardiac involvement and their severity correlates with increases in left ventricular mass. In most cases, cardiovascular complications might benefit from treatment directed towards the pituitary adenoma but in our case, despite the tumor removal, the sustained ventricular arrhythmias were uncontrollable due to the underlying end-stage acromegalic cardiomyopathy.

fibro-adipose foci, interstitial fibrosis

Unconventional approach to atrial fibrillation in friedreich's ataxia.S Suhas Jadhav¹; E Keelan²; D Ward¹¹Adelaide & Meath Hospital, CRY-P, Dublin, Ireland; ²Connolly Hospital Blanchardstown, Cardiology, Dublin, Ireland

Background: Friedreich's ataxia (FA) is an autosomal recessive, progressive, degenerative disorder. It causes neurological dysfunction & cardiomyopathy, with left ventricular hypertrophy. Cardiac arrhythmia & heart failure (HF) are the predominant cause of death & impaired quality of life (QOL) in FA. Management of atrial fibrillation (AF) in already fragile FA patient can be challenging. Case description: 32 year old male FA patient referred for cardiac assessment. He reported extreme fatigue since starting B-blocker (BB) for asymptomatic ectopic beats. At 1st consultation he was asymptomatic with stable mildly reduced ejection fraction EF ~48%. We stopped his BB & QOL improved. 2 years later he was hospitalised with 1st documented AF episode & decompensated HF. Initial attempt at rhythm control failed. After 5 days of amiodarone therapy he converted to sinus rhythm, EF returned to baseline & he was discharged on ramipril, amiodarone, aspirin, furosemide, digoxin, eplerenone. In next 28 months he was hospitalised on 3 occasions for paroxysmal AF related HF. We sought 2 separate electrophysiologist's (EP) opinion on each admission, were advised that AF-ablation was not indicated or likely to be successful & recommended medical therapy, including stopping amiodarone & uptitration of BB on 3rd admission. After stopping amiodarone, he went into permanent AF. In spite of optimization of medications, OPD review confirmed poor HR control, reduced EF & poor tolerance of BB as before. Possible options and our approach: 1) Continue BB (+/- increase dose) to improve rate control (side-effects likely to further impair QOL). 2) Stop BB (in the short term might improve QOL, but with frequent bursts of tachycardia would likely result in further reduction in EF and negatively impact on his morbidity & mortality). 3) AF-ablation (invasive with uncertain outcome in reduction in AF) 4) Biventricular pacing and AV-node ablation (on the positive side would remove the need for BB, but it has never been attempted in FA patients, to our knowledge, so outcome again uncertain).

Discussion & Conclusion: Use of rate control medications did not achieve the target & severely impaired QOL. While 2 experts EP agreed that ablation for AF was of doubtful assistance, a speculative staged biventricular pacing & AV-node ablation plan was agreed with 3rd EP. This allowed us to stop the BB amiodarone. Post ablation 3 months follow up confirms improved QOL & EF 55%. We suggest in complex patients that lack of evidence for a therapeutic approach could be interpreted as evidence of no benefit, but in a rare condition such as FA, randomised controlled trials to guide therapies will be difficult to achieve. Standard medications can be poorly tolerated in these patients. Although life expectancy is reduced in FA, aggressive intervention can be beneficial—immediately for QOL we hope longer term in increased longevity. We suggest invasive therapy on an individual basis & proactive advocacy by the treating Physician for their patient if warranted.

Heart rate and EF Vs Period

Management of an idiopathic left ventricular aneurysm presented with sustained ventricular tachycardiaD Menci¹; FM Righini¹; V Zaca¹; M Cameli¹; C Baiocchi¹; S Mondillo¹; R Favilli¹¹University of Siena, Department of Cardiovascular Diseases, Siena, Italy

We report a case of a 67 year-old patient who displayed a monomorphic ventricular tachycardia with a finding of a left ventricle (LV) aneurysm of the basal segment of postero-lateral wall assessed by echocardiography. Coronary angiography ruled

out an ischemic cardiopathy and cardiac magnetic resonance (CMR) showed a non-ischemic pattern of fibrosis in the aneurismal wall combined with adipose tissue replacement. An implantable cardioverter defibrillator (ICD) was implanted in secondary prevention and an antiarrhythmic therapy with amiodarone was started without recurrence of the ventricular arrhythmia in one year of follow-up. We also report some little evidence at our disposal about non-ischemic left ventricular aneurysms management.

Figure 1

A singular cardiac structure and morphologyC Catia Costa¹; ML Pitta¹; P Matos²; E Oliveira³; M Leal¹¹Hospital of Santarem, Cardiology, Santarem, Portugal; ²Hospital CUF Infante Santo, Lisbon, Portugal; ³University Hospital De Santa Maria, Lisbon, Portugal

We report the case of an 85-year-old male, with type 2 diabetes and dyslipidaemia. He had no living ascendants or descendants. He was referred to Cardiology evaluation after documentation of a single cardiac morphology of unknown etiology. The patient was in NYHA class II and had frequent polymorphic ventricular extrasystole.

The 2D and 3D echocardiographic assessment revealed a dilated left ventricle, with mild systolic dysfunction, as well as multiple digitiform images at the inferior and posterolateral walls, as many bands and false tendons inside the cavity. Cardiac magnetic resonance confirmed the presence of numerous muscular digitiform images, with lesser sensitivity in detecting the bands and false tendons. It did not revealed changes in the late enhancement study or presented criteria for left ventricular non-compaction.

The myocardial perfusion scintigraphy documented the presence of myocardial ischemia, which has not translated into significant epicardial disease on coronary angiography.

The patient evolved to NYHA class I after beginning of beta-blocker therapy and suppressing therapy of the renin-angiotensin-aldosterone system, with better control of the arrhythmias. Although the optimized treatment, this patient had a relatively benign course of his cardiomyopathy with late detection and long survival.

This is a rare case of muscular dysplasia not yet classified, designated by scarce reports as sawtooth cardiomyopathy, an unreliable designation after evaluation by 3D echocardiography that showed a more complex intracavitary structure, including not also multiple muscular digitiform images, as well as several bands and false tendons, presumably translating a deranged myofibril organization pattern.

Rhyme and reason for a bad rhythm: triple ripple; 1. recurrent atrial fibrillation, 2. mitral periprosthetic leak, 3. constrictive pericarditis

VR Vinutha Rajesh¹; N Ushler¹; F Mookadam¹

¹Mayo Clinic, Arizona, Cardiology, Phoenix, United States of America

Background: Postoperative constrictive pericarditis is rare following open heart surgery. Patients presenting with heart failure (CHF) or arrhythmias late after cardiac surgery should have a complete investigation of the etiology of CHF. We describe a case post mitral valve annuloplasty repair for severe mitral regurgitation with recurrent atrial fibrillation and congestive heart symptoms. An unusual case with uncommon treatment strategies was successfully managed. Case: A 63-year-old man with recurrent atrial fibrillation and past medical history of mitral valve repair with annuloplasty ring, maze procedure, PFO closure, and single vein graft to the left anterior descending artery one year earlier. Following surgery, the patient had recurrent atrial fibrillation requiring three radiofrequency ablation procedures at an outside hospital was referred for repeat ablation with acute New York Heart Association (NYHA) Class II–III CHF symptoms. Physical exam was significant for distention of the neck veins to 25 cm of H₂O, positive Kussmaul's sign, 3/6 holosystolic murmur, decreased breath sounds of the lower lungs bilaterally, with ascites and 3+ pitting pedal edema. Decision Making: Clinical examination was suspicious for CHF, recurrent periprosthetic mitral regurgitation and pericardial constriction. The transthoracic echocardiography showed constrictive pericarditis and a large periprosthetic mitral regurgitation as shown in Panel 1. Cardiac catheterization confirmed the constrictive physiology. Patient was recommended for re-do mitral valve surgery and pericardectomy. Patient declined surgery and preferred medical management. Constriction was treated with triple therapy including Colchicine, Non-Steroidal Anti-inflammatory Drugs (NSAIDs) and steroids for 2 months and followed by NSAIDs and Colchicine for 4 months. While the constrictive symptoms improved, persistent heart failure requiring diuretic for the management of NYHA class II symptoms secondary to periprosthetic mitral regurgitation. Patient was referred for percutaneous mitral valve periprosthetic leak closure. Post procedure echocardiography showed resting gradient of 5 mm of Hg after successful deployment of a single Amplatzer PDA closure device. Four years later patient remains in NYHA Class I.

Conclusion: This complex case demonstrates the importance of a good physical examination in the evaluation of the heart failure symptoms. A high index of suspicion is needed in the diagnosis of constrictive pericarditis and the severity of the periprosthetic mitral valve leak causing persistent CHF after the constriction has resolved. It is unusual for constriction beyond one year of surgery to respond to medical management. In the current era, where repeat open heart surgery is not an option because of patient preference or excessive surgical risk, alternative strategies for symptomatic periprosthetic leak can be successfully undertaken in expert hands.

Plasma fibroblast growth factor 23 is associated with poor outcome and unsuccessful uptitration of guideline-recommended pharmacotherapy in patients with worsening heart failure

This project was funded by a grant from the European Commission: FP7-242209-BIOSTAT-CHF

J M Jozine Ter Maaten¹; AA Voors¹; M Metra²; P Van Der Harst¹; K Dickstein³; F Zannad⁴; JG Cleland⁵; HL Hillege¹; K Damman¹; MH De Borst¹

¹University Medical Center Groningen, Groningen, Netherlands; ²University of Brescia, Brescia, Italy; ³Stavanger University Hospital, Stavanger, Norway;

⁴University of Lorraine, Nancy, France; ⁵Imperial College London, London, United Kingdom

Background: Recent studies suggest that fibroblast growth factor (FGF) 23 promotes sodium retention yet its potential value in worsening heart failure (WHF) has not been explored.

Purpose: To investigate the relation between FGF23 and clinical outcomes in patients with WHF.

Methods: We measured plasma C-terminal FGF23 levels in 2,399 of the 2,516 patients included in the BIOlogy Study to Tailored Treatment in Chronic Heart Failure (BIOSTAT-CHF) trial, in which patients with WHF were to be uptitrated to guideline recommended doses of angiotensin converting enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB). The association between FGF23 and outcome was evaluated by Cox regression analysis adjusted for potential confounders, such as renal function. Results Median FGF23 was 218.0 [117.1–579.3] RU/ml, and patients with higher FGF23 levels had a worse NYHA class and more signs of congestion (all $P < 0.005$). Patients with higher baseline FGF23 levels were less likely to use ACEi or ARB therapy at baseline and less likely to reach target dose after 3 months of uptitration. In multivariable Cox regression analysis, log transformed FGF23 was independently associated with all-cause mortality (1.25 (1.14–1.37) per log increase, $P < 0.001$), and the combined endpoint of all-cause mortality and heart failure hospitalization (1.20 (1.11–1.29) per log increase, $P < 0.001$). The predictive value of FGF23 for all-cause mortality was significantly greater than that for BNP (Univariable Harell's c-statistic: 0.689 vs. 0.649, respectively, $P < 0.001$).

Conclusion: Higher plasma FGF23 levels are independently associated with less successful uptitration of guideline recommended therapies and an increased risk of all-cause mortality and heart failure hospitalization in patients with WHF.

Survival curve per quintiles of FGF23

Prognostic burden of heart failure diagnosed in primary care or secondary care: a population-based linked electronic health record cohort study in 2.1 million people

PLN foundation (hartspierziektepln.nl); Wellcome Trust (0938/30/Z/10/Z); DHF (Dekker 2014T001); UCL hospitals NIHR Biomedical Research Centre S Koudstaal¹; M Pujades-Rodriguez²; S Denaxas²; JMIH Gho¹; AD Shah²; CP Gale³; AW Hoes⁴; JG Cleland⁵; FW Asselbergs¹; H Hemingway²

¹University Medical Center Utrecht, Dept of Cardiology, Utrecht, Netherlands;

²University College London, Farr Institute of Health Informatics Research, London, United Kingdom; ³Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; ⁴University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands; ⁵Imperial College London, Dept of Cardiology, London, United Kingdom

Background: Heart failure (HF) is a heterogeneous disease and as such frequently encountered by caregivers across the entire health care system. No studies have evaluated prospectively collected information on distribution of HF and possible differences in HF prognosis based on level of care (i.e. primary care (PC) patients who are never hospitalised, PC patients who are also acutely hospitalised for HF, and patients hospitalised for HF but not known with HF in PC).

Purpose: To objective of this study was to assess the distribution of HF and compare its prognosis for patients seen in primary care, hospital admissions, both, or, have heart failure recorded as cause of death.

Methods: Linked electronic health record database of 2.13 million patients aged ≥ 18 years in England registered with a general practice contributing to CPRD between January 1997 and March 2010, linked with relevant hospital (HES) and mortality (ONS) registries. Patients aged 18 years or older with no prior history of HF who were diagnosed with HF throughout followup were included. Time to 90-day and 5-year all cause mortality and heart failure related mortality were modelled using Cox models.

Results: From a population of 2,134,615 people, we identified 89,554 patients with a diagnosis of heart failure, 23,547 (26%) in primary care who were never hospitalised for HF, 23,681 (26%) in primary care and hospitalised at least once for HF, 30,629 (34%) hospitalised for HF without ever receiving a PC diagnosis, and 11,697 (13%) with heart failure on their death record but no PC and/or hospital record (figure 1). The median age at diagnosis was 79.9 (interquartile range 71.9 to 86.3) years and 51.3%, 49.7%, 52.3%, and 53.3% were women in each of the above strata respectively. The 5-year survival was 88.1% (95%CI 87.9% - 88.3%) in the age and sex matched general population, compared to 43.9% (95%CI 43.2% - 44.6%) for HF patients in PC only, 39.8% (95%CI 39.2% - 40.5%) for PC with at least one hospital admission for HF, and 21.7% (95%CI 21.1% - 22.2%) for patients only hospitalised for HF without a PC record, respectively. Heart failure related mortality varied between groups and patients who were hospitalised for HF were more likely to die of HF compared to patients who were never hospitalised (hazard ratio, adjusted for age, sex and GP practice 1.71, 95% CI 1.63 - 1.78, $P < 0.0001$). Furthermore, an acute hospital admission as the first presentation of the disease was associated with increased mortality, compared to HF diagnosed in PC (hazard ratio, adjusted for age, sex and GP practice 1.66, 95% CI 1.63 to 1.69, $P < 0.0001$).

Conclusions: Important differences in terms of all-cause and HF related mortality exist depending on the level of care in which patients were diagnosed. Failure to address this heterogeneity in clinical practice or research may lead to biased estimates of the prognostic impact of a heart failure diagnosis.

Figure 1. Number and percentage of records in primary care (CPRD), hospital admissions (HES), and mortality registry (ONS) for heart failure across three national sources (n= 89 554 patients)

Treatment with insulin increases mortality in diabetic patients with chronic heart failure: data from the GISSI-HF Trial.

D Cosmi¹; S Barlera²; S Masson²; L Staszewsky²; A P Aldo Pietro Maggioni³; L Tavazzi⁴; G Tognoni²; F Cosmi¹; R Latini²

¹Valdichiana Cardiology, USL 8, Cardiovascular and Neurological Disease Department, Arezzo, Italy; ²IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Department of Cardiovascular Research, Milan, Italy; ³ANMCO Research Center, Florence, Italy; ⁴Maria Cecilia Hospital, GVM Care & Research - ES Health Science Foundation, Cotignola, Italy

Background: Recent studies have found that insulin-treated diabetes (DM) is often associated with a significantly worse prognosis in patients with chronic heart failure (HF). However, the lack of general agreement on the detrimental effects of insulin in patients with HF and DM prompted this post-hoc analysis of the large database of the GISSI-HF trial.

Purpose: In patients with DM and chronic HF, we evaluated whether insulin treatment was independently associated with excess mortality compared to other anti-diabetic treatments. Methods. The association between anti-diabetic treatment and total mortality was evaluated with adjusted Cox proportional hazard models in the 6975 patients with chronic HF enrolled in the multicenter clinical trial GISSI-HF, of whom 1.974 (28.3%) had DM at entry. Of these, 313 were treated only with hypoglycemic diet, 1.119 only with oral hypoglycemic agents (OHAs), and 542 with insulin. Results were fully adjusted for demographic, clinical and laboratory covariates associated with mortality ($p < 0.05$).

Results: The median follow-time of the study was 3.9 years. All-cause mortality in DM patients was 675 (34.3%) versus 1294 (25.9%) in non-diabetics ($p < 0.0001$). The figure shows the adjusted risk of total mortality in patients with DM treated with diet, OHAs or insulin, compared to non-diabetic patients; there was a significant excess of risk only in the latter group.

Conclusions: In the GISSI-HF trial, DM patients treated with insulin showed a 38% higher mortality compared to those without DM. Prospective studies are warranted to confirm these results in a population commonly found in clinical practice, but orphan of hypoglycemic treatment with validated efficacy and safety.

Conclusions: In the GISSI-HF trial, DM patients treated with insulin showed a 38% higher mortality compared to those without DM. Prospective studies are warranted to confirm these results in a population commonly found in clinical practice, but orphan of hypoglycemic treatment with validated efficacy and safety.

Genetic screening in dilated and non-dilated cardiomyopathy: should we broaden our perspective?

M R Mark Hazebroek¹; J Verdonchot¹; E Vanhoutte²; I Krapels²; M Hoos¹; L Van Montfort¹; A Van Den Wijngaard²; H Brunner²; S Heymans¹

¹Maastricht University Medical Center, Department of Cardiology, Maastricht, Netherlands; ²Maastricht University Medical Centre (MUMC), Clinical Genetics, Maastricht, Netherlands

Background: The current ESC guidelines recommend genetic screening merely in patients with dilated cardiomyopathy (DCM). However, a significant subgroup presents with non-dilated cardiomyopathy also known as left ventricular (LV) dysfunction and recognized as a potential precursor of DCM. The presence of genetic or familial predisposition and the prognosis of patients with LV dysfunction versus DCM patients is currently unknown.

Objectives: To evaluate the diagnostic yield of next generation sequencing (NGS) gene testing, familial inheritance and prognosis in LV dysfunction patients versus DCM patients. **METHODS.** Within the Maastricht Cardiomyopathy registry 389 patients with initially unexplained CMP – excluding patients with ischemic, valvular, hypertensive, and congenital heart disease – were enrolled between January 2004 and September 2015. All patients underwent complete diagnostic evaluation including electrocardiography, echocardiography, 24h Holter registration and genetic screening. Genetic or familial predisposition is defined as familial inheritance pattern and/or the identification of a (likely) pathogenic mutation using next-generation sequencing (NGS). Familial inheritance is defined as the presence of ≥ 2 affected individuals in a single family or the presence of a 1st-degree relative with unexplained sudden cardiac death <60 years. Long-term outcome used a combined endpoint of life-threatening arrhythmia, heart transplantation, and all-cause death.

Results: A total of 262 consecutive DCM and 127 LV dysfunction patients were included. Baseline characteristics demonstrated no differences in the number of co-morbidities ($P = 0.81$), but as expected a significant lower LVEF and higher age in DCM as compared to LV dysfunction (28 ± 11 vs 37 ± 10 ; $P < 0.001$ and 58 ± 12 vs 55 ± 13 ; $P < 0.019$, respectively). A genetic or familial predisposition was found to a similar extent in DCM as compared to LV dysfunction without dilatation (100 (38%) vs 57 (45%); $P = 0.21$). As expected, a (likely) pathogenic mutation was more frequently found in patients with positive as compared to negative familial inheritance, irrespective of a DCM or LV dysfunction phenotype (20 (25%) vs 17 (9%); $P = 0.001$ and 12 (27%) vs 11 (13%) $P = 0.049$, respectively). After a median follow-up of 56 [31-82] months, long-term outcome did not differ between DCM and LV dysfunction (Log-rank $P = 0.671$). However, outcome in patients with a genetic or familial predisposition was worse as compared to patients without a genetic or familial predisposition, in both the DCM and LV dysfunction phenotype (Figure 1, Log-rank $P = 0.006$ and Log-rank $P = 0.049$, respectively).

Conclusion: The diagnostic yield of NGS gene testing in DCM and LV dysfunction without dilatation is equally high. Moreover, the presence of genetic or familial predisposition exhibits a worse prognosis in both DCM and LV dysfunction patients. Therefore, genetic screening should not merely be restricted to patients with DCM.

Event-free survival

678

Renal venous pattern: a new parameter for predicting cardiorenal syndrome progression

A Puzzovivo¹; M Massimo Iacoviello²; F Monitillo³; M Leone³; C Rizzo³; MS Lattarulo³; D Grande³; P Terlizze³; F Massari¹; MM Ciccone⁴

¹Cardiology Unit, Murgia Hospital, Cardiovascular department of Bari, Altamura, Italy; ²Institute of Cardiology - University of Bari, Bari, Italy; ³University of Bari, School of Cardiology, Bari, Italy; ⁴Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

Background: In chronic heart failure (CHF) patients, renal congestion plays a key role in determining the progression of renal dysfunction, that has been demonstrated to be associated with a worse prognosis.

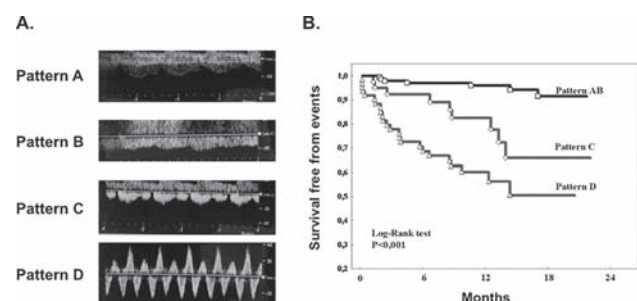

The aim of this study was to define whether Doppler venous patterns which reflect renal congestion, could play a role in predicting heart failure progression.

Methods: We enrolled 254 outpatients (76% males, 64 ± 14 years, NYHA class 2.2 ± 0.7 , left ventricular ejection fraction, LVEF, $33 \pm 9\%$) with CHF (ESC criteria), in stable clinical conditions (> 1 month) and in conventional therapy (86%

ACE-inhibitors and/or ARBs, 94% betablockers). All patients underwent a clinical evaluation, a routine chemistry, an echocardiogram and a renal echo-Doppler. Pulsed Doppler flow recording was performed, at the level of interlobular renal right veins in tele-expiratory phase, inviting the patients to hold the breath. The venous flow patterns have been divided into 4 groups as shown in Figure A. Group A: flow patterns with normal decrease in flow velocity and biphasic pattern with no interruption of flow in tele-diastole; Group B: pattern of continuous flow with minimal fluctuations; Group C: Pattern monophasic or biphasic with interruption of the flow in tele-diastole; Group D: pattern of intermittent flow.

Results: During a median follow-up of 12 months (interquartile range 8-16 months), 40 patients experienced heart failure progression (hospitalization, heart transplantation or death due to heart failure worsening).

Venous patterns C (HR 6.01;95%CI:2.08-17.35; $p < 0.001$) and D (HR 2.99;95%CI: 1.17-7.62; $p < 0.022$) were associated with events at univariate Cox regression analysis. Moreover both pattern C (HR: 5.88; 95%CI:2.09-16.6; $p < 0.001$) and D (HR: 3.10; 95%CI: 1.28-7.50; $p < 0.012$) remained associated to events at multivariate Cox regression analysis after correction for the independent predictors of the reference model, with a high discrimination (correlation of 0.90 according to the C-statistic). Moreover, the addition of venous flow patterns to the reference model significantly improved reclassification according to both NRI 91% (0.58-1.25; $p < 0.001$) and IDI (45% 95% CI: 0.01-0.08; $p = 0.012$). Figure shows Kaplan Meier curves for pattern A-B, C and D. In conclusion, our findings demonstrate the independent and incremental role of Doppler venous patterns reflecting renal congestion in predicting HF progression among CHF patients, thus suggesting its possible utility in daily clinical practice in order to better characterize patients with cardio-renal syndrome.

The metabolic exercise cardiac and kidney indexes (meckl) score: a new prognostic tool in patients with heart failure. a multicenter comparison with seattle and hfss in a large cohort of patients

M Massimo Mapelli¹; RL La Gioia²; ME Emdin³; RR Raimondo⁴; GL Limongelli⁵; AS Scardovi⁶; CL Lombardi⁷; GS Sinagra⁸; UC Corra⁹; PA Agostoni¹

¹Cardiology Center Monzino IRCCS, Milan, Italy; ²"S. Maugeri" Foundation, IRCCS, Institute of Cassano Murge, Division of Cardiology, Bari, Italy; ³Fondazione Gabriele Monasterio, Pisa, Italy; ⁴Fondazione Salvatore Maugeri, Tradate, Italy; ⁵AO dei Colli-Monaldi Hospital, Naples, Italy; ⁶Hospital Santo Spirito, Rome, Italy; ⁷Civil Hospital of Brescia, Brescia, Italy; ⁸University Hospital Riuniti, Trieste, Italy; ⁹Fondazione Maugeri, Veruno, Italy

Background: Heart failure (HF) prognostication is a challenging medical judgment, constrained by a magnitude of uncertainty. Cardiopulmonary exercise test (CPET)

is a well-recognized, valuable and accurate tool for risk stratification in HF. Peak oxygen uptake (VO₂) and the relationship between ventilation and CO₂ production (VE/VO₂ slope) have been identified as robust predictors of HF prognosis. Risk stratification with CPET-derived parameters need to be integrated into clinical practice. MECKI score is a simple 6-variables (VO₂, VE/VO₂, Hemoglobin, Sodium, MDRD, left ventricle ejection fraction (LVEF)) score validated for systolic HF patients considering CPET data combined with clinical, laboratory and echocardiographic measurements.

Purpose: We evaluated the prognostic value of a new simple score (MECKI Score) in a large population of patients with systolic HF compared with two of the actually most-used and available scores Heart Failure Survival Score (HFSS) and Seattle Heart Failure (SHF).

Methods: We selected 4862 consecutive patients with systolic HF (LVEF < 40%) clinically stable admitted in 21 cardiology departments. In every patient we collected clinical history, physical examination, blood sample, 12 derivations ECG, transthoracic echocardiogram, CPET. When all the data were available we calculated the MECKI, HFSS and Seattle Score and we calculated the Receiver Operating Characteristic (ROC) curves and the area under the ROC curve (AUC). We used the method proposed by DeLong to compare different AUCs.

Results: Study cohort consisted of 4862 (mean age 61.3 ± 12.6 years) consecutive systolic HF patients, recruited and prospectively followed in 21 Italian HF centers (mean follow up 3.6 ± 2.6 years). 998 patients died or underwent urgent transplantation during the follow-up period. Available data allowed calculation of MECKI score in 4139 patients, HFSS in 4007 and SHF in 2833. All the three scores were calculated in 2762 pts. At 1, 2 and 4 years AUC were 0,757, 0,742, 0,729 respectively. Including all the patients (by estimating the missing variables) AUC were 0.782, 0.767 and 0.756. In both cases MECKI's AUCs were significantly higher ($p < 0.001$ vs. HFSS and SHF) (Fig. 1).

Conclusions: MECKI score is a simple, reliable, easy to calculate, personalized heart failure prognostic tool. At present, MECKI is the most accurate prognostic score for systolic HF.

Endothelial deletion of protein tyrosine phosphatase-1B promotes angiogenesis and protects against pressure overload-induced heart failure in mice

Deutsche Forschungsgemeinschaft; Universitätsmedizin Mainz
R Gogiraju¹; MR Schroeter¹; ML Bochenek²; T Muenzel²; G Hasenfuss¹; K Schaefer²

¹Department of Cardiology and Pulmonary Medicine, Goettingen, Germany;

²University Medical Center of Mainz, Center for Cardiology, Cardiology I, Mainz, Germany

Background: Cardiac angiogenesis is an important determinant of heart failure, and previous studies underlined the essential role of vascular endothelial growth factor (VEGF) signalling during cardiac angiogenesis.

Purpose: To examine the hypothesis that protein tyrosine phosphatase (PTP)-1B, a negative regulator of VEGF receptor-2 activation, is causally involved in the cardiac microvasculature rarefaction during hypertrophy and that deletion of PTP1B in endothelial cells prevents the development of heart failure.

Methods: Cardiac hypertrophy was induced by transverse aortic constriction (TAC) in mice with inducible, endothelial cell-specific deletion of PTP1B (End.PTP1B-KO) and controls (End.PTP1B-WT).

Results: Survival was improved in End.PTP1B-KO mice up to 20 weeks after TAC. Serial echocardiography measurements revealed a better systolic pump function in End.PTP1B-KO vs. End.PTP1B-WT mice as well as a less pronounced cardiac hypertrophy (as determined by left ventricular [LV] mass and heart-to-body weight ratio) and LV dilation. Histologically, banded hearts from End.PTP1B-KO mice exhibited increased numbers of PCNA-positive, proliferating endothelial cells resulting in preserved cardiac capillary density and improved perfusion as well as reduced hypoxia, apoptotic cell death and fibrosis. Western blot analysis of banded heart protein lysates confirmed higher levels of phosphorylated VEGFR2 and p42/44 MAPK in End.PTP1B-KO vs. End.PTP1B-WT mice, which may have contributed to the observed changes. Absence of PTP1B in endothelial cells also promoted neovascularisation following peripheral ischaemia, and bone marrow transplantation experiments excluded a major contribution of Tie2-positive haematopoietic cells to the improved angiogenesis in End.PTP1B-KO mice. Increased expression of caveolin-1 as well as reduced NADPH oxidase-4 expression, ROS generation and TGF β signalling were observed and may have mediated the cardioprotective effects of endothelial PTP1B deletion.

Conclusions: Endothelial PTP1B deletion improves cardiac VEGF signalling and angiogenesis and protects against chronic afterload-induced heart failure and mortality. PTP1B may thus represent a useful target to preserve cardiac function during hypertrophy.

Introduction: Cardiovascular diseases remain the predominant cause of death worldwide, with the prevalence of heart failure continuing to increase. Despite increased knowledge of the metabolic alterations that occur in heart failure, novel therapies to treat the observed metabolic disturbances are still lacking. The present study investigated the involvement of microRNA-146a and its downstream metabolic target dihydrolipoyl succinyltransferase (DLST) in cardiac hypertrophy and failure.

Methods: In our study, we show that microRNA-146a is critically involved in the development of pressure overload-induced cardiac hypertrophy and heart failure. We used a conventional model of murine heart failure by the administration of angiotensin-II in an osmotic minipump during four weeks.

Results: * While overexpression of microRNA-146a in cardiomyocytes provoked cardiac hypertrophy and heart failure in vivo, genetic knockdown or pharmacological blockade of microRNA-146a with antimiR blunted the hypertrophic response and prevented cardiac dysfunction at 4 weeks.

* We found that the metabolic profile of microRNA-146a knockout cardiomyocytes was different compared to that of wild type cells: there was partial preservation of oxidative metabolism and the energetic efficiency of the mitochondria was higher in the absence of microRNA-146a. Mechanistically, we discovered that microRNA-146a targets dihydrolipoyl succinyltransferase (DLST) – the E2 sub-component of ketoglutarate dehydrogenase complex (KGDHC), a rate-limiting tricarboxylic acid (TCA) cycle enzyme.

* While DLST levels significantly decrease upon pressure overload in wild type mice – paralleling a decreased oxidative metabolism – DLST protein levels and hence oxidative metabolism are maintained in microRNA-146a knockout mice. Subsequently, oxidative metabolism through TCA cycle flux is more preserved in angiotensin-II-exposed microRNA-146a knockout mice compared to their wild type littermates.

* Moreover, overexpression of DLST in wild type mice with AAV9-vector technology significantly decreased cardiac hypertrophy in vivo. The same protection was observed in wild type mice to which dichloroacetate (DCA) was administered, a stimulator of oxidative phosphorylation through increased flux in the TCA cycle, confirming a critical role for oxidative metabolism in cardiac hypertrophy and failure.

Conclusions: The up-regulation of microRNA-146a in pressure-overloaded hearts is detrimental for heart failure progression. MicroRNA-146a decreases DLST causing an impaired oxidative metabolism in cardiomyocytes. Overexpression of DLST in cardiomyocytes protects against hypertrophy development. Altogether we show that the microRNA-146a – DLST axis is a crucial metabolic pathway in heart failure, with therapeutic potential.

Introduction: Heart failure with preserved ejection fraction (HFpEF) represents 50% of patients with heart failure and its prevalence is associated with metabolic syndrome (MetS). The mechanisms underlying cardiovascular disease in MetS are complex and include, among others, metabolic and mitochondrial alterations, which culminate with increased oxidative stress. Thus, we intend to evaluate mitochondrial function and oxidative stress in an animal model of HFpEF triggered by MetS.

Methods: Lean ZSF1 (ZSF1Ln, n=7) and obese ZSF1 (ZSF1Ob, n=7) rats were submitted an effort testing to determine the maximal O₂ consumption (VO₂max) and echocardiographically evaluated, at 20-25 weeks. Left ventricular (LV) samples were collected for mitochondrial functional studies, protein expression by immunoblotting and for in situ detection of myocardial oxidative stress by immunofluorescence.

Results: ZSF1Ob rats have a lower tolerance to VO₂max effort and anaerobic threshold, despite the increased cardiac output. Echocardiographically, the ZSF1Ob group showed increased LV mass, which was accompanied by preserved ejection fraction and LV diastolic dysfunction. Mitochondrial functional studies showed that ZSF1Ob group presents significant dysfunction of complex 1 and a trend in complex 2, alterations in the permeability of the mitochondrial pore and an increase in the time for the repolarization of the membrane potential, evidences further supporting mitochondrial deterioration. Protein studies revealed a significant increase in the expression of NADPH oxidase 2 and a significant decrease in NADPH oxidase 4 in ZSF1Ob rats, enzymes responsible for regulating the formation of reactive oxygen species (ROS). In situ detection of superoxide anion was significantly higher in ZSF1Ob rats, which proves the formation of ROS. Additionally, ZSF1Ob group presented a decrease in eNOS phosphorylation revealing an impairment in nitric oxide production.

Conclusion: Mitochondrial dysfunction induced by oxidative stress in rats with MetS is an important pathophysiological mechanism in HFpEF.

Maturation assessment of recellularized human cardiac tissue by means of simultaneous voltage and calcium mapping

Supported in part by grants from the Spanish Ministry of Science and Innovation (PLE2009-0152), the Instituto de Salud Carlos III (Ministry of Economy AM Andreu Climent¹; E Garreta²; ME Fernandez-Santos¹; R Sanz¹; MS Guillem³; JC Izpisua Belmonte⁴; N Montserrat²; F Fernandez-Aviles¹

¹University Hospital Gregorio Marañon, Cardiology Department, Madrid, Spain;

²Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain; ³Polytechnic University of Valencia, ITACA, Valencia, Spain; ⁴Salk Institute for Biological Studies, Gene Expression Laboratory, La Jolla, United States of America

Background: Human cardiomyocytes differentiated from induced pluripotent stem cells (CM-hiPS) represent a powerful tool to investigate and treat cardiac dysfunctions. However, technology used for their characterization is mainly limited to single cell analysis (e.g. patch-clamp).

Purpose: In the present study we evaluate the possibility to use simultaneous voltage and calcium mapping to characterize CM-hiPS cultures.

Methods: hiPSC cells were differentiated into cardiomyocytes and cultured on two different substrates (i.e. matrigel and decellularized extracellular cardiac matrices dECM). Electrophysiological properties of cardiac cultures were evaluated 30 days after culturing by simultaneously recording transmembrane voltage and intracellular

calcium levels in a tissue of 2x2cm (i.e. di-4-ANBDQPPQ voltage sensitive dye and rhod-2(AM) as Ca²⁺ sensitive probe). Main tissue electrophysiological properties were compared (i.e. wavefront propagation conduction velocity (CV) and upstroke time of the calcium transient).

Results: After 30 days of culture, cardiac structures presented electrically and mechanically connected functional activity (see figure). Our results demonstrated a dramatic increase in the mean conduction velocity from 2.54 ± 0.75 cm/s in matrigel coated wells to 7.45 ± 0.94 cm/s in ventricular dECMs. This increase in the conduction velocity in dECMs cultures was associated with a higher maturation in the kinetics of Ca²⁺ that produced an increase in the upstroke velocity of the calcium transient (44.82 ± 0.13ms in the dECM vs. 85.75 ± 0.15ms in petri dishes).

Conclusion: Culture of hiPSC-derived cardiomyocytes in decellularized extracellular cardiac matrices has demonstrated to favor tissue maturation.

Background: and Purpose: Endothelial derivatives of human pluripotent stem cells may offer regenerative treatments in ischemic cardiovascular diseases. We aimed to investigate the regulatory role of PI3K/FOXO1A signalling pathway on arterial and venous identity of endothelial subpopulations as well as the fate of generated cells in 3D cultures.

Methods and Results: To optimize endothelial differentiation, human embryonic stem cells (hESC) were differentiated via either embryoid body (EB) or monolayer method under normoxic and hypoxic conditions. CD31-positive endothelial cells (EC) were sorted by FACS and compared with human induced pluripotent stem cell-derived endothelial cells (hiPSC-EC). Both hESC-EC and hiPSC-EC showed mature endothelial phenotype in vitro, including cobblestone pattern, ac-LDL uptake and tube formation. Proteome profiling revealed high abundance of angiogenesis-related proteins both in cell lysates and supernatant. Expressions of arterial (EphrinB2, Notch1-2) and venous (EphB4) endothelial markers were increased during differentiation, suggesting the presence of mixed endothelial population in culture. Transfection of hESC-EC/hiPSC-EC with plasmids encoding FOXO1A-eGFP or pmxGFP was carried out by electroporation. Human ESC-EC and hiPSC-EC with high FOXO1A showed downregulated expressions of universal (CD31, angiopoietin-2 and ve-cadherin) as well as arterial and venous markers. Indeed, arterial index (EphrinB2/EphB4 mRNA ratio) decreased in response to FOXO1A overexpression (hESC-EC 8.16 ± 3.22 vs. 2.24 ± 0.49, p < 0.01; hiPSC-EC 6.46 ± 2.75 vs. 1.67 ± 0.72, p < 0.05; n = 3 biological replicates). This suggests a key role of PI3K/FOXO1A signalling pathway in the modulation of arterial and venous phenotype. For engineering 3D vascular constructs decellularised human aortic slices (300µm) were repopulated with hESC-EC and hiPSC-EC. Cells remained viable on engineered matrices. Imaging with Calcein AM live staining and 3DHistech analysis proved recellularisation with CD31-positive, viable endothelial cells.

Conclusions: We found that PI3K/FOXO1A signalling pathway has strong effects on arterial and venous endothelial identity. Human ESC-EC and hiPSC-EC remained viable on 3D vascular matrices. In-depth analyses of phenotype and functional characteristics of hESC-EC and hiPSC-EC may enhance their application for vascular tissue engineering.

MODERATED POSTER SESSION 3 - TOP NEWS ON BIOMARKERS

Background: Proenkephalin (pro-ENK) has emerged as a novel biomarker associated with both renal function and cardiac function, but its significance in heart failure patients is not so far evaluated.

Purpose: To evaluate the association between pro-ENK and indices of glomerular and tubular function and clinical outcome in patients with acute and chronic heart failure.

Methods: The association between pro-ENK and markers of renal function was evaluated in 120 chronic heart failure patients who underwent renal hemodynamic measurements including renal blood flow (RBF) and glomerular filtration rate (GFR) using 131I-Hippuran and 125I-iothalamate clearances, respectively. The association between pro-ENK and clinical outcome in acute heart failure was assessed in another 2033 patients.

Results: Pro-ENK was strongly correlated with both RBF ($r = -0.66$, $P < 0.001$) and GFR ($r = -0.71$, $P < 0.001$), but not with renal tubular markers. Blood urea nitrogen and brain natriuretic peptide were also determinants of pro-ENK. In the acute heart failure cohort, pro-ENK was a predictor of death through 180 days, heart failure rehospitalization through 60 days, and death or cardiovascular or renal rehospitalization through day 60 in univariable analyses, but its predictive value was lost in a multivariable model, when other renal markers were entered in the model. Changes in pro-ENK from baseline (day 1) to day 2 and from baseline to day 7, did not associate to prognosis.

Conclusions: In patients with chronic and acute heart failure, pro-ENK is strongly associated with glomerular function, but not with tubular damage. Pro-ENK provides limited prognostic information in heart failure patients on top of established renal markers.

Background: Biomarkers play a pivotal role in the management of heart failure (HF). In adults, several parameters are known to provide accurate information on diagnosis, prognosis and treatment response. However, reference values and insights from validation studies in adults cannot be extrapolated to the paediatric age group as it differs substantially from the adult population in pathophysiology, comorbidity and compensatory reserve.

Purpose: Our aim was to assess the diagnostic performance of 3 novel biomarkers in paediatric HF and to elucidate their accuracy differentially in patients with cardiomyopathy (CMP) and congenital heart disease (CHD), respectively. Reference data from healthy children are presented.

Methods: Mid-regional pro-Atrial Natriuretic Peptide (MR-proANP), sST2 and Growth Differentiating Factor 15 (GDF-15) were measured cross-sectionally in 111 HF patients and 87 controls (mean age 7.9 ± 5.9 years; range 5 days to 24 years). N-terminal pro-B Natriuretic Peptide (NT-proBNP) was used as a reference standard. A receiver-operating characteristic (ROC) was plotted to assess the diagnostic performance of the novel biomarkers alone or in combination with NT-proBNP. This was performed in all patients and, separately, for subgroups of patients with CHD ($n = 68$) and CMP ($n = 43$). In 38 patients with dilated CMP, left ventricular ejection fraction (LVEF) and diastolic volume were measured by echocardiography or magnetic resonance imaging. Associations with biomarker levels were assessed by logistic regression analysis.

Results: MR-proANP and NT-proBNP showed good diagnostic accuracy in the general population as well as in the CMP and CHD subgroups (Graph). By contrast, GDF-15 and sST2 did not perform sufficiently. None of the novel parameters improved the accuracy of NT-proBNP alone when combined with it. In the subgroup with dilated CMP, only NT-proBNP was associated with an impaired LVEF. Moreover, NT-proBNP and sST2 were predictive of left ventricular dilatation.

Conclusion: This is the first comprehensive assessment of novel biomarkers of HF in children and adolescents. MR-proANP can detect HF with accuracy comparable to that of the reference standard, NT-proBNP. This was the case in, both, CHD and CMP as the causal diagnosis. By contrast, neither sST2 nor GDF-15 were of any diagnostic usefulness, alone or in combination with NT-proBNP. Further research is needed to evaluate the prognostic significance of novel biomarkers in specific paediatric cardiac diseases.

Receiver-operating characteristics

Circulating relaxin as a biomarker of pulmonary hypertension and right heart overload in acute heart failure

M Pintahao¹; P Castro-Chaves¹; F Vasques-Novoa¹; F Goncalves¹; L Mendonca¹; R Fontes-Carvalho¹; P Lourenco²; P Almeida²; A Leite-Moreira¹; P Bettencourt²

¹Faculty of Medicine University of Porto, Department of Physiology and Cardiothoracic Surgery, Porto, Portugal; ²Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal

Background/Introduction: Serelaxin has recently shown promising results as a new potential acute heart failure (HF) therapy. Yet, its clinical use preceded the understanding of the role of the endogenous relaxin system in HF.

Purpose: We aimed to evaluate relaxin serum levels in a population of acute HF patients and their association with clinical and echocardiographic parameters of right and left heart overload.

Methods: We studied patients from a registry of acute HF patients. Admission serum relaxin levels were measured using an ELISA kit (Immunodiagnostik, Germany, detection limit 0.5pg/ml). Relaxin was dichotomized according to the median value of its distribution. Clinical, analytical and echocardiographic parameters of right and left heart overload were compared between relaxin groups.

Results: Relaxin serum levels were evaluated in 117 acute HF patients. Median age was 82 years (IQR 72-87), 41% of the patients were male and 63% had systolic dysfunction. Median serum relaxin was 31.4 pg/mL (range <0.5-1689.2). Patients with relaxin levels above the median had more clinical signs of right heart overload and significantly higher sodium retention score (mean 4.80 ± 1.53 vs. 3.60 ± 1.96 , $p < 0.001$). These findings were supported by the echocardiography data. Patients with higher relaxin levels had a significantly higher systolic pulmonary arterial pressure [median 47.0 (IQR36.0-61.0) vs. 34.5 (IQR25.0-51.0) mmHg, $p = 0.02$], a higher risk of right ventricle (RV) systolic dysfunction (OR 3.38 95%CI 1.21-9.41), a higher prevalence of RV dilation (31.0% vs. 5.3%, $p < 0.001$) and right atrial dilation (66.1% vs. 36.5%, $p = 0.002$) and less inferior vena cava diameter variability with inspiration (41% vs. 60%, $p = 0.01$), suggesting an association between relaxin circulating levels and right heart overload. BNP admission levels were also positively associated with RV dysfunction. However, relaxin was able to predict RV dysfunction independently of BNP (adjusted OR 4.10; 95%CI 1.35-12.44; $p = 0.01$). No differences were noted regarding admission blood pressure, lung congestion, left chambers dimensions or parameters of left ventricle systolic and diastolic function.

Conclusion: In our population of acute HF patients, admission serum levels of relaxin were associated with clinical and echocardiographic markers of pulmonary hypertension and RV dysfunction and overload, suggesting a role for circulating relaxin as a biomarker in this setting.

Methods: From 43 biomarkers measured in 2033 serum samples of patients hospitalized for acute heart failure, 16 biomarkers predictive for 180 day mortality were selected. Biomarker values were compared with the levels of 12 acute heart failure specific miRNAs in a subset of 100 patients, at baseline and 48 hours. Patients were divided in 4 pre-defined groups, based on clinical parameters during hospitalization. Correlation analyses between miRNAs and biomarkers were performed and complemented by miRNA target prediction and pathway analysis.

Results: No significant correlations were found at hospital admission. However, after 48 hours of hospitalization, 7 miRNAs were significantly negatively correlated to biomarkers indicative for a worse clinical outcome in the patient group with the most unfavorable in-hospital course ($n = 21$): miR-16-5p was correlated to C-reactive protein ($R = -0.66$, $p\text{-value} = 0.003$), miR-106a-5p to creatinine ($R = -0.68$, $p\text{-value} = 0.002$), miR-223-3p to growth differentiation factor 15 ($R = -0.69$, $p\text{-value} = 0.001$), miR-652-3p to soluble ST-2 ($R = -0.77$, $p\text{-value} < 0.001$), miR-199a-3p to procalcitonin ($R = -0.72$, $p\text{-value} < 0.001$) and galectin-3 ($R = -0.73$, $p\text{-value} < 0.001$) and miR-18a-5p to procalcitonin ($R = -0.68$, $p\text{-value} = 0.002$). MiRNA target prediction and pathway analysis identified several pathways related to cardiac diseases, which could be linked to some of the miRNA-biomarker correlations.

Conclusions: The majority of correlations between circulating acute heart failure specific miRNAs were related to biomarkers predictive for a worse clinical outcome in a subgroup of worsening heart failure patients at 48 hours of hospitalization. These findings suggest a time-dependent effect of circulating miRNAs and highlight the susceptibility to individual patient characteristics influencing potential relations between miRNAs and biomarkers.

¹Ramathibodi Hospital, Section for Clinical Epidemiology and Biostatistics, Faculty of Medicine, Bangkok, Thailand; ²University of Newcastle, Center for Clinical Epidemiology and Biostatistics, Newcastle, Australia

Background: Previous studies have demonstrated an inverse association between serum and dietary magnesium (Mg) intake and total cardiovascular (CV) disease risk. However data on this association in the setting of heart failure (HF) is conflicting.

Purpose: To estimate effects of hypomagnesemia and hypermagnesemia on CV mortality and all-cause mortality (ACM) of HF patients when compared with normomagnesemia. Method: Medline and Scopus databases were used for identifying relevant studies published from inception until June, 2015. The selection was based

Background: Circulating microRNAs (miRNAs) emerge as potential heart failure biomarkers. In the present study, we aimed to identify associations between acute heart failure specific circulating miRNAs and well-known heart failure biomarkers.

on original prospective studies that examined serum Mg concentration and the outcome of CV and all-cause mortality in heart failure patients. The risk ratio (RR) was estimated using Poisson regression and then a multivariate meta-analysis was applied for pooling RRs across studies. Source of heterogeneity was explored by performing a meta-regression and subgroup analysis with possible confounders.

Results: Seven prospective studies, including a total of 5,172 HF patients with 913 and 1,438 patients die from cardiovascular and all causes, respectively, were eligible for the meta-analysis. Those patients with baseline hypermagnesemia had a significantly higher risk of CV mortality (RR:1.38; 95% CI: 1.07, 1.78) and significantly higher risk of ACM (RR:1.35; 95% CI: 1.18, 1.54) than those with baseline normomagnesemia. In contrast, HF patients with hypomagnesemia did not have an elevated risk of cardiovascular and all-cause mortality (RR:1.11; 95% CI: 0.79, 1.57 and RR: 1.11; 95% CI: 0.87, 1.41, respectively).

Conclusions: The present systematic review and meta-analysis suggests that HF patients with hypermagnesemia associated with increased risk of CV mortality and ACM but this was not observed for those with hypomagnesemia. This finding is limited to the elderly patients who have reduced LV systolic function. Systematic review registration: The review protocol has been registered at PROSPERO

Belgrade, Belgrade, Serbia

Aims: To evaluate parathyroid hormone (PTH) levels in elderly men with stable chronic heart failure (CHF), and to investigate its relationship with all-cause mortality.

Methods: This prospective study included 73 men (mean age 67 ± 7 years) with systolic CHF (NYHA class II/III) with 6-years follow-up for all-cause mortality. Baseline PTH, 25-hydroxyvitamin D (25-OHD), and N-terminal pro-brain natriuretic peptide (NT-proBNP) were measured. Echocardiography, 6-minute walk test, Minnesota-Living with Heart Failure Questionnaire, and osteodensitometry were performed according to the standard protocol. Patients were grouped according to PTH cut-off levels of 65 pg/ml [>65 pg/ml =secondary hyperparathyroidism (SHPT) vs. normal PTH].

Results: 43 (59%) patients presented with SHPT. A total of 65 (89%) of patients were vitamin D insufficient. Patients with SHPT vs. normal PTH group were of similar age but with higher levels of PTH (98 ± 27 vs. 47 ± 10 pg/ml, $p < 0.0001$), NT-proBNP [$2452(3399)$ vs. $918(1372)$ pg/ml, $p < 0.0001$], while 25-OHD (29 ± 15 vs. 35 ± 14 nmol/l), and creatinine clearance (60 ± 22 vs. 69 ± 21 ml/min) were similar between studied groups. SHPT patients had more severe CHF compared to the patients with normal PTH regarding NYHA functional class (2.4 ± 0.5 vs. 2.1 ± 0.2 , $p = 0.001$), quality of life score (34 ± 14 vs. 24 ± 12 , $p = 0.005$), 6-minute walking distance (378 ± 79 vs. 446 ± 73 m, $p < 0.0001$, total hip bone mineral density (0.90 ± 0.16 vs. 1.01 ± 0.13 g/cm²), and left ventricular ejection fraction (27 ± 8 vs. 31 ± 7 %, $p = 0.019$). A total of 41 (56%) patients died within 6 years of follow-up. ROC curve analysis showed that both PTH and NT-proBNP, but not 25-OHD, had the ability to detect patients at risk of death (AUC 0.683, $p = 0.008$ vs. AUC 0.746, $p < 0.0001$, respectively). The patients with SHPT had worse survival, with a hazard ratio for death of 2.4 [CI 1.2-4.8] ($p = 0.012$) in univariate analysis. Further, age, log-transformed NT-proBNP, left ventricular ejection fraction, and creatinine clearance were associated with impaired survival ($p < 0.05$ for all). In multivariate analysis, only log-transformed NT-proBNP remained significantly related to impaired survival [HR 3.7 (CI 1.9-7.1), $p < 0.0001$].

Conclusion: SHPT was highly prevalent in stable elderly men with CHF along with vitamin D insufficiency. Patients with SHPT had more impaired status compared to the patients with normal PTH levels. Unlike to vitamin D status, SHPT was associated with increased risk of death. Further studies are warranted to evaluate beneficial potential of PTH suppression in CHF patients.

Netherlands; ²Eindhoven University of Technology, Department of Mathematics

and Computer Sciences, Eindhoven, Netherlands; ³University Medical Center

Groningen, Department of Nephrology, Groningen, Netherlands

Purpose: High galectin-3 levels are associated with increased risk for adverse outcome. However, determinants of increasing galectin-3 level have not been established. Therefore, we aimed to identify baseline determinants of (temporal) change in galectin-3 level.

Methods: Galectin-3 plasma levels were studied in the PREVEND study, a cohort derived from the general population. Galectin-3 was measured at 3 different time points: at baseline and after ~4 and ~9 years. The association of baseline risk factors and (temporal) change in galectin-3 level was assessed using multivariable mixed-effects regression analysis.

Results: In 4,355 subjects, galectin-3 plasma levels were available at all time points (mean age: 48 ± 12 years; 50% female). 324 (7%) of these subjects had increasing galectin-3 levels over time across the general accepted threshold for heart failure of 17.8 ng/mL. We found that urinary albumin excretion (chi square (χ^2): 34.03, p -value: < 0.0001) and systolic blood pressure (χ^2 : 16.81, $p = 0.002$) were independent determinants of temporal change of galectin-3. Furthermore, eGFR (χ^2 : 210.27, $p < 0.0001$), gender (χ^2 : 43.85; $p < 0.0001$), BMI (χ^2 : 19.68, $p = 0.0001$), NT-proBNP (χ^2 : 18.76, $p = 0.0001$) and total cholesterol (χ^2 : 8.63, $p = 0.01$) were independent determinants of galectin-3 level.

Conclusion: In the general population, urinary albumin excretion > 30 mg/24h and systolic blood pressure > 170 mmHg are important determinants of increasing galectin-3 levels over time. Furthermore, we confirmed that impaired renal function is a very strong determinant of elevated galectin-3 levels. These results implicate that treatment of high blood pressure might be important to prevent increasing galectin-3 levels.

Background: Recently, we have proposed a new definition of iron deficiency (ID) based on serum hepcidin and soluble transferrin receptor (sTfR), beyond traditionally used serum ferritin and transferrin saturation (Tsats). Pathophysiologically, low hepcidin reflects depleted iron stores, while high sTfR indicates augmented iron requirement for intracellular metabolism. We compared the clinical profile of patients with heart failure with reduced ejection fraction (HFrEF) based on aforementioned biomarkers of iron status.

Methods: We analyzed data of 291 patients with stable HFrEF (85% men, mean age: 61 ± 11 years, NYHA III-IV: 34%, LVEF: 26 ± 7 %). Abnormal values of iron biomarkers were derived as the 5th percentile of hepcidin (< 14.5 ng/mL) and the 95th percentile of sTfR (≥ 1.59 mg/L) from a control group of healthy subjects, published previously.

Results: We identified 4 groups of patients with HFrEF with: (A) both low hepcidin and high sTfR ($n = 15$, 5%); (B) isolated high sTfR ($n = 76$, 26%); (C) isolated low hepcidin ($n = 11$, 4%), and (D) preserved iron status ($n = 189$, 65%). Serum ferritin was slightly reduced in patients with isolated high sTfR ($p < 0.05$), and was markedly diminished in those with low hepcidin (both with and without high sTfR) as compared to those with preserved iron status ($p < 0.01$). Tsat was reduced in patients with either isolated low hepcidin or isolated high sTfR, and was markedly reduced in patients with abnormal values of these 2 biomarkers (additive associations with both biomarkers, both $p < 0.001$). There were no differences in haemoglobin level between analyzed groups, however low hepcidin and high sTfR were independently associated with reduced red cell indices (MCH, MCHC) (all $p < 0.05$). As compared

to patients with preserved iron status, those with either isolated low hepcidin and isolated high sTfR had more severe HF (reflected by higher NT-proBNP, advanced NYHA class and higher daily dose of loop diuretics) with the most advanced HF in those with both high sTfR and low hepcidin (additive relationships with both iron status biomarkers, all $p < 0.05$). Low hepcidin ($p < 0.05$), but not high sTfR ($p > 0.2$), was associated with impaired renal function (low GFR).

Conclusions: Although both low hepcidin and high sTfR reflect systemic iron deficiency, some patients with HFrEF develop abnormalities only within one biomarker. There are some clinical differences between patients with HFrEF, varying of serum hepcidin and sTfR, which may preclude diverse pathophysiological importance of these 2 biomarkers.

Coronary artery vasospasm in cardiac allograft presenting with malignant arrhythmia and left bundle branch block pattern in early post-transplantation period.

A Konopka¹; M Malgorzata Celinska-Spodar¹; M Demkow²; M Sobieszczanska-Malek³; K Komuda³; J Stepinska¹; M Kusmierczyk⁴

¹Institute of Cardiology in Anin, Cardiac Intensive Care Department, Warsaw, Poland; ²Institute of Cardiology, Coronary Artery and Structural Heart Disease Department, Warsaw, Poland; ³Institute of Cardiology, Department of Heart Failure and Transplantation, Warsaw, Poland; ⁴Institute of Cardiology, Department of Cardiac Surgery and Transplantation, Warsaw, Poland

Coronary vasospasm is a rare incidence in cardiac allograft (CA) and it's been reported mainly in late CA vasculopathy or rejection. There is limited data referring to it in early post-transplantation period. We report the case of 64-year old man with a history of cardiac transplantation 4 weeks before who had syncope related to wide complex ventricular tachycardia (VT) recorded on hospital ECG monitoring. Post-operative cardiac performance was stable with good ventricular function. On week 4 patient developed recurring, asymptomatic, self-limiting bouts of monomorphic nonsustained VT one of which degenerated into 60 second sustained VT with transient loss of consciousness. Palpitations, chest pain, dyspnea were negated. The results of physical examination were unremarkable. ECG showed sinus rhythm, with no conduction disturbances, nor ST-segment modification. Transthoracic echocardiogram (TTE) revealed normal biventricular function. Immunosuppressive agents blood concentrations were within therapeutic range. CA rejection was excluded already by endomyocardial biopsy. On the following day when patient was at rest sudden heart rate drop from 75 to 60 bpm ensued with significant QRS complex widening captured on continuous ECG tracking. ECG showed prominent ST-segment elevation (Fig.1). Serial ECG recordings in the complete absence of symptoms demonstrated dynamic changes in ECG waveform leading to complete resolution of ST segment elevation with lateral T-wave inversion in 7 minutes. The hypothesis of a possible vasospastic component of lumen narrowing was advanced. TTE showed normal regional kinesis. As a rise of troponin T to 354 ng/l (ULN-14) and CK-MB to 9,37 ng/ml (ULN-6,73) were detected angiography was performed which showed myocardial bridging over the left anterior descending artery (LAD) followed by long significant stenosis, furthermore another significant focal stenosis in the left circumflex artery (LCx) (Fig.2). Successful stenting of LCx and LAD was performed. Recurrent asymptomatic QRS complex widening the same evening linked to new LBBB pattern in ECG (Fig.3) prompted repeat catheterization that revealed severe coronary spasm involving first diagonal branch, fully relieved by intracoronary isosorbide dinitrate (Fig.4). Diagnosis of CA multivesel disease with a significant vasospastic component was established. Treatment with calcium channel blockers and nitrate was started. Pharmacotherapy along with precedent successful angioplasty resulted in cessation of VT episodes and conduction disturbances at 4-week follow up period. As cardiac catheterization of donor heart is not routinely performed there are concerns regarding transmission of coronary artery disease to recipient. As a result of cardiac denervation patients very rarely present with typical syndromes of ischemia. It's worth considering as noninvasive diagnostic tool routine 24-h 12-lead Holter monitoring for an assessment of ST-segment modification or presence of arrhythmia.

749

Prosthetic valve dysfunction, acute myocardial infarction, and cardiogenic shock following an uncomplicated pregnancy: what else could have been done?

JC Perez Gamez¹; O Calvillo Arguelles¹; CR Sierra Fernandez²; A Aranda Fraustro³; H Rodriguez-Zanella⁴; BE Dominguez Mendez⁴; LL Rodriguez Chavez¹; LA Gonzalez Tapia¹

¹National Institute of Cardiology Ignacio Chavez, Clinical Cardiology, Mexico City, Mexico; ²National Institute of Cardiology Ignacio Chavez, Coronary Care Unit, Mexico City, Mexico; ³National Institute of Cardiology Ignacio Chavez, Pathology Department, Mexico City, Mexico; ⁴National Institute of Cardiology Ignacio Chavez, Echocardiography Laboratory, Mexico City, Mexico

Case: A 18-year old female with history of VSD closure and AVR was found to be pregnant at her routine clinical evaluation. An echocardiogram showed normal post-thetic valve function. Five months after pregnancy termination she presented to the ED with chest pain and dyspnoea. PE revealed severe aortic stenosis and signs of congestive heart failure. The EKG showed LVH and diffuse ST-segment depression. Laboratory tests were remarkable for troponin I (12.74 ng/ml) and NT-ProBNP (24,225 pg/ml). Initial treatment included mechanical ventilation, inotropic support and anticoagulation. Echocardiographic evaluation showed a dilated left ventricle, severe systolic dysfunction (LVEF 22%) and severe aortic stenosis (mean gradient 72 mmHg). Coronary angiography showed normal coronary arteries. Percutaneous aortic balloon valvuloplasty was performed as a bridge to AVR. After the procedure the patient presented clinical deterioration with progressive troponin elevation and refractory shock. The patient developed ventricular tachycardia and died. Autopsy revealed a bioprosthetic aortic valve with heavy calcification, a hypertrophic LV and evidence of pulmonary oedema. Histopathologic findings were relevant for micro calcifications within the lumen of coronary arterioles and multiple myocardial infarctions.

Discussion: There are 3 main problems to analyze in this case: prosthetic valve dysfunction (PVD), the acute event, and the role of aortic balloon valvuloplasty (ABV). The mechanism of PVD was obstruction and central regurgitation. In the setting of calcified cusps, the presumed aetiology is primary structural failure, which usually occurs after 10 years of valve implantation. Pregnancy related early valve failure has been previously reported.

The initial clinical picture was one of an acute myocardial infarction. Microembolism could have been the most likely cause since the EKG showed diffuse

ischemic changes and coronary angiography showed a diminished TMP grade probably related to microvascular obstruction. Spontaneous calcium embolization is extremely rare and it has been previously reported in the literature. In this case it is difficult to conclude whether it occurred before and/or after ABV. Severe aortic stenosis itself produces diffuse subendocardial ischemia and it can rarely mimic acute myocardial infarction, but it might have contributed to the clinical presentation. ABV is a procedure associated with multiple complications. It is reserved as bridge to AVR in high risk patients. The clinical decompensation after the procedure suggests an ABV-related myocardial infarction secondary to coronary calcium micro embolization, which was confirmed in the autopsy.

Conclusions: Pregnancy related early PVD and a salvage treatment contributed to death of this patient. The use of a LVAD and/or heart transplantation could've changed the patient's prognosis, nevertheless limited access to such therapies is a reality in developing countries.

Look carefully: acute heart failure after pregnancy

C I Clara Ines Saldarriaga¹; C Gallego¹; A Agudelo¹

¹Cardiovascular Clinic Santa Maria, University of Antioquia cardiology department, Medellin, Colombia

The presentation of acute heart failure in the puerperium period is unusual and requires a careful evaluation to rule out differential diagnoses. Description of the problem: a 32 year-old woman presented to the emergency room with sudden shortness of breath and chest pain. Three months prior, she delivered a healthy baby without any complications. Her past medical history was negative for cardiovascular diseases, preeclampsia, or hypertension. The physical examination revealed BP 100/70, HR 90 BPM, and multiple signs of pulmonary congestion and acute heart failure. An EKG showed signs of an anterior STEMI. An emergency coronary angiography was performed, revealing a diffuse lesion of LAD and CX of 70% with a lot of thrombotic material. An infusion of tirofiban was started, and she was admitted to the ICU. 24 hours later, she started to have episodes of NSVT with hypotension and pulmonary edema. The echocardiogram showed an EF of 30% with hypokinesia of apical segments. A new coronary angiography with showed a dissection of the left main those extents to the LAD and CX that were treated with DES. Afterwards, she required IABP implantation and inotropic support for 48 hours. Her clinical condition improved, and 7 days later, she was discharged home with optimal medical therapy that included carvedilol, enalapril, eplerenone ivabradine, aspirin, and clopidogrel. She was followed-up in a heart failure clinic where optimization of the medical therapy was performed. After 2 months, a new echocardiogram showed an EF of 35%, and an ICD was implanted for primary prevention. Currently, the patient is in NYHA class II and returned to her work and normal life. Questions and problems: the main differential diagnoses of chest pain and acute heart failure in the puerperium period are acute pulmonary embolism, acute myocardial infarction, and aortic dissection. Answers and discussion: in this case, the evaluation of signs and symptoms and the EKG were the clues for the diagnosis. The initial coronary angiography did not show the dissection. The clinical evolution of the patient to cardiogenic shock suggested that the cause was not identified and treated.

Conclusions: acute myocardial infarction in women during childbearing age is rare. However, it is related to a high maternal mortality and morbidity, such as ventricular dysfunction and heart failure. This entity must be suspected in pregnant or post-partum woman with chest pain and acute heart failure.

751

Tachycardia-induced cardiomyopathy after 16 years of incessant PJRT

G Giorgi Papiashvili¹; K Etsadashvili²

¹The Jo Ann Medical Center, Tbilisi, Georgia Republic of; ²Chapidze Heart Center, Tbilisi, Georgia Republic of

We present a case of exceptionally longstanding incessant supraventricular tachycardia that resulted in tachycardia-induced cardiomyopathy. The patient was 39 years old woman who presented to the emergency department with complaints of fatigue, shortness of breath and increasing exercise intolerance. On admission she was noted to have a tachycardia 100 bpm and her echocardiography revealed cardiomegaly with severely depressed LV EF (18%) and marked dilatation of all four chambers of the heart. Her ECG showed wide-complex tachycardia with LBBB-like morphology, QRS duration of 130 msec and 1:1 AV-relationship with negative P waves in leads II, III and aVF and positive P waves in lead V1. The patient stated that she had this tachycardia constantly for about 16 years already and it was always attributed to her emotional stress and dysautonomia. Multiple drugs were not successful in controlling her heart rate. The patient was sent to the arrhythmia specialist for electrophysiologic evaluation. The EP study was performed and the tachycardia was identified to be an orthodromic circus movement tachycardia utilizing slowly conducting decremental concealed posteroseptal accessory pathway (PJRT) which was successfully ablated from within the coronary sinus.

The patient was started on ACE inhibitors, aldosterone antagonists and carvedilol

and her heart failure status markedly improved. After 1 year of treatment and already on full dose carvedilol she did not have an arrhythmia recurrence and her LV EF increased to 40% and she has no symptoms related to heart failure.

To our knowledge this is the first case of incessant tachycardia lasting 16 years. The relatively slow heart rate during tachycardia, patient's young age and the lack of comorbidities must have prevented earlier development of tachycardia-induced cardiomyopathy.

Tachycardia

Acute exacerbation of heart failure attributed to complete atrioventricular block in a patient with left univentricular pacing by cardiac resynchronization therapy

N Nobuhiro Nishiyama¹; S Takatsuki¹; K Nakajima¹; S Kashimura¹; Y Katsumata¹; T Nishiyama¹; T Kimura¹; Y Aizawa¹; K Fukumoto¹; K Fukuda¹

¹Keio University Hospital, Department of Cardiology, Tokyo, Japan

A 77-year-old man with combined cardiac resynchronization therapy-defibrillator (CRTD) for dilated cardiomyopathy (DCM), ventricular tachycardia (VT), reduced ejection fraction (EF), complete left bundle branch block (LBBB), and New York Heart Association (NYHA) Class III underwent the 3rd replacement of the generator (Guidant COGNIS, 100-D) 1 year previously. The generator had been implanted under the skin of the chest wall with a screw-in right ventricular (RV) lead (Guidant 0154) placed in the septum of the right ventricle, a left ventricular (LV) lead (Guidant 4542) placed in the posterolateral branch of the coronary sinus, and a right atrial lead (Guidant 4472) in the right atrial appendage. At the time, it appeared that LV-only pacing mode with paced AV delay of 110 ms and sensed AV delay of 70 ms was the most effective mode for obtaining the narrowest QRS width. The QRS morphology of the electrocardiogram (ECG) was fusion beat of LV pacing and intrinsic right bundle branch conduction. Both the echocardiographic (UCG) parameters and the SmartDelay algorithm (which is available on Cognis P107) confirmed this result. During follow-up, the patient was well after the operation and less symptomatic (NYHA Class II), the atrial, ventricular and shock lead parameters were functioning normally, no shock and no necessary hospital admission during the previous year. He visited the out-patient clinic with complaints of breath shortness (NYHA class IV), the presence of weight gain and pitting edema. The cardiothoracic ratio (CTR) increased from 49.0% to 58.8% on chest X-ray, plasma brain natriuretic peptide (BNP) level rose from 256 pg/ml to 420 pg/ml on a blood test. The QRS morphology of the ECG was LV only pacing. He developed complete atrioventricular block (CAVB). As a relapse of ventricular dyssynchrony could cause acute exacerbation of heart failure, changing the mode to biventricular pacing and optimization of pacing intervals were performed using ECG and UCG parameters. Biventricular pacing mode with paced AV delay of 110 ms, sensed AV delay of 70 ms and VV (LV-RV) delay of 40ms was the most effective mode for obtaining the best ECG and UCG parameters. He had improvement of symptoms from NYHA class IV to NYHA class II without any change of oral medications. In conclusion, when programming the LV-only pacing mode in particular, it is important to be aware that the likelihood of developing CAVB can have some clinical implications. We report a rare case of acute exacerbation of heart failure which was attributed to CAVB in a patient with left univentricular pacing by CRTD.

Recurrent episodes of life-threatening vasodilatory shock following unintentional intoxication with calcium channel blocker, amlodipine

C Chris Kapelios¹; G Karamanakos¹; S Liatis¹; M Polizois¹; M Sarafadi¹; D Basoulis¹; D Tsilingiris¹; C Fytli¹; I Papoutsis²; A Kokkinos¹

¹Laiko University General Hospital, Athens, Greece; ²National & Kapodistrian University of Athens, Athens, Greece

Calcium channel blockers (CCBs) overdose is associated with sustained hypotension and non-cardiogenic pulmonary edema. Importantly, in all cases reported, the intoxication was known at the time of patients' presentation. We present the case of a 72-year-old man with a history of hypertension who presented to the emergency department with sustained hypotension refractory to infusions of crystalloids and vasoconstrictors. His history started 2 months prior when he was admitted to the hospital for syncope, which was attributed to amiodarone overdosing. Two more hospitalizations with symptoms of shock followed; in the first one, due to refractory hypotension (SAP < 40 mmHg), severely hypokinetic and dilated right ventricle and elevated d-dimers he was treated with thrombolysis, based on the perceived diagnosis of pulmonary embolism (PE). His condition did not improve and he remained on hemodynamic support, while his renal function declined and was treated with hemodialysis. The patient's perfusion scintigram was negative for PE or chronic thromboembolic disease. After improvement, he was discharged on day 17 in good clinical status and having discontinued his anti-hypertensive medication. After a few days, he was admitted to our hospital due to a new episode of hypotension refractory to intravenous fluids and mineralocorticoids. He was started on intravenous antibiotics and noradrenaline under the presumptive diagnosis of septic shock. Detailed evaluation did not identify a cause for the shock. Due to anuria and dyspnea he was treated with hemodialysis, to which the patient responded and was finally discharged asymptomatic on day 20. He was transferred back to the clinic 16 hours later due to a new episode of sustained hypotension (SAP:65mmHg). Apart from hypotension, his physical examination was unremarkable. His laboratory results were notable for anemia, hyperglycemia and elevated creatinine. The patient was oliguric. Serum values for troponine, thyroid stimulating hormone, cortisol, adrenocorticotrophic hormone and trypsin were normal. Multiple urine and blood cultures were negative. Prolonged pharmacologic support and intermittent hemofiltration induced stabilization and recovery. An extensive diagnostic workup to elucidate the cause of his condition was unfruitful, posing a conundrum for our team. The recurrent nature of presentation along with its incidence after the patient's leaving the protected setting of the hospital suggested the effect of an environmental factor. For this reason, a urine sample obtained on admission, was sent to the toxicology department for examination. The results, available ten days later, revealed high levels of amlodipine in the urine. The patient had discontinued the medication 40 days earlier; however, it was still available at his residence. CCB overdose should always be suspected in patients with sustained, refractory hypotension, who have no other apparent cause of shock and have access to the medication.

754

An unusual high risk pregnancy: severe preeclampsia, cardiac tamponade and previously undiagnosed left ventricular non-compaction with severe systolic dysfunction

O Calvillo Arguelles¹; JC Perez Gamez¹; G Melendez Ramirez²; H Rodriguez-Zanella³; BE Dominguez Mendez³; R Vera Urquiza²; LL Rodriguez Chavez¹; LA Gonzalez Tapia¹; CR Sierra Fernandez⁴

¹National Institute of Cardiology Ignacio Chavez, Clinical Cardiology, Mexico City, Mexico; ²National Institute of Cardiology Ignacio Chavez, Cardiovascular Imaging, Mexico City, Mexico; ³National Institute of Cardiology Ignacio Chavez, Echocardiography Laboratory, Mexico City, Mexico; ⁴National Institute of Cardiology Ignacio Chavez, Coronary Care Unit, Mexico City, Mexico

Case Description: A 18 year-old female presented to a general hospital with progressive shortness of breath and peripheral oedema. Her past medical history was relevant for a twin pregnancy interrupted two months earlier because of severe preeclampsia. She was found with signs of heart failure and initial management included diuretic and vasodilator therapy with subsequent worsening hypotension and dyspnoea. She was referred to our institution on inotropic support. Initial PE revealed hypotension, tachycardia, hypoxemia, JVD, bilateral rales and peripheral oedema. EKG showed low voltage in the limb leads and NT-ProBNP was elevated (9,989 pg/ml). Echocardiographic evaluation was remarkable for a large pericardial effusion with signs of hemodynamic compromise, biventricular enlargement, reduced LVEF and NC/C myocardium ratio of 3.12 to 1. After initial stabilization, 400 ml of clear pericardial fluid were surgically drained. Pericardial biopsy and pericardial fluid analysis were non-diagnostic. Inotropic support was continued and 1 week later she was discharged on medical therapy. A cardiac MR confirmed the presence of LVNC with a NC/C ratio of 6:1, trabeculated LV mass of 36%, and biventricular systolic dysfunction (LVEF 12.7%, RVEF 18.2%).

Discussion: The patient presented 3 different cardiovascular conditions that complicated the last stage of her pregnancy and post-partum period. Nulliparity and twin pregnancy are risk factors for preeclampsia, but the relationship of severe preeclampsia and cardiac tamponade is not well established and its diagnosis requires a high index of suspicion. Aggressive diuretic and vasodilator therapy for HF might have triggered the hemodynamic decompensation in the presence of pericardial effusion. LVNC is a relatively rare inherited cardiomyopathy with a wide range of clinical presentations. Since diagnostic criteria are morphological, their diagnostic accuracy remains uncertain. Some patients with LVNC may exhibit morphologic features of other cardiomyopathies. The clinical picture of this case mimics a peripartum cardiomyopathy, with preeclampsia and multifetal pregnancy as risk factors. Whether this case represents a previously asymptomatic patient with LVNC and ADHF secondary to a pregnancy complicated by severe preeclampsia, or a peripartum cardiomyopathy with overlapping morphological LVNC features is hard to tell. In either case, the presence of severe biventricular dysfunction represents a poor prognostic sign and the relationship with cardiac tamponade is not clear.

Conclusions: Physiologic changes that occur during pregnancy in patients with previously undiagnosed cardiovascular disease may predispose to a more complicated pregnancy course. Different conditions such as pericardial effusion and systolic dysfunction may coexist and require a high index of suspicion since therapy for the more obvious HF syndrome may be followed by hemodynamic decompensation.

CLINICAL CASE 2: WHAT A MASS! CASES OF CARDIAC MASSES AND OTHER STRUCTURAL ABNORMALITIES

Giant coronary aneurysms as cause of heart failure

E Ammirati¹; L Brevetti¹; A Moreo¹; L Scudiero¹; D Artioli¹; M Frigerio¹; F Oliva¹
¹Niguarda Ca' Granda Hospital, Milan, Italy

A 59-year-old Filipino man without previous illness presented to the emergency department with a recent history of worsening dyspnea. On arrival he was afebrile with stable hemodynamic parameters and diminished breath sounds bilaterally. Laboratory tests revealed increased high sensitivity troponin T level 860ng/L, proBNP 3850ng/L, C-reactive protein 3mg/dL. ECG showed sinus rhythm with diffuse flattened T waves. Echocardiography detected dilated cardiomyopathy with decreased left ventricular ejection fraction (LVEF 30%). Three large cystic aneurysmal structures were noted, one located at the level of the atrioventricular groove partially protruding inside the right atrium. The other two cystic structures that were in connection with the left main stem were located between the aorta and the pulmonary trunk. A contrast-enhanced cardiac magnetic resonance showed large circular masses compatible with giant coronary artery aneurysms (GCAAs) of all three coronary arteries with a maximum diameter of 63 mm in each vessel. The figure shows massive organized thrombosis inside the right coronary artery (RCA) and the left circumflex artery (LCx) with sluggish blood flow inside. No areas of myocardial oedema were observed. Coronary angiogram confirmed the diagnosis of GCAAs. A FDG-PET/CT of the chest and abdomen excluded an active vasculitis. A coronary angio-CT allowed to characterize the coronary aneurysms: the left anterior descending and RCA were characterized by 2 sequential fusiform aneurysms in the proximal and middle segments of the vessel, with calcified non-stenotic coronary tracts interspersed between the aneurysmal tracts. The presence of proximal coronary aneurysms with coronary calcifications, Asian origin, in the absence coronary stenosis and without probable alternative diagnosis made the clinical picture attributable to presumed late sequelae of antecedent Kawasaki disease (KD). As KD, a self-limiting vasculitis, mainly affects children younger than 5 years, the patient was not be able to recall details of his childhood illness. The patient presented an AHA risk level IV for KD, due to the presence of GCAAs with indication for long-term antiplatelet therapy and warfarin. Also heart failure (HF) medications were started. During hospitalization the patient experienced 2 episodes of symptomatic ventricular tachycardia that required DC shock to restore sinus rhythm, thus implantable cardioverter defibrillator was implanted as secondary prevention. Cardiac surgery to exclude the aneurysms was deemed unfeasible. The patient was considered to be at an unpredictable risk of sudden cardiac death by coronary rupture or total occlusion of the aneurysmal coronaries, and for this reason a screening for heart transplantation was commenced. After 5 months of follow up LVEF improved to 38% and he was asymptomatic. As our case shows, the severe sequelae of prior missed KD must be considered in the differential diagnosis of ischaemic cardiomyopathy with GCAA.

¹Sao Joao Hospital, Department of Cardiology, Porto, Portugal; ²Sao Joao Hospital, Department of Cardiothoracic Surgery, Porto, Portugal

A 58-year-old male patient presented to our hospital with complaints of shortness of breath on exertion and generalized weakness and fatigue for several weeks. The chest X-ray showed an cardiothoracic ratio. Further evaluation with transthoracic and transesophageal echocardiogram revealed a large mass occupying almost the entire and severely dilated right atrium (RA), associated with a large pericardial effusion. Cardiac computed tomography (CT) angiogram confirmed the presence of a vascularized intramural mass originating from the RA free wall that widely invaded superior vena cava and pericardium. Pericardiocentesis was inconclusive. Coronary angiography showed a large area of hypervascularized myocardium near the right ventricle projection that was supplied by the acute marginal branches of the right coronary artery. In order to minimize the blood loss caused by surgical trauma, we opted to perform embolization of the heart tumor, which was successfully performed using polyvinyl alcohol, platinum coils and a covered stent. Cardiac surgery included the excision of the mass, RA, superior vena cava (SVC) and inferior vena cava (IVC). The RA, SVC, and IVC were further reconstructed using bovine pericardium and a cardiovascular patch. The RA mass proved to be an angiosarcoma with resection margin clear on permanent pathology. The patient has been doing well five months after being discharged from the hospital and is currently undergoing adjuvant chemotherapy. Although primary cardiac tumors, namely angiosarcomas, are rare, complete surgical resection of the tumor is the most successful treatment for improving patients survival rate. In our patient, preoperative embolization of the tumor helped to control blood loss during tumor resection. To the best of our knowledge, this is the first reported case of a hybrid approach involving an endovascular treatment of a cardiac tumor followed by surgical tumor excision.

788

Transitory thrombotic storm associated with myocardial infarction and dramatic systemic impactC Stan¹; N Natalia Patrascu²; DJ Mihalcea²; VD Vintila²; A Nicolescu¹; AM Vladareanu²; D Vinereanu²¹University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania;²University of Bucharest Carol Davila, Bucharest, Romania

Introduction: Arterial thrombosis is mainly related to complicated atherosclerotic plaques. Nevertheless, proinflammatory and also hereditary prothrombotic disorders are other causes. Alternatively, venous thrombosis is due to pro-coagulant settings, hereditary or acquired and to the risk factors, the most significant being primary or secondary cancers (with a combined hazard of the presence of the tumor, patient's characteristics and the hemostatic system).

Case presentation: Female, 56 years old, no cardiovascular history, followed up in the Haematology department with paroxysmal nocturnal haemoglobinuria (PHN), was admitted for acute coronary syndrome with anterior ST-segment elevation, echocardiographic image of severe left ventricle systolic dysfunction and pericardial effusion. Angiography showed coronary thrombosis of LAD without evidence of underlying atherosclerosis requiring thrombus aspiration without stenting, with optimal flow regaining. In the follow-up we recorded worsening of clinical status along with increased pericardial effusion, acute peripheral ischemia syndrome with radial artery thrombosis and transient language disturbances, then fully developed ischaemic stroke, in context of acute massive thrombosis in the left common carotid artery and also new ventricular apical thrombosis at the echographic review.

Questions, problems, differential diagnosis: Given the context of multiple arterial thrombosis, apparently without a unique proven cause, an abdominal-pelvic CT scan was performed, showing expansive tumoral mass originating from the descendent colon. At colonoscopy, the biopsy showed vilous adenoma with high grade intraepithelial neoplasia. We also note the tomographic images of suprahepatic, common iliac veins and right external iliac vein thrombosis. After discharge, we recommended a surgical opinion in order to treat the malignant disease. Surgery was performed in a curative manner with an immediate favorable outcome, improvement of LV ejection fraction and no residual thrombosis recorded at 1-year follow up. Answers and discussion: This complex case is particular by the thrombotic "storm" in the context of PHN, usually associated with haemolytic anemia but also with thrombosis, predominantly venous and seldom arterial, with no clinical manifestations so far for this patient. This fact drove to investigation of other possible causes, namely a source of superimposed malignancy. The vital double major risk, pro-thrombotic and haemorrhagic, dictated the difficulty of therapeutic management.

Conclusions/implications: We present the case of a young patient with STEMI of non-atherosclerotic etiology (in situ thrombosis), as the first event in a fulminant process of multiple thrombosis (arterial, venous, intracardiac), triggered not by the haematologic disease but as a systemic hypercoagulant response of a potentially curable malignancy.

reported history of cocaine abuse for 3 years (interrupted 5 years before) and frequent paroxysmal AF events treated with catheter ablation. He had no history of ischaemic heart disease, infective disease or other cases of cardiovascular disease. There were blood pressure of 150/90 mmHg at both upper limbs, mitral systolic murmur and lung cracklings. ECG revealed AF with ventricular rates of 120 beats/min. The laboratory exams showed sideropenic anemia, hyperglycemia, increased NT-proBNP, hypokalaemia and normal cardiac necrosis markers. No evidence of viral infection, thyrotoxicosis, impaired urinary electrolyte and alcohol abuse was found. The echocardiography revealed dilated left ventricle (LV) with uniform reduction of ejection fraction (40%) and severe mitral regurgitation. Patient underwent coronarography that showed normal major epicardial vessels. 24-h urinary cortisol excretion, urinary and serum fractionated metanephrines, aldosterone-renin ratio under standardized conditions were analysed and resulted normal. In addition, there were no alterations of parenchyma and of artery at renal ultrasound examination. The colonoscopy showed left colonic angiodysplasia. Despite the normal laboratory parameters values, abdomen computed tomography (TC) was performed and showed a solid mass of both adrenal glands. Then, 123I-labelled meta-iodobenzyl-guanidine (MIBG) scanning reported a marked uptake of the left adrenal gland (PHEO). He refused adrenalectomy and was discharged with the diagnoses of HYP secondary to PHEO determining DCM and HF complicated by AF and therapy with dose-adjusted vitamin K antagonist, beta-blockers, diuretics, calcium antagonist, aldosterone antagonist and angiotensin-converting enzyme inhibitors. In this case report PHEO coexisted with several important causes of DCM. Coronarography excluded an ischemic aetiology. The patient had limited cocaine abuse history that was not sufficient to explain LV dysfunction. Tachycardiomyopathy was excluded because our patients showed a recent onset of AF and previous efficacy catheter ablation. The laboratory values, ultrasound and TC findings excluded secondary form of HYP of renovascular hypertension, Cushing's syndrome and Conn syndrome. The clinical evidence suggested performing an imaging test to reach PHEO diagnosis. The reported case shows that in the management of patients is necessary a holistic approach. In the patient described dyspnoea could have had cardiac or extracardiac causes (anemia).

789

Dilated cardiomyopathy due to pheochromocytoma: a review of one caseC D'amore¹; P Perrone Filardi¹¹Federico II University Hospital, Department of Advanced Biomedical Sciences, Naples, Italy

Dilated cardiomyopathy (DCM) is a rare cardiovascular expression of pheochromocytoma (PHEO). Usually, the coexistence of other cardiovascular risk factors makes difficult the diagnosis of PHEO. We describe the case of a patient with DCM and paroxysmal atrial fibrillation (AF) due to PHEO. A 60-year old man with history of hypertension (HYP) for 4 years (treated by furosemide, ramipril, nifedipine) was admitted at our hospital due to progressive dyspnoea and palpitation. The patient

From shock to shunt - from bench to bedsidePHT Timmermans¹; T Adriaenssens²; PJ Palmers³; F Rega⁴; E Troost⁵; S Janssens³

¹Gasthuisberg University Hospital, Heart Failure and transplantation, Leuven, Belgium; ²Gasthuisberg University Hospital, Cardiology; interventional cardiology, Leuven, Belgium; ³Gasthuisberg University Hospital, Cardiology, Leuven, Belgium; ⁴Gasthuisberg University Hospital, Cardiac surgery, Leuven, Belgium; ⁵Gasthuisberg University Hospital, Adult congenital cardiology, Leuven, Belgium

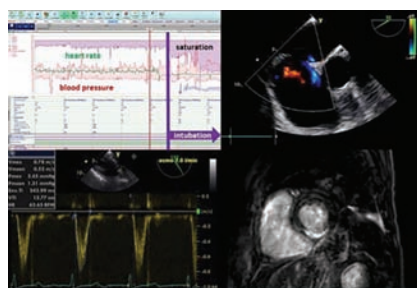

Introduction: A man of 78y was admitted because of chest pain. ECG showed an inferior STEMI. Occlusion of the proximal RAC was seen on angiography. Primary PCI was performed.

Course during hospitalization: He developed cardiogenic shock with low blood pressures and refractory hypoxemia. Tracheal intubation was performed a few hours after admission. The patient now developed intractable hypoxemia (top left).

Differential diagnosis: The combination of an inferior STEMI with hypoxemia should raise the suspicion of an RV infarction with a PFO, resulting in right-to-left shunting. This was confirmed by urgent TEE (top right). The hypoxemia deteriorated right after intubation because in contrast to the effect on the LV, positive pressure ventilation increases RV afterload, resulting in an increased shunt flow in this case.

Discussion: Because of shock and hypoxemia, bedside percutaneous VA-ECMO was implanted. Systemic desaturation persisted because of the shunt and varied between 90 and 98%. On d3, contractile reserve was noted by TEE (bottom left). On d4, the patient was successfully weaned from the ECMO and a few hours later also from the ventilator. He had a smooth recovery both on the ICU and ward. Saturation remained around 92%. TEE and CMR showed a small persistent shunt and severe RV dysfunction due to infarction of the free wall (bottom right). After discussion with the adult congenital cardiology specialists, we decided not to close this PFO. First, saturations in rest as well as during exercise were above 90%. Second, the RV dysfunction could be aggravated by closing the "pressure valve". The patient was discharged from the hospital 2 weeks after admission, and is still in ambulatory FU > 1 year after admission.

Conclusion: RAC infarction can be complicated by cardiogenic shock, and in combination with a PFO, also refractory hypoxemia. VA-ECMO can treat both the failing RV and the systemic desaturation. It is not mandatory to close the PFO in the acute nor in the recovery phase of heart failure. By converting our "text-book" knowledge on LV and RV physiology and their responses on positive pressure ventilation + VA-ECMO therapy, it is not only possible to understand what is going wrong with the patient bedside, but also to treat him adequately.

from shock to shunt.

A rare case of left atrial myxoma and disseminated tuberculosis in a patient with a history of peripartum cardiomyopathyD Dharmaraj Karthikesan¹; AS Saad¹; KS Liew¹; NUH Adznan¹; WF Wan Rahimi Shah¹; GJ Mathews¹; AF Mohd Ezanee¹; AY Khamis²; S Krishnan¹; O Ismail¹¹Hospital Sultanah Bahiyah, Department of Cardiology, Alor Setar, Malaysia;²Penang Hospital, Department of Cardiothoracic, Penang, Malaysia

Introduction: The management of cardiomyopathy is a challenge for most clinicians. A methodical approach is paramount when multiple etiologies are concerned. Case report: A 31-year-old lady presented with heart failure symptoms for 1-week duration postpartum. Clinical features and transthoracic echocardiogram (TTE) suggested peripartum cardiomyopathy. After 6 months of treatment, she defaulted follow up. She was seen again 4 years later during subsequent pregnancy and TTE revealed good left ventricular ejection fraction (LVEF). However, bilateral atrial enlargement was noted which was similar to the previous TTE. Assessment 6-weeks postpartum showed reduced LVEF with new onset of regional wall hypokinesia. Before further evaluation could be instituted, she once again defaulted follow up. She presented to the emergency department 2 months later with anasarca, worsening failure symptoms, productive cough, and significant weight loss for a 1-month duration. She had gross proteinuria and hypoalbuminemia with normal renal function. Chest radiograph, sputum smears for acid-fast bacilli and cultures confirmed pulmonary tuberculosis. Antituberculosis treatment was commenced. The computed tomography (CT) scan showed evidence of pulmonary and renal tuberculosis. Cardiac magnetic resonance imaging (MRI) revealed a mass in the left atrium with features suggestive of previous peripartum cardiomyopathy or myocarditis. TTE showed impaired LVEF, pulmonary hypertension and the presence of a left atrial mass. In view of the chronically dilated left atrium, we suspected left atrial thrombus with underlying disseminated tuberculosis. Proteinuria was attributed to renal tuberculosis or secondary amyloidosis precipitated by tuberculous infection. Anti-coagulation with warfarin was commenced. Repeated TTE showed increasing size of left atrial mass despite optimal anticoagulation. The diagnosis was revised to left atrial myxoma. She underwent surgical excision of the left atrial mass. Histopathological studies confirmed atrial myxoma. Antituberculosis regime was completed uneventfully. Recent TTE showed marked improvement of LVEF with no recurrence of left atrial mass and there was complete resolution of proteinuria.

Discussion: This case raises several important questions. What was the primary cause of heart failure in this patient? What is the association between peripartum cardiomyopathy, left atrial myxoma and tuberculosis? Did secondary amyloidosis occur from tuberculous infection resulting in the nephrotic syndrome? It is clear that successful treatment of peripartum cardiomyopathy and disseminated tuberculosis with surgical excision of left atrial myxoma resulted in improvement of cardiac function.

Conclusion: To the best of our knowledge, this is the first reported case of peripartum cardiomyopathy, atrial myxoma and disseminated tuberculosis occurring in a single patient. A comprehensive guideline for management is currently unavailable.

POSTER SESSION 2

Sunday 22 May 2016 08:30–18:00

ACUTE HEART FAILURE

P803

The frequency and causes of acute heart failure in women middle aged and elderly with acute myocardial infarction

I Irina Zheltova¹; IA Sukmanova¹

¹Altay Regional Cardiology Centre, Cardiology department for patients with acute myocardial infarction, Barnaul, Russian Federation

Introduction: The most common complication of acute myocardial infarction (AMI) is the development of acute heart failure (AHF). The absence of infarct artery revascularization (IRA), as well as the nature of multivessel coronary lesions contributes to poor clinical and hemodynamic parameters, development of AHF and cardiac arrhythmias in patients with AMI.

Purpose: To evaluate the frequency and the factors that contribute to the development of acute heart failure (AHF) in women with acute myocardial infarction (AMI) of middle and old age.

Methods: The study involved 76 women of middle and advanced age with AMI (32 (42,1%) patients of middle age and 44 (57,9%) older), the average age of them was $62,3 \pm 0,8$ years. In addition to laboratory tests evaluate the level of NT-PROBNP, conducted Holter (ECG) monitoring, echocardiogram and coronary angiography (CAG).

Results: In 54 (71,1%) patients with AMI showed no signs of AHF (Killip I), 11 (14,5%) - diagnosed with stage II for Killip, pulmonary edema (Killip III) was detected in 5 (6,6%), cardiogenic shock (Killip IV) - 5 (6,6%). Left ventricular (LV) systolic dysfunction was detected in 41 (53,9%) women. Average level NT-PROBNP in the group of patients with AHF was $1085 \pm 231,6$ pg/ml in group without signs AHF - $590,3 \pm 62,4$ pg/ml ($p = 0,0001$). Recanalization IRA with stenting were 36 (47,4%) women, 10 (13,2%) held thrombolytic therapy (TLT), 36 (47,4%) patients had not been carried out coronary revascularization. Arrhythmias were detected in 24 (31,6%) women. In the group of patients with TLT Killip I diagnosed in 8 (80%), Killip II - y 1 (10%) patients, Killip IV - y 1 (10%). The average level of LV ejection fraction in this group was $55,8 \pm 1,6\%$. Arrhythmias in patients with TLT were found in 4 (40%). In the group of patients with PCI, AHF has not been revealed in 29 (80,5%), Killip II - in 5 (13,8%), cardiogenic shock was diagnosed in 3 (8,3%). The level of the average LV ejection fraction in patients with PCI was $56,9 \pm 1,6\%$. Arrhythmias in this group were found in 14 (38,8%) patients. In 36 (47,4%) patients had not been carried out revascularization IRA. In this group, Killip I was detected in 29 (80,5%), Killip II in 4 (11,1%), Killip IV - 3 (8,3%). The average level of LV ejection fraction in this group was $57,8 \pm 1,5\%$, and arrhythmias - in 21 (58,3%).

Conclusions: The incidence of AHF in women with AMI middle aged and older was 27,6%, with stage II for Killip - 14,5%, Killip III - 6,6%, Killip IV- 6.6%. The primary cause of AHF in patients with AMI is no revascularization IRA. Level NT-PRO-BNP is associated with the degree of LV dysfunction is an important predictor of the development of AHF in patients with AMI.

P804

Repetitive decompensation of heart failure leads truly to deterioration of organ function

S Ishihara¹; K Takagi¹; N Sato¹

¹Nippon Medical School Musashi-Kosugi Hospital, Internal Medicine and Cardiology, Kawasaki, Japan

Backgrounds: Heart failure is an increased burden all over the world due to the frequent hospitalization. The post-discharge mortality and re-hospitalization rate are unacceptably high despite the advances in management of chronic heart failure (HF), such as evidence-based medication and mechanical device, including implantable cardioverter-defibrillator or cardiac resynchronization therapy. It is believed that repetitive decompensation of HF may be associated with progressive deterioration

of cardiac and/or non-cardiac function, however, it has not been well confirmed in real world.

Methods: We enrolled 250 consecutive acute decompensated HF patients who were hospitalized in our institute from January 2014 to December 2015. Among those patients, 45 patients experienced repetitive decompensation of HF (2 times: 28 patients, 3 times: 17 patients) after discharge and we evaluated the changes in hemodynamic and laboratory data.

Results: Mean age was 78.8 years old and ejection fraction was 43.4 % who experienced repetitive decompensated HF. Repetitive decompensation resulted in decreases in systolic blood pressure (SBP) 152.9 mmHg, 132.5 mmHg and 129 mmHg and heart rate 93 bpm, 86 bpm and 77 bpm ($p = 0.03$ and 0.07 , respectively). Blood urea nitrogen increased 26.9 mg/dl, 29.5 mg/dl and 42.5mg/dl, serum creatinine increased 1.22 mg/dl, 1.38 mg/dl and 1.73 mg/dl, N-terminal pro B-type natriuretic peptide increased 7494 pg/ml, 11046 pg/ml and 15995 pg/ml ($p < 0.001$, 0.03, 0.13, respectively). The percentages of guideline-based treatments at admission were also increased in renin angiotensin inhibitors 42.2 %, 75.6 % and 82.4%, beta blockers 35.6%, 57.8% and 64.7%, anti-aldosterone blockers 17.8%, 42.2% and 70.6% ($p < 0.01$, < 0.01 , and 0.04 , respectively).

Conclusions: Despite the fact that guideline-based medications were performed better, prognostic factors including SBP, renal function and natriuretic peptides were deteriorated more over times.

P805

Contemporary assessment of lung ultrasound, BNP and echocardiography for outcome prediction in patients with decompensated heart failure

A Palazzuoli¹; M Beltrami¹; G Ruocco¹; R Nuti¹; JG Cleland²

¹University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine, Siena, Italy; ²Harefield Hospital, National Heart & Lung Institute, Imperial College, London, United Kingdom

Background: Pulmonary and systemic congestion at discharge remain strong predictors for poor prognosis in patients with Decompensated Heart Failure (DHF). Lung ultrasound (LUS) has been proposed as a simple, accurate, fast and economic tool to assess pulmonary congestion by imaging 'comets' or B-lines. Measurement of LUS, B-type natriuretic peptide (BNP) and echocardiographic variables could improve diagnosis and prediction of outcome.

Purpose: 1) To investigate the relation amongst B-lines, BNP, and echo measurements (E/e', systolic pulmonary arterial pressure [PAPs], restrictive left ventricular (LV) filling pattern E/A>1 and left ventricular ejection fraction [LVEF]) at admission. 2) To evaluate the prognostic power of admission compared to pre-discharge B-lines. 3) To explore potential differences in patients with DHF and LVEF below or above 50%.

Methods: We performed LUS, echocardiographic and BNP assessment in patients with DHF within 12h of admission. B-lines and BNP values were also evaluated at discharge. Patients were followed for 6 months for HF events. Data are shown as median and quartile (Q) range.

Results: Of 140 patients enrolled, 95 had HFrEF and 45 had HFpEF. For patients with HFrEF, the median number of B-lines at admission was 28 (IQR 22 to 36) and on discharge 20 (15 to 26) with a BNP of 1220 pg/mL (838 to 1810) and 725 pg/mL (406 to 1247) respectively. For patients with HFpEF, the median number of B-lines at admission was 31 (26 to 37) and on discharge 20 (15 to 25) with a BNP of 837 pg/mL (669 to 1083) and 512 pg/mL (316 to 864) respectively. In the overall population, the number of B-lines at admission correlated with BNP ($r = 0.54$; $p < 0.001$), E/E' ($r = 0.29$; $p = 0.001$) E/A ($r = 0.45$; $p < 0.001$) and PAPs ($r = 0.09$; $p = 0.289$). In the overall population, neither B-lines nor BNP at admission predicted HF events but either measured at discharge predicted 6 month outcome (AUC:0.72 [0.63-0.80], AUC:0.70 [0.60-0.79] respectively $p < 0.001$; 6 month HF event rate for Q1 v Q4 was 17% vs 62% [$p < 0.001$] and Q1 v Q4 was 16 vs 61% [$p < 0.001$] respectively). There was a strong relationship between Δ B-lines from admission to discharge (AUC: 0.83; CI: 0.75-0.91; $p < 0.001$). In patients with HFrEF, there was a strong relationship between both B-lines and BNP levels at discharge (AUC:0.72 [0.62-0.83], AUC:0.71

[0.57-0.75] respectively $p < 0.001$). However for HFpEF, only B-lines predicted outcome (AUC 0.74 CI 0.58-0.89 $p < 0.01$). Conclusions- LUS may be a useful tool to assess and monitor pulmonary congestion to identify patients at high risk of HF events. Pulmonary congestion at discharge evaluated by LUS was the strongest predictor of outcome in this study of patients with DHF. The power prediction of LUS is similar in both HFpEF and HFpEF patients.

P806

Influence losartan and lisinopril indicators for exercise tolerance and quality of life parameters in patients with chronic heart failure

UK Kamilova¹; ZD Rasulova¹; DR Tagaeva¹; SS Irgasheva¹

¹Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan

Purpose: To study the effect of lisinopril and losartan on the exercise capacity and quality of life parameters (QL) in patients with chronic heart failure (CHF) I-III functional class (FC).

Research methods: The subjects were 120 patients with ischemic heart disease (IHD) I-III FC CHF (mean age 53.3 ± 5.8 years). The first group (I) accounted for 60 patients with FC I (18), II FC (22) and FC III CHF (20 patients), took over 6 months with standard therapy (spironolacton, beta-blockers, antiplatelet agents) - losartan; the second group (II) - 60 patients with FC I (19), II FC (21) and FC III CHF (20) - lisinopril (mean dose of losartan was 66.3 ± 25.6 , lisinopril - 6.8 ± 2.6 mg / day). The average age of patients was 62.3 ± 5.6 years. The control group consisted of 20 healthy individuals. All patients underwent a six-minute walk test (SWT) study of QL of patients with the help of "Minnesota questionnaire" on the total index (TI QL), the clinical condition was evaluated on a scale of assessment of the clinical status of patients with chronic heart failure (SACS). The results showed that patients with Group I and II to FC II of CHF was observed a decrease in the distance SWT 17.1% and 15.4% ($p < 0.01$) and III CHF FC 48% and 47.7% ($p < 0.001$), respectively, compared with patients with SWT I FC CHF. Indicators SACS were significantly higher in patients with FC II and III heart failure compared with patients with FC I ($p < 0.001$). Analysis of QL assessment on the results of the Minnesota questionnaire showed a significant increase in quality of life by increasing the TI QL. Against the background of 6 months of treatment with the inclusion of losartan or lisinopril it noted: patients with CHF FC I the first group during treatment TI QL score on a scale SACS increased by 32.4%, 50.7% ($p < 0.001$), and Group II patients is 25% and 42.6% ($p < 0.001$); with CHF FC II patients of the first group by 23.8% and 29.2% ($p < 0.001$), while the second group by 12.8% and 41.8% ($p < 0.001$); with FC III patients in the losartan group by 13.9%, 22.5% ($p < 0.001$), in the lisinopril group by 8.5% ($p < 0.005$), 18.2% ($p < 0.001$), respectively, compared from baseline that was accompanied by an increase in the distance SWT patients I, II and III FC in the first group by 13.1%, 14.5% and 16.6% ($p < 0.001$), and the second group by 16.3%, 9.4% and 13% ($p < 0.005$).

Conclusions: Thus, in patients with CHF was observed significant improvement in quality of life and increase exercise tolerance with increasing six-minute walk distance and decrease on the total index of "Minnesota questionnaire", the amount of points on the scale SACS in the dynamics of the six-month treatment in both groups with misleading advantage in the losartan group.

P807

Prevalence, risk factors and prognostic impact of bleeding complications in patients in cardiogenic shock in intensive care unit

T Tatiana Duarte¹; S Goncalves¹; B Ribeiro¹; G Domingos¹; I Goncalves¹; R Ribeiro¹; F Seixo¹; R Caria¹

¹Hospital Center of Setubal, Cardiology, Setubal, Portugal

Introduction: Cardiogenic shock occurs in 7-8% of patients with acute myocardial infarction (AMI) and is associated with a higher morbidity and a worse prognosis, with a hospital mortality rate of 50%.

The progress in antithrombotic therapy and revascularization has reduced mortality in patients (pts) with acute coronary syndrome (ACS), but these therapeutic advances are associated with an increased risk of bleeding. The prevention of major bleeding has an important role in the prognosis impact of pts with ACS.

Aim: To evaluate the prevalence, risk factors and prognostic impact of bleeding complications in pts admitted for cardiogenic shock in the context of AMI in a polyvalent intensive care unit (ICU).

Methods: We evaluated consecutive pts admitted with cardiogenic shock in the context of AMI in a polyvalent intensive care unit, over a period of 5 years. The population was characterized according to baseline characteristics, type of MI, in-hospital complications (death and bleeding - defined in moderate or severe according to the GUSTO classification) and death, reinfarction, or readmission in the ICU at follow-up.

Results: We studied 42 pts (64.3% male sex, mean age 69 ± 15 years). Thirty-six percent ($n = 15$) had bleeding complications.

Age, gender, cardiovascular risk factors, antiplatelet or anticoagulant therapy and invasive procedures were not associated with a higher bleeding risk.

The intra-aortic balloon has been used in the majority of patients, 64% ($n = 27$), without a negative impact at short and long term.

In terms of prognostic impact, bleeding complications were associated with a longer hospital stay (10 ± 8 vs 5 ± 6 days, $p = 0.027$), but without statistical significance in terms of mortality, reinfarction, or readmission in the ICU.

Conclusion: In this population, hemorrhagic complications in context of cardiogenic shock were frequent and associated with prolonged hospitalization. Identification and correction of predisposing factors may be useful to minimize the risk of bleeding in these pts.

P808

Higher brachial-ankle pulse wave velocity is closely associated with lower functional capacity in especially heart failure patients

K Takabayashi¹; A Ikuta¹; M Okazaki¹; R Fujita¹; S Kitaguchi¹; R Nohara¹

¹Hirakata Kohsai Hospital, Hirakata, Japan

Background: Previous studies demonstrated that brachial-ankle pulse wave velocity (baPWV) was associated with cardio vascular disease, but clinical characteristics and functional capacity in cardiopulmonary exercise testing (CPX) have not been well documented.

Purpose: The purpose of this study is to identify the association of baPWV with functional capacity in acute heart failure (AHF) and acute myocardial infarction (AMI) patients.

Methods: We have enrolled 146 patients (pts) doing cardiac rehabilitation with CPX in pts with AHF and AMI discharged from March 2014 to February 2015. We compared the baseline clinical characteristics, CPX variable and functional capacity between pts with baPWV ≥ 1800 cm/s ($n = 44$; high baPWV) and the other pts ($n = 102$; normal baPWV). We excluded the pts with ankle brachial index < 0.9 .

Results: The pts with high baPWV were older, and had lower body mass index than those with normal baPWV (74.5 ± 7.6 vs. 65.8 ± 10.9 years of age; $p < 0.01$; 22.5 vs. 24.3 ; $p < 0.01$, respectively). They were more likely to have diabetes or chronic obstructive pulmonary disease (40.9% vs. 22.6% ; $p = 0.03$; 13.6% vs. 2.0% ; $p < 0.01$, respectively). There was no significant difference in other co-morbidities. In pts with high baPWV, peak VO2 and VO2/pulse were significantly lower (15.5 ± 4.5 vs. 18.4 ± 4.6 ml/kg/min; $p < 0.01$, 8.1 ± 2.5 vs. 9.6 ± 3.3 ; $p < 0.01$, respectively) at baseline. In AMI pts, there was no difference in peak VO2 or VO2/HR between high baPWV and normal baPWV (17.5 ± 5.5 vs. 18.8 ± 4.8 ml/kg/min; $p = 0.35$, 8.4 ± 2.5 vs. 10.2 ± 4.0 ; $p = 0.07$, respectively). However, in AHF pts, high baPWV was associated with lower peak VO2 and VO2/pulse (14.2 ± 3.4 vs. 16.8 ± 4.0 ml/kg/min; $p < 0.01$, 7.8 ± 2.0 vs. 9.1 ± 2.8 ; $p = 0.04$, respectively). Hand grip strength, isokinetic knee extension muscle strength and calf circumference were lower in pts with high baPWV than those with normal baPWV (23.3 ± 8.0 vs. 30.6 ± 9.0 kg; $p < 0.01$, 21.5 ± 5.4 vs. 32.4 ± 11.0 ; $p < 0.01$, 31.7 ± 3.3 vs. 34.0 ± 3.5 cm; $p = 0.02$ respectively).

Conclusion: In AHF pts, higher baPWV was closely associated with lower functional capacity; peak VO2, VO2/HR, muscle strength and calf circumference.

Continuous infusion versus bolus administration of intravenous furosemide in acute heart failure patients

Novartis - educational grant

I Ivan Varga¹; P Lesny¹; M Luknar¹; V Simovicova¹; K Cenkerova¹; E Goncalvesova¹

¹National Institute of Cardiovascular Diseases (NICVD), Bratislava, Slovak Republic

Background: Data on optimal diuretic treatment in patients (pts) with congestive heart failure (HF) remain scarce. Aim: To compare characteristics and prognosis of acute HF (AHF) pts treated with intravenous (IV) furosemide in a continuous infusion (CI) versus bolus administration (BA).

Methods: We used the data from SLOVASEZ II, nationwide multicenter AHF survey with 592 consecutive pts enrolled between 1 April and 31 June 2014. We analysed 77 variables in relation to clinical manifestation, management and outcome of AHF in univariate analysis, significant of them ($p < 0.05$) were used for multivariate analysis.

Results: 368 (82.5%) pts were enrolled into CI group (CIG) and 78 (17.5%) in BA group (BAG). Pts in CIG were younger (65 ± 14 vs 73 ± 11 years), severely symptomatic (NYHA class 3.6 vs 3.3) and frequently hospitalized due to AHF in last year (56 vs 32%; all $p < 0.001$). CIG pts were more admitted for acute decompensation of chronic HF (74 vs 45%), with dilative cardiomyopathy and arterial hypertension as more frequent primary etiology (22 vs 12 and 24 vs 17% resp., both $p < 0.05$), as well as with higher incidence of renal failure (60 vs 39 %, $p < 0.001$; mean serum creatinine and estimated glomerular filtration - eGFR were 156 vs 126 μ mol/L and 0.8 vs 0.9 ml/s resp.; both $p < 0.05$). Pts in CIG had lower systolic blood pressure (mean 124 vs 142 mmHg, $p < 0.001$), but more often signs of congestion as S3 gallop or jugular vein distension (23 vs 11 or 60 vs 39 % resp.; both $p < 0.005$). They were more treated with digoxin and furosemide (41 vs 20 and 85 vs 70 % resp., both $p < 0.005$) as well as eplerenone and warfarin (24 vs 13 and 31 vs 18 % resp., both $p < 0.01$) before admission. Pts in

CIG had more dilated left ventricle with lower ejection fraction (median 62vs54 mm and 34vs42 % resp., both $p < 0.01$). The number of pts with implanted defibrillators/resynchronisation therapy or administered inotropes was higher in CIG (26vs7 % and 17vs2%, resp., both $p < 0.001$). The in-hospital mortality was high (14vs10 % in CIGvsBAG, $p=ns$), with longer hospitalization in CIG (11vs9 days, $p < 0.05$). There was symptomatic improvement in both groups (NYHA class 2.5vs2.4 in CIGvsBAG) without detected worsening in renal function (eGFR 0.8vs0.9 ml/s in CIGvsBAG) at discharge. Parameters independently associated with CI administration of IV furosemide were age, history of HF and renal failure (all $p < 0.01$).

Conclusion: Administration of IV furosemide in continuous infusion is often, effective and safe therapeutic strategy in AHF pts which should be considered even more in high-risk subgroups, especially older pts with history of HF and renal failure.

P810

Body mass index and gender-specific clinical outcome measures of congestive heart failure with reduced ejection fraction: a Middle Eastern population study

S Khaled¹; L Faour¹; K Khaled Salem¹

¹ King Abdullah Medical City, Cardiology Departement. Heart failure program, Makkah, Saudi Arabia

Background: Low body mass index (BMI) has been linked with congestive heart failure mortality. However, gender-specific BMI-related clinical outcome measures are not well defined.

Aim: We examined the correlation between BMI gender variability and clinical mortality, cerebrovascular accident (CVA), transient ischaemic attack (TIA), composite outcome of myocardial infarction (MI), unexplained syncope, infection and bleeding outcome measures of heart failure in patients with reduced ejection fraction (HFrEF).

Methods: A group of 166 consecutive HFrEF patients, 37 females and 129 males, were enrolled in a prospective HFrEF single-centre registry from December 2014 to December 2015.

Results: Males with lower BMI had higher composite MI/CVA/mortality, (42% vs. 25%, $P = 0.05$) for BMI of 25.9 ± 5.3 vs. 29.8 ± 7.2 kg/m², $P = 0.08$. They also showed higher rates of CVA/TIA/unexplained syncope than the high-BMI males (23% vs. 4.1%, $P = 0.01$ for BMI of 23.9 ± 5.4 vs. 28.4 ± 6.1 kg/m², $P = 0.018$). However, length of stay (LOS) at the hospital was shorter for low-BMI females (3.6 ± 2.4 vs. 9.7 ± 8.15 , $P = 0.024$ for BMI 29.7 ± 6.2 vs. 35.8 ± 7.2 kg/m², $P = 0.01$). Low-BMI females had lower rates of infection/bleeding (26% vs. 0%, $p = 0.001$ for BMI of 35.8 ± 7.2 vs. 27.8 ± 4.9 kg/m²).

Conclusion: Among the examined HFrEF patients, low BMI in males was associated with high incidence of MI/CVA/mortality and composite rates of CVA/TIA/unexplained syncope. Low BMI in females was associated with low all-cause infection/bleeding rate and short LOS.

Low BMI and CVA/TIA/syncope outcome

P811

Non invasive evaluation of hemodynamic effects of continuous positive airway pressure in acute heart failure with right ventricular dysfunction.

I Ilaria Battistoni¹; M Marini¹; L Angelini¹; M Shkoza¹; M Francioni¹; A Gili¹; S Moretti¹; GP Perna¹

¹ University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy

Background: beneficial effects of continuous positive airway pressure (CPAP) in patients (pts) with acute pulmonary edema (APE) have been already demonstrated.

However, few it is known regarding the effects of CPAP on pts with acute heart failure (AHF) and contemporary right ventricular dysfunction. This lack of data is mainly due to concerns about possible harmful hemodynamic effects on right function in this subgroup of pts. The purpose of our study is to evaluate the hemodynamic effects of CPAP, measured by echocardiography, in pts with acute HF and right ventricular dysfunction.

Methods: we evaluated 30 pts with acute HF referring to our ICU department of which 11 (37%) had right ventricular dysfunction. Acute HF was defined as a left ventricular ejection fraction < 0.45 associated with at least one criteria between dyspnea at rest, pulmonary rales or radiological signs of pulmonary congestion. Right ventricular dysfunction was defined as a reduction of tricuspid annular plane systolic excursion (TAPSE) ≤ 16 mm evaluated by transthoracic echocardiography. Echocardiographic hemodynamic assessment was performed at presentation (T0) and at 30 minutes (T1), 24 h (T2) and 48 h (T3) after C-PAP beginning. Patients were treated with a different level of positive end expiratory pressure (PEEP 5-7,5-10 mmHg) chosen according to clinical needs.

Results: mean cardiac output (CO) significantly increased during CPAP therapy (3.7 l/min at T0 vs. 4.2 l/min at T2; $p = 0.03$) as well as mean cardiac index (CI) (1.9 l/min/m² at T0 vs. 2.2 l/min/m² at T2; $p = 0.04$). There were no significant variations of systolic, diastolic and mean systemic blood pressure during the two days of treatment while mean ejection fraction improved at 48 h (31.7 % vs. 35.7%, $p = 0.04$). Right ventricular function did not deteriorate after application of PEEP (mean TAPSE of 14.5 compared to 14.5 at T0 to T1) and central venous pressure (CVP) has increased but not significantly (mean 9.3 at T0 vs. 9.8 at T1). Systolic pulmonary pressure did not vary significantly after C-PAP (38.72 ± 13.66 vs 37.31 ± 13.15 p:0.8). We have not had adverse cardiovascular events. All patients were discharged alive.

Conclusion: C-pap is safe in patients with right ventricular dysfunction and provides significant hemodynamic support even in this subgroup of patients. The beneficial effects of C-PAP could be explained mainly by the reduction of pulmonary vascular resistances due to correction of hypoxia levels compare to the decrease of venous return which is not significant in euvoletic patients. These encouraging results should be confirmed with larger numbers or maybe dedicated trials

P812

Treatment of acute myocardial infarction in shock with ECMO: beyond the intraaortic balloon pump

I Iago Sousa Casasnovas¹; F Diez-Delhoyo¹; J Garcia-Carreno¹; A Ayesta-Lopez¹; C Devesa-Cordero¹; M Juarez-Fernandez¹; F Sarnago-Cebada¹; J Elizaga-Corales¹; M Martinez-Selles¹; F Fernandez-Aviles¹

¹ University Hospital Gregorio Marañon, Madrid, Spain

Background: Cardiogenic shock is a well known complication of acute myocardial infarction (AMI). At this moment there is controversy about the utility of intraaortic balloon pump in this context, and different devices are being used to support the patients. One option is the use of venoarterial extracorporeal membrane oxygenation (VA-ECMO), that can be implanted percutaneously in the catheterization laboratory.

Methods: We analyzed our experience in the treatment of AMI complicated with refractory shock with percutaneous VA-ECMO since July 2013, when our program started, to December 2015. ECMO Cardiohelp (Maquet AG) was percutaneously implanted in the Cath Lab by interventional cardiologists in all cases, using femoral approach.

Results: During the period of study 11 patients with AMI in refractory shock were treated with VA-ECMO. Eight patients were men, with a median age of 52.4 (range [42.5-63.1]). Mean LVEF was 0.13, lactic acid 9.14 ± 3.27 mmol/L, time of cannulation 21.6 ± 9.4 min, time of support 4 ± 2.5 days. During the ECMO therapy 4 patients presented major bleeding (36%), 2 patients presented limb ischemia (18%), 1 patient required venovenous hemofiltration (9%). Weaning from ECMO was achieved in 7 of the 11 cases (63.6%), 2 patients required implantation of a ventricular assist device as bridge to heart transplantation (18.2%). One patient died after weaning due to electrical storm and 2 patients died during the therapy. Global survival to discharge was 72.7%.

Conclusion: Our experience with percutaneous VA-ECMO in the treatment of AMI complicated with cardiogenic shock is favourable, with a high survival in a scenario of bad prognosis with conventional treatment. We think it is a useful tool to take into account in the catheterization laboratory.

P813

Venoarterial extracorporeal membrane oxygenation in adults: clinical experience in heart failure and cardiac arrest.

G Gabriella Arlotta¹; M Calabrese¹; A Scapiati²; ME Antoniucci¹; L Martinelli²; F Bevilacqua¹; F Cavaliere²

¹ Polyclinic Agostino Gemelli, cardiovascular science, Rome, Italy; ² Catholic University of the Sacred Heart, cardiovascular science, Rome, Italy

Background: Venoarterial extracorporeal membrane oxygenation (VA-ECMO) is an established treatment for severe heart failure not responding to conventional

therapy, for failed weaning from cardiopulmonary by-pass in post-cardiotomy and post-transplantation patients, to facilitate specific intervention (i.e. coronary angiography or percutaneous coronary intervention) and in cardiac arrest when initial cardiopulmonary resuscitation (CPR) is unsuccessful.

Purpose: This report reviews our experience with VA-ECMO in adult in-patients of a Cardiovascular Science Department of a University hospital.

Methods From October 2012 to December 2015, 12 adult patients affected by acute severe cardiac failure or cardiac arrest with potentially reversible cause, were placed on VA-ECMO using heparin-coated circuits. In cardiac arrest, the indications were no-flow time <5 minutes, low-flow time between 10 and 60 minutes, age <65 years, and absence of other contraindications.

Data were obtained from patient records. Continuous variables were presented as mean \pm SD whereas discrete variables were presented as frequencies. Differences were compared with unpaired student t test.

Results: VA-ECMO was utilized in 12 patients, aged 52.4 ± 14.7 years (range 29 – 73), seven males and five females. ECMO was instituted during CPR in six patients (50%), in the operating room because of inability of weaning from cardiopulmonary bypass in three patients (25%), and for acute heart failure in three patients (25%) (one for valvular disease, one during a percutaneous coronary intervention and one for a catastrophic antiphospholipid syndrome). Nine patients were successfully weaned from AV-ECMO (75%); three of them died in the hospital (30%) and six (50%) were alive three months later. The peak value of serum LDH during ECMO was significantly lower in survivors than in non-survivors (637.8 ± 110.4 vs. 1536.6 ± 910.1 IU/L; $p=0.03$). Also plasma lactate was significantly lower in survivors than in non-survivors after 3 hours (6.3 ± 2.8 in vs. 10.3 ± 3 mmol/L; $p=0.05$) and 24 hours (2.8 ± 2 vs. 6.7 ± 3.7 ; $p=0.05$) the beginning of ECMO support.

Conclusions: In our series of patients treated with AV-ECMO, three month survival was 50% and eCPR was characterized by the highest mortality (66%). These results are consistent with the literature (3). Survivors presented lower levels of plasma lactate in the first 24 hours after starting ECMO. Higher values of serum LDH during support may be associated with poor outcome.

P814

Clinical characteristics and social backgrounds in super elderly patients of acute congestive heart failure in community-based registry; kickoff registry

K Takabayashi¹; A Ikuta¹; Y Okazaki¹; R Fujita¹; S Kitaguchi¹; R Nohara¹

¹Hirakata Kohsai Hospital, Hirakata, Japan

Background: Heart failure (HF) is frequent in the elderly. HF in the elderly patients (pts) was closely associated with social backgrounds, but in a suburb of city, social backgrounds of HF have not been well documented. Very few trials have reported participants about home living situation, social support and social backgrounds in the Asia Pacific region, Japan.

Purpose: This study aimed to identify the association of super elderly and social backgrounds, home living situation, social support and so on, in acute heart failure (AHF) patients (pts).

Methods: We have enrolled 374 inpatients with AHF in the KICKOFF Registry (13 hospitals in Kitakawachi, Osaka, Japan). The KICKOFF Registry is a community-based survey of HF pts in Kitakawachi which is located at the eastern end of the city of Osaka, Japan. The age distribution of the population in Kitakawachi is similar to that in the city of Osaka, as well as that in Japan. We compared the clinical characteristics and social backgrounds between HF pts ≥ 80 years (elderly pts; $n=190$) and the other pts (control; $n=184$).

Results: We had 50.8% of super elderly pts. The elderly pts were more in female, had lower body mass index, and longer mean length of hospitalization than control (64.2% vs. 36.4%; $p<0.01$, 20.3 ± 3.7 vs. 23.0 ± 4.2 ; $p<0.01$, 29.2 ± 26.8 vs. 22.6 ± 19.9 days; $p=0.02$, respectively). They had more valvular disease and chronic kidney disease (40.2% vs. 27.0%; $p=0.01$, 63.9% vs. 46.7%; $p<0.01$, respectively). There was no significant difference in other co-morbidities between them, history of heart failure, ischemic heart disease, hypertension, diabetes and atrial fibrillation. Elderly pts were more likely to need support by others; less by living alone, own drug therapy monitoring or own dietary manager than control (16.7% vs. 40.9%; $p<0.01$, 45.1% vs. 86.1%; $p<0.01$, 22.2% vs. 42.3%; $p<0.01$, respectively). In elderly pts, there were more of downgrade ADL, long-term care insurance available, dementia and limb motion disorder (33.3% vs. 16.1%; $p<0.01$, 73.6% vs. 19.0%; $p<0.01$, 45.1% vs. 11.7%; $p<0.01$, 40.3% vs. 13.9%; $p<0.01$, respectively).

Conclusion: There was 50.8% of super elderly pts in our study. The elderly pts with HF need more support by other person, and they had lower ADL, dementia and limb motion disorder. Therefore, more strict social supporting systems of elderly pts should be constructed in the Asia Pacific region, Japan.

P815

Effect of ivabradine on the infarct size and remodeling in patients with STEMI

A A S Ahmed Ashraf Abdel Salam Eissa¹

¹Ain Shams University, cardiology division, Cairo, Egypt

Objective: To assess the effect of ivabradine on LV function and remodeling in patients with STEMI immediately after primary PCI (PPCI).

Methods: Fifty seven patients who presented with STEMI within the time window of reperfusion (12hrs) were included in our study. These patients were divided into two groups: Group 1: optimal medical treatment (OMT) including beta-blockers + Ivabradine; Group 2: OMT including beta-blockers without Ivabradine. within 24 hours of PPCI all the patients did baseline echocardiography (LVEF, LVESD, LVESD) and SPECT (LVEF, LVESD, LVESV, 17-segment score). After 21 days, echocardiography and SPECT study were repeated.

Results: our patients were predominantly males (84.2%) with mean age of 48.8 ± 10.53 yrs. All the patients underwent PPCI and the most revascularized vessel was LAD (93%). Admission HR was 95.71 ± 12 bpm. Both groups revealed no significant difference after 21 days of treatment apart from significant HR reduction to 68 bpm with Ivabradine (group I) ($P<0.001$). Subgroup analysis of Group I diabetic patients with HR >100 bpm showed significant reduction of echocardiographic LVESD by -4.80 ± 2.09 mm; ($P=0.015$) and significant improvement of SPECT LVEF to $+14.10 \pm 7.06$ % ($P=0.03$).

Conclusion: In the setting of STEMI treated with PPCI, Ivabradine significantly reduced the HR. In a subgroup of Diabetic patients with HR >100 bpm, Ivabradine significantly reduced the echocardiographic LVESD and improve the SPECT LVEF.

Diabetic patients with HR>100

	Diabetic patients with HR > 100 bpm on Ivabradine + BB (n = 10)	Diabetic patients with HR > 100bpm on BB (n = 6)	P.Value	
	Mean \pm SD	Mean \pm SD

P816

What makes inter-hospital mortality difference in acute heart failure: a study from the KorAHF registry

CH Chee Hae Kim¹; SE Lee¹; H Lee¹; W Choe¹; H Cho¹; HY Lee¹; BH Oh¹

¹Seoul National University Hospital, Division of Cardiology, Department of Internal Medicine, Seoul, Korea Republic of

Background: Inter-hospital mortality difference in acute heart failure (HF) still exists despite emphasis on standardized evidence-based guidelines. Previous research for acute HF lacks comparison of inter-hospital difference.

Purpose: We aimed to investigate treatment factors affecting different outcomes of acute HF between hospitals.

Methods: We used data from a multi-center national registry for acute HF patients registered between May 2011 and March 2014. We chose two biggest university hospitals in the registry, which are in the same urban area, with similar scale. We assessed data for 1,511 patients, 690 in hospital A and 821 in hospital B. We compared in-hospital mortality, baseline characteristics, HF severity and treatment factors between the two hospitals.

Results: In-hospital mortality rate was significantly higher in hospital A than B (8.4% vs. 3.7%, p -value <0.001). It remained statistically significant even after adjusting for possible confounders including age, hypertension, diabetes, obesity, renal failure, acute myocardial infarction, left ventricular (LV) function, hypotension and hyponatremia (adjusted OR 2.1, p -value = 0.002). The mortality difference remained significant in various subgroups defined by factors such as age, gender, LV function, de novo or not, and blood pressure. There was significant difference in prescription of beta-blockers and ACEI/ARBs between the hospitals. Beta-blockers were less frequently prescribed in hospital A than B not only before admission (30.4% vs. 37.5%, p -value 0.004) but also during the hospitalization (48.7% vs. 66.0%, p -value <0.001). ACEI/ARBs were used similarly before admission but less used for HF with reduced ejection fraction (HrEF) during the hospitalization in hospital A (75.1 vs. 85.9%, p -value <0.001). ACEI/ARBs were less frequently prescribed in hospital A regardless of blood pressure. Use of parenteral inotropes was more frequent in hospital A in all subgroups, especially in patients with blood

pressure over 100mmHg (53.8% vs. 27.0%, $p < 0.001$). Following adjustment of the prescription of ACEI/ARBs, beta-blockers and parenteral inotropes, inter-hospital mortality difference was disappeared (adjusted OR 1.2, p -value = 0.544).

Conclusion: Though it is hard to clarify the causal relationship in this analysis, the difference in medical care between the hospitals could result in different mortality. Inter-hospital comparison study might contribute to upward standardization of medical treatment of acute HF.

P817

Hemodynamic effects of continuous positive airway pressure in patients with acute heart failure

I Ilaria Battistoni¹; MM Marini¹; LA Angelini¹; MS Shkoza¹; MF Francioni¹; AG Gili¹; SM Moretti¹; GPP Perna¹

¹University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy

Background: Continuous positive airway pressure (CPAP) reduces the need for invasive mechanical ventilation and has been associated, in some reports on patients with acute pulmonary edema (APE) with a reduction of mortality. In current guidelines its use is recommended only in patients with acute heart failure (AHF) and APE unless systemic hypotension is present (SBP < 85 mmHg). However, in clinical practice, the rate of CPAP utilization is very low, varying from 2.3% up to 13.9% (data from registers).

Aim: the aim of the present study is to evaluate the hemodynamic effects of CPAP, measured by echocardiography, in patients with AHF.

Methods: 30 patients (median age 71 years) with AHF referring to our ICU department, have been enrolled. Of those, 25 (83%) had a first diagnosis of HF, while 5 (17%) presented an AHF decompensation. AHF was defined as a left ventricular ejection fraction (LVEF) < 0.45 associated with at least one criteria among dyspnea at rest, pulmonary rales, radiological signs of pulmonary congestion and/or respiratory distress. Five patients (17%) presented with APE, 12 (40%) with acute HF with normal blood pressure, 2 (6.6%) with AHF with low blood pressure (SBP < 90 mmHg) and 9 (30%) with cardiogenic shock. 93% of patients had an acute coronary syndrome. Echocardiographic hemodynamic assessment was performed at presentation (T0), then at predefined time points after CPAP beginning: 30 min (T1), 24 h (T2) and 48 h (T3).

Results: Mean cardiac output (CO) significantly increased during CPAP therapy (3.9 l/min at T0 vs. 4.4 l/min at T3; $p = 0.01$). Mean cardiac index (CI) significantly increased too (2.1 l/min/m² at T0 vs. 2.4 l/min/m² at T3; $p = 0.01$) as well as mean stroke volume index (28 ml/m² at T0 compared to 33 ml/m² at T3, $p = 0.001$). There were no significant variation of systolic, diastolic and mean systemic blood pressure during the three days of treatment while LVEF improved at 48 h (33% vs. 36%, $p = 0.02$). Despite a significant increase of the mean central venous pressure (9.23 mmHg vs. 9.83 mmHg, $p = 0.04$), there was no worsening of right ventricular function (TAPSE from 17.6 mm to 17.9 mm) and mean pulmonary systolic pressure significantly decreased (37.1 mmHg at T0 vs. 32.7 mmHg at T4, $p = 0.03$). We have not had MACE.

Conclusion: CPAP provides significant hemodynamic support in patients with AHF. This is due to the reduced left ventricle afterload which can increase stroke volume and systemic perfusion. Furthermore in euvoletic patients, C-PAP did not worsen right ventricular function. CPAP is safe in this setting of patients and therefore should always be considered as a treatment urgent and indispensable in view of its beneficial effects respiratory and hemodynamic.

P818

Medium-term outcomes in patients post va-ecmo

J Justin Teng¹; B Dunne¹; K Lam²

¹Royal Perth Hospital, Perth, Australia; ²Fiona Stanley Hospital, Advanced Heart Failure and Cardiac Transplant Service, Perth, Australia

Purpose: Venous-Arterial Extracorporeal Membrane Oxygenation (VA-ECMO) has been shown to improve short-term outcomes in patients with refractory cardiogenic shock (RCS). However the medium-term outcomes are unclear. We aim to examine the course of those patients surviving their initial admission requiring VA-ECMO.

Methods: This study was a retrospective, single-centre review of patients who received VA-ECMO for RCS. Baseline patient characteristics, aetiology of RCS, survival as well as cardiovascular and neurological outcomes both at hospital discharge and at 1 year were collected by review of medical records.

Results: From 2008 to 2014, 34 patients received VA-ECMO for RCS. Mean age was 43 years (+ 19), 65% were male and total time on VA-ECMO was 6 days (+ 4.3). The aetiology of RCS was acute myocarditis in 9 (25%), post-cardiac surgery in 6 (18%), post heart/lung transplant in 5 (15%), acute myocardial infarction in 4 (12%), decompensated cardiomyopathy in 4 (12%), right heart failure in 3 (9%) and other in 3 (9%). 18 (53%) patients survived to hospital discharge, of whom 14 (41%) made a full neurological recovery. 8 (24%) patients were medically managed without advanced therapy, 6 (18%) required heart transplantation, 3 (9%) required left ventricular assist devices (LVAD) and 1 patient (3%) was listed for

heart transplantation. At 1 year, 14 patients (44%) were still alive. 5 (16%) patients were medically managed. 6 (19%) patients had required heart transplantation. 2 (6%) patients required LVAD support and 1 (3%) was listed for transplant. During this time, 1 patient was newly listed for transplant, 1 patient had progressed from medical therapy to LVAD and 1 patient progressed from LVAD to transplant.

Conclusion: Patients receiving VA-ECMO for RCS who survive to discharge have a favourable medium-term prognosis however a significant proportion will require LVAD support or transplantation. A minority of patients survive to 1 year without advanced therapy highlighting the need for all ECMO survivors to have close follow-up by a heart failure/transplant unit

Trauma-induced cardiomyopathy requiring emergency extracorporeal life support.

E Bellanti¹; M Bugetti¹; G Harmelin¹; G Sani¹; M Bonacchi¹

¹University of Florence, Cardiac Surgery Unit - Dept of Experimental and Clinical Medicine, Florence, Italy

Introduction: The sequelae of severe poly-trauma may include myocardial dysfunction followed by acute heart failure and death. Trauma-induced cardiomyopathy or Inverted-Takotsubo Cardiomyopathy (ITC) is a variant of stress cardiomyopathy, characterized by a contractile abnormality with extensive left ventricular circumferential dyskinesia or akinesia with a hyperkinetic apex. We report our experience with refractory cardiogenic shock and/or cardiac arrest, treated with extracorporeal life support.

Methods: From June 2008 to December 2015, we treated 6 adult poly-trauma patients (5 men, 1 woman, mean age: 28.4 ± 15.4 years, mean ISS score 52.5 ± 17.2) with veno-arterial (V-A) extracorporeal life support for cardiopulmonary failure/cardiogenic shock refractory to conventional treatment, due to inverted-Takotsubo cardiomyopathy. We used a miniaturized extracorporeal life support (ECLS) device. **RESULTS.** ITC myocardial dysfunction appeared 14.6 ± 12.4 h after intensive care unit admission and rapidly evolved to refractory cardiopulmonary failure and cardiac arrest (within 3.4 ± 3.2 h of the onset). At ECLS, initiation median pH was 7.11 ± 0.15 (6.91-7.25), median lactate was 6.9 ± 3.1 (4-10) mmol/l and median vasoactive-inotropic score was 184.4 ± 51.4 μ g/kg/min. Tissue perfusion

improved significantly within 4 h on ECLS. Cardiac function improved gradually but consistently. Initial median ejection fraction was $12.8 \pm 5.1\%$ and median global longitudinal strain test was -7.1 ± 4.8 . At complete cardiac recovery, they were 60.51 ± 8.1 and $-17.83 \pm 3.2\%$, respectively. After that, 2 patients survived and were sent to neurological rehabilitation before hospital discharge. In the other 2 cases, post-traumatic cerebral death occurred and they underwent organ explantation.

Conclusions: Rapid heparin-free ECLS may improve outcome in the most severe cases of poly-traumatized patients demonstrating refractory trauma-induced cardiomyopathy.

P820

Prognostic value of decreased peripheral congestion detected by Bioelectrical Impedance Vector Analysis (BIVA) in patients hospitalized for acute heart failure.

S Simona Santarelli¹; V Russo¹; I Lalle¹; B De Berardinis¹; L Magrini¹; E Di Stasio²; A Piccoli³; L Castello⁴; G Avanzi⁴; S Di Somma¹

¹Sant' Andrea Hospital, Emergency Medicine, Rome, Italy; ²Catholic University of the Sacred Heart, Institute of Biochemistry and Clinical Biochemistry, Rome, Italy; ³University of Padova, Department of Medicine, Padua, Italy; ⁴University of Eastern Piedmont, Translational Medicine, Novara, Italy

Background: Acute heart failure (AHF) is a frequent reason for patients to be admitted. Exacerbation of chronic heart failure is linked with a progressive worsening of the disease with increased incidence of death. Fluid overload is the main mechanism underlying acute decompensation in these patients. Bioelectrical Impedance Vector Analysis (BIVA) is a validated technique able to quantify fluid overload.

Purpose: To investigate the prognostic role of quantitative reduction of congestion during hospitalization assessed by BIVA serial evaluations in patients admitted for AHF.

Methods: a prospective, multicenter, observational study in AHF and no AHF patients in 3 Emergency Departments centres in Italy. Clinical data and BIVA evaluations were performed at admission (t0), and discharge (tdis). A follow-up phone call was carried out at 90-days.

Results: 336 patients were enrolled (221 AHF and 115 no AHF patients). We found that clinical signs showed the most powerful prognostic relevance. In particular the presence of rales and lower limb edema at tdis, were linked with events relapse at 90 days. At t0, congestion detected by BIVA was observed only in AHF group, and significantly decreased at tdis. An increase of Resistance variation (dR/H) > 11 Ohm/m during hospitalization, was associated with survival. BIVA showed significant results in predicting total events, both at T0 (AUC 0.56, $p < 0.04$) and at Tdis (AUC 0.57, $p < 0.03$). When combined with clinical signs, BIVA showed a very good predictive value for cardiovascular events at 90 days (AUC 0.97, $p < 0.0001$).

Conclusions: In AHF patients, an accurate physical examination evaluating the presence of rales and lower limbs edema, remains the cornerstone in the management of patients with AHF. A congestion reduction, obtained as a consequence of therapies and detected through BIVA analysis, with an increase of dR/H > 11 Ohm/m during hospitalization seems to be associated with increased 90 day survival in patients admitted for AHF.

Clinical characteristics of patients with moderate to severe mitral regurgitation admitted for an episode of acute heart failure

K Yarmova¹; I Ivelin Sharabanski¹; M Milanova¹

¹Emergency University Hospital Pirogov, Clinic of cardiology, Sofia, Bulgaria

Objective: To determine the clinical characteristics of patients with moderate to severe mitral regurgitation, admitted for acute heart failure.

Methods: It is a limited clinical observational study on one year period-01 October 2014 to 01 October 2015, on patients presenting with moderate to severe mitral regurgitation and an episode of acute heart failure.

Results: We study 78 patients, 55 female (70%) and 23 male (30%), with mean age of all patients' group 69,7 years of age. The study shows that more than two thirds of the selected patients were with acute ischaemic attack-n 68, 87%, related to left main or multivessel disease-n 59, 75%. Only two patients, 2%, had prolapse or flail mitral valve. Patients with moderate to severe functional mitral regurgitation due to primary dilated cardiomyopathy, were 8, 10%. Trough the study we registered 14 % in hospital death and one patient died one month after discharge.

Conclusion: Ischaemic heart disease and associated risk factors-arterial hypertension, diabetes, atrial fibrillation, chronic renal disease, linked to acute ischaemic attack are the prevalent causes for acute heart failure in patients with moderate to severe mitral regurgitation.

P822

Acute heart failure and infections

M Miroslav Pernický¹; J Murin¹; ¹Comenius University, 1st Department of Internal Medicine, Bratislava, Slovak Republic;

Objective: Acute heart failure (AHF) can be triggered by "some" risk factors. We looked at infection as a trigger of AHF.

Patients and methods: From 1.st June to 31.st December 778 patients (pts) were admitted to Internal Department, 140 with AHF (71 ys old, 47% men), diagnosed clinically (NTproBNP, ECG, echocardiography included). Infection was diagnosed clinically (CRP, leukocytes, FW, X-ray included).

Results: * infections deteriorated chronic HF in 36 pts (26% of AHF admissions), uncontrolled hypertension 25 pts (18%), diabetes 24 pts (17 %) ** infections: pneumonia/acute bronchitis (17 from 36 pts, 47%), uroinfections (10/36 pts, 28%), other (9/36 pts, 25%). *** Characteristics of AHF pts (infections/noninfections): women (53%/55%), age (72ys/69ys), smokers (39%/32%), less mobility of pts (22%/16%), comorbidities: diabetes (35%/28%), renal insufficiency (45%/36%), anemia (15%/12%), NYHA III (40%/26%), NYHA IV (12%/8%).

Conclusion: AHF patients admitted due to infection are: more women, elderly, smokers, weaker pts with more comorbidities (diabetes, renal insufficiency, anemia) and higher NYHA classes.

P823

Descriptiveness predictor of acute heart failure development in patients with acute myocardial infarction and obesity.

N Ryndina¹; G Ganna Tytova¹; A Yermak¹; T Soe¹; PG Kravchun¹; ¹Kharkiv National Medical University, Kharkiv, Ukraine; **Purpose:** To investigate predictor informativeness of copeptin, MRproADM and troponin I in the development of acute heart failure in patients with acute myocardial infarction and obesity

Material and methods: 75 patients with acute myocardial infarction and obesity were examined. All patients were divided into 2 groups according to presence or absence of acute heart failure (AHF). 1st group consisted of 39 patients who had a complicated AMI by acute heart failure: Killip class 1 was found in 23% of patients, Killip class 2- in 27% and 50% of patients had Killip class 3. 1nd group - 36 obese patients with acute myocardial infarction without acute heart failure.

Table 1. Data results

Data, units	Patients with AMI and obesity		
I group	II group		
Copeptin ng/ml	179,29 ± 13,04	149,59 ± 13,85	0,05
MRproADM ng/ml	649,21 ± 26,38	559,77 ± 24,49	<0,01
Troponin I ng/ml	5,42 ± 1,35	7,06 ± 1,13	> 0,05

Results: Results are shown in the Table 1. Patients of the 1st group found significantly higher levels of MRproADM - 19.85% ($p < 0.01$) compared with patients of the 2nd group. Concentration of copeptin revealed a tendency ($p = 0.05$) to increase the chance of appearance of AHF in patients with AMI and obesity, which did not reach the level of probability when compared with patients of second group. Troponin I level did not differ significantly in both groups ($p > 0.05$).

Conclusion: The results indicate that the presence of AHF in patients with AMI and obesity is associated with increased activity of MRproADM, which makes it possible to use it as a marker of prognosis.

Abstract 60801 Table

AH	AF	Diabetes	Chronic renal disease	Acute ischaemic attack	EF<35%	LM or multivessel disease	Mechanical moderate to severe MR (prolapse or flail mitral valve)	Functional MR

P824

Mid-term outcomes of acute heart failure with preserved left ventricular ejection fraction

S-Y Song-Yi Kim¹; J-G Lee¹; J-H Choi¹; K-S Kim¹; S-J Joo¹¹Jeju National University Hospital, Jeju, Korea Republic of

Purpose: Approximately 40~50% of patients with acute heart failure (AHF) have preserved left ventricular ejection fraction (LV EF). They are known to have different clinical characteristics, but similar prognosis compared with those with decreased LVEF. However, long-term outcomes of acute heart failure with preserved EF (HFpEF) were rarely investigated in Korea, especially in one community.

Method: We enrolled 405 patients with AHF from Jan. 2005 to July 2013. They were divided into three groups according to LV ejection fraction; reduced EF (Group 1, EF < 40%, n = 142), mild LV dysfunction (Group 2, 40 ≤ EF < 50, n = 72) and normal EF group (Group 3, EF ≥ 50, n = 191). Clinical characteristics and laboratory findings were reviewed from medical records. They were followed at least 2 yrs. Clinical end-points were death or readmission due to congestive HF (CHF). Results: Total 191 patients (47.2%) had normal EF. They were older (69.82 ± 14.4, 71.85 ± 14.3 vs. 75.77 ± 11.4 years, p < 0.001) and female predominant (40%, 52.8% vs 70.2%, p < 0.001). Among the three groups, Gr 3 showed the least peak proBNP level (8717.89 ± 8789.2, 6226.40 ± 7871.5 vs. 5068.37 ± 6157.9, p < 0.001) and better CKMB and troponin level. 1-year and 2-year survival rates were not different in three groups (84.5% : 73.2%, 90.2% : 76.4% and 84.2% : 74.2%, p = 0.876). 2-year CHF-free survival rates were low in all groups but not different (57.7%, 66.7% vs. 65.3%, p = 0.260). These findings consisted with age and gender subgroups. Conclusions: LVEF was preserved in 47% of patients with acute decompensated heart failure. Their mid-term prognosis was as poor as those with reduced LVEF.

Reversible acute heart failure in young females

V Agrawal¹; JC Jagdish Mohan²¹Medanta Heart Institute, The Medicti, Cardiology, Gurgaon, India; ²Fortis Hospital, New Delhi, India, Cardiology, New Delhi, India

Background: There is an increased awareness and interest in young females who present with acute heart failure (AHF) or cardiogenic shock following physical or emotional discomfort. These physical stimuli can be time of ovulation, pre-menstrual discomfort, any forms of anaesthesia, abdominal surgery or caesarean section. Purpose. The purpose of this study is to report demographics of acute heart failure or cardiogenic shock in young females, their clinical and echocardiographic features, management and follow-up Methods: Eight young females (age range 19-38 years) who presented with acute heart failure with subsequent complete recovery of systolic and diastolic function over one week and without any known cause of AHF are reported.

Results: Four patients presented with acute pulmonary oedema, three had cardiogenic shock and one patient developed rash followed by syncope and persistent hypotension. Initiating events were caesarean section in two, acute on chronic cholecystitis in two, puncture for cardiac catheterisation, premedication before general anaesthesia and ovulation in one each and no identifiable initiating event in the remaining one. All the patients had evidence of global or segmental left ventricular systolic dysfunction, rise in BNP and troponins. None had associated right ventricular dysfunction or arrhythmias. Recovery was complete in all. One patient required Intra-aortic balloon pump insertion for four days. The patients in shock were managed with fluids and those in pulmonary oedema with diuretics and oxygen therapy. Ivabradine was used to control sinus tachycardia in five patients.

Conclusion: Transient global or segmental left ventricular systolic dysfunction leading to AHF or cardiogenic shock is rare in young females. Possibly, it is a variant of Takotsubo cardiomyopathy.

Clinical characteristics and outcomes of elderly patients with acute heart failure: a secondary analysis of the ALARM-HF registry

V Bistola¹; PS Simitsis¹; DF Farmakis¹; SK Katsanos¹; GB Bakosis¹;FF Follath²; AM Mebazaa³; IL Lekakis¹; GF Filippatos¹; JP Parissis¹¹Attikon University Hospital, Heart Failure Unit, Cardiology Department, Athens, Greece; ²University Hospital Zurich, Zurich, Switzerland; ³Hospital Lariboisiere, Department of Anesthesiology and Critical Care Medicine, Paris, France

Introduction: Clinical characteristics and outcomes of elderly patients with acute heart failure (AHF) differ from younger patients according to previous European and American registries.

Aim: To compare the clinical characteristics and in-hospital outcomes between elderly and younger patients with AHF who were enrolled in the global survey Acute Heart Failure Global Survey of Standard Treatment (ALARM-HF).

Methods: We performed a secondary analysis of the ALARM-HF, a retrospective survey via questionnaire that included 4953 AHF patients from 9 countries. Patients were divided to 2 age groups using a cut-off age of 75 years (elderly > 75, younger ≤ 75). Age groups were compared regarding their clinical characteristics and mortality up to either hospital discharge or 30 days of hospitalization.

Results: The group of elderly patients comprised 29% of the study population, and compared to the younger age group, included a higher percentage of female patients (49.4% vs 32.7% in the younger group, p < 0.001), and had more frequently a history of arterial hypertension (74.8% vs 68.3%, p < 0.001), coronary artery disease (36.6% vs 28.3%, p < 0.001), chronic HF (38.6% vs 35.4%, p = 0.033), atrial fibrillation (33.2% vs 20.9%, p < 0.001), and chronic renal dysfunction (28.9% vs 18.3%, p < 0.001); more frequently had as underlying cause of AHF arrhythmias (29.1% vs 26%, p = 0.029), infections (18.3% vs 15.5%, p = 0.017) and valvular heart diseases (15% vs 12.7%, p = 0.035); and more often presented with pulmonary edema (39.6% vs 35.6%, p = 0.008), with preserved systolic arterial pressure (> 110 mmHg: 69.8% vs 59.3%, p < 0.001), and preserved left ventricular ejection fraction (LVEF) (26.4% vs 21.8%, p = 0.004). Younger patients were more frequently than their elderly counterparts obese (28.3% vs 22.1% in elderly, p < 0.001) and current smokers (29.8% vs 8.5%, p < 0.001); more often had acute coronary syndrome as underlying cause (40.4% vs 28.4%, p < 0.001) and presented with cardiogenic shock (12.6% vs 9.6%, p = 0.003) with reduced LVEF (78.2% vs 73.6%, p = 0.004). In-hospital mortality of elderly patients was higher than their younger counterparts (13.5% vs 9%; median survival 24.7 ± 0.4 vs 26 ± 0.3 days, p < 0.001).

Conclusions: Elderly as compared to younger patients with AHF have more comorbidities and higher in-hospital mortality.

P827

Acute heart failure in patients with acute coronary syndrome: a retrospective analysis

A Andrew Solomonchuk¹; L. Rasputina²; YU Mostovoi²; V. Rasputin¹; V. Gladkykh¹

¹Municipal Institution "Vinnytsya Regional Center for Cardiovascular Pathology", Vinnytsia, Ukraine; ²Vinnytsya National Medical University named after M.I. Pyrogov, Propedeutics of Internal Medicine, Vinnytsia, Ukraine

Relevance: Acute heart failure (AHF) is a frequent complication of acute coronary syndrome (ACS) with ST-segment elevation. Presence of AHF is associated with a 3-4-fold increase in hospital mortality, in particular the incidence of cardiogenic shock ranges from 7% to 15%, and hospital mortality reaches 78%. Objective. The objective of our work was to assess the prevalence of AHF in patients with ACS, features of the sex-age structure and prognosis for such patients based on a retrospective analysis. Methods and materials. We conducted a retrospective analysis of the prevalence of AHF in patients with ACS (class III-IV) for 2010-2014 at the Cardiology Department of the city hospital. A total of 2167 patients were on treatment. 1938 patients were discharged from the hospital, 229 patients died. Results. It was established that the signs of AHF were diagnosed in 317 patients (14.63%). The sex structure of patients with AHF was distributed as follows: 185 were men (58.36%) with the average age of 64.8 ± 6.9 years, 132 were women (41.64%) with the average age of 76.8 ± 3.5 . The age characteristic of patients with AHF differs slightly among men and women, thus in the group aged 40 and under and in the age group aged 40-49 there were only men, and in the group aged 50-59 men dominated over women with 46 men (24.86%) and 8 women (6.06%) respectively, $p=0.05$; there was no significant difference between men and women in the group aged 60-69 with 28.65% and 28.03% respectively, whereas among patients older than 70 years AHF was found significantly more often among women than men: 36.22% and 65.91%, $p=0.05$. In 237 patients (75%) AHF was diagnosed with the first heart attack. Mortality after myocardial infarction is 229 people (10.57%). AHF has made significant contribution to the causes of death in patients with ACS: in particular, there were 114 deaths (49.78%). However, among the discharged patients there were 203 patients with early diagnosed AHF (10.47%).

Conclusions: Therefore, we found that the prevalence of AHF is quite substantial (14.63%) among patients who died, the share of people with AHF is 47.78%, there was no significant difference between men and women but AHF was diagnosed in men at a young age while in women at the age of over 70.

P828

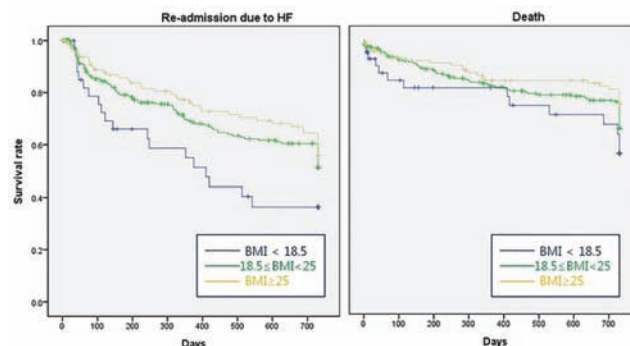

Body mass index and prognosis in acute decompensated heart failure

S-Y Song-Yi Kim¹; J-G Lee¹; J-H Choi¹; K-S Kim¹; S-J Joo¹

¹Jeju National University Hospital, Jeju, Korea Republic of

Purpose: In patients with chronic heart failure (CHF), previous studies have reported reduced mortality rates in patients with increased body mass index (BMI). The aim of this study was to determine whether BMI influences the mortality risk in acute decompensated HF.

Method: We enrolled 419 patients with AHF from Jan. 2005 to July 2013. They were divided into three groups; underweight group (Group 1, BMI < 18.5, n=43), normal (Group 2, $18.5 \leq \text{BMI} < 25$, n=253) and overweight to obese group (Group 3, BMI ≥ 25 , n=123). Clinical characteristics and laboratory findings were reviewed from medical records. They were followed at least 2 yrs. Clinical end-points were death or readmission due to congestive HF (CHF). Results; Patients of higher BMI group were younger (73.22 ± 12.7 vs. 70.82 ± 14.2 , $p=0.003$), less female portion (74 %, 53% vs. 55%, $p=0.036$) and had more diabetes (23%, 20.5% vs. 39%, $p=0.001$). Among the three groups, Gr 3 showed the least peak proBNP level (10745.29 ± 1894.6 , 8329.83 ± 557.8 vs. 3951.61 ± 376.8 , $p < 0.001$) and better echocardiographic parameters, such as LV EF and E/E'. By BMI category, patients who were normal and overweight had mortality risks that were 27.7% and 20.3%, respectively, lower as compared with the mortality risk of healthy weight patients with HF, whereas patients who were underweight had a 32.6%. 2-year heart failure rate and 2 year mortality were the highest in underweight group. (Cox hazard ratio 1.987, 95% CI; 1.15-3.43; $p=0.014$ and Cox hazard ratio 2.034, 95% CI; 1.06-3.92; $p=0.034$) Conclusions; In this single center cohort of hospitalized patients with acute decompensated HF, higher BMI was associated with a significantly lower mortality and readmission risk independent of other prognostic variables.

Chitotriosidase enzyme can be a negative acute phase protein in acute heart failure unlike coronary artery diseases

S Sara Cetin Sanlialp¹; BS Yildiz¹; B Barutcuoglu²; M Sanlialp³; A Ergin³; H Evrengul³; HA Kaftan³

¹pamukkale university, cardiology, Denizli, Turkey; ²Ege University, Izmir, Turkey;

³Pamukkale University, Denizli, Turkey

Introduction: Heart Failure (HF) is a complex, neurohumoral and inflammatory syndrome. Recent studies show that proinflammatory cytokines contribute heart's systolic or diastolic dysfunction causing cardiac depression. Chitotriosidase (CHIT), an enzyme released from active macrophages, plays a role in many diseases involving inflammation. Therewithal, it has been observed that CHIT activity in plasma is significantly high in ischemic heart diseases with arterial inflammation. This thesis aims to figure out the role of CHIT in HF and the relationship between other cytokines.

Method: 43 New York Heart Association (NYHA) class III/IV acute heart failure (AHF) patients who were hospitalized in the coronary intensive care unit (CICU), 48 chronic heart failure (CHF) patients and 45 healthy controls included in the study. All participants' detailed echocardiography, doppler and tissue doppler measurements were performed and left ventricular ejection fractions (LVEF) were calculated by Simpson method. All participants' plasma CHIT IL-1 β , TNF- α , IL-6, Hs-CRP and NT-proBNP levels were determined by ELISA method.

Results: The lowest CHIT activity in plasma ($527,876 \pm 323,04$ ng/ml) is detected in AHF patients. It was observed that when LVEF of acute heart failure patients decrease their CHIT activity levels decrease as well. Also a negative correlation ($p=0,038$ and $r=-0,32$) occurred between CHIT activity levels and NYHA class levels in AHF patients.

Conclusion: CHIT enzyme may play a role as a negative acute phase protein in AHF. Plasma CHIT value of AHF patients decreases when left ventricular systolic dysfunction increases and it is negatively correlated with NYHA values.

P830

Clinical characteristics, management and outcomes of very elderly patients hospitalized with heart failure in internal medicine units of Tuscany

C Bazzini¹; V Verdiani¹; G Panigada²; A Fortini³; L Masotti⁴; S Meini⁵; P Biagi⁶

¹Grosseto Hospital, Internal Medicine, Grosseto, Italy; ²Pescia Hospital, Internal Medicine, Pescia (PT), Italy; ³New Hospital San Giovanni di Dio, Internal Medicine, Florence, Italy; ⁴Hospital of Santa Maria Nuova, Internal Medicine, Florence, Italy; ⁵Santa Maria Annunziata Hospital, Internal Medicine, Florence, Italy; ⁶Nottola Hospital, Internal Medicine, Siena, Italy

Introduction: In Italy most of very elderly patients (pts), defined as age 85 years and older, with Heart Failure (HF) are admitted in Internal Medicine Units (IMU). In these pts HF is a major cause of morbidity and mortality and the prevalence

Abstract	60069		Correlation		Analyse		in		AHF		patients	
	NT-proBNP		hs-CRP		IL-6		IL-1		CHIT		TNF- α	
p	r	p	r	p	r	p	r	p	r	p	r	p
NYHA	0,683	0,06	0,433	0,12	0,665	0,07	0,359	0,14	0,038	-0,32	0,102	0,25
sPAP	0,226	0,19	0,090	-0,26	0,320	-0,15	0,087	-0,26	0,705	-0,06	0,707	0,06
LVEF	0,246	-0,18	0,678	-0,07	0,912	-0,02	0,064	-0,28	0,022	0,35	0,136	-0,23
RVEF	0,835	-0,03	0,035	-0,32	0,171	-0,21	0,546	-0,10	0,974	-0,01	0,938	-0,01

is expected to increase in the future. However these pts are under-represented in randomized clinical trials. The objective of the present study was to evaluate clinical characteristics, management and outcomes of unselected very elderly pts hospitalized with HF in IMU of Tuscany (Italian region with 3.7 million inhabitants). Methods. A multicenter observational study on pts consecutively hospitalized for HF between January 30th and February 28th 2014 in most of Tuscany IMU (32 of 35) was performed. There are not exclusion criteria. Clinical and echocardiographic data was collected; the degree of disability was calculated by Barthel Index. The pooled population (770 pts) was divided into two age groups: ≥ 85 years (groupA: n=365, age 89.3 ± 3.4 years) and < 85 years (groupB: n=405, 76.3 ± 7.6 years) for comparison. Results. Female gender was more common among the very elderly (64.9 vs 47.4%, $p < 0.0001$). In the groupA a lower prevalence for diabetes (27.7 vs 41.5%, $p = 0.001$), but an higher prevalence of chronic kidney disease (96.7 vs 90.4%, $p = 0.006$), dementia (46 vs 17.3%, $p < 0.0001$) and of three or more co-morbidities (78.3 vs 65.4%, $p = 0.001$) was evident. The echocardiogram was performed in 204 (55.9%) pts of groupA and in 287 (70.9%) pts of groupB ($p < 0.001$); a preserved ejection fraction was revealed in 45.6% of pts in the groupA and in 37.6% of groupB ($p = 0.989$). The mean length of hospital stay was comparable (groupA: 7.6 ± 4.3 days, groupB: 8.2 ± 5.3 days, $p = 0.098$). Overall in-hospital death occurred in 27 (7.4%) pts of groupA and in 19 (4.7%) of groupB ($p = 0.475$). At discharge in the very elderly a lower prescription of β -blockers, aldosterone antagonists, statins and warfarin ($p < 0.01$ for all), a greater disability (61.6% of pts with Barthel Index score ≤ 40 , $p < 0.0001$), a greater number of transfer in a nursing home or geriatric wards ($p = 0.02$) than groupB were observed; a follow-up program (home care or in-hospital program) was performed less frequently in older patients ($p = 0.02$ vs groupB).

Conclusions: This study revealed that in the real word of Tuscany IMU the very elderly constitute 47% of pts hospitalized with HF and that in these pts diagnostic and therapeutic approach is different from HF guidelines. The HF very elderly, compared with younger pts, are undertreated and the echocardiogram and follow-up program were carried out less frequently.

P831

Iron deficiency and anemia in acute heart failure: a problem?

L Reis¹; I Almeida¹; R Teixeira¹; A Fernandes¹; M Madeira¹; P Dinis¹; J Ribeiro¹; J Nascimento¹; L Goncalves¹

¹ University Hospitals of Coimbra, Coimbra, Portugal

Introduction: Anemia is a frequent comorbidity in heart failure and further worsens prognosis and disability. Regardless of anemia status, iron deficiency (ID) is a common and usually unidentified problem in patients with heart failure.

Purposes: To evaluate the prognostic impact of ID, with or without the presence of anemia, in patients (P) with acute heart failure (AHF).

Methods: Retrospective study with 201 P, admitted in a cardiac intensive care unit, between February 2010 and September 2015. The selected patients (n = 104) had a iron study done. Anemia has been defined with hemoglobin < 13 g/dL in men and < 12 g/dL in women. IF was classified according to the ferritin value: absolute IF – ferritin < 100 ng/mL; relative IF – ferritin between 100-300 ng/mL and transferrin saturation $< 20\%$. After the two variable association, the sample was divided into 3 groups: group 1 (G1: without anemia and without IF, n = 35), group 2 (G2: without anemia but with IF, n = 22) and group 3 (G3: with anemia and with IF, n = 27). Clinical follow-up (24 months) was performed targeting for readmission with AHF.

Results: The sample had an average age of 68 ± 14 years old with a majority of male (78%). In 28% P the etiology was ischemic. The average FEVE was of $33 \pm 12\%$. Readmission with AHF occurred in 38% and mortality was of 40%. Anemia has been identified in 51% of P. In what concerns to IF: 68% didn't have IF, 16% had absolute IF and 16% had relative IF. The groups presented similar clinical and analytical characteristics: congestive HF (G1 100% vs G2 91% vs G3 100%), ischemic etiology (G1 28%, G2 4.1% and G3 22%) and NT-proBNP values (G1 13270 ± 10513 pg/nL vs G2 13895 ± 16897 pg/nL vs G3 13895 ± 16897 pg/nL). Regarding therapeutics, most had intravenous diuretic (G1 72% vs G2 62% vs G3 63%). Inotropic support with dobutamine was used in all the groups (G1 24% vs G2 14% vs G3 26%) and levosimendan was predominantly used in G1 (G1 76% vs G2 32% vs G3 37%). Noninvasive ventilation was used in 52% of G1, 41% of G2 and 56% of G3. The survival rate was statistically similar for the 3 groups at 12 and 24 months (79% vs 63% vs 54% e 72% vs 51% vs 29%; Log rank $P = 0.089$).

The multivariate analysis showed that IF was not a predictor of follow-up events, even if there is an higher risk trend in this P (HZ = 2.3, HF 95% = [0.8-6.7], $P = 0.13$). Patients with both anemia and IF had a 3 times superior mortality risk (HZ = 2.8, HF 95% = [1.1-7.5], $P = 0.04$).

Conclusions: According to our data, the IF has an impact in the prognosis when associated with anemia, in patients with HF.

Adrenaline use is related to prominent deterioration in cardiac and renal biomarker profiles in cardiogenic shock

T Tarvasmaki¹; J Lassus²; A Sionis³; L Kober⁴; J Spinar⁵; M Banaszewski⁶; J Parissis⁷; S Di Somma⁸; A Mebazaa⁹; V-P Harjola¹

¹Helsinki University Central Hospital, Emergency Care, Helsinki, Finland; ²Helsinki University Central Hospital, Heart and Lung Center, Helsinki, Finland; ³Hospital de la Santa Creu i Sant Pau, Cardiology Department, Barcelona, Spain;

⁴Rigshospitalet - Copenhagen University Hospital, Division of Heart Failure, Pulmonary Hypertension and Heart Transplantation, Copenhagen, Denmark;

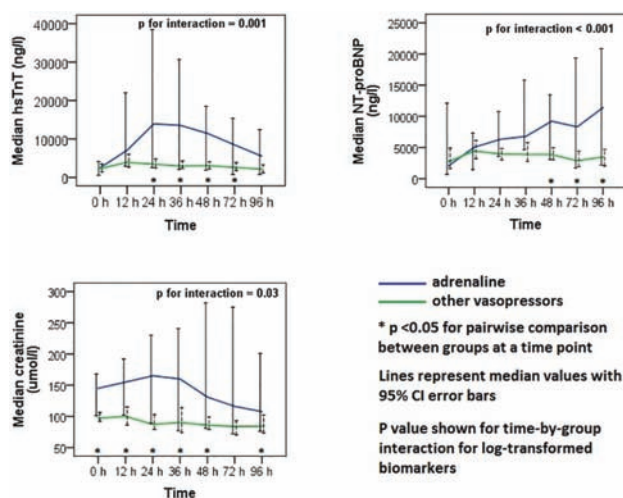

⁵University Hospital Brno, Department of Internal Medicine and Cardiology, Brno, Czech Republic; ⁶Institute of Cardiology, Intensive Cardiac Therapy Clinic, Warsaw, Poland; ⁷Attikon University Hospital, Heart Failure Clinic and Secondary Cardiology Department, Athens, Greece; ⁸Sant' Andrea Hospital, Emergency Medicine, Rome, Italy; ⁹Hospital Lariboisiere, INSERM U942, Paris, France

Purpose: Use of adrenaline has been proposed to be harmful in cardiogenic shock (CS) due to, for example, an increase in oxygen consumption and myocardial ischemia. We are, to our knowledge, the first to assess serial measurements of cardiac and renal biomarkers in patients with CS in order to detect patterns in injury and function of these organs over time in relation to adrenaline use.

Methods: The CardShock study is a European multicenter study including 219 patients with CS. Serial plasma samples were collected in 178 patients, of which 95 had samples taken until 96 hours from the study baseline. The samples were immediately frozen at -80°C . Creatinine, high-sensitivity troponin T (hsTnT) and NT-proBNP were analysed centrally. Use of vasoactive medications was registered until 96 hours from baseline. Survival analyses were performed with X2-test and propensity score adjustment. Differences in biomarkers at each time point between groups were analyzed with Mann-Whitney U test. Linear mixed modeling was used to analyse differences in changes of biomarkers between groups over time.

Results: Of the patients with baseline plasma samples, 146 received vasopressors. In this cohort, mean age was 66 (SD 12) years, 74% were men and 82% had acute coronary syndrome as CS etiology. Adrenaline was used in 29 (20%) patients whereas other vasopressors (noradrenaline, dopamine) were used in 117 (80%) patients. Overall 90-day mortality was 46% and significantly higher in adrenaline group vs other vasopressors: 90% vs 35%, $p < 0.001$. The strong association of adrenaline with increased mortality remained even after propensity score adjustment. Evolution of cardiac and renal biomarker levels were much worse in adrenaline patients over the first 96 hours (figure). Especially NT-proBNP levels persistently increased over time in adrenaline patients.

Conclusions: Compared with use of other vasopressors, adrenaline use was associated with markedly worse evolution of cardiac and renal biomarker profiles over the initial 96 hours in CS. This may, in part, explain significantly higher mortality among patients receiving adrenaline.

Optimisation of decongestion in acute decompensated heart failure: role of tolvaptan and aquapheresis.

Otsuka

ES Chung¹; C Dadosky¹; JL Jefferies²; GF Egnaczyk¹; TM O'Brien¹; SG Menon¹¹The Christ Hospital, Cincinnati, United States of America; ²Cincinnati Children's Hospital Medical Center, Heart and Vascular Center, Cincinnati, United States of America

Background: Symptom relief for acute decompensated heart failure (ADHF) requires decongestive therapies. Standard of care is based on loop diuresis, but vasopressin inhibition and aquapheresis offer additional options. We performed a single center pilot study in ADHF patients to compare these three approaches.

Methods: We enrolled 45 patients with ADHF with evidence of volume overload, BNP > 300, serum Na < 145, and serum creatinine < 3. They were randomized within 12 hours of admission to either 1) standard of care (SC) - continuous drip furosemide, 2) tolvaptan (Tol), SC plus daily dose of tolvaptan, or 3) aquapheresis (Aq). Data were collected at baseline, and daily until end of treatment or 4 days. Results Baseline characteristics were similar between the three groups. Volume loss in SC and Aq groups were similar, while greater in the Tol group. Dyspnea was similarly improved in all 3 groups. Effect of treatment on BUN, creatinine, and urinary nGAL suggest a neutral effect of SC and Tol on renal function, while Aq may lead to early renal injury. Conclusions In this pilot trial comparing three approaches to decongestion, the addition of tolvaptan to loop diuretic appeared to achieve the best balance between volume removal and renal injury. In contrast, aquapheresis did not remove more volume and was associated with worse quality of life and a rise in uNGAL.

Table

	Standard care (SC, n = 15)	Tolvaptan (Tol, n = 15)	Aquapheresis (Aq, n = 15)

Telephone intervention in chronic heart failureM May Khateeb¹; BB Bدير¹; TARA Conboy¹¹King Abdulaziz Medical City, Riyadh, Saudi Arabia

Background: Heart failure (HF) remains a serious global health problem associated with poor quality of life, diminished functional class and frequent hospital admissions which leads to heavy personal, social, and economic burdens. Nurse-based telephone interventions have been associated with clear clinical benefits for patients with HF, in the West; however, their effectiveness is unknown in this region. Objective The purpose of this study was to assess the effectiveness of a telephone intervention in patients with heart failure (HF) attending a nurse-led HF clinic in King Abdulaziz cardiac Center (KACC). Method Quality initiative project which assigned the first 50 consecutive HF patients to standard care in the nurse-led HF out-patient clinic (control group) and the second 50 consecutive patients to standard care in addition to a telephone intervention (Intervention group). Patient's symptoms, quality of life, risk factor control was followed over 3 months. Analysis was performed using SPSS Advanced Statistics for Windows, version 18. Result A total of 100 patients (75%

Male, mean age 62 years) were included in this study. The patients who received telephone calls showed improvement in blood sugar control and LDL control. Significant Improvement in medication adherence in the intervention group compared to the control group using Morisky Medication Adherence Scale (MMAS-8-Item) Conclusion Out comes Improves in the cardiac patient who received a Telephone follow on addition to regular care

P835

Is undiagnosed heart failure common on orthopaedic wards?EM Thet¹; RWG Prescott¹; RJH Gregory¹; C Johnstone¹; T Johnston¹;M Charnley¹; L Corkin¹; L Brooke¹; JJ Murphy¹¹County Durham and Darlington NHS Foundation Trust, Cardiology, Darlington, United Kingdom

Introduction: Approximately 1–2% of the adult population in the United Kingdom has heart failure (HF), with the prevalence rising to ≥10% among people aged 70 years or older. Osteoarthritis, rheumatoid arthritis and orthopaedic fractures share both risk factors for HF and potentially a common pathophysiology.

Purpose: To discover whether undiagnosed heart failure was common in patients on orthopaedic wards and to explore diagnostic strategies.

Methods: The study was conducted on 2 orthopaedic wards, one receiving elective admissions (group A) and the other receiving patients admitted following fragility fractures (group B). Between 20th January 2014 and 5th April 2015, 419 patients over the age of 65 were screened. After exclusion of patients with known heart failure, 100 consecutive new patients in each group consented to participate. Serum BNP was measured and if >35 ng/l (pg/ml), transthoracic echocardiography was performed using British Society of Echocardiography accredited physiologists. Diagnosis of heart failure was based on the European Society of Cardiology definition, sub-classified in to HF with preserved (HFpEF) or reduced (HFrEF) ejection fraction (EF).

Results: Of the 156 patients admitted for elective orthopaedic surgery, 10 (6%) were known to have heart failure. In the remaining group of 146, 100 patients agreed to participate in the study (mean age 74 years, female 57%, hypertension 35%, ischaemic heart disease (IHD) 4%, AF 3%, Diabetes 6%). 65% had possible heart failure symptoms and 6% had heart failure related signs. Their mean haemoglobin (Hb) was 133, creatinine 76, TSH 2.1, PT 11. ECG abnormalities were identified in 50% and chest X rays were suggestive of heart failure were 24%. The BNP level was above 35 pg/ml in 52% (maximum 677 pg/ml) of which 3 had HFpEF and 3 had asymptomatic low EF (6% undiagnosed HF). In the 263 patients with fragility fractures, 39 (15%) had known HF, and a further 14 (5%) were diagnosed with heart failure by the clinical team following admission. Of the remaining 210, 100 consented to participate (mean age 82 years, female 83%, hypertension 31%, IHD 7%, AF 8%, Diabetes 8%). 57% had heart failure related symptoms and signs. Their mean Hb was 108 (post fracture), creatinine 78, TSH 2.1, PT 12.8 (within normal range). ECG abnormalities were found in 58% and the CXR was suggestive of heart failure in 23%. BNP level was above 35 pg/ml in 84% (maximum 759 pg/ml) and 3 proved to have HFrEF, 10 had HFpEF and 1 has asymptomatic low EF (14% undiagnosed HF).

Conclusion: Patients with fragility fractures were older and had more risk factors for HF. 84% had a serum BNP above the threshold of which 17% had heart failure. Screening for undiagnosed heart failure identified a significant number of new cases, particularly in the fragility fracture population. Screening for HF should be considered in orthogeriatric units.

P836

Cardiac tumor mimicking heart failureJ Joffrey Eduardo Lujan Valencia¹; F Lopez Valdivieso¹; C Fernandez Vivancos¹; CGonzalez Matos¹; P Caravaca Perez¹; A Garcia Guerrero¹; R Hidalgo Urbano¹¹Virgen Macarena University Hospital, Sevilla, Spain

Introduction: Cardiac tumors (CT) are extremely rare and may be asymptomatic or have symptoms that mimic heart failure (HF). We studied the cases simulating HF in order to recognize the different pathophysiologies than can cause these symptoms.

Method: We retrospectively reviewed patients with a diagnosis of CT from 1979 to 2015 and analyzed the most outstanding of these epidemiological characteristics. Our sample was selected from a surgical serie so that data may differ from other series.

Results: We found 55 cases of which 30 CT simulated HF symptoms. Average age was 55 ± 17 years, with a 57% of women. The diagnosis was achieved by transthoracic echocardiography in 83% of cases. With regard to histopathological diagnosis, 20 were benign tumors (66.7%), being mostly of them myxomas and only one hamartoma. Of the remaining 10 CT, two patients were cardiac angiosarcomas and 8 were secondary tumors. The most common symptoms were dyspnoea (100% of patients), congestive heart failure (33%), palpitations or oedema (16%) and constitutional syndrome (13%). Regarding the pathophysiology of the symptoms, fourteen (46.7%) cases were due to valvular obstruction in the outflow tract, seven (23%) to direct invasion of the myocardium or pericardium; among other causes, there were two (6.7%) cases of pulmonary embolism, two (6.7%) adjacent lung invasion or

metastasis, one (3.3%) case of valvular regurgitation, three (10%) cases of constitutional syndrome and five (16%) cases from unknown causes. No patient died during surgery and mortality directly related to the tumor during follow-up was 23.3%, in all cases they were malignant neoplasms.

Conclusions: Cardiac tumors can mimic symptoms of HF through different mechanisms. Despite they are an unfrequent etiology of heart failure or dyspnoea, it's adequate diagnosis is mandatory because they are in most cases treatable causes.

P837

Prognostic value of hyponatremia among patients with chronic heart failure

D Dalila Elbaghdadi¹; F Arhlade¹; A Asadi¹; R Habbal¹

¹Ibn Rochd University Hospital, cardiology, Casablanca, Morocco

Background: Hyponatremia - lowering of sodium in blood serum below 135 mmol/l - is a frequent disorder of electrolyte metabolism in patients with chronic heart failure (CHF). It is an established predictor of adverse outcomes in hospitalized patients with reduced ejection fraction (EF).

Aim: To evaluate the incidence of hyponatremia in ambulatory patients diagnosed with chronic heart failure in order to establish a correlation with the risk factors, evolution and prognosis.

Methods results: We examined the prevalence, risk factors, and long-term outcomes of hyponatremia (serum sodium ≤ 135 mEq/L) in ambulatory HF with reduced EF. The cohort consisted of 1240 admitted in the therapeutic unit of heart failure (TUHF) between 2006 and 2014.

Hyponatremia was present in 19.6 %. Mean serum levels of natremia and were 131.3 meq/l. Hyponatremia was associated with male sex, diabetes, stroke attack, coronary heart disease. Compared with normonatremic patients, those with hyponatremia had lower systolic blood pressure and lower functional capacity during six - minute walk. Also, Hyponatremia was associated with cardiac decompensation, diastolic dysfunction ($p=0.014$), severe renal insufficiency and higher doses of diuretics ($p<0.0001$), whereas beta-blockers were inversely associated ($P<0.0001$).

Conclusion: Patients with heart failure and hyponatremia showed a higher risk of long-term morbidity than patients without.

P838

Risk stratification for heart failure: comparison between the new proposed HLM classification and the classic NYHA

P Paolo Severino¹; S Calcagno¹; M Pucci¹; MP Germano¹; M Mancone¹; F Fedele¹

¹Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrology, Anesthesiology and Geriatric Sciences, Sapien, Rome, Italy

Purpose: Among all HF classifications, NYHA is the most commonly used. However, it doesn't include a global clinical evaluation of patients, nor the assessment of other organs involvement. We proposed HLM classification, a new staging system for HF, similar to the TNM evaluation used in Oncology. HLM refers to heart damage (H), lung involvement (L), and malfunction of peripheral organs, such as kidney, liver, brain and hemopoiesis. The aim of this study was a preliminary comparison between HLM and NYHA in HF patients, to work out the most accurate prognosis in term of rehospitalization and mortality.

Methods: We performed a prospective and observational registry of 500 consecutive patients. Any alterations in heart (H instead of T), lung (L instead of N), organs as kidney, liver, brain and blood (M as Multiorgan, instead of Metastasis), was evaluated, based on HLM nosology. Four stages were determined by the sum of H, L and M values (i.e. score): stage 1 (score of 1 or 2); stage 2 (score 3-4); stage 3 (score 5-6); stage 4 (score >6). Each patient was also classified according to the NYHA system.

Results: Among 500 patients, regarding to the "H" parameter, left ventricular (LV) systolic dysfunction rate was 8.45%, right ventricle systolic dysfunction rate was 12.42%, LV diastolic dysfunction was 19.22%. Regarding to the "L" parameter, 70% of patients showed a pulmonary involvement. Regarding to the malfunction of other organs, kidney was involved in 8.45% of patients, liver in 37.1%, brain in 9.7%, blood in 21.33%. According to HLM, patients were classified as follows: 13.4% in stage 1; 36.77% in stage 2; 44.2% in stage 3 and 5.76% in stage 4. Considering the NYHA classification, 7% was in class I, 45% in class II, 41.27% in class III and 5.81% in class IV. The mortality rate for each stage of HLM and NYHA, the mortality rate was: 0% in HLM 1 vs 0% in NYHA I ($p=1.000$); 2.6% in HLM 2 vs 4.4% in NYHA II ($p=0.559$); 10.7% in HLM 3 vs 13.2% in NYHA III ($p=0.508$); 52.1% in HLM 4 vs 21.7% in NYHA IV ($p=0.065$). The rehospitalization rate was as follows: 0% in HLM stage 1 vs 0% in NYHA I ($p=1.000$); 4.7% in HLM stage 2 vs 6.5% in NYHA II ($p=0.633$); 14.2% in HLM 3 vs 16.1% in NYHA III ($p=0.55$); 60.6% in HLM 4 vs 26.2% in NYHA IV ($p=0.037$). ROC curve analysis shows a AUC=0.663 for HLM versus a AUC=0.547 for the NYHA classification (Figure 1).

Conclusions: HLM classification seems to be more accurate than NYHA to stratify risk for HF patients in term of rehospitalization and mortality, mostly in advanced stages. According to our preliminary data, HLM can be useful for the physician in the patient management and to perform the best patient-centered therapy. Differently from NYHA, HLM includes the evaluation of objective parameters of cardiac, pulmonary and multi-organ involvement.

P839

Altered left ventricular diastolic function in subjects with spinal cord injury

J R De Rossi¹; L G T Zacharias¹; W Cirillo²; W Nadruz Jr¹; J R M Jose Roberto Souza²

¹FCM-UNICAMP, Campinas, Sp, Brazil; ²UNICAMP - State University of Campinas, Department of Cardiology, Campinas, Brazil

Purpose: Subjects with spinal cord injury (SCI) have increased cardiovascular risk in comparison to able-bodied ones. This study investigated the cardiac structure and function of SCI individuals and the impact of metabolic, hemodynamic and inflammatory factors in this regard.

Methods: We evaluated 65 nondiabetic, nonhypertensive, nonsmoker men (34 with SCI and 31 healthy subjects) by medical history, blood pressure measurement, hemodynamic parameters, anthropometry, routine laboratory tests, echocardiography and tissue doppler imaging. Seric levels of C-reactive protein (CRP), TNF-Receptors I and II, ICAM-1, VCAM-1, E-selectin and TGF-beta were also assessed. Data are given as mean \pm standard error.

Results: SCI (18 quadriplegic and 16 paraplegic) subjects had similar age, body mass index, cardiac output, glucose and lipid levels, but lower systolic blood pressure (109 ± 3 vs 120 ± 2 mmHg; $p=0.09$) in comparison to controls. Injured individuals exhibited higher levels of CRP (6.2 ± 1.7 vs 1.1 ± 0.3 mg/mL; $p=0.001$), TNF-Receptor I (1.81 ± 0.13 vs 1.48 ± 0.14 ng/mL; $p<0.05$) and TNF-Receptor II (3.14 ± 0.05 vs 2.93 ± 0.07 ng/mL; $p<0.05$) than able-bodied ones. SCI group presented similar left ventricular (LV) structural and systolic parameters, but lower Em (9.2 ± 0.5 vs 12.3 ± 0.5 cm/s; $p<0.0001$) and higher E/Em ratio (7.7 ± 0.5 vs 6.1 ± 0.3 ; $p<0.01$) compared to controls, even after adjustment for CRP. Conversely, we found that SCI subjects with E/Em > 8 ($n=13$) had lower Sm, cardiac output and higher relative wall thickness than SCI individuals with E/Em < 8 ($n=24$) but similar age, body mass index, blood pressure, injury level, metabolic parameters and inflammatory markers.

Conclusion: Subjects with SCI presented impaired LV diastolic function in comparison to able-bodied ones. In addition, worse left ventricular diastolic function was paralleled by signs of reduced volemia, a pattern of LV concentric remodeling and decreased systolic function among subjects with SCI. These findings might contribute to explain the increased cardiovascular risk reported for SCI individuals.

P840

Metabolic effects of betablockers, assessed by cardiac magnetic spectroscopy, in patients with systolic heart failure

R Roberto Spoladore¹; G Fragasso¹; G Perseghin²; G Calori¹; F De Cobelli¹; A Del Maschio¹; A Margonato¹

¹San Raffaele Hospital (IRCCS), Milan, Italy; ²University of Milan-Bicocca, Milan, Italy

Background: The addition of Betablockers to standard treatment has been shown to improve left ventricular (LV) function in patients with systolic heart failure. The aim of this study is to non-invasively assess, by means of in vivo ³¹P-magnetic resonance spectroscopy (³¹P-MRS), the effects of betablockers on LV cardiac phosphocreatine and adenosine triphosphate (PCr/ATP) ratio in patients with systolic heart failure.

Methods and Results: Ten heart failure patients (pts) on full medical therapy were beta-blocked by either carvedilol (6 pts) or bisoprolol (4 pts). Before and after three months of treatment, exercise testing, 2D echocardiography, MRS, New York Heart Association (NYHA) class, ejection fraction (EF), maximal rate-pressure product and exercise metabolic equivalent system (METS) and NT-pro BNP analysis were evaluated. Relative concentrations of PCr and ATP were determined by cardiac ³¹P-MRS. After beta-blockade, NYHA class decreased (from 2.2 ± 0.54 to 1.9 ± 0.52, p = 0.05), whereas EF (from 33 ± 7 to 44 ± 6%, p = 0.0009) and METS (from 6.74 ± 2.12 to 8.03 ± 2.39, p = 0.01) increased. Accordingly, the mean cardiac PCr/ATP ratio increased by 33% (from 1.48 ± 0.22 to 1.81 ± 0.48, p = 0.03). Serum NT-pro BNP improved (from 1831 ± 1360 to 1023 ± 641 pg/ml; p = 0.04).

Conclusions: Beta-blockade induced symptomatic and functional improvement in patients with systolic heart failure is associated to increased PCr/ATP ratio, indicating preservation of myocardial high-energy phosphate levels.

P841

Multi-biomarker strategy improves prediction of mortality in heart failure and aortic stenosis

R&D Grant

A Cai¹; R Dworakowski¹; N Sunderland¹; S Piper¹; T Gibbs¹; S Redding¹; O Wendler¹; J Byrne¹; P Maccarthy¹; T McDonagh¹

¹King's College Hospital, London, United Kingdom

Background: There is an increasing number of serum biomarkers that are validated in studies to assess prognosis in patients with a variety of cardiovascular disease. However, many of these studies involving heart failure do not standardise optimal medical management and even fewer studies have investigated the role of biomarkers in severe aortic stenosis.

Purpose: We intended to investigate how novel and traditional biomarkers predicted outcome in patients with severe non-valvular heart failure (EF < 40%) who were on optimal medical and device therapy according to latest ESC guidelines or severe aortic stenosis who were undergoing transcatheter aortic valve implantation (TAVI) to assess how individual or panel of markers could add to the clinical assessment of these patients.

Methods: We studied 140 patients and obtained baseline biomarkers including NT-pro BNP, ST2, Galectin3, Osteopontin, PIIINP, TIMP1 and cardiotrophin. Patients were followed up for up to 2 years. Statistical analysis was performed on SPSS 22, outcome was analysed by Kaplan Meier curves and the receiver operating characteristics were analysed as a continuous variable per individual biomarker and as a panel, this was added as a total area under the curve.

Results: Area under the curve for ST2 at baseline appeared to be the most promising of all the biomarkers (0.612) compared with NT-pro BNP (0.610), TIMP1 (0.610), Cardiotrophin (0.602) Osteopontin (0.601), PIIINP (0.353), Galectin 3 (0.370) for 1 year mortality; 2 year mortality was similar. However, when novel biomarkers were combined (cardiotrophin, osteopontin and TIMP1), this improved the AUC (0.690). Adding ST2 and BNP gave AUC of 0.721.

Conclusions: A multi-biomarker adds to the assessment of high risk patients in both severe aortic stenosis and heart failure, and larger trials should be performed to validate their use in prognostic scoring.

P842

Clinical-pharmacist intervention reduces clinically relevant drug-drug interactions in patients with heart failure: a randomized, double-blind, controlled trial

M Lainscak¹; T Roblek²; A Deticek²; B Leskovic³; M Horvat⁴; A Belic⁴; A Mrhar²; S Suskovic⁵

¹General Hospital Celje, Celje, Slovenia; ²University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia; ³General Hospital Trbovlje, Trbovlje, Slovenia; ⁴Lek d.d., Ljubljana, Slovenia; ⁵University Clinic of Respiratory and Allergic Diseases Golnik, Division of Cardiology, Golnik, Slovenia

Background: Incidence of drug-drug interactions (DDIs) increases with the complexity of treatment regimens and comorbidities, as observed in heart failure (HF). Clinically relevant DDIs need to be identified and managed accordingly. This randomized, double-blind study evaluated the intervention of the pharmacist on the prevalence of clinically relevant DDIs (NCT01855165).

Methods: Patients admitted with acute HF were screened for clinically relevant DDIs, and randomized into the control or intervention group. The attending physician in the control group received standard advice about pharmacological therapy. In the intervention group, the attending physician received written alerts about clinically relevant DDIs. The primary endpoint was prevalence of clinically relevant DDIs on admission and at discharge.

Results: Of 213 screened patients, 51 (mean age, 79 ± 6 years; male, 47%; eGFR, 49 ± 22 mL/min/1.73 m²) had a total of 66 clinically relevant DDIs and were randomized. The most common DDIs were between angiotensin-converting enzyme inhibitors or angiotensin receptor blockers and spironolactone (14% of all DDIs). In the intervention group (n = 26), compared to the control group (n = 25), significantly fewer patients had clinically relevant DDIs at discharge (8 vs. 18; p = 0.003). Similarly, the total number of clinically relevant DDIs at discharge was significantly lower in the intervention group than in control group (10 vs. 31; p = 0.0049). From admission to discharge, in the control group, the number of clinically relevant DDIs was reduced (46 vs. 31; p = 0.018), and further in the intervention group (40 vs. 10; p = 2.08 × 10⁻⁶). During the 6-month follow-up, 11 patients in the control group and 9 in the intervention group were re-hospitalized or died. No significant differences were seen between the control and intervention groups for the group of patients (78%) with eGFR < 60 mL/min/1.73 m², in terms of the composite of death or re-hospitalizations (10 vs. 7; p = 0.74).

Conclusions: The pharmacist intervention significantly reduced the number of patients with clinically relevant DDIs and the number of clinically relevant DDIs. However, this did not reduce the clinical endpoints 6 months after discharge.

P843

Persistent referral of stable heart failure patients to primary care using a seamless heart failure care program

M Niesing-Lut¹; C M H B Caroline Lucas¹; P Van Pol¹; A Van Haarlem¹; J Eysink Smeets¹; J Flaman-Vd Hoogt¹

¹Rijnland Hospital, Leiderdorp, Netherlands

Purpose: Since 2013 a seamless heart failure program has been applied in the region Alphen a/d Rijn in the Netherlands. Purpose of the program has been to share care for heart failure patients across all lines of care as a method to cope with the rise in number of heart failure patients. As has already been shown in 2015 there has been a marked increase in number of stable patient being referred to primary care compared to previous years. As the program itself has been expanded including more primary care facilities additional numbers have been collected in 2015 about this referral to primary care including reasons for referral.

Methods: Data have been collected about all heart failure patients being referred to primary care for their HF care in the region around Alphen a/d Rijn. Numbers collected from 2000 until 2013 have been compared to numbers from 2014-2015 during those years that the seamless heart failure program has been conducted.

Results: For 100 patients in this region, total heart failure care responsibility has been taken by the general practitioners in the years from 2000 until 2013. In this same region from 2014 until the end of 2015 74 patients in total have been discharged from the heart failure outpatient cardiology clinic to primary care. Five patients because of complete recovery of left myocardial function, 22 because of stable heart failure, 3 because of endstage heart failure and 22 patients because of frailty. Twelve patients were discharged because of other reasons. After referral to primary care 16 of the 74 patients have deceased. Three out of these 74 patients were rehospitalized, all 3 previously been discharged because of endstage heart failure or frailty. None of the remaining 55 patients have been referred back to the heart failure outpatient clinic.

Conclusion: A seamless heart failure care program as has been started several years ago results in progressive referral of a large group of HF patients to primary care. Majority because of stable heart failure or frail patients. As the numbers show, it appears safe to do as it does not result in large numbers of rehospitalized patients or patients being referred to the outpatients heart failure clinic. This referral can be an important method to be able to cope with the growing number of heart failure patients in the future. As number of patients included in this heart failure program will grow in the near future prospective data will be collected about the future follow-up of these patients.

P844

Comparison of the effects of two training modalities on chronic heart failure patients.

N Dimaki¹; M Andriopoulou¹; A Damoulianos¹; K Karzis¹; E Chamodrakas¹; K Kifnidis¹; A Manolis¹

¹Asclepion Voulas Hospital, Cardiac Rehabilitation, Athens, Greece

Introduction: Chronic Heart Failure (CHF) as the common final stage of all heart diseases is associated with significant mortality and morbidity. Clinical characteristics of CHF include dyspnoea, fatigue and exercise intolerance. Current evidence has recommended exercise-based cardiac rehabilitation (CR) programs as a key component in the management of CHF patients aiming to the reduction of symptoms and the improvement of clinically relevant outcome parameters. The best established training modalities in CHF are Moderate Intensity Continuous Exercise (MICE) and High Intensity Interval Training (HIIT). However, the optimum exercise modality remains unclear. **PURPOSE:** The objective of this study was the comparison of the two prevalent training programs (MICE vs HIIT) in CHF patients.

Methods: 15 haemodynamically stable patients with CHF (NYHA II, III) were divided into 2 groups and followed a 3 months supervised exercise program (3 times per week). Group A (n = 8, mean aged 75.25 y, SD ± 5.6) followed MICE program on

treadmill (60-80% of Heart Rate Reserve) and group B (n=7 mean aged 59.3 y., SD ± 11.4) followed HIIT program on cycle ergometer (30/60 s). Additionally, both groups performed functional resistant lower limbs exercise program (squat, toe standing, step ups). Blood pressure, oxygen saturation and heart rate were monitored at each session using the Cardiowise software. All patients were assessed prior to and after the 3 months CR program with the six minute walking test (6MWT). **Results:** T-test was used for the statistical analysis and p-value level was set at 0.05. Group A showed statistically significant increase at mean walking distance from 387,25 m (SD: $\pm 78,5$ m) to 461,6m (SD: $\pm 70,4$ m) ($p < 0.05$). Respectively, group B increased the mean walking distance from 494 m (SD: $\pm 135,8$) to 559m (SD: $\pm 154,5$) ($p < 0.05$). However, comparing the improvement to mean walking distance of group A (MO: 73,8, SD: $\pm 23,8$) with that of group B (MO: 64,7, SD: $\pm 9,6$), there was no statistically significant difference ($p = 0.3$). **Conclusions:** Supervised exercise-based CR programs improve exercise intolerance in CHF patients regardless of the training modality used.

P845

Rivaroxaban in resolution of thrombus in the left ventricle

V Vanessa Carvalho¹; PM Sarmento¹; J Sa¹

¹Hospital Luz, Internal Medicine, Lisbon, Portugal

Treatment efficacy of new oral anticoagulants (NOACs) for prevention of thromboembolism in patients with thrombus in the left ventricle (LV) was not determined. The authors (AA) intended to demonstrate the efficacy and safety of Rivaroxaban in patients with thrombus in LV.

Material and Methods: The AA present a case series of patients with thrombus in the left ventricle in whom was used Rivaroxaban as anticoagulant.

Resultados: 4 patients were included: 3 men, mean age 65.5 ± 17.5 years. 50% of patients were hospitalized for decompensated heart failure, 25% for myocardial infarction and 25% for left hemiparesis. All patients had LV systolic dysfunction with a mean ejection fraction of 37%. The most sensitive method for visualization of thrombi was MRI. 1 patient initially started anticoagulation with warfarin, while one with enoxaparin. 50% of patients started immediately anticoagulation with Rivaroxaban. The doses used were 15 mg and 20 mg 50% to 50%. 75% of patients had thrombus resolution. There were no complications with anticoagulant treatment. A patient is waiting for an echocardiogram to confirm the disappearance of thrombus. **Conclusion:** The Rivaroxaban showed to be an effective and safe therapeutic treatment of patients with a thrombus in the left ventricle. Larger scale studies should be conducted to verify the results.

Do oral nitrates affect all-cause mortality and hospitalization in systolic heart failure?

D Dilek Ural¹; A Kandemir²; K Karauzum¹; C Baydemir²; I Yilmaz¹; S Bozyel¹; G Kozdag¹; A Agacdiken¹

¹Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey; ²Kocaeli University, Department of Biostatistics, Kocaeli, Turkey

Background and Purpose: Hydralazine-nitrates combination is a recommended therapy for systolic heart failure (HFrEF) patients who are symptomatic despite optimal medical therapy. However, use of nitrates alone on top optimal therapy is controversial. They are effective for relieving angina in associated coronary artery disease; but, are not shown to affect clinical endpoints. This study aims to evaluate the association of oral nitrates usage with all-cause mortality and hospitalization risk in HFrEF patients.

Methods and Results: This study was a retrospective propensity-matched analysis of HFrEF patients attending a HF clinic between years 2003 and 2014. Nitrates use at baseline and its association with all-cause mortality and HF hospitalization was examined in median 56 months (range 6-132 months) follow-up. Of 648 patients (mean age 65 ± 12 years; 65% men), 216 (33%) were prescribed oral nitrates. After propensity-matching, 212 couples were established according to presence and absence of baseline nitrates usage. During the follow-up period, 269 (42%) patients died. In Cox regression analysis, oral nitrates use was associated with a slightly increased mortality risk compared to not using nitrates (HR = 1.29; 95% CI 1.01-1.65; $p = 0.040$), but this was not statistically confirmed by the propensity-matched analysis (HR = 1.26; 95% CI 0.95-1.68; $p = 0.102$). In both prematch and propensity matched analysis, nitrates use was not associated with risk of hospitalization. Evaluation of the effects according to presence or absence of coronary artery disease did not change these findings. **Conclusions—**In this study, oral nitrates therapy in HFrEF patients did not affect all-cause mortality and hospitalization risk during long-term follow-up.

Aldactone in Patients with Heart failure: Friend or Foe?

MAY Alkhateeb¹; BB Bdier¹; TARA Conboy¹

¹King Abdulaziz Medical City, King Abdulaziz Cardiac Center, Riyadh, Saudi Arabia

Background: The guidelines recommend using spironolactone in moderate to severe heart failure (HF) and reduced left ventricular systolic function, if there is no contraindication. Spironolactone was shown to have a significant mortality and morbidity benefit in the placebo-controlled trials. **Objective:** To study the frequency and causes of discontinuing spironolactone in Saudi HF patients in HF nurse-led clinic at King Abdulaziz medical city (KAMC) cardiac center. **Method:** A Retrospective observational study which included all patients with HF enrolled from 2000 -2010 who were prescribed spironolactone at any period and had at least one follow-up visit. **Result:** A total of 565 patients (49 % Male, mean age 55.6 years) were included in this study. Spironolactone was discontinued in 277/565 patients (49 %); 187/565 patients (33 %) were discontinued secondary to improved ejection fraction (EF) and/or functional class; 83/565 patients (14.3 %) were stopped due to worsening renal function and/or hyperkalemia ; other side effects such as hypotension, gynecomastia affected the remaining < 1%.

Conclusion: Nearly half of Saudi HF patient discontinue Spironolactone within 2 years ;the majority of the discontinuation is due to improved EF or/and functional class.

P848

The magnitude and management of chronic heart failure in the netherlands

S De Groot¹; S Sadacharan¹; GCM Linssen²

¹Novartis Pharma B.V., Medical Affairs CardioMetabolic, Arnhem, Netherlands;

²ZiekenhuisGroep Twente, Department of Cardiology, Almelo, Netherlands

Purpose: To understand the magnitude and management of patients with chronic heart failure (CHF) in the Netherlands (NL) in order to identify possible opportunities to improve medical care.

Methods: A survey of cardiologists in NL utilizing a structured iPad-based questionnaire with the following items: number of patients CHF per hospital; most valued diagnostic tool in CHF; use of biomarkers in CHF; therapeutic decisions based upon biomarkers; first line treatment for CHF; conditions for a change in CHF therapy; preferred change in CHF therapy; follow-up in outpatient setting; involvement and tasks of heart failure nurses.

Results: A total of 31 cardiologists, representing 34% of hospitals in NL, took part in this survey conducted from Sept 2015 to April 2016. Preliminary data based on 12 hospitals are presented. On average 1095 patients with CHF per hospital are managed in an out-patient setting. Echocardiography (100%) was valued most when confirming the diagnosis of CHF, followed by physical exam (67%), ECG (50%), cardiac biomarkers (50%) and chest X-ray (25%). The use of (NT-pro)BNP in the management of CHF was reported by 83% of the respondents. Therapeutic decisions based on fluctuations in biomarkers were made: up-/down titration of the existing CHF therapy (92%), followed by the addition of a new therapy (33%). Preferred first line treatment for new CHF patients consisted of an ACE-inhibitor and a beta blocker with (57%) or without (21%) a diuretic. A change in CHF therapy was considered when signs and symptoms worsened (92%), a rise in biomarkers (42%), pre-discharge (50%) or post-discharge (17%) following an acute event. 91% of respondents would prefer up- or down titration of the existing CHF therapy when considering a change in therapy. A patient would visit the outpatient between 2 to 8 times depending on the stability of their CHF. 92% of hospitals have dedicated heart failure nurses, who provide patient education (100%), up titrate existing CHF therapy (100%), initiate new medical therapy on request of the physician (58%) and perform in-practice monitoring (50%).

Conclusions: Extrapolating the results of this survey to all cardiology outpatient clinics in the NL 84% of CHF patients in the NL would be under supervision in an outpatient setting, assuming a prevalence of 130.000 CHF patients (Dutch Heart Foundation, 2012). Guideline recommended therapy for new CHF patients is strictly adhered. Biomarker guided management of CHF is not well-embedded into daily practice yet. Dedicated heart failure nurses continue to play a profound role in the management of CHF in the NL.

Risk predictors of heart failure in STEMI patients on mid-term follow-up

A Alexandru Scafa Udriste¹; O Tautu¹; V Bataila¹; M Micheu¹; C Zaharescu¹; L Calmac¹; B Dragoescu¹; GP Tatu Chitioiu¹; M Dorobantu¹

¹Emergency Hospital Bucharest, Bucharest, Romania

Purpose: The present study aims to identify in-hospital risk predictors to develop heart failure in ST-elevation myocardial infarction (STEMI) patients

Methods: A questionnaire based study analysed a total of 493 consecutive STEMI patients treated by primary PCI in a single centre, with a follow up period for over 3 years. The main question was addressing heart failure symptoms - evaluates the exertion capacity using as a parameter the number of floors the patients were able to climb without experiencing heart failure symptoms. Thus the exertion capacity was quantified in 4 levels (similar to NYHA classes). **Results :** The mean age of the study group was 64,56 years (IQR: 27 – 89), there were more men (351; 71,1%) and the mean follow-up time was 3,29 years. The prevalence of smoking in study population was 37,7 % and 68,8% were hypertensives. 23,1% of patients were diabetes mellitus and 54% had dislipidemia. The discharge mean LV (left ventricle)

ejection fraction was 42,87% (IQR: 10 – 60). 96.3% were in sinus rhythm, 3.3% of patients were in atrial fibrillation and 0.4% were in rhythm of pacemaker. Follow up treatment in STEMI patients was with beta-blocker in 86,9%, with renin-angiotensin aldosterone system (RAAS) inhibitor in 73,6%, with diuretic in 35% and with statin in 84%. The significant correlations were found between exertion capacity and ejection fraction ($p=0,014$), but also with age ($p<0,01$), gender ($p<0,01$), hypertensive ($p<0,01$), smoking ($p<0,01$) and cardiac rhythm ($p=0,011$). Patients being treated with RAAS inhibitors had a better exercise capacity, while those with diuretic treatment was poorer.

Conclusions: It is well known as the LV ejection fraction is an independent predictor of evolution after myocardial infarction. Our study showed that in STEMI patients the appearance of heart failure symptoms is also associated with older age, female gender, smoking, hypertension and non-sinus rhythm. The beta-blocker therapy did not influence their exertion capacity, but the patients with RAAS inhibitors appear to have a better quality of life, and those requiring diuretic treatment have a reduced exercise capacity.

P850

Flu vaccine reduces recurrent hospitalizations in heart failure outpatients

H Hakki Kaya¹; MB Yilmaz¹

¹Cumhuriyet University, Cardiology, Sivas, Turkey

Purpose: to evaluate the influence of regular annual flu vaccination onto cardiovascular (CV) death and HF-related hospitalization in chronic stable HF outpatients

Methods: Turkish Research Team-HF (TREAT-HF) network has been testing a questionnaire to investigate several aspects of HF outpatients. TREAT-HF 1 and 2 cohorts were recorded in the last month of 2013 and 2014 overall reaching 1003 HF outpatients out of 16 HF centers. Follow up data were available for 657 patients for hospitalizations.

Results: Mean EF was $32 \pm 8\%$ with a mean follow up of 15 ± 6 months. Other baseline characteristics, which were significantly different between vaccinated and not vaccinated patients, were presented in Table 1. At the end of follow up; 113 (18%) patients experienced CV death with no significant difference in between those who had flu vaccine versus who did not (16% vs 19%, $p=0.377$). 303 (46%) patients experienced recurrent HF-related hospitalization. Rate of recurrent HF-related hospitalization was lower in patients who had flu vaccine regularly than those who did not have flu vaccine (16% vs 66%, $p<0.001$). In multivariate Cox proportional-hazards model, vaccination status remained to be independently associated with risk of recurrent HF-related hospitalization.

Conclusion: It seems that regular vaccination against flu does not influence the rate of CV deaths, however, decrease recurrent HF-related hospitalizations in HF outpatients.

Table 1

Systolic heart failure outpatients on ACEi/ARB+b-Blocker low dose (<50%), ivabradine addition improves survival

A V Simoes¹; L Sargento¹; S Longo¹; N Lousada¹; R Palma Reis¹

¹Hospital Lisbon North, Hospital Pulido Valente, Lisbon, Portugal

Introduction: Systolic heart failure (SHF) medical therapy optimization algorithm includes the prescription and up-titration of ACEi/ARB, b-blocker and spironolactone. After this optimization, those in sinus rhythm and heart rate > 70/min should receive ivabradine.

Objective: Evaluate in SHF outpatients, already on optimized therapy, the effect on survival of ivabradine according to the dose level of the ACEi/ARB plus b-blocker combination.

Methods: 159 patients with SHF (LVEF<40%) from one Heart Failure Clinic, all in sinus rhythm, all on ACEi/ARB+b-blocker therapy, and with optimal heart failure therapy according to the ESC guidelines and confirmed by 2 senior HF specialists of the clinic were included in the study. ACEi/ARB+b-blocker combination was categorized according to the percent dose in relation to target dose of both drugs: 1-49%; 50-99% and target dose (TD). Follow-up time was 3 years and the outcome all cause death.

Statistics: The hazard risk was calculated with Cox Regression for each ACEi/ARB+BB dose level according to ivabradine (No/yes) therapy.

Results: (1) Forty-three (27%) patients died. (2) Of the 160 patients 55 (34.6%) received ivabradine; ACEi/ARB-BB therapy- 1-49% TD in 57.2%, 50-99% 33.3 and TD of both drugs 9.4%. (3) The heart rate was similar for each ACEi/ARB+BB dose level by the ivabradine therapy. (4) Patients receiving ACEi/ARB+BB <50% target dose the ivabradine addition improved the survival curve (KM Log-Rank $p=0.066$) and decreased the risk of death (HRcox 0.49 95% CI 0.22-1.06; $p=0.072$).

Conclusion: SHF patients on optimized therapy, for similar heart rate values, ivabradine had an important impact in the survival of those receiving <50% target dose of both ACEi/ARB and b-blocker.

ACEi / ARB + BB	n	Ivabradine	KM (Log-rank)	HRcox (95% CI);p	Heart Rate	p

Objectives, activities, organization of a nurse-led heart failure outpatient clinics: data from a community-based cardiovascular observatory

D Radini¹; G Sola¹; N Zeriali¹; E Grande¹; F Humar¹; K Stellato¹; L Tarantini²; G Pulignano³; G Barbati¹; A Andrea Di Lenarda¹

¹A.S.S. n 1, Cardiovascular Center, Trieste, Italy; ²UOC Cardiologia Azienda ULSS numero 1, Belluno, Italy; ³San Camillo Forlanini Hospital, Rome, Italy

Background: Cardiovascular (CV) diseases are the first cause of death in the world population. To preserve the effectiveness of cardiological therapeutic interventions,

the elderly patient with chronic heart diseases (CHD), heart failure (HF) or atrial fibrillation (AF) need a global taking care, carried out by a multi-professional team. The aim of this study is to describe the organization, purposes and preliminary results of a nurse-led cardiology outpatient clinic with particular focus on heart failure (HF) patients.

Methods: Between November 1st, 2009 and October 31st, 2014, the Nurse-led Cardiological Outpatient Clinic provided care to 2,081 patients. 1,875 of these patients received nurse-led interventions in HF care (n=402, 19.3%), in CHD care (n=451, 21.7%) and in AF care (n=1022, 49.1%), while 206 patients, 9.9%, underwent Nursing Triage. Clinical multidimensional analysis, with identification of relevant health issues and planning of a nursing intervention (education, intensified monitoring, support to therapy) was shared with the cardiologist in a joint report. Data were derived from the E-data chart for Outpatient Clinic collected in the community-based population of Cardiovascular Observatory.

Results: The clinical characteristics and the social care needs of the patients who received nurse-led care were extremely heterogeneous. Patients with HF were the oldest (79 years), most severe (57.7% hospitalized last year), more prescribed drugs (72.4% ≥ 7 drugs daily), more frequent comorbidities (Charlson Index ≥ 3 : 82.8%). The majority of them had medium-to-low education levels and more frequently lived alone, with disabilities and inadequate self-monitoring and self-care behaviors. The patients of HF nurse-led clinics were those who came most frequently after hospital discharge, presented mainly clinical instability and problems of adherence to the therapeutic programs, and needed in most cases a therapeutic intervention associated with an intensification of clinical/behavioral monitoring. These patients showed the most severe prognosis with 1-year death in 19.6% of patients, CV hospitalization in 45.1%, non CV hospitalization in 46.6%, all-cause hospitalization in 58.2%.

Conclusion: Patients cared by Nurse-led Outpatient Clinic are very different from those enrolled in multicenter trials on which guidelines rely. Nursing assessment in HF patients effectively supports the specialist's intervention by intensifying clinical surveillance and therapeutic intervention and providing multidimensional information, essential to better understand patients' health and social care needs and to suggest and coordinate a tailor-made plan.

Treatment patterns in patients with chronic heart failure in Germany: a retrospective study of the health risk institute healthcare claims database

This research was funded by Novartis Pharma AG, Basel, Switzerland
S Hupfer¹; F Calado²; D Souto²; R Handrock¹; J Jacob³; J Walker³; S Klebs¹
¹Novartis Pharma GmbH, Nuernburg, Germany; ²Novartis Pharma AG, Basel, Switzerland; ³Elsevier, Berlin, Germany

Background: Data are limited regarding pharmacological treatment of patients with chronic heart failure (CHF) in clinical practice in Germany. Therefore, a retrospective study of anonymized healthcare claims data from the Health Risk Institute database was conducted.

Purpose: The objective was to investigate how patients with CHF are treated in Germany.

Methods: Data from patients with at least two recorded CHF-related diagnoses based on ICD-10 German Modification codes for CHF in a hospital or ambulatory setting in 2011 were analysed. A subgroup of patients with new CHF diagnoses was identified based on the absence of a CHF diagnosis in the year before first diagnosis in 2011. Prescription data for CHF medication were retrieved; single and combination agents were analysed separately.

Results: β -blockers (58.4%), high-ceiling diuretics (50.6%) and ACEIs (43.1%) were the most frequently prescribed agents in the 123 925 patients identified. Prescription frequency of diuretics (high-ceiling, low-ceiling or potassium-sparing), β -blockers and ACEIs generally rose with disease progression (Figure). Patients received CHF medication as monotherapy (24.4%), or dual (30.3%), triple (21.3%) or quadruple therapy (7.6%), more than four agents (0.9%) or no CHF drug therapy (15.4%). Among 26 368 patients with new diagnoses, β -blockers (63.2%), high-ceiling diuretics (52.3%) and ACEIs (45.5%) were the most frequently prescribed agents. Prescription of diuretics and ACEIs declined in this group over the 2 years after first CHF diagnosis (relative decrease from Q1 to Q8: high-ceiling, 10.9%; low-ceiling, 14.9%; potassium-sparing, 15.3%; ACEIs, 9.1%), whereas prescription of ARBs increased by 18.8%.

Conclusions: Prescription rates of ACEIs decline over the 2 years after first diagnosis of CHF, whereas prescriptions of ARBs increase in this period.

Drug prescriptions in patients with CHF

Dose response to Tolvaptan in repetitive admission for heart failure

N Nahikari Salterain Gonzalez¹; A Esteban¹; R Eiros¹; FJ Lavilla²; JJ Gavira¹

¹University of Navarra, Cardiology, Pamplona, Spain; ²University of Navarra, Nephrology, Pamplona, Spain

Purpose: Tolvaptan, a vasopressin receptor antagonist, is a safe and effective therapeutic alternative for refractory hyponatremia (plasma sodium (Na) ≤ 135 mEq/L despite fluid restriction and/or administration of hypertonic saline). The aim of this study was to assess the response to Tolvaptan in patients with hyponatremia and repetitive heart failure (HF) admissions. **Methods:** A retrospective study of patients with several admissions for HF and refractory hyponatremia treated with Tolvaptan was made. Evaluation of Na, potassium (K) (mEq/L), creatinine (Cr) (mg/dL) and glomerular filtration rate by MDRD (< 60 mL/min/1.73m²) in plasma, rate of diuresis (mL/h), blood pressure (mmHg) and weight (kg) when Tolvaptan administered, and 24 and 48 hours later, was made. **Results:** 15 patients were included (nine (60%) women) with an average age of 70 ± 17 years. Nine (60%) had renal impairment with baseline Cr and MDRD levels of 1.4 ± 0.1 mg/dL and 45 ± 10 mL/min/1.73m² respectively. Most common cardiomyopathies were ischemic (26%) and valvular disease (26%). Four (27%) patients had severe ventricular dysfunction. NYHA functional status was III in 60%. All carried optimal treatment for HF and 100% standard diuretic therapy at home. Median number of admissions was 3 (range of 2-9). In the first 5 hospitalizations, 15mg of Tolvaptan was the dose of choice. Na levels increased in 3 mEq/L at 24 hours (0-5) and in 4 mEq/L by 48 hours (0-6). Urine output increased in all of the hospitalizations, with an increase of 64 mL/h (20-126) at 24 hours and 42 mL/h (3-117) at 48. Clinically no relevant changes were detected in levels of K, Cr, MDRD and blood pressure.

Conclusions: Our study shows that Tolvaptan is an effective and safe treatment for patients with multiple admissions for HF, increasing plasma sodium levels and improving urine output.

Sodium and urine output

Heart Failure Management Programme improves prognosis and reduces costing

MC Murru¹; M F Massimo Francesco Piepoli¹; L Surdi¹; U Corvi¹; A Verde¹; S Binno¹; GQ Villani¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Background: We evaluated whether multidisciplinary disease management programme developed with collaboration of physicians and nurses inside and outside general district hospital settings can affect clinical outcomes in heart failure population over a 12-month period.

Methods: 571 patients hospitalised with CHF were referred to our unit and 509 patients agreed to participation. The intervention team included physicians and nurses from Internal Medicine and Cardiac Dept., and the patient's general practitioners. Contacts were on a pre-specified schedule, included a computerised programme of hospital visits and phone calls; in case of NYHA functional class III and IV patients, home visits were also planned.

Results: The median age of patients was 77.7 ± 9 years (43.3% women). At baseline the percentage of patients with NYHA class III and IV was 56.0% vs. 26.0% after 12 months ($P < 0.05$). Programme enrolment reduced total hospital admissions (82 vs. 190, -56%, $P < 0.05$), number of patients hospitalised (62 vs. 146, 57%, $P < 0.05$). All NYHA functional class benefited (class I=75%, class IV=67%), with reduction in the costing (-48%, $P < 0.05$). Improvement in symptoms (-9.0 ± 3.2) and signs (-5.2 ± 3.1) scores was measured ($P < 0.01$). Therapy optimisation was obtained by 20.5% increase in patients taking betablockade and 21.0% increase in those on anti-aldosterone drugs.

Conclusions: Multidisciplinary approach to CHF management can improve clinical management, reducing hospitalisation rate and costing.

P856

Effect of CPAP therapy in obese patients with chronic heart failure with preserved ejection fraction and severe obstructive sleep apnea

A Kuchmin¹; AA Kazachenko¹; IV Makarova¹; EP Umanskaya¹; SN Shulenin¹

¹Military Medical Academy, St. Petersburg, Russian Federation

Purpose: To assess efficacy of CPAP therapy in obese patients with chronic heart failure with preserved ejection fraction and severe obstructive sleep apnea

Methods: We conducted a study of 18 men aged 62 - 75 years with CHF (II-III classes according to NYHA functional classification system). All patients had severe

obstructive sleep apnea. Performed blood tests besides routine biochemical parameters also included N-terminal pro-BNP (NT proBNP). Echocardiography parameters of systolic and diastolic LV function, dimensions of heart chambers, tissue Doppler parameters were assessed prospectively at baseline and after 6 month after the onset of study. CPAP therapy was added to evidence-based therapy of chronic heart failure.

Results: After 6 months of the beginning of CPAP therapy levels of NT proBNP decreased from $769,3 \pm 102,4$ pg/mL (at baseline) to $585,3 \pm 38,2$ pg/mL (at 6-month follow up) ($p < 0,05$). Diameter of left atrium decreased by 9%, parameters of diastolic function determined by tissue Doppler improved, exercise tolerance increased, mean NYHA functional class decreased from $2,75 \pm 0,79$ to $2,47 \pm 0,86$. CPAP therapy also relieved symptoms and improved quality of life and function in these patients.

Conclusions: CPAP therapy in obese patients with chronic heart failure with preserved ejection fraction and severe obstructive sleep apnea was accompanied with improvement of diastolic function of left ventricle, clinical symptoms, exercise capacity and quality of life.

P857

Implementation of European guidelines in real practice of congestive heart failure treatment in Russia 2002 - 2012

EM Seredenina¹; JL Begrambekova¹; V YU Mareev¹

¹M.V. Lomonosov Moscow State University, Medical Research and Education Center, Moscow, Russian Federation

It is proved that neurohormonal modulators (Renin angiotensin system blockers = RASB, beta-adrenergic receptor blockers = BAB and mineralocorticoid receptor antagonists = MRA) can improve survival and reduce risk of worsening of CHF. In modern European guidelines administration of these three classes of drugs in optimal doses seems the cornerstones of successful treatment.

Aim of the study was to analyze implementation of European guidelines for treatment of CHF in real clinical practice in Russia during decade 2002-2012.

Results received from three databases: EPOCH-O-CHF trial 2002 (n=1051), EPOCH-CHF trial 2007 (n=897) and National heart failure registry 2012 (n=1176) conducted in 36 sites across Russia. All three registries included pts with clinically relevant CHF (NYHA II-IV) hospitalized due worsening of CHF. Treatment regimens studied twice: in time of discharge from the hospital and on outpatient basis 6-9 months after discharge.

In 2002 in hospital 81,2% received RASB, 51,5% BAB and only 7,7% MRA. On outpatient basis this figures dramatically decreased to 45,5% for RASB ($\Delta=35,7\%$), to 13,7% for BAB ($\Delta=37,8\%$) and to 1,1% for MRA ($\Delta=6,6\%$). Five years later (2007) hospital treatment of CHF pts improved: RASB have been prescribed to 87,7% pts, BAB to 80,1% and MRA to 49,2% of pts. After discharge on outpatients basis administration of RASB slightly decreased to 78,9% ($\Delta=8,8\%$), BAB decreased to 58,7% ($\Delta=21,4\%$) and MRA drop to 11,4% ($\Delta=35,2\%$). Ten years later (2012) already 95,0% of pts in hospital have been treated with RASB (+13,8% compare with 2002), 91,1% with BAB (+40,2% compare with 2002) and 56,4% with MRA (+48,7% compare with 2002). On outpatient basis the treatment was less effective: with 87,3% still on RASB ($\Delta=7,7\%$), 75,6% on BAB ($\Delta=15,5\%$) and 31,6% still on MRA ($\Delta=24,9\%$), but for all three drugs difference in administration between hospital and ambulatory treatment diminished. During ten years frequency of prescribing RASB in ambulatory practice increased by 42,1%, BAB by 61,9% and MRA by 31,5%, respectively, but still the gap between guidelines and real practice remains.

Moreover pts with CHF in real ambulatory practice received 46% (mean) of recommended doses of ACEI and 37% (mean) doses of BAB

Conclusion: During the 10-year period from 2002 to 2012 implementation of European guidelines for treatment of CHF in real practice in Russia significantly increased. However, in outpatient, the usage of basic therapy and doses of RASB and BAB remains insufficient.

P858

Therapeutic effects of metabolic therapy with a modified release trimetazidine in patients with chronic stable heart failure and angina (Russian study PERSPECTIVE)

M G Marina Bubnova¹; DM Aronov¹; MJ Ilchenko¹

¹State Scientific Research Center for Preventive Medicine, Moscow, Russian Federation

Introduction: Cardiac energy metabolism is altered in heart failure (HF) and can contribute to the progression of myocardial dysfunction in HF.

Purpose: Investigate clinical efficacy the long-term addition of modified release trimetazidine (TMZ MR) to standard current treatment of patients (pts) with stable ischemic HF and angina (SA) in real practice settings in 40 Russian cities.

Methods: 806 pts with HF I-III functional class (FC) NYHA and with (NYHA functional class II-III) and SA (II-III CCS), aged 35-65 years were randomized into two groups (gr): 1 gr receiving TMZ MR at a dose of 35 mg twice daily on top of standard therapy, n = 691) and 2 gr - control (the standard therapy, n = 115). The mean weekly number of angina attacks (AA) and nitroglycerine consumption (NC), the standard

ECG corrected QT dispersion (QTdc), left ventricular ejection fraction (LVEF), LV end-systolic volume, level of high sensitivity C-reactive protein (hsCRP), leukocytes, sum of cardiac hospitalizations were evaluated during 12 months follow-up.

Results: TMZ MR reduced AA by 62,8% ($p < 0.0001$) and NC by 67,7% ($p < 0.0001$) per week after 12 month, but not in control gr. LVEF increased significantly by 8,7% ($p < 0.001$) and LV end-systolic volume decreased by 10,3% ($p < 0.05$) after 12 months in pts receiving TMZ MR. No significant change was observed in the control gr. The addition of TMZ MR reduced QTdc by 10,5% ($p < 0.05$) after 12 months. The 12-month TMZ MR treatment was associated with a reduction in serum hsCRP level by 17,4% ($p < 0.05$) and leukocytes by 4,2% ($p < 0.05$) vs a significant increase the inflammatory biomarkers in pts of control gr. We observed a new hospitalization for cardiovascular causes and heart failure in 7,1% pts in TMZ MR gr and 19,1% in control gr ($-62,8\%$, $p < 0.001$) at 12 months.

Conclusion: The long-term addition of TMZ MR therapy for up to 12 months provides a reduce angina pain, improvement the left ventricular function and the remodeling process in HF pts with SA in primary care settings in various Russian regions. The results also suggest that TMZ MR may limit the inflammatory process and prevent of new hospitalization in pts with chronic ischemic HF and SA.

P859

Geographic variation in the access to heart transplantation in the

J Jan Benes¹; S Pansinova¹; P Nemecek²; H Bedanova²; J Pirk¹; I Malek¹; J Kautzner¹; V Melenovsky¹

¹IKEM, Prague, Czech Republic; ²Center of cardiovascular surgery and transplantation, Brno, Czech Republic

Background: Heart transplantation (HTx) is the last resort therapeutic option in management of end-stage heart failure (HF). Geographic variation in incidence of HTx may disclose regional bias in the access to health care. The purpose of the study was to evaluate regional distribution of HTx in the Czech Republic.

Methods: We retrospectively analyzed data from all patients who underwent HTx in the Czech Republic between 1.1.2008 and 30.9.2013 and determined the incidence of HTx in all counties ("okresy") and higher administrative regions ("kraje"). In addition, we determined whether such regional incidence of HTx was related to geographical, demographic, socioeconomic factors or regional variation in coronary artery disease (CAD) or diabetes mellitus (DM) prevalence.

Results: Within the period above, 496 HTx were performed in the only two national transplant centers (8.211 per year and million inhabitants). Their regional incidence ranged between 4.4 and 12.2 per year and million inhabitants without a significant difference. On the level of counties, difference in HTx incidence was statistically significant ($p < 0.0001$) with five counties out of seventy-seven being responsible for uneven distribution. The incidence of HTx was not related to the distance to the nearest HTx center ($p = 0.09$ for counties, Fig. 1A, $p = 0.28$ for regions) and was similar in regions with and without a complex cardiovascular center (7.77 ± 2.17 vs. 7.94 ± 1.56 , $p = 0.87$ per year and million inhabitants). Similarly, there was no relationship between the distance of the county of residence to the nearest complex cardiovascular center and the HTx incidence in that county ($r^2 = 0.0008$, $p = 0.80$, Fig. 1B). The incidence of HTx was unrelated to the number of hospitalizations for CAD in regions ($p = 0.78$), number of patients with DM in regions ($p = 0.10$), percentage of males both in regions ($p = 0.32$) and counties ($p = 0.76$) and age of population ($r^2 = 0.006$, $p = 0.79$ for regions, $r^2 = 0.009$, $p = 0.42$ for counties). HTx incidence also did not correlate with average salary in regions ($p = 0.30$) and unemployment rate both in counties ($p = 0.76$) and regions ($p = 0.89$).

Conclusion: Regional incidence of HTx was found evenly spread throughout regions, indicating no geographic restrictions in access to this advanced therapy in the Czech Republic. The variation in regional HTx incidence was unrelated to average regional age, gender, incidence of CAD or DM, income or unemployment rate.

Effects of febuxostat on cardiorenal function in patients with heart failure and hyperuricemia: effect study

Grant from Japan Promotion Society for Cardiovascular Diseases

Y Nagatomo¹; T Funamizu¹; Y Izumi¹; M Yagawa¹; K Mahara¹; Y Hen¹; H Ito¹; M Ueda¹; M Suzuki¹; T Yoshikawa¹

¹Sakakibara Heart Institute, Department of Cardiology, Fuchu, Japan

Background: It has been shown that serum uric acid (UA) level is an independent predictor of adverse clinical outcomes in patients with heart failure (HF). Actually allopurinol, a xanthine oxidase (XO) inhibitor, was shown to improve the prognosis of HF patients, whereas benzbromarone which promotes the excretion of UA showed no clinical benefit. These findings suggest that the suppression of reactive oxygen species production by XO inhibition might account for its beneficial effect. However, the clinical benefit of UA lowering agent for cardiorenal pathology in HF has yet to be fully determined.

Purpose: Effect study was a proof of concept study to examine the effect of a potent, specific XO inhibitor, febuxostat on cardiorenal function in patients with HF

Methods: The present study was conducted in an open-label, randomized manner. Thirty seven HF patients with New York Heart Association class II-IV symptom and hyperuricemia (≥ 7.0 mg/dl) were enrolled. Three patients were excluded since 1 patient died before the initiation of study drug and 2 patients withdrew consent. Thirty four patients were randomly assigned to febuxostat (10-40mg/day, F, n = 19) or conventional therapy (C, n = 15). Cardiorenal function and other clinical parameters including biomarkers which represent inflammation or oxidative stress were examined at 12 and 48 week after the initiation of study drugs. Primary endpoint was defined as the change of estimated glomerular filtration rate (eGFR).

Results: There were no significant differences in baseline characteristics between F and C. UA decreased and significantly lower in F compared to C at 48 weeks (F, 8.2 ± 1.8 to 5.8 ± 0.3 mg/dl, C, 8.0 ± 1.5 to 7.7 ± 0.3 mg/dl, $P < 0.001$ at 48 week). eGFR did not change significantly in either group. E/E' tended to decrease in F compared to C (F, 15.1 ± 2.4 to 13.7 ± 2.8 , C, 20.3 ± 2.7 to 19.5 ± 3.5 , $P = 0.09$ by repeated measures ANOVA). Left atrial volume decreased and significantly lower in F compared to C (F, 109 ± 29 , to 92 ± 30 ml, C, 161 ± 128 to 145 ± 76 ml, $P < 0.001$ by repeated measures ANOVA). There were no significant differences in the time course of left ventricular volume, ejection fraction, N-terminal pro-brain natriuretic peptide level, C-reactive protein or biomarkers indicating oxidative stress. There were no significant differences in all cause death or hospitalization due to HF. The addition of HF medication tended to be more common in C than F ($P = 0.06$).

Conclusions: Febuxostat safely decreased serum uric acid level in patients with HF. However, its effect on cardiorenal function was of borderline significance. Further investigation which includes more number of subjects will be warranted.

P861

Heart transplantation in Korea: 20-years of experience

M S Oh¹; E S Jeon¹; G Y Lee¹; J O Choi¹

¹Samsung Medical Center, Division of Cardiology, Department of Medicine, Seoul, Korea Republic of

Background: Heart transplantation has become the gold standard treatment option for end-stage heart failure. We reports 20-years of experience in Korea. **Methods:** From January 1992 to December 2012, 742 patients were undergone heart transplantation. We excluded 27 patients with multi-organ transplantation and reviewed the medical records retrospectively. **Results:** Heart transplantation had been performed in 10 institutes. Mean age of recipients was 42.9 ± 16.8 years and 72.6% were men. Gender-matched transplantation was preceded in 75.0%. Leading indication for transplantation was dilated cardiomyopathy (60.6%). Short-term mortality (within 1 month) was 4.5% (n = 32) and infection was the most common cause of death (50% of all-cause death, n = 16). After 1-, 5-, 10- years of follow-up, overall survival rates were 87.3%, 78.2%, and 74.8%, respectively. Rejection-free survival rates were 71.0%, 66.3%, and 65.2%, and malignancy-free survival rates were 99.1%, 97.7%, and 96.9%. Chronic allograft vasculopathy was occurred in 10 patients. After 2003, rejection rate was lower than that of before 2003 ($p < .001$), but all-cause mortality ($p = .10$) and malignancy-free survival rate ($p = .58$) was not statistically remarkable. **Conclusion:** With upgrading of procedural techniques and postoperative care including immunosuppressant therapy, outcome of heart transplantation has been improving.

Cause of Death in HT Recipients

Variables	Total (n = 219)	1992-2002 (n = 103)	2003-2012 (n = 116)
Infection	66 (30.1)	33 (32.0)	33 (28.4)
Acute or technical graft failure	36 (16.4)	19 (18.4)	17 (14.7)
Cardiovascular	35 (16.0)	13 (12.6)	22 (19.0)
Organ failure	21 (9.6)	8 (7.8)	13 (11.2)
Chronic graft failure	15 (6.8)	8 (7.8)	7 (6.0)
Malignancy	14 (6.4)	10 (9.7)	4 (3.4)
Suicide	4 (1.8)	3 (2.9)	1 (0.9)
Others	28 (12.8)	9 (8.7)	19 (16.4)

All variables are expressed in number (% of all cause death). HT=heart transplantation.

All-cause Death Survival of HT Recipient

Return to work following first hospitalization for heart failure

R Roerth¹; EL Fosbol¹; MC Petrie²; PS Jhund²; UM Mogensen¹; GH Gislason³; JJV McMurray²; C Torp-Pedersen⁴; L Kober¹; SL Kristensen¹

¹Rigshospitalet - Copenhagen University Hospital, Heart Center, Department of Cardiology, Copenhagen, Denmark; ²University of Glasgow, BHF Cardiovascular Research Centre, Glasgow, United Kingdom; ³Gentofte University Hospital, Department of cardiology, Gentofte, Denmark; ⁴Aalborg University, Department of Health, Science and Technology, Aalborg, Denmark

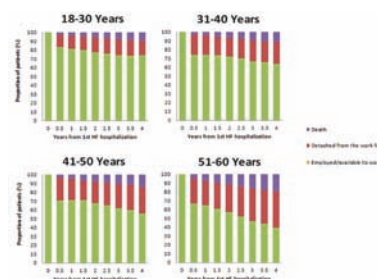

Background: Return to work is important financially, as a marker of functional status and for self esteem in patients suffering from chronic illness.

Purpose: We examined return to work after first heart failure (HF) hospitalization.

Methods: By individual-level linkage of nationwide Danish health and administrative registries, we identified 11880 patients of working age (18-60 years) who were employed prior to HF hospitalization. We estimated odds ratios (OR) for associations between patient age, length of hospital stay, sex, level of education, income, comorbidity and return to work one year after first HF hospitalization.

Results: One year after first HF hospitalization, 8040 (68%) returned to the work force, 2981 (25%) did not and 805 (7%) died, with return to work most likely among the youngest patients (81%) and highest 1-year mortality in the oldest age group (8%). Predictors of return to work included younger age (18-30 vs. 51-60 years, OR 3.28; 95% CI 2.53-4.26), male sex (OR 1.24 [1.13-1.36]), and higher levels of education (long-higher vs. basic school OR 2.07 [1.64-2.63]). Conversely, hospital stay > 7 days (OR 0.56 [0.51-0.62]) and comorbidity including history of stroke (OR 0.55 [0.44-0.69]), chronic kidney disease (OR 0.46 [0.36-0.59]), COPD (OR 0.62 [0.52-0.74]), diabetes (OR 0.75 [0.67-0.84]) and cancer (OR 0.49 [0.39-0.60]) were all significantly associated with lower chance of return to work.

Conclusion: Patients employed prior to HF hospitalization had low one-year mortality but high risk of detachment from the labour force. Young age, male sex, and higher level of education were predictors of return to work.

Return to work after HF hospitalization

P863

Dyslipidemia as a factor of heart remodeling and failure processes

N Nona Kakauridze¹; N Nikolaishvili²; M Ananovi³

¹Tbilisi State Medical University (TSMU), Internal medicine, Tbilisi, Georgia Republic of; ²GIDMEDI "Georgia-Israel joint clinic, Echocardiography, Tbilisi, Georgia Republic of; ³Cardiologic center "Mzcard", Cardiology, Kutaisi, Georgia Republic of

Cardiac remodeling is generally accepted as a determinant of the clinical course of heart failure (HF). The aim of our work is revealing the dyslipidemia parameters status in different types of heart remodeling in CHD patients with heart failure.

Materials and methods: 120 patients were investigated among them- 45 persons from control group. Patients with CHD and HF (75 pts) were divided in four group by Ganau classification: I group – patients with normal geometry (NG), II group

– concentric hypertrophy (CH), III group –eccentric hypertrophy (EH), IV group – concentric remodeling (CR) Blood for investigation was taken after 13 hours fasting. Lipid spectrum (TC, LDLC, HDLC, Triglycerides) was studied in blood serum using spectrophotometer by enzyme method. Ultrasonographic investigation of heart was performed by recommendations of the American Society of Echocardiography. Obtained data was statistically analyzed by Microsoft Office SPSS – 11.5 program.

Results and Conclusion: lipid spectrum of NG group is characterized by comparative normal lipid spectrum in comparison with other groups, and its parameters did not differ from control group. The most changes in lipid spectrum was observed in CH groups confirmed by statistically differences in LDLC (elevation), TG (elevation), HDLC (decreases) with control and NG groups, while between NG and CR and EH groups differences were observed only in TG ($p < 0.01$). The involvement of HDLC in remodeling processes indicates the negative correlation between mass of LV and HDLC in all groups of remodeling more expressed in CR group ($r = -0.99$) and EH group ($r = -0.64$) and in functions of compensatory mechanisms, reflected in positive correlation with EF in all groups. Atherogenic LDLC and TG play an important role in heart remodeling reflected by significant correlation (but less as with HDLC) between mass of LV, as well as with EF (one sides) and LDLC and TG (in other sides). Thus: Dyslipidemia is one of the important factor provoked heart remodeling, hemodynamic changes and heart failure by circulatory factors (atherosclerosis) and metabolism disturbance action. Especially HDLC levels correction have a significant role in prevention of heart failure.

P864

The relationship between clinical and echocardiographic characteristics and beta-blockers and antialdosterone treatment in patients with heart failure

G Gabriela Raileanu¹; M Chivulescu¹; IM Coman¹; E Apetrei¹; C Ginghina¹;

¹Institute of Cardiovascular Diseases Prof. C.C. Iliescu, cardiology, Bucharest, Romania

Introduction: The relation between the causes of heart failure (HF) and the election of the effective treatment has always been a challenge, in finding out an improvement in clinical or echocardiographic parameters in treated patients.

Purpose: To make a nowadays description of some clinical and echocardiographic parameters in patients with HF receiving beta-blockers or/and antialdosterone agents.

Methods: We included into a retrospective survey, 262 patients with HF, admitted between January 2014 to February 2015 in our hospital, found into NYHA III (82.9% patients) or IV. The statistical analysis was performed using StataSE 12 (significant $p < 0.05$).

Results: 55.3% were men. The mean age was 64.9 years old. 74.8% patients received antialdosterone agents. 82.06% patients received beta-blockers. The main cause of HF was: 36.26% ischemic HF, 32.06% valvular HF, 31.68% other causes of HF. Those who received beta-blockers, 41.86% had ischemic HF, 31.6% had valvular HF, 26.51% had another cause of HF ($p < 0.01$). The mean left ventricular ejection fraction (LVEF) was 48.53% in valvular HF, 39.22% in ischemic HF and 43.97% in other cause of HF ($p < 0.01$). The mean systolic blood pressure was with 12.26 mmHg higher ($p = 0.0004$) and the mean diastolic one with 5.74 mmHg higher in those without antialdosterone treatment ($p = 0.0021$). The mean LVEF was with 9.2% lower ($p < 0.01$) and the pulmonary artery pressure systolic was with 5.9 mmHg higher in those with antialdosterone treatment ($p = 0.04$). The mean LVEF was with 7.5% lower in patients with beta-blockers ($p = 0.0008$). The pulmonary artery pressure systolic was with 12.68 mmHg higher in those without beta-blockers ($p = 0.0001$). In those who needed beta-blockers, the glomerular filtration rate estimated with MDRD Formula was with 14.6 ml/min/1.73 m² lower than in others ($p = 0.0005$). In patients into sinus rhythm (52.2% of all patients) those with antialdosterone treatment had the mean LVEF with 12.34% lower than others ($p < 0.01$) and those with beta-blockers had the mean LVEF with 14.38% lower than others ($p < 0.01$). In patients with AF, those with antialdosterone treatment had a mean LVEF with 5.7% lower than others ($p = 0.04$). There was no significant difference of the mean LVEF in patients with AF with beta-blockers.

Conclusions: Most of the patients who needed beta-blockers had an ischemic HF. The highest mean LVEF was found in patients with valvular HF, the lowest in those with ischemic HF. The pulmonary artery pressure systolic was higher in patients who received antialdosterone agents but was lower in patients who received beta-blockers.

The mean LVEF for different causes of HF

Plasma testosterone levels in men with ischemic left ventricular dysfunction

G M C Giuseppe M C Rosano¹; A Aversa²; G Marazzi¹; C Vitale¹; R Massaro¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy; ²Umberto I Polyclinic of Rome, Rome, Italy

Background: High androgen levels have been linked with an increased cardiovascular risk. However, more recent data suggest that low androgens levels are associated with adverse cardiovascular outcomes. Aim of the present study was to evaluate the relationship between plasma sex hormone levels and presence and degree of CAD in patients with moderately reduced LV function (40-50%) or with ischemic left ventricular dysfunction (<40%) undergoing coronary angiography and in matched controls.

Methods: We studied 98 consecutive male patients (mean age 59±3 years, range 46-72) referred for diagnostic coronary angiography but without acute coronary syndromes or prior diagnosis of hypogonadism. Patients were matched with healthy volunteers.

Results. All pts, had proven coronary artery disease, more specifically 16 of them had one, 61 two and 22 three vessel disease respectively. Patients had significantly lower levels of testosterone than controls (2.6 ± 1.6 and 3.5 ± 1.3 ng/dL; $p < 0.01$). Also, both free and bioavailable testosterone, free androgen index and plasma estradiol levels were lower in patients as compared to controls. Patients had lower levels of estradiol-17b than control group (10.2 ± 1.5 and 12.9 ± 3.7 ng/dl $p < 0.04$). Hormone levels were compared in cases with 1, 2, or 3 vessel disease showing significant differences ($p < 0.01$) associated with increasing severity of coronary disease and degree of left ventricular dysfunction. An inverse correlation between the degree of coronary artery disease and plasma testosterone levels was found.

Conclusions: In conclusion patients with ischaemic left ventricular dysfunction have lower testosterone and estradiol levels than healthy controls. These changes are inversely correlated to the degree of CAD and left ventricular dysfunction.

P866

Influence of levosimendan on a life quality of patients with severe chronic heart failure

A Asel Isabekova¹

¹Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan

Purpose of the research: Studying of Levosimendan's influence on life quality of patients with Acute decompensation of Chronic Heart Failure in comparison with a standard therapy of Chronic Heart Failure.

Material and methods: 50 patients were involved in this research. 30 patients (14 men and 16 women) with Acute decompensation of CHF class IV by NYHA. The comparison group included 20 patients with decompensated CHF matched for sex and age, getting a standard therapy. The total duration of the research was 1 month. Results of the research. During the course of receiving levosimendan comparing with a standard therapy of CHF, it was noted a considerable improvement of life quality of the patients. The survey of the patients of both groups showed that the quality of life of patients treated with levosimendan after 48 hours increased by 40%, and by the end of the observation period was 54.2 ± 16.17 points which is 43% over than the initiative indicators ($p < 0.05$). In the comparison group by the end of the observation period the quality of life improved by 22.8%. A 6 minute walk test conducted by us showed the exercise tolerance increased by 60% after infusion of levosimendan within 48 hours, and by the end of the observation period increased by 63.5%. Whereas in the control group this indicator increased by 10% in 1 month. On a scale of assessment of clinical states an average number of points of the studying levosimendan patients really reduced by 50% (from 13.1 ± 3.04 points to 6.85 ± 1.20 points), and by the end of the observation period by 51.5% $p < 0.05$. In the control group this indicator decreased by 20%. This therapy helped to reduce the severity of Chronic Heart Failure and it facilitated to switch patients high functional class to lower one. The number of levosimendan group patients switched from class IV to class III were 64.3%, to class II were 35.7%. In the control group there were 21.1% of patients with class IV, 76.3% of them changed to class III and 2.6% to class II. Conclusion. Levosimendan significantly improves the quality of life of patients with Acute decompensation of Chronic Heart Failure.

P867

Heart failure increased due to poor hospital financial care

O Oswald Londono Sanchez¹; A Sevy Elias²; E Atroshenko³

¹Medical and Cardiology Centre, Dr. Londono, Barcelona, Spain; ²University of Barcelona, Economy, Barcelona, Spain; ³Republican Scientific and Practical Centre of Cardiology, Cardiology, Minsk, Belarus

Abstract: This article is focused around two important things in medicine: the lack of money in Europe and the quality of life. Europe is in crisis, but as always the best way to save money is in health for the citizen. We want to talk about crisis as the important cause of morbidity and mortality in our Hospitals, last 7 years, especially in cardiovascular surgery.

Introduction: There are currently very few articles discuss the effects that has brought the crisis in Europe on the quality of medicine and, above all, in cardiovascular surgery. This is an issue that affects millions of European citizens, because due to the crisis European hospitals have been forced to save a lot of money on materials: stents and prostheses and dismiss physicians. For primary angioplasty there is unanimous consent that a direct immediate mechanical opening of the occluded artery with angioplasty is preferable. Unlike in stable coronary syndromes there is no discussion whether patients should be better off in terms of prognosis and long term relief of symptoms after bypass surgery or coronary angioplasty or simply remaining on medical therapy, a difficult decision in individual cases that often leads to fierce discussions in our multidisciplinary meetings.

Conclusions: As we could see in our graphics and descriptions, the crisis in all European countries have an important considerations in global health for their citizens. As a conclusion we can say that 75% of European countries have difficult times and only Germany, France and United Kingdom can keep their status and give support to the health public system. Baltic countries have serious problems and will be very difficult to eradicate their economic problems is Hospitals, when many physicians are moving out to other EU countries and USA. Health system recovery in Greek will take more than 30 years. About Spain.

The risk of thrombosis after implantation

The risk of stent thrombosis, cobalt-chromium everolimus stent compared to some other types of stents

Stent	The ratio of opportunity (95% confidence interval)
Bare metal	0.23 (0.13-0.41)
Paclitaxel-eluting	0.28 (0.16-0.48)
Standing polymer-based sirolimus eluting	0.41 (0.24-0.70)
Phosphorylcholine-based zotarolimus-eluting	0.21 (0.10-0.44)
Resolute zotarolimus-eluting	0.14 (0.03-0.47)

The risk of thrombosis after implantation of metal stents.

Arrhythmias and heart failure in patients with medial arterial calcification

L Ludovit Gaspar¹; A Dukat¹; P Gavornik¹; A Komornikova¹; I Gasparova²; M Bendzala¹; L Strbova¹

¹University Hospital Bratislava, Bratislava, Slovak Republic; ²Institute of Biology, Genetics and Clinical Genetics, Comenius University, Bratislava, Slovak Republic

Introduction: Decreased ankle-brachial pressure index (ABI) is a well-known marker of increased cardiovascular mortality. However, also the values of ABI 1.3 and more, typical in medial arterial calcification (MAC), are associated with increased cardiovascular and all-cause mortality.

Purpose: To determine the prevalence of heart failure, cardiac arrhythmias and myocardial ischemia in a group of patients with type 2 diabetes mellitus and medial arterial calcification.

Methods: 41 patients with type 2 diabetes mellitus (25 male and 16 female), mean age 59 ± 8 years were investigated. MAC with ABI at least 1.3 was present in all members of our group. Arterial hypertension was present in 35 patients (85.3%), history of MI in 8 patients (19.5%) and history of stroke was present in 7 patients (17.1%). Holter ECG monitoring with an average recording duration of 22.36 hours was carried out by GE-Marquette MARS PC-ambulatory ECG Holter system (USA). MAC was detected by the BOSO ABI-system 100 (Germany). After physical examination blood samples with biochemical analysis, blood count and standard echocardiography was done.

Results: 12 patients (29.2%) had signs of heart failure (9 patients NYHA II and 3 patients NYHA III). Normal Holter ECG records without ischemia or arrhythmias were present only in 10 patients (24.4%). Complex forms of arrhythmias were in 18 patients (43.9%), Lown IIIB in 12 patients and Lown IVA in 6 patients. Myocardial ischemia was present in 6 patients (14.6%).

Conclusion: Patients with medial arterial calcification are threatened by serious cardiac complications such as cardiac arrhythmias and heart failure. We have detected high incidence of cardiac arrhythmias, including complex forms and myocardial ischemia on Holter ECG monitoring (75.6%). 12 patients (29.2%) had also signs of heart failure. Holter ECG monitoring in patients with MAC is highly recommended since subsequent cardiology management can improve their prognosis.

P869

Type D personality, negative emotions and quality of life in coronary artery disease patients with heart failure

VM Violetta Gazizianova¹; EV Khazova¹; OV Boulashova¹; AA Nasybullina¹; MI Malkova¹

¹Kazan State Medical University, Kazan, Russian Federation

Introduction: Type D personality, or distressed personality, refers to the joint tendency to experience negative emotions and to inhibit self-expression in social interactions. Type D personality has been associated with a variety of emotional and social difficulties as well as with poor prognosis in patients with established heart failure. But the relationship between type D, negative emotions and quality of life in heart failure patients was detected by some investigators, however, the factors that can explain this association remain unclear.

Purpose: To examine the effects of negative emotions, type D personality on the quality of life in coronary artery disease patients with heart failure.

Methods: We enrolled 80 HF patients (average age – 65.9 ± 8.4 years, left ventricular ejection fraction – $53.8 \pm 11.4\%$, I-II FC – 45% , III-IV – 55%). Duration of heart failure did not exceed 6 years. In the study of emotional status for the diagnosis of type D personality used a DS-14 test, to determine the anxiety/depression – The Hospital Anxiety and Depression scale. Questionnaire Minnesota living with heart failure used in the study of quality of life.

Results: The prevalence of type D personality within the study population was 32.5% (30 patients). Type D personality patients had experienced negative emotions (anxiety and depression) in 83.4% cases, but the prevalence of negative emotions in non-type D personality patients was 50%. Distressed personality patients scored significantly lower on health status – 40.4 ± 9.6 than non-type D patients – 60.9 ± 8.8 . Anxiety and depressive symptoms, type D personality were all found to be determinants of decreased quality of life ($p < 0.05$).

Conclusion: Type D personality and negative emotions were independent predictors of impaired quality of life in CHF.

P870

Estimating canadian heart failure prevalence using prescription treatment patterns

Novartis Pharmaceuticals Canada Inc.

A Aren Fischer¹; N Zaur²; J Caron³; R Borrelli¹; K Jobin Gervais²

¹IMS Health Brogan, Health Access and Outcomes, Toronto, Canada; ²Novartis Pharmaceuticals Canada Inc., Health Policy and Patient Access, Dorval, Canada;

³IMS Health Brogan, Statistical Services, Montreal, Canada

Purpose: It is currently estimated that over 600,000 Canadians have heart failure (HF). As diagnosis database coverage can be limited in Canada, We used IMS Health Brogan's (IMS) national patient-level longitudinal retail prescription database (LRx) to understand HF prevalence and its demographic variances. We therefore developed a prediction algorithm identifying Canadian HF patients using retail prescription patterns from a national database to understand and update HF prevalence estimates.

Methods: Patient data from IMS's E360 Canadian electronic medical record database were used to develop a decision tree prediction algorithm to identify treatment patterns in HF patients. The final study cohort was composed of 675 HF diagnosed (ICD-9 428) patients and 804 randomly sampled non-HF patients. All studied patients were aged ≥ 18 years, had ≥ 2 doctor visits between January 2006 - January 2015, and had been prescribed an ATC-1 cardiovascular product. The resulting algorithm was validated against a test dataset to evaluate the models prediction accuracy. To estimate age group, and gender prevalence, the algorithm was applied to IMS's LRx dataset to all patients with > 6 months follow-up.

Results: Age and standardized duration treated with beta-blockers, ACEs/ARBs, high ceiling diuretics, or vasodilators were strong indicators of a HF diagnosis, while physician referral and gender variables were not. When validated on a test dataset, the model demonstrated an 80.0% accuracy, 81.1% positive predictive value, and 79.5% negative predictive value. Overall, we estimated a 2014 national HF prevalence of 2.31%, or 657,902 patients aged ≥ 18 years. This estimate aligned well with literature population estimates - 590,416 and 626,199 patients. Elderly patients (aged ≥ 65 years) made up 76.08% of the 2014 HF patients with a prevalence of 8.97%, while those aged 18 to 64 years represent 23.92% of 2014 HF patients with a prevalence of 0.69%. Nationally, the 2014 prevalence was slightly higher in women (2.44%) compared to men (2.17%).

Conclusion: The prediction algorithm's overall HF prevalence estimates align well with literature prevalence estimates; overall, we estimate 657,902 Canadians are treated for HF. Prior cost studies demonstrated a substantial cost per HF hospitalization. As HF is associated with a high rate of mortality and hospitalization, treatments that reduce the number of patients requiring hospitalization events can materially lower the overall utilization and cost burden on the Canadian healthcare system.

Sudden cardiac death in muscular dystrophy patients

J Nurkovic¹; E Regic²; S Nurkovic³; Z Dolicanin¹

¹State University of Novi Pazar, Novi Pazar, Serbia; ²Special hospital for the treatment of progressive muscular and neuromuscular diseases, Novi Pazar, Serbia;

³General Hospital Novi Pazar, Novi Pazar, Serbia

Introduction: Muscular dystrophy (MD) is a group of inherited diseases in which the muscles that control movement progressively weaken. In several forms of muscular dystrophy, cardiac dysfunction occurs, and cardiac disease may even be the predominant manifestation of the underlying genetic myopathy. Sudden cardiac death (SCD) is an unexpected death due to cardiac causes that occurs in a 1 hour of symptom onset.

Methods: The study was conducted in a Special hospital for treatment of progressive muscular and neuromuscular diseases in Serbia, from 2009 to 2014. The study included 70 patients with Duchenne, Becker, myotonic, limb girdle, Emery-Dreifuss and facioscapulohumeral muscular dystrophy. All of them had electrocardiograms (ECG). Results. Of the 70 patients with MD, 43 (61.4%) had SCD during the five years of our research. Diagnosis of SCD is based on the history, clinical findings, ECG findings and certain biochemical tests. Conclusion. The heart become necrotic in MD patients resulting in cardiorespiratory failure as the leading cause of death. Managing cardiac dysfunction, therefore, is the most important component of MD treatment. Cardiac screening has been recommended for MD mutation carriers, particularly beginning after the teenage years, as these individuals are known to be at risk for developing cardiomyopathy.

P872

Prognostic value of Minnesota index determined at discharge after acute decompensated congestive heart failure

G Gheorghe¹; AS Hodorogea¹; A Ciobanu¹; ADC Gheorghe²; IT Nanea¹

¹University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; ²Coltea Clinical Hospital, Bucharest, Romania

Aim: To study prognostic implications for rehospitalizations of the self reported global health status by Minnesota index (MS), correlated with left ventricular ejection fraction (LVEF) and NTproBNP values in patients (pts) discharged after acute decompensated congestive heart failure (HF)

Method: 100 pts hospitalized for decompensated HF were included in the study, mean age 72 ± 10 years, 57% male. Echocardiographic determination of LVEF, NTproBNP (normally below 900 pg/mL) and MS were performed at discharge, after the compensation of HF. MS above 75 was considered high. History of hypertension, ischemic heart disease, myocardial infarction, diabetes mellitus, chronic kidney disease and also NYHA class at discharge were noted. After three months pts were contacted by phone and were interviewed about the rehospitalization for decompensated HF. Data were correlated with MS, LVEF and NTproBNP at discharge. Statistical analysis was performed using Statistica 8.

Results. 37% pts were in NYHA class II, 56% in NYHA III, 7% in NYHA IV, with no differences between men and women. Mean LVEF was 41 ± 12%. Mean NTproBNP was 2547 ± 1036 pg/ml, with no differences related to NYHA class, sex and etiology of HF. Mean MS was 66 ± 20. MS above 75 was recorded in 53% of the pts in NYHA III, versus 21% pts with NYHA II ($p = 0.002$) and 57.14% pts with NYHA IV. MS above 75 was correlated with increased frequency of rehospitalization, regardless of NYHA class ($r = 0.71$). NTproBNP had higher mean values in pts with MS above 75 (2790 ± 890 pg/ml), compared with those having MS below 75 (2304 ± 912 pg/ml), without statistical significance ($p = 0.08$).

Conclusions: High Minnesota score value at discharge, comprising objective and subjective self-assessment data of patients with HF, correlates with rehospitalization rate, regardless of NYHA class and LVEF. NTproBNP was higher in the pts with high Minnesota score but without statistical significance.

P873

A description of unselected patients with heart failure: a swedish population-based study

This research was funded by Novartis Pharma AG, Basel, Switzerland J Stalhammar¹; K Boman²; M Olofsson²; K Lindmark³; R Lahoz⁴; S Corda⁴; V Wintzell⁵; R Linder⁶; A Gondos⁶; G Wikstrom⁷

¹Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden; ²Umea University, Research Unit, Medicine and Geriatric, Skellefteå County Hospital, Department of Public Health, Umea, Sweden; ³Umea University, Heart Centre, Department of Public Health and Clinical Medicine, Umea, Sweden; ⁴Novartis Pharma AG, Basel, Switzerland; ⁵IMS Health Sweden, Stockholm, Sweden; ⁶IMS Health Germany, Berlin, Germany; ⁷Uppsala University, Institute for Medical Sciences, Uppsala, Sweden

Background: The signs and symptoms of heart failure (HF) are non-specific, age- and gender-dependent; a better understanding of patient characteristics, especially amongst elderly patients, is needed.

Purpose: To characterize patients newly diagnosed with HF (main ICD-10 code I50) in Uppsala County, Sweden.

Methods: Patients were identified via electronic medical records from primary

(~90% coverage) and secondary (100% coverage) care and the local echocardiography registry. Patients aged ≥18 years with a first HF diagnosis from 1 January 2010 to 31 March 2015 were included. A 9-year look-back period to 1 January 2001 excluded prevalent HF cases. Echocardiography, electrocardiogram and natriuretic peptide testing were used to diagnose HF, assessed within 6 months after first diagnosis. Data were linked with the Swedish Prescribed Drug Register, Patient Registry and Cause of Death Registry. Co-medications used in the year before first diagnosis and comorbidities in the 5 years before first diagnosis were assessed.

Results: Of 8777 records, 4070 patients with newly diagnosed HF (47.1% women) were identified; 31.3% and 68.3% were diagnosed in primary care or secondary care, respectively. Mean (standard deviation [SD]) age at first diagnosis was 78 (13) years. The largest proportion of patients (33.6%) was aged ≥85 years; 32.1% were aged 75–84 years; 19.9% were aged 65–74 years; 8.2% were aged 55–64 years; and 6.2% were aged 18–54 years. The mean (SD) body mass index (BMI) was 27 (6) kg/m². The commonest pre-diagnosis co-medications were antithrombotic agents (used by 71.8%), beta blocking agents (68.0%) and high-ceiling diuretics (47.9%). The commonest comorbidities were hypertension (56.0% of patients) and atrial fibrillation (36.4%). Overall, 1168 patients (28.7%) received echocardiography: 10.8% had HF with preserved ejection fraction (HF-pEF; left ventricular EF > 50%), 17.9% had HF with reduced EF (HF-rEF; left ventricular EF ≤ 50%); 71.3% were diagnosed with HF but echocardiography was not performed. Patients with HF-pEF had a mean (SD) age of 76 (12) years, mean (SD) BMI was 28 (6) kg/m² and 54.8% were women. Patients with HF-rEF were younger (mean [SD] age: 71 [15] years), had a mean (SD) BMI of 27 (5) kg/m² and the minority (33.1%) were women.

Conclusions: A large proportion of patients in this cohort were aged ≥85 years. The majority did not have an identified HF phenotype, which would delay appropriate treatment. This warrants targeted diagnostic and therapeutic strategies in primary and secondary care settings.

P874

Heart failure in cvdmp daily practice: characteristics, management and outcomes

R Raed Odeh¹; BM Bdeir¹; M Al-Khateeb¹

¹King Abdulaziz Medical City, Riyadh, Saudi Arabia

Background: The characteristics and outcomes of heart failure (HF) patients were described by numerous studies worldwide. However very limited information about Saudi HF patients is available. Aim: To determine the general characteristics, treatments and outcomes of Saudi patients with the diagnosis of HF who are followed up in a Nurse Led Cardiovascular Disease Management Program (CVDMP).

Methods: This is a retrospective chart review study, that included all HF patients who are followed up in King Abdul Aziz Cardiac Center (KACC) CVDMP over the time period from 2000-2015. Data extracted from the cardiac electronic data base (Apollo) for all patients who have at least 2 visits; enrollment (EV) and last follow up (LV).

Results: A Total of 2298 patients (72 % Male, mean age 58 STD 12.7 years) included in this study. Ischemic cardiomyopathy presented in 60% of patients, Diabetes mellitus in 66 %, Dyslipidemia in 76% and 64 % of patients were hypertensive. Majority of patients had both Systolic and Diastolic HF (70%), with stage C HF in EV and LV. Average EF Improved from 32 -38 % ($P = 0.0001$). Over 90 % of the patients were on ACE, ARBs or the combination during EV and LV. Overall Mortality over 15 years follow up was 12.1%. (further analysis and results to follow)

Conclusion: Saudi heart failure patients are relatively younger with higher prevalence of cardiac risk factors. Nurse led CVDMP in KACC did improve survival in Saudi HF patients compared to international figures.

P875

Features of lesions of the coronary channel at coronary heart diseases patients with low ejection fraction

HG Fozilov¹; TA Abdullayev¹; RSH Beckbulatova¹; I A Igor Tsoy¹; AM Karimov¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

Objective: to study features of lesion of coronary channel at CHD patients with low ejection fraction (EF) of left ventricle (LV) subjected to percutaneous coronary interventions (PCI).

Material and methods: From January 2013 to January 2015 y, selective coronary angiography has been executed at 1876 pts of cardiovascular diseases. Selective CAG at CHD pts with EF LV less than 45 % have been executed at 257 (14.1 %) pts. From them at 158 (62.4 %) pts have been executed PCI; 54 (20.7 %) are recommended to pnts carrying out CABG, at 45 (28.5 %) pts were therapy is continued: in 55.5 % (25) cases - coronary arteries were without changes, and in 45.5% (20) - were patients with various degree of lesion of coronary arteries. Criterion of an exception - echo-poor pts, pts in which anamnesis, were available

earlier transferred operations of myocardial revascularization (CABG and/or PCI) for more than 1 year.

Results: At carrying out diagnostic CAG at 144 CHD pts with low EF of the LV atherosclerotic lesions have been revealed in 352 arteries that has on the average made 2,44 arteries counting on 1 pt. According to selective CAG 29.9 % (43) pts had an one-vascular lesion, and for 70.1 % (101) – multivascular lesions. Most often lesions were localised (taking into account artery branches) in anterior descending branch of left coronary artery (LAD LCA) – 152 (43.2 %); in circumflex branch of LCA – 92 (26.1 %); in right coronary artery(RCA) – 92 (26.1 %); in a.intermedia–6 (1.7 %). Hemodynamic significant (≥ 50 %) lesion of a trunk of the left coronary artery (LCA) has been revealed in 10 (2.9%) cases. By CAG results it has been revealed 402 hemodynamic significant lesions of coronary arteries: of 56.3 % (174) have made type stenoses of them “B”, stenoses of type “C” – 34.3 % (106) and stenoses of type “A” – 6.5 % (29) from total of the revealed narrowings. Among lesions of coronary arteries occlusion have made 23.1 % (93), from them in 76.4 % (71) cases are revealed chronic total occlusion.

Conclusions: the analysis of our experience shows that at pts with CHD (EF LV less than 45 %) most often meet multivascular lesions of a coronary channel – in 70.1 % (101) cases. As a whole lesions of coronary arteries of “high” risk (type “C” on morphology classification stenotic atherosclerotic defeat ACC/AHA) type have made 44.1 %.

P876

Prevalence of P wave dispersion and interatrial block in patients with systolic heart failure and their relationship with functional status, hospitalisation and one year mortality.

AHMED T Abdellah¹; MERHAN Elmagary²

¹Cardiology Department, Suez Canal University, Ismailia, Egypt; ²Internal Medicine Department, Port Said General Hospital, Port Said, Egypt

Background: P wave dispersion (PWD) and Interatrial block (IAB) are common in heart failure (HF), and could be associated with cardiac events.

Purpose: To assess the prevalence of PWD and IAB and their relationship with functional status, hospitalization and mortality rate in patients with systolic HF.

Methods: We enrolled 110 HF patients in sinus rhythm & LVEF <50%. Patients had undergone clinical evaluation, 6 minutes walking test (6MWT), 12-lead electrocardiography (ECG), 24-hour Holter ECG & echocardiogram. PWD was defined as the difference between maximum & minimum P wave duration > 40 msec. IAB was defined as maximum P duration > 110 msec. Measurements were done by 2 blinded investigators using a caliper, a ruler and a magnifying lens.

Results: Mean age was 58.9 ± 9.7 years and 67.3% were males. Prevalence of PWD and IAB was 68.2% and 57.3%, respectively. Patients with PWD showed these features: 84% in NYHA class III or IV HF, 77.4% had LVEF <35%, 78.7% had paroxysmal Atrial Fibrillation (AF) and 89.4% couldn't complete > 200 meters (m) in 6MWT. Patients with PWD had more hospitalizations (72% vs 28.6%, P value < 0.02) and higher 1-year mortality rate (20% vs 8.6%, P value < 0.04) than patients without PWD. Likewise, patients with IAB had nearly similar clinical features, hospitalization and mortality as patients with PWD (refer to table).

Conclusion: PWD and IAB are prevalent in patients with systolic HF and they are significantly associated with low LVEF, paroxysmal AF, poor functional capacity, hospitalization and mortality rate.

Features of HF patients with PWD & IAB

Parameter	PWD	No PWD	P value
NYHA class III or IV	84%	34.4%	0.01
Paroxysmal AF	78.7%	11.4%	0.001
LVEF <35%	77.4%	22.8%	0.001
6MWT <200 m	89.4%	45.7%	0.01
Hospitalization	72%	28.6%	0.02
1-year Mortality	20%	8.6%	0.04
	IAB	No IAB	
NYHA class III or IV	87.3%	42.6 %	0.01
Paroxysmal AF	77.8%	27.6%	0.001
LVEF <35%	79.4%	31.9%	0.01
6MWT <200 m	90.5%	55.3%	0.01
Hospitalization	61.9%	38.3%	0.019
1-year Mortality	22.3%	4.3%	0.012

Abbreviations are listed in the abstract text.

P877

Duration of heart failure and outcomes in patients with heart failure and reduced ejection fraction

M Meenakshi Tomer¹; J Gannuscio¹; M Valentova²; G Fonarow³; C Adamopoulos⁴; I Kanonidis⁵; P Deedwania³; W Aronow⁶; S Anker⁷; A Ahmed¹

¹Veterans Hospital, Center for Health and Aging, Washington, United States of America; ²University of Göttingen, Göttingen,, Germany; ³University of California Los Angeles, Los Angeles, United States of America; ⁴St. Paul's General Hospital,, Thessaloniki, Greece; ⁵Aristotle University of Thessaloniki,, Thessaloniki, Greece; ⁶New York Medical College , Vallhalla, New York, United States of America; ⁷Charité - Campus Berlin Buch (CBB), Berlin,, Germany

Objective: The pathophysiology of heart failure (HF) is believed to evolve with disease progression and the duration of HF may impact outcomes. In the current study, we examined the association of HF duration with outcomes in patients with HF and reduced ejection fraction (HFrEF).

Methods: The 2706 patients with advanced HF and EF <35% in the Beta-Blocker Evaluation of Survival Trial (BEST) were categorized into 4 groups based on their quartiles of HF duration: 26% had 1–12 months, 25% had 13–36 months, 26% had 37–72 months, and 23% had 73–456 months. Using multivariable-adjusted Cox regression models, we examined association of HF duration with outcomes during an average of 2 years of follow-up, using 1st quartile as reference.

Results: Patients had a mean age of 60 years, 22% were women and 23% African American. Association of HF duration with all-cause hospital admission and all-cause mortality are displayed in Table. Associations of longer HF duration with increased risk of HF hospitalization were similar to that with all-cause hospitalization.

Conclusion: In patients with advanced HFrEF, duration of HF appears to have

61749 Outcomes in Heart Failure by Duration

Table. Outcomes in heart failure by duration of heart failure

Outcome	Duration (months)	Unadjusted events % (n/N)	Hazard ratios (95% confidence intervals)
Unadjusted	Age-sex-race-adjusted	Multivariable-adjusted*	
All-cause hospital admission	1-12	55% (395/714)	1 (Reference)
13-36	64% (430/658)	1.24 (1.08-1.42)	1.22 (1.07-1.40)
37-72	67% (472/704)	1.40 (1.23-1.60)	1.37 (1.19-1.56)
73-456	66% (406/620)	1.14 (1.08-1.19)	1.12 (1.07-1.17)
All-cause mortality	1-12	25% (179/714)	1 (Reference)
13-36	30% (200/658)	1.24 (1.02-1.52)	1.17 (0.96-1.44)
37-72	35% (243/704)	1.50 (1.24-1.82)	1.42 (1.17-1.73)
73-456	38% (237/620)	1.22 (1.14-1.30)	1.17 (1.10-1.25)

*Adjusted for age, sex, race, smoking, coronary artery disease, chronic kidney disease, diabetes mellitus, atrial fibrillation, hypertension, hyperlipidemia, peripheral arterial disease, randomization to beta-blocker bucindolol, the use of ACEI or ARB, digitalis, diuretics, vasodilators, anticoagulants, NYHA class, cardiothoracic ration, pulmonary edema, heart rate, systolic and diastolic blood pressure, left and right ventricular ejection fraction, serum potassium and hemoglobin

stronger independent associations with all-cause and HF hospitalization than with all-cause mortality.

P878

Incidence and predictors of stroke among patients with chronic heart failure

D Dalila Elbaghdadi¹; G Mouhsine¹; C Chehboune¹; R Habbal¹

¹Ibn Rochd University Hospital, cardiology, Casablanca, Morocco

Background: Stroke is associated with poor prognosis in patients with heart failure. This study investigated the incidence and predictors of stroke among this population.

Methods and results: We examined the prevalence, risk factors of stroke in ambulatory HF with reduced EF. The cohort consisted on 3000 patients admitted in the therapeutic unit of heart failure (TUHF) between 2006 and 2015. During the study period 3042 patients were diagnosed with heart failure with reduced ejection fraction < 0.50. Thirty-five per cent were women. Of these patients, 11% of them presented an ischemic stroke with a male predominance (12% versus 11%, sex ratio 2). Patients with HF with ejection fraction superior to 30% exhibited similar risk of stroke as those with reduced ejection fraction inferior to 30%: 13% versus 8% per 100. Eleven per cent of patients without atrial fibrillation presented a stroke. Among the studied population, 17.5% had a prior history of myocardial infarction. When we compared the incidence of stroke among patients without atrial fibrillation in terms of medical treatment, there was 10% of stroke in the group taking vitamin K antagonist and 11% in the group taking antiplatelet therapy.

Conclusion: In our study, it seems that female patients were at lower risk of stroke, in the other hand, prior history of myocardial fraction was predictor of stroke; however the severity of left ventricle systolic dysfunction did not influence the risk of embolic events.

P879

Increased epicardial adipose tissue volume correlates with cardiac sympathetic denervation in patients with heart failure

V Parisi¹; G Rengo¹; S Paolillo²; R Formisano¹; G Gambino¹; T Pellegrino³; A Cuocolo³; P Perrone Filardi³; N Ferrara¹; D Leosco¹

¹University of Naples Federico II, Department of Translational Medical Sciences, Naples, Italy; ²SDN Foundation IRCCS, Naples, Italy; ³Federico II University of Naples, Advanced Biomedical Science, Naples, Italy

Background: It has been reported that epicardial adipose tissue (EAT) may affect myocardial autonomic function. Purpose. The aim of this study was to explore the relationship between EAT and cardiac sympathetic nerve activity in HF patients. Methods. We evaluated the correlation between echocardiographic EAT thickness and cardiac adrenergic nerve activity, assessed by 123I-metaiodobenzylguanidine (123I-MIBG), in 110 patients with systolic HF. Further, catecholamine levels, catecholamine biosynthetic enzymes, and sympathetic nerve fibers were measured in EAT and subcutaneous adipose tissue (SCAT) biopsies obtained from HF patients undergone cardiac surgery. Results. EAT thickness correlated with 123I-MIBG early and late H/M ($r = -0.30$, $p = 0.001$; $r = -0.33$, $p = 0.0001$, respectively), and SPECT TDS ($r = 0.70$, $p = 0.0001$) but not with left ventricular ejection fraction (LVEF). EAT resulted an independent predictor of 123I-MIBG early and late H/M, and SPECT TDS and had significant additive predictive value ($p < 0.05$) on 123I-MIBG planar and SPECT results over demographic and clinical data (age, gender, body mass index, NYHA class, heart failure of ischemic etiology, diabetes, hypertension and dyslipidemia). Although no differences were found in sympathetic innervation between EAT and SCAT, EAT presented an exalted sympathetic activity. In fact, EAT showed a 5.6 fold increase of norepinephrine levels compared to SCAT (0.168 ± 0.026 vs 0.030 ± 0.008 ng/ml; $p < 0.0001$) and a 2 fold increase compared to plasma (0.168 ± 0.026 vs 0.085 ± 0.014 ng/ml; $p = 0.017$). Epinephrine levels were significantly higher in EAT than in SCAT (0.016 ± 0.001 vs 0.008 ± 0.0005 ng/ml; $p < 0.0001$) but lower than in plasma (0.016 ± 0.001 vs 0.06 ± 0.008 ng/ml; $p < 0.0001$). mRNA levels of NE synthesizing enzymes, TH and DBH, were both significantly higher in EAT than in SCAT (8.6 fold and 6.5 fold increase, respectively), explaining the higher NE concentrations in EAT. We observed a robust increase of both TH and PNMT protein levels in EAT compared to SCAT ($p = 0.002$; $p < 0.001$, respectively).

Conclusions: This study provides the first evidence of the correlation between EAT thickness and cardiac sympathetic denervation in HF

P880

Association of left ventricular function parameters and maximal duration of apnea/hypopnea event in heart failure patients with central sleep apnea

K Waga¹; M Adamek²; J Biernat¹; A Drzewiecka¹; KS Golba³

¹Upper Silesian Cardiology Center, Electroradiology Department, Katowice, Poland; ²Medical University of Silesia, Chair and Dept of Thoracic Surgery, Faculty of Medicine and Dentistry, Katowice, Poland; ³Medical University of Silesia, Department of Electroradiology and Heart Failure, School of Health Sciences, Katowice, Poland

Introduction: Central sleep apnea (CSA) in heart failure with reduced ejection fraction (HFrEF) is highly prevalent and associated with more severe forms of heart dysfunction. The repetitive episodes of hypoxemia leading to oxidative stress and elevated levels of circulating catecholamines have detrimental effects on myocardial oxygen supply and ventricular performance. There is only few data concerning association between maximal duration of apnea/hypopnea event (Tmax A/H) and ventricular function in these patients.

Methods: 27 consecutive patients (20 males and 7 females, 63.7 ± 9.7 years) with HFrEF (LVEF < 35%) were enrolled. In 17 cases HFrEF resulted from ischemic heart disease, and from non-ischemic cardiomyopathy in 10. All patients underwent echocardiographic examination using standard protocol and polysomnography.

Results: The average left ventricular (LV) ejection fraction (EF) was $25 \pm 3\%$ (Simpson EF) with mean end diastolic (EDD) and end systolic (ESD) diameters of 69.2 ± 2 mm and 58.6 ± 2.5 mm respectively and average LV diastolic and systolic volumes of 278.3 ± 63.5 and 209.6 ± 33.5 respectively. Sleep apnea with predominant CSA was diagnosed in 20 patients, in 3 patients CSA coexisted with obstructive apneic events and 4 patients had no sleep-breathing disorders. In subjects diagnosed with CSA mean apnea/hypopnea index (AHI) was 23.98 ± 13.05 . In these patients Tmax A/H lasted between 52.5 and 339.5 s. EF exhibited statistically significant negative correlation to Tmax A/H; $r = -0.51$, $p = 0.0206$. However no correlation was observed between Tmax A/H and LV diameters (EDD, ESD) as well as LV volumes (EDV, ESV).

Conclusion: The maximal duration of apnea/hypopnea event is significantly associated with deterioration of LV function in heart failure patients with central sleep apnea.

P881

Hyponatremia increases significantly across worse NYHA functional class categories in chronic heart failure patients with reduced ejection fraction: results from TREAT HF

Y Yuksek Cavusoglu¹; S Eraslan¹; H Kaya²

¹Eskisehir Osmangazi University, Eskisehir, Turkey; ²Cumhuriyet University, Cardiology, Sivas, Turkey

Purpose: Hyponatremia has been established as a strong predictor for worse clinical outcomes for both in outpatients and hospitalized patients with heart failure (HF). NYHA functional class has also been known to be a strong marker of poor prognosis. TREAT HF (Turkish Research Team-HF) data were analyzed to evaluate any relation of blood sodium levels or hyponatremia with NYHA functional class categories in patients with chronic HF and reduced ejection fraction (HFrEF).

Methods: TREAT HF is a network which undertakes multicenter, national, observational studies designed to evaluate HF patient's clinical characteristics and current treatment modalities and enrolled ambulatory patients with the diagnosis of HFrEF and > 18 years of age. 908 patients who had blood sodium measurement and ECG-based heart rhythm were included in this analysis. Hyponatremia was defined as blood sodium level < 135 mEq/L. Patients with recent acute coronary syndromes, severe hepatic or renal dysfunction, severe chronic obstructive pulmonary disease, severe anemia, cancer, hyper-/hypothyroidism and pregnant women were excluded from the study.

Results: Mean blood sodium level was 137.9 ± 4.1 mEq/L in overall study population. Among 908 patients, hyponatremia was found in 219 (24.1%) patients and 689 (75.9%) patients had normonatremia. Mean sodium level was 138.5 ± 3.4 mEq/L in those with NYHA class I, 138.2 ± 3.9 mEq/L in those with NYHA class II, 137.7 ± 4.3 mEq/L in those with NYHA class III and 135.9 ± 4.4 mEq/L in those with NYHA class IV and overall, sodium levels were found to significantly decrease across NYHA functional class categories ($p = 0.001$). Hyponatremia was found in 17 patients (15.7%) in those with NYHA class I ($n = 108$), 89 patients (22.1%) in those with NYHA class II ($n = 403$), 94 (26.9%) in those with NYHA class III ($n = 350$) and 19 patients (40.4%) in those with NYHA class IV ($n = 47$) and overall, the prevalence of hyponatremia was also found to gradually and significantly increase across NYHA functional class categories ($p = 0.004$). There found no significant difference in prevalence of hyponatremia between NYHA I and NYHA II ($p = 0.181$), and also between NYHA II and NYHA III ($p = 0.075$) while patients with NYHA IV showed significantly higher rate of hyponatremia when compared those with NYHA III, NYHA II or NYHA I ($p = 0.042$, $p = 0.006$ and $p = 0.001$, respectively), and also those with NYHA III had higher prevalence of hyponatremia when compared to those with NYHA I ($p = 0.011$).

Conclusions: These results suggest that hyponatremia increases significantly across worse NYHA functional class categories in chronic HFrEF patients.

P882

Pulmonary hypertension secondary to left heart disease: clinical characteristics and correlations between right heart catheterization and non-invasive parameters

M Kaluzna-Oleksy¹; J Migaj¹; M Mroz²; A Nowak¹; E Straburzynska-Migaj¹

¹Poznan University of Medical Sciences, 1st Department of Cardiology, Poznan, Poland; ²Poznan University of Medical Sciences, Poznan, Poland

Introduction: Left heart disease is the main cause of pulmonary hypertension (PH). PH is considered a risk factor for worse outcomes in patients with heart failure. Initial evaluation of PH patients involves non-invasive methods including echocardiography and B-type natriuretic peptide tests (BNP); however, the final diagnosis requires right heart catheterization (RHC).

Aim: To characterize patients with heart failure with reduced ejection fraction (HFrEF) with and without PH, and to evaluate the role of echocardiography and BNP tests in diagnosis of PH in HFrEF patients.

Methods: This was a prospective analysis of 55 patients (both genders) with HFrEF (LVEF <40 %) hospitalized at a tertiary health care center, undergoing qualification process for heart transplantation. The following were analyzed: medical history, epidemiological data, chosen laboratory test results (including BNP), and chosen parameters obtained in echocardiography and RHC (thermodilution method). PH was diagnosed according to the ESC guidelines. Correlation tests were performed for RHC parameters, BNP and chosen echocardiographic parameters. Analysis was performed using Statistica 10, Statsoft. Correlations were tested using the Spearman's test. $P < 0.05$ was considered significant.

Results: Mean age was 51.3 ± 9 . Most patients were men (91.5%). Mean NYHA class was 2.5. There were 37 patients with PH and 18 without. The patients with PH did not differ significantly from those without as to age (50.8 vs. 52.1 respectively), gender, cause for HF and NYHA class. Patients with PH showed significantly higher BNP test results (783.5 pg/mL vs. 269 pg/mL; $p < 0.0001$), larger left ventricle (LV) in echocardiography (74.5 mm vs. 64.8 mm; $p = 0.0039$), lower LVEF (20 % vs. 25.4 %; $p = 0.0154$), and higher right ventricular systolic pressure (RVSP) (44.9 mm Hg vs. 34.9 mm Hg; $p = 0.0017$). There were no significant differences as to size of right ventricle and left atrium. BNP test result showed a significant positive correlation with mean pulmonary arterial pressure (mPAP) ($r = 0.58$), with mean right atrial pressure ($r = 0.37$), with mean right ventricular pressure ($r = 0.44$), with pulmonary capillary wedge pressure (PCWP) ($r = 0.45$) and with pulmonary vascular resistance (PVR) ($r = 0.37$). There was no significant correlation between BNP and transpulmonary gradient (TPG). Indirect evaluation of PH, i.e. RVSP measurement in echocardiography correlated significantly with mPAP measured in RHC ($r = 0.57$). There were also significant correlations between RVSP and PCWP ($r = 0.40$), TPG ($r = 0.58$) and PVR ($r = 0.44$).

Conclusions: Patients with PH secondary to HFrEF have lower EF, larger LV hypertrophy and higher BNP test results in spite of similar clinical profile. BNP test results and RVSP measured in echocardiography correlate with invasive RHC parameters.

Cardiac extracellular matrix accumulation is associated with adverse outcome in patients with chronic heart failure

Austrian fellowship grant, KLI 246, KLI 245 and the Austrian Society of Cardiology, the Österreichischer Herzfonds

F Franz Duca¹; CT Zotter-Tufaro¹; AK Kammerlander¹; AP Panzenboeck¹; BB Boerries¹; SA Aschauer¹; HA Agis²; RK Kain³; JM Mascherbauer¹; DB Bonderman¹

¹Medical University of Vienna, Cardiology, Vienna, Austria; ²Medical University of Vienna, Oncology, Vienna, Austria; ³Medical University of Vienna, Pathology, Vienna, Austria

Background: Accumulation of extracellular matrix (ECM) is known to play a crucial role in the pathophysiology of heart failure. However, its prognostic relevance is poorly investigated.

Purpose: We aimed to elucidate the influence of ECM area on outcome in non-ischemic heart failure (HF).

Methods: 73 HF patients who underwent left ventricular (LV) endomyocardial biopsy (EMB) were enrolled in our study. ECM area was quantified by TissueFAXS and ImageJ software. Patients were followed prospectively. The study endpoint was hospitalization for cardiac reason or cardiac death. Multivariable Cox regression analyses was used for survival analyses. Influence of ECM area on invasively assessed hemodynamic parameters was tested as well.

Results: During follow-up 34 patients reached the combined endpoint. Median ECM area was 30.5%. Patients with ECM area $\geq 30.5\%$ experienced more events ($p < 0.001$). ECM area was independently associated with outcome in the total HF cohort ($p < 0.001$) as well as in HF patients with preserved (HFpEF, $p = 0.014$) and HF patients with reduced ejection fraction (HFrEF, $p = 0.011$). ECM area correlated with pulmonary artery wedge pressure ($p = 0.042$, $R = 0.249$), mean pulmonary arterial pressure ($p = 0.258$, $R = 0.035$), as well as right atrial pressure ($p = 0.353$, $R = 0.003$). Stroke volume index ($p = 0.045$, $R = -0.247$) was negatively correlated with ECM area. Conclusion. ECM area within the LV myocardium is a determinant of left and right heart hemodynamics and crucially impacts clinical course in various non-ischemic HF types.

Baseline Characteristics

Diastolic wall strain and vortex formation time: new parameters in assessment of heart failure with preserved ejection fraction

Acknowledgments: This work was supported by Governmental grant IGA MZ ČR 14087-3/2013 and Specific University Research Grant MUNI/A/1270/2015.

M Spinarova¹; J Meluzin¹; H Podrouzkova²; R Stepanova²; L Spinarova¹; ¹St. Anne's University Hospital, First Department of Internal Medicine - Cardioangiopathy Faculty of Medicine, Brno, Czech Republic; ²International Clinical Research Center, Brno, Czech Republic;

Introduction: Heart failure with preserved ejection fraction (HFpEF) is currently observed in 30-50% of all patients with chronic heart failure. Diagnosis of HFpEF is frequently challenging and relies upon careful clinical evaluation, echo-Doppler cardiography, and invasive hemodynamic assessment. However, a simple echocardiographic parameter has not been established so far. The aim of this work is to evaluate new indexes, that could be calculated from routine 2D echocardiography, to improve the current non-invasive diagnostics of HFpEF. Diastolic wall strain of posterior wall (DWS PW) has been proposed as a marker of left ventricular stiffness. Vortex formation time (VFT) is an index of the optimal conditions for vortex formation in early diastole.

Methods: Echocardiographic data from 111 subjects with exertional dyspnea having normal left ejection fraction (Group A) and 20 healthy volunteers (Group B) were retrospectively evaluated. In addition to the standard parameters used in the diagnosis of HFpEF, DWS PW and VFT were assessed in all patients. HFpEF has been proved in 38 patients with dyspnoea (Group A1). The remaining 73 patients have not met established criteria for positive diagnosis of HFpEF (Group A2).

Results: Patients with HFpEF (Group A1) were compared with other subjects with dyspnea (Group A2) and significantly different values were found: DWS PW (0.261 \pm 0.064 vs 0.329 \pm 0.066, $p < 0.001$), E/e' (11.00 \pm 2.61 vs. 8.2 \pm 1.95, $p < 0.001$), e' (7.10 \pm 1.47 cm/sec vs. 9.10 \pm 1.89 cm/s, $p < 0.001$), LV mass index (106.70 \pm 25.90 g/m² vs. 83.30 \pm 17.04 g/m², $p < 0.001$), NT-proBNP (326.60 \pm 280.41 pg/ml vs. 119.70 \pm 83.82 pg/ml), s' (peak mitral annular systolic velocity, 7.40 \pm 0.98 cm/sec vs. 8.80 \pm 1.49 cm/s, $p < 0.001$) and VFT (3.00 \pm 1.14 vs. 4.1 \pm 1.50, $p < 0.001$). No difference was observed between the group A2 and the control group B. Multivariate analysis, which includes standard parameters for the diagnosis of HFpEF as well as new parameters, revealed, that NT-proBNP (Odds Ratio 1.136, 95% CI 1.052 to 1.226), LV mass index (Odds Ratio 1.307, 95% CI 1.1055 to 1.620) and DWS PW (Odds Ratio 0.848, 95% CI 0.750 to 0.959) independently predict the presence of HFpEF.

Conclusion: The data indicates a potential role for DWS PW and VFT as a part of an integrated approach to the non-invasive assessment of diastolic function. Moreover DWS PW appears to be an independent predictor of HFpEF presence.

P885

The severity of dyspnea predicts the final diagnosis of heart failure and is related to BNP level in patients admitted to the emergency departmentG Gabrielius Jakutis¹; J Celutkienė²; V Polevoda¹; V Juknevičius³¹Vilnius University, Faculty of Medicine, Vilnius, Lithuania; ²Vilnius University, Clinic of Heart and Vascular diseases, Vilnius, Lithuania; ³State Research Institute, Vilnius, Lithuania

Background/Introduction: Criteria of diagnosis and therapeutic strategies for heart failure (HF) patients still remain under discussion. Emergency departments became a major entry point for the initial management of acute heart failure (AHF) patients. Misdiagnosis, under or overtreatment, or inappropriate admission may place patients at increased risk for adverse events. The severity of dyspnea might be helpful for differentiating HF from other related clinical conditions. Purpose. The study evaluated whether the severity of dyspnea could be used as a prognostic marker of the final diagnosis of AHF and if it correlates with the degree of cardiomyocyte stress assessed with the use of biochemical parameter – BNP value. Methods. 151 consecutive patients admitted to the emergency department were enrolled in the study. Inclusion criteria were: dyspnea and suspected conditions of acute or recently decompensated HF, exacerbation of chronic obstructive pulmonary disease, pneumonia and pulmonary embolism. The exclusion criterion was acute coronary syndrome. Patients fulfilled the dyspnea test scale with marks from 1 to 10. Patient groups were defined based on the dyspnea test

Results: significant dyspnea group (SDG) – dyspnea test value ≥ 6 and moderate dyspnea group (MDG) – dyspnea test value < 6 . Final HF diagnosis was independently adjudicated on the basis of electronic case records including a discharge letter by heart failure cardiologist. Data was analysed using SPSS v23 statistical package. Results. 83 (55%) patients were male and 68 (45%) female. SDG consisted of 91 (60,3%) patients and the MDG of 60 (39,7%). 96 (63,6%) patients with the final diagnosis of acutely decompensated HF or de novo HF demonstrated significantly higher dyspnea test grades ($6,83 \pm 2,43$) compared to 55 (36,4%) patients who were not diagnosed with HF ($5,85 \pm 2,36$) ($p=0,018$). Mean concentration of BNP cardiac biomarker in the SDG patients' serum was $944,81 \pm 1236,00$ pg/mL and $667,67 \pm 780,87$ pg/mL in MDG ($p > 0,05$). There was a statistically significant positive correlation between the severity of dyspnea and BNP concentration in patients' serum ($G=0,334$, $p=0,012$). All patients with three or more cardiovascular co-morbidities presented with significantly greater dyspnea than patients with less than three cardiovascular co-morbidities ($p=0,025$). Binary logistic regression analysis revealed that patients with BNP serum concentration greater than 400 pg/mL were 4,92 times more likely to be diagnosed with acute, recently decompensated or de-novo HF ($p=0,025$).

Conclusions: Dyspnea is a significant predictor of the final diagnosis of acute, recently decompensated or de-novo HF. Patients with AHF and de-novo HF have more severe clinical presentation of dyspnea compared to patients with other related clinical conditions. Serum concentration of BNP cardiac biomarker is significantly related to the severity of dyspnea.

P886

Predictors of one year mortality in chronic systolic heart failureH M Hadj Mohammed Ali Lahmar¹; N Laredj¹; L Hammou¹¹University Hospital Center of Oran, department of medicine, Oran, Algeria

Introduction and problematic: heart failure is a common pathology, with a heavy morbidity and mortality. Its prevalence in the world varies between 1 and 2% of the adult population and reaches 10% after 70 years. It represents the ultimate evolution of many cardiovascular diseases, especially ischemic and hypertensive. Heart failure is associated with high morbidity and mortality. A lot of progress where new techniques have emerged and made possible functional improvement and, especially a better survival, to certain category of patients. Therefore, the prognostic evaluation becomes a crucial step in the management of heart failure, to guide treatment decisions based on individual risk. Objective : identifying and measuring predictors of one-year mortality in newly diagnosed chronic systolic heart failure

Methods: we conducted a longitudinal prospective analytical bi – centric study, with one year follow-up.

Results: 206 patients were enrolled with a mean age of $54,9 \pm 1,8$ years, a sex ratio of 1,9. The prevalence of diabetes mellitus was 39,8%, hypertension 30,1%. Coronary artery disease was present in 50,5%, dilated cardiomyopathy in 30,1% and toxic cardiomyopathy in 1,9%. The mortality rate was 12,7% (11,7% in men vs 14,2% in women, p not significant) and re-admission rate was 17,6% (23,1 % for men vs 6,6% in women, $p=0.004$). Most clinical, echographic, biological and functional parameters cited in the literature have demonstrated prognostic predictive value with different rates of sensitivity and specificity. In multivariate analysis, pulmonary vascular resistance (new highly sensitive and specific parameter , RR 47), BNP , TAPSE , dP / dt, the distance travelled in six-minutes' walk test and serum sodium level were predictors of mortality in heart failure. The median survival by Kaplan- Meier was 24 months, with no gender difference. All parameters influencing mortality had an impact on survival. Improving the quality of life as measured by the six minutes' walk test and the questionnaire was significantly improved in patients

remained alive. Finally, the evaluation of drug prescriptions trends, according to new international guidelines, is quite reassuring in that the new molecules that allowed a significant reduction in morbidity and mortality in heart failure are widely prescribed in our patients.

P887

In - hospital results of the percutaneous coronary interventions at coronary heart diseases pts with low ejection fractionHG Fozilov¹; TA Abdullayev¹; NA Kurbanov¹; I A Igor Tsoy¹; AM Karimov¹¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The purpose: the analysis of in hospital results of the percutaneous coronary interventions at coronary heart disease (CHD) pts with low ejection fraction (EF) of the left ventricle (LV).

Materials and methods: From January, 2013 year to December 2014 y PCI have been executed at 1266 pts with various forms of CHD. At CHD pts with low EF of the left ventricle PCI have been executed in 11.9 % (151) cases. 138 pts have been included in the research conducted by us with low EF of LV (less than 45 %) defined by method Teicholz by which in the subsequent it has been executed PCI. At 138 pts it has been spent 161 PCI. At 21 pts PCI it has been executed in 2 stages, and at one pt in 3 stages. Criterion of an exception - echo-poor pts, pts in which anamnesis, were available earlier transferred operations myocardial revascularization (CABG and/or PCI) for more than 1 year. Pts of a male have made - 80.4 % (111), and female - 19.6 % (27). The age of pts fluctuated from 35 till 78 years, and has on the average made 58.9 ± 8.6 years. From the standard risk factors most often met an arterial hypertension - at 79.7 % (110) pts, hyperlipidemia - at 75.4% (104); a diabetes mellitus at 34.7 % (48) pts. The EF of the LV fluctuated from 18 % to 45 %, and has on the average made 37.6 ± 5.6 %. In 42.9 % (69) cases PCI have been executed at pts with acute myocardial infarction; in 41.6 % (67) cases at a stable angina II-IV FC, and in 15.5 % (25) cases at an unstable angina. In total it has been implanted 259 stents (on the average 1.8 stents on one pt) from them of 85.3 % (221) drug eluting stents; 12 % (31) bare metal stents and 2.7 % (7) bioabsorbed vascular skeletons 'ABSORB'. Average diameter drug eluting stents 3.4 ± 1.56 mm, and length 26.4 ± 7.8 mm; diameter bare metal stents 3.04 ± 0.32 mm, and length 19.4 ± 6.8 mm.

Results: In our research frequency of angiographic success at implantation stents at CHD pts with low EF LV has made 89.4 % (144), the in-hospital success of procedure has made 85.7 % (138), and clinical success - 89.4 % (144). Frequency of complications has made 8.1 % (13) cases; from them in dissection a coronary artery has developed in 69.2 % (9) cases; occlusion a side branch - in 15.4 % (2) and in 15.4 % (2) cases has developed the phenomenon 'no-reflow'. Frequency of the major adverse cardiac events (an acute myocardial infarction, a lethal outcome, coronary artery bypass grafting) has made - 1.2 % (2); in both cases the non Q-wave acute myocardial infarction has developed. The reasons of development of not fatal acute myocardial infarction in 1 case was occlusion a side branch, and in 1 case – dissection a coronary artery.

The conclusion: Thus, the analysis of our experience shows that PCI at CHD pts with low ejection fraction of the left ventricle is an effective and safe method revascularization. Frequency of clinical success at a hospital stage of supervision has made 89.4 % (144) cases, and frequency of development major adverse cardiac events – 1.2 % (2).

P888

Role of investigation of b-natriuretic peptide in chronic heart failureMI Juraev¹; KHA Mamatkulov¹; MX Usarov¹; AA Bozorov¹¹Tashkent Medical Academy, ?1 Republican Clinical Hospital, Tashkent, Uzbekistan

Purpose: Study of the level of correlation - B - natriuretic peptide (BNP) in patients with CHF.

Materials and methods: The study tested 40 patients with CHD and heart failure, aged 45 to 68 years (mean age 56.6 ± 1.3), including 15 women and 25 men admitted urgently with pain in the No.1 Republican Clinical Hospital over the 2015, at echocardiography studied ejection fraction was over than 50%. All participants underwent an electrocardiogram, chest X-ray, general clinical and biochemical study: lipid profile, blood glucose, cardiac markers (troponin, myoglobin, BNP). Results and discussion. Recommendation to determine BNP levels at CHF questionable part of the modern clinical guidelines with the highest level of evidence A. Ejection fraction in our patients was $51.8 \pm 1,6\%$ (for Simpson). According to clinical manifestations of heart failure, all patients distributed as follows: 18 patients-the first stage, and 22-the second stage. According to the results of our study, the level of BNP in our patients ranged from 80.0 to 375.0 and amounted to 216.4 ± 2.7 pg /ml. At the same time, with first stage of CHF, it was significantly lower than with second stage (126.2 ± 2.1 in the first and 233.8 ± 3.3 in the 2nd; $P < 0.05$). In the treatment of 22 patients with CHF with second stage, 12 patients moved into the first. In the dynamic study of the content of BNP is equal to 104.71 ± 3.4 in the first and 181.6 ± 2.7 – in the 2nd stage. Conclusion. Thus, determination of BNP in CHF

helps to identify heart failure in the early stages, and can be recommended for monitoring the effectiveness of the treatment of CHF. BNP levels had a direct correlation with the stage of heart failure, and along the improvement patient's health, the level decreased respectively.

P889

Simplified ultrasound diagnosis of pulmonary oedema in heart failure.

M Mikheil Tsverava¹; DM Tsverava²

¹Tbilisi Medical Academy, Tbilisi, Georgia Republic of; ²MediClubGeorgia Tbilisi Clinic, Medicime, Tbilisi, Georgia Republic of

Pulmonary edema (PE), due to fluid retention and redistribution is the cardinal manifestations of heart failure (HF). The aim of this investigation was to study the effectiveness of simplified thoracic sonography in diagnosis of PE

Material and Methods: 400 patients with II-IV NYHA functional class HF were evaluated (105 patients with diastolic and 295 with systolic HF). The control group consisted of 160 patients with different heart diseases (CHD, Hypertension, Aortic valve diseases), but without HF. Sonographic examination of a lung was done with 3,0-4,0 MHz convex or sector probe, from 10 points on thoracic wall (cross points of midclavicular line with II, IV and V intercostal spaces and anterior axilar line with IV and V intercostal spaces), which corresponded to the projection of lower, middle and upper lobes of right lung and upper and lower lobes of left lung.

Results: During ultrasound examination 94.5% of patients with HF had "Comet tail phenomenon" (CTPh), which was registered only in 35.5% patients without HF ($p > 0.001$). In DHF group CTPh was registered in 90.5% and in systolic HF group in 95.9% patients. In 91% of patients with HF CTPh was registered from 3 and more registration points. In control group CTPh was registered from more than 3 points only in 2 (1.3%) patients. The best results in diagnosis of DHF can be achieved if we take "3 and more registration points" as a reference point for diagnosis of pulmonary congestion (sensitivity - 0.911, specificity - 0.942, positive predictive value 0.975). The time of examination by simplified method for evaluation of CTPh and pleural space took 3-4 minutes.

Conclusion: In patients with HF during pulmonary ultrasound examination significantly often was registered CTPh. The count of registration points from the thoracic wall of CTPh 3 and > is sensitive and specific sign of HF. The simplified thoracic ultrasound is highly effective in diagnosis of PE in patients with HF

P890

Raised red blood cell distribution width as a predictor of heart failure and mortality in patients with st-elevation myocardial infarction

T Ellouze¹; T Triki Faten¹; R Hammami¹; S Charfeddine¹; S Mallek¹; L Abid¹; S Kammoun¹

¹University of Sfax, Department of cardiology Sfax Tunisia, Sfax, Tunisia

Background: Recent studies have reported increased red blood cell distribution width (RDW), a measure of red blood cell size heterogeneity, has been associated with adverse outcomes in heart failure and stable coronary disease. We investigated the association between RDW and risk of heart failure in patients with ST-elevation myocardial infarction (STEMI).

Methods: We prospectively enrolled 147 patients admitted for STEMI within 24 hours of symptom onset in our hospital from September 2012 to August 2013 (mean age 63.1 ± 11.6 years; men 77.6%). According to the median RDW at baseline (13.5%) on admission, the patients were divided into two groups: a low-RDW group (RDW <13.5%, $n = 77$) and a high-RDW group (RDW $\geq 13.5\%$, $n = 70$). The patients were followed up for clinical outcomes for up to 1 year after discharge.

Results: Patients in the highest RDW group (RDW ≥ 13.5) had higher risk of Heart failure during hospitalization (40% vs. 15.6%; $p = 0.001$) compared to those in the lowest group (RDW <13.5). The value of RDW was correlated with the severity of heart failure according to KILLIP classification ($p = 0.01$). High RDW remained significantly associated with increased risk for in-hospital mortality and left ventricular dysfunction (FE < 40%) (17.1% vs. 6.5%, $P = 0.04$ and 39.1% vs 14, 3% $p = 0.001$ respectively). Twenty-two patients (15%) died during follow-up. The cumulative incidence of all-cause death was significantly higher in the high-RDW group than in the low-RDW group (hazard ratio: 3.12; 95% confidence interval: 1.22-7.97; $p = 0.018$). The area under the receiver-operating characteristic curve of the RDW was 0.678 (0.548-0.809, $P = 0.008$).

Conclusion: RDW is an independent predictor of all-cause mid-term mortality in NSTEMI patients. It was associated with increased risk for heart failure during hospitalization. Further studies are needed to clarify the mechanisms of this association between RDW and adverse outcomes in patients with coronary artery disease.

P891

Non selective characterisation of heart failure with preserved ejection fraction in patients presenting to A and E

J Jessica Webb¹; J Draper¹; Y Yiu¹; S Piper²; T McDonagh²; R Rajani¹; S Kapetanakis¹; G Carr-White¹

¹St Thomas' Hospital, Cardiology Department, London, United Kingdom; ²King's College Hospital, Cardiology Department, London, United Kingdom

Background: The incidence of Heart Failure with preserved Ejection Fraction (HFpEF) has been estimated to be approximately 50%, although more recent publications suggest that adherence to the ESC guidelines result in a smaller incidence of HFpEF patients.

Purpose: At our institution, all patients presenting with possible heart failure undergo NT-proBNP testing. Those with results above 400ng/l automatically receive an echocardiogram with a dedicated heart failure sonographer, if a study had not been done in the last 6 months, and a heart failure consultant review. We reviewed all the plasma NT-proBNP results in our institution over one year and characterised those in whom the heart failure consultant subsequently diagnosed HFpEF.

Methods: All consecutive patients who had plasma NTpro-BNP requested between 10/09/2014 and 09/09/2015 were included. Hospital databases and records were used to identify diagnoses, length of stay and inpatient mortality. Outpatient mortality was confirmed using Summary Care Records (follow up range 4 to 16 months). Data was collected as part of our Institution's approved Clinical Audit.

Results: In total, 2135 patients had plasma NTpro-BNP tested between 10/09/2014 and 09/09/2015. 1791 patients had NT-proBNP over 400ng/litre. Of these, 605 patients had heart failure - 138 patients were diagnosed with HFpEF (22.8%), 398 with Left Ventricular Systolic Dysfunction - LVSD (65.7%) and 69 patients with Right Heart Failure (11.4%). There was no difference in the average time to review between these patients (1.01 days, SD 0.51). The patients with HFpEF had lower plasma NTpro-BNP - 5342.7ng/litre (SD 6808) compared to the patients with LVSD 12,298.0ng/litre (SD 16613.9) and RHF 6633.1ng/litre (SD 8967.4). The length of stay was shorter 7.7 days (SD 39 days) compared to patients with LVSD (12 days, SD 9.8) and patients with RVF (11.3 days, SD 7.3). The mortality was reduced in patients with HFpEF (12.5%) compared to patients with LVSD (25.8%) and RVF (22%).

Conclusions: In our institution over one year, only 22.8% of the patients presenting acutely with heart failure symptoms were diagnosed with HFpEF. These patients had lower plasma NT-proBNP, duration of stay and mortality than patients with LVSD and RHF.

P892

Using intrinsic cardiac shear waves to measure myocardial stiffness: initial results on a patient cohort with heart failure with preserved ejection fraction and hypertrophic cardiomyopathy

J Webb¹; O Holub¹; R Clough¹; G Carr-White²; R Razavi¹; R Sinkus¹

¹King's College Hospital, Cardiology Department, London, United Kingdom; ²St Thomas' Hospital, Cardiology Department, London, United Kingdom

Background: Transient Magnetic Resonance Elastography (tMRE) has been shown to detect stiffness in many organs and so we have applied this concept in vivo to assess whether myocardial stiffness can be measured in patients with Heart Failure with preserved Ejection Fraction (HFpEF) and Hypertrophic Cardiomyopathy (HCM).

Methods: Aortic valve closure results in a shear wave that propagates through the myocardium. The speed of this wave can be measured if the sequence is timed to the exact valve closure time. Cardiac Magnetic Resonance (CMR) imaging individual sequences are ECG and navigator gated and take approximately 90 seconds; the complete scan including planning takes approximately 40 minutes. Increased myocardial stiffness results in increased speed of shear wave propagation.

In this study the speed of propagation was compared in normal volunteers, patients presenting acutely with HFpEF ($n = 4$) and patients with HCM ($n = 4$). All 8 patients had echocardiographic evidence of diastolic dysfunction. The speed of propagation was compared with age, echocardiographic measures of diastolic dysfunction and plasma NT-proBNP.

Results: Motion-encoded images (with a motion sensitized gradient at 165Hz) demonstrated myocardial wall shear waves associated with the aortic valve closure at 329ms (range 280-380ms) after the R wave (Figure 1 A B C). tMRE successfully showed a difference in speed of propagation between volunteers, patients with HFpEF and patients with HCM (speed volunteers $12.6\text{m/s} \pm 2.0\text{m/s}$, speed HFpEF $19.5\text{m/s} \pm 3.5\text{m/s}$, speed HCM $23.3\text{m/s} \pm 5.8\text{m/s}$, $p < 0.05$, Figure 1D). One HFpEF patient who had invasive pressure volume loop studies was found to have increased left ventricular end diastolic pressure (LVEDP) and prolonged tau (represents the exponential decay of the ventricular pressure during isovolumic relaxation). There was no clear correlation shown between the speed of propagation in patients and age or the degree of diastolic dysfunction (measured by LVH, LA dilatation and E/E') but the Pearson coefficient with plasma NT-proBNP was 0.63 in patients presenting with acute heart failure.

Conclusions: The speed of propagation of the shear wave generated by the aortic valve was statistically higher in patients with Hypertrophic Cardiomyopathy, than patients with HFpEF than healthy volunteers. This suggests myocardial stiffness is increased more in HCM than in HFpEF, and in HFpEF more than in normal volunteers. tMRE has the potential to be an important diagnostic tool for the early detection of myocardial stiffness.

Transient Cardiac Elastography

Comparison of clinical presenting features of patients admitted with right versus left predominant heart failure. a single large tertiary referral centre retrospective studyS Chatur¹; S Reynolds²; J Howlett²; P Campbell³¹University of British Columbia, Medicine, Vancouver, Canada; ²Libin Cardiovascular Institute Of Alberta, Cardiology, Calgary, Canada; ³Mater Private Hospital, Heart And Vascular Centre, Dublin, Ireland

Background: HF affects more than 10% of adults aged 70 years or older and is associated with significant morbidity, mortality and frequent hospital admissions. Research efforts mainly focus on left ventricular (LV) dysfunction, while the syndrome of right heart failure (RHF) is overlooked. The prevalence and significance of predominantly right versus left sided heart failure in a cohort admitted with decompensated symptoms remains poorly described. Objective: To describe the prevalence of predominantly RHF in a cohort admitted for decompensated symptoms, and to assess for differences in clinical characteristics and length of stay (LOS) in those with predominantly RHF vs. LHF. Methods/

Results: 442 patients hospitalized for decompensated HF between January 2010 and January 2011 were identified and the health records retrospectively analyzed as part of a larger ongoing study. Based on signs and symptoms, a diagnosis of predominantly RHF or LHF was determined by a panel of HF experts according to current guidelines. The prevalence of RHF was 22% and LHF was 78%. RHF was associated with fatigue ($p < 0.0001$), pre-syncope/ syncope ($P < 0.01$), loss of appetite ($p = 0.01$), increased abdominal girth ($p < 0.0001$) and abdominal discomfort ($p < 0.001$). LHF was associated with orthopnea ($P = 0.0003$), PND ($p = 0.003$), and chest pain ($p < 0.001$). RHF patients had more hepatomegaly ($p = 0.0001$), ascites ($p < 0.0001$) and anasarca ($p = 0.0006$) while LHF patients more often had rales ($p < 0.0001$) and pulmonary edema ($p < 0.0001$). Both a longer mean duration of HF symptoms prior to admission (46.7 ± 81.6 vs. 21.0 ± 37.6 , $p < 0.0001$) and a longer LOS (18.0 ± 20.5 vs. 14.6 ± 12.6 , $p = 0.04$) was observed among those with RHF.

Conclusions: More than 1 in 5 patients admitted with decompensated symptoms had predominantly RHF. The clinical syndromes of predominantly right and left sided HF are associated with distinct sets of presenting features. Patients with RHF had a significantly longer LOS. In ongoing work, we are assessing for differences in the frequency of HF re-admissions and of time to re-admission among the two groups.

P894

What is the role of strain analysis by speckle tracking on the evaluation of left ventricular systolic and diastolic function in patients with type 2 diabetes?A L Ana Calvo¹; JM Portugues¹; VH Pereira¹; M Oliveira¹; B Faria¹; MR Lourenco¹; O Azevedo¹; FC Almeida¹; F Ferreira¹; A Lourenco¹¹Alto Ave Hospital Center, Cardiology, Guimaraes, Portugal; ²University of Minho - Life and Health Sciences Research Institute (ICVS), Braga, Portugal

Background: Diabetic cardiomyopathy (DC) describes left ventricle (LV) dysfunction secondary to diabetes and not attributable to hypertension, coronary or valvular disease. Diastolic dysfunction is considered to be the earlier feature of DC. Few studies have evaluated systolic and diastolic function by strain analysis in diabetic patients.

Objective: Assess systolic and diastolic LV function in patients with type 2 diabetes with strain analysis by speckle-tracking.

Methods: Prospective study including 43 patients with type 2 diabetes and 20 healthy controls. All subjects were submitted to transthoracic echocardiogram with evaluation of LV systolic and diastolic function using conventional echocardiography, tissue Doppler imaging (TDI) and strain analysis by speckle tracking.

Results: Patients with type 2 diabetes were older than controls (59 ± 12 vs 48 ± 13) and gender was not significantly different between groups (51% vs 35% males; $p = 0.231$). Time since diagnosis of diabetes was 12 ± 8 years, and the mean glycated hemoglobin was $7.9 \pm 1.6\%$. Hypertension was present in 63% of diabetic patients. Diabetic patients presented higher thickness of the interventricular septum (9.8 ± 1.6 vs 8.2 ± 1.2 mm, $p < 0.001$) and posterior wall (8.9 ± 1.4 vs 7.8 ± 0.9 mm, $p < 0.002$) and higher LV mass (83 ± 20 vs 71 ± 12 g/m², $p < 0.025$). Diabetic patients and controls were similar regarding ejection fraction ($65 \pm 5\%$ vs $66 \pm 4\%$, $p < 0.347$) and TDI

systolic velocity (8.4 ± 1.5 vs 8.7 ± 1.5 cm/s, $p < 0.367$). However, global longitudinal strain (GLS) was significantly worse in diabetic patients (-20.3 ± 1.7 vs $-21.2 \pm 1.3\%$, $p < 0.046$). Diabetic patients presented significantly lower TDI early diastolic velocities (9.2 ± 2.4 vs 11.8 ± 2.3 cm/s, $p < 0.001$) and higher E/e' ratio (9.2 ± 3.6 vs 6.6 ± 1.7 , $p < 0.002$). Strain analysis revealed that diabetic patients also presented worse early diastolic strain rate (EDSR) (1.54 ± 0.31 vs 1.95 ± 0.19 , $p < 0.002$). No differences were found between hypertensive and non-hypertensive diabetic patients regarding GLS (-20.3 ± 2.0 vs $-20.9 \pm 1.3\%$, $p = 0.800$) and EDSR (1.51 ± 0.26 vs 1.60 ± 0.39 , $p = 0.315$). Multivariate linear regression analysis revealed that diabetes mellitus was a predictor of GLS ($p < 0.049$) independent from age ($p < 0.839$).

Conclusion: In diabetic patients, both TDI analysis and strain analysis by speckle-tracking showed that diastolic dysfunction occurred earlier than systolic dysfunction. This suggests that strain analysis by speckle-tracking offers no incremental value over TDI regarding the detection of diastolic dysfunction. However, strain analysis by speckle-tracking played an important role in the evaluation of LV systolic function in diabetic patients, allowing an early diagnosis of systolic dysfunction while conventional and TDI parameters were still normal. Diabetes mellitus is a predictor of GLS, independent from age.

P895

State-of-the-art multilayer strain to study left ventricular contractility at rest and during exercise in patients with sickle cell anemiaA Ceccaldi¹; R Isnard¹; K Stankovic Stojanovic²; F Lionet²; S Hatem¹; N Hammoudi¹¹Hospital Pitie-Salpetriere, Cardiology, Paris, France; ²Hospital Tenon, Paris, France

Background: Left ventricular (LV) systolic dysfunction was reported in patients with sickle cell anemia (SCA) and is considered as the reflection of chronic sub-endocardial ischemia due to microcirculatory disorders. The contribution of LV systolic dysfunction to functional limitation of these patients has never been specifically investigated.

Purpose : Using multilayer strain technology, the aim of the study was to explore LV sub-endocardial layer function at rest and during exercise in SCA patients with chronic dyspnea. In addition we sought to investigate the contribution of LV systolic dysfunction to exercise functional limitation of these patients.

Methods: Echocardiography at rest and during maximal symptoms limited exercise was performed in 60 SCA patients referred for assessment of dyspnea and in 20 healthy controls matched for sex and age. The exercise capacity in metabolic equivalent (METs) was determined and the global longitudinal strain values of the three LV layers were measured. The results were compared between groups. Correlations between LV systolic parameters and exercise capacity were assessed in SCA patients.

Results: Compared with controls, patients had a severe impairment of exercise capacity (5.8 ± 1.1 vs. 10.3 ± 2.2 METs; $p < 0.001$). While epicardial and mid layers LV longitudinal strain were impaired in patients compared to controls (-16.3 ± 2.2 vs. -17.6 ± 2.2 ; $p = 0.02$ and -18.6 ± 2.3 vs. -19.8 ± 2.2 ; $p = 0.04$) sub endocardial strain was similar at rest (-21.2 ± 2.5 vs. -22.4 ± 2.3 ; $p = 0.08$). During exercise, patients and controls had similar LV contractile reserve and multilayer LV strain values were similar. No correlation was found between myocardial contractility measures and patient exercise capacity (table 1).

Conclusion: Exercise LV contractility of SCA patients with dyspnea was similar to healthy controls and do not contribute to exercise functional limitation of these patients.

Table 1: Correlation between myocardial contractility measures and patient exercise capacity (n = 60)

Variable	r	P-value
LVEF at rest	0.06	0.66
LVEF at 20 Watts	-0.01	0.97
LVEF at peak	0.03	0.83
Endocardial GLS at rest	-0.22	0.10
Endocardial GLS at 20 Watts	-0.21	0.11
Endocardial GLS at peak	-0.18	0.18
LVEF : left ventricular ejection fraction.

Reliability of diagnostic parameters from echocardiography and cardiopulmonary exercise testing in heart failure patients with preserved ejection fraction: results from Aldo-DHF trialR Ruhdja Lindhorst¹; A Bobenko¹; T Trippel¹; K Nolte²; G Hasenfuss²; HD Duengen¹; G Gelbrich³; R Wachter³; B Pieske¹; F Edelmann¹

¹Charité - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany; ²University Medical Center Göttingen (UMG), Department of Cardiology and Pneumology, Göttingen, Germany; ³University Julius Maximilian of Würzburg, Institute for Clinical Epidemiology and Biometry, Würzburg, Germany

Aims: Echocardiography (E/e') and cardiopulmonary exercise testing (peak VO₂) are common tests for evaluation of diastolic dysfunction; however their reliability remains uncertain. The aim of this study was to investigate the reliability of E/e' and peak VO₂ in the Aldo-DHF cohort. **Methods and**

Results: Echocardiography and cardiopulmonary exercise testing (CPET) were performed on all 422 included patients of the Aldo-DHF trial twice, at baseline and repeated after a week (± 1 day) under stable conditions without any changes in medication. All observed patients (mean age 67 years) presented with New York Heart Association class II or III heart failure, preserved left ventricular ejection fraction of $\geq 50\%$, diastolic dysfunction $\geq I^\circ$. To analyse reliability of the respective method, Bland Altman analysis were used. For E/e' mean difference was 0,1046. 95 % of variations in measurements were within the upper limit of 3,70 and the bottom limit of -3,49. We found a mean difference in peak VO₂ of 0,15 ml/kg/min with having an upper and bottom limit of 3,10/-2,81 ml/kg/min.

Conclusion: Taking in account that there was no clearance of outliers, the results from E/e' and peak VO₂ show a clinically high reliability for evaluating heart failure patients with preserved ejection fraction in recurrent examination. Although the Altman plot for peak VO₂ shows a crescendo for higher values, this effect was not clinically significant for the values of Aldo-DHF cohort with diastolic dysfunction but may have a different impact in testing a healthy, younger high performance population.

Altman plot for E/e' and peak VO₂

Hemodynamic effects of ivabradine in patients with advanced heart failure

This research was sponsored by Servier the manufacturer of ivabradine. R Ramon Tschierschke¹; A Ruhparwar²; P Ehlermann¹; HA Katus¹; PW Raake¹
¹University Hospital of Heidelberg, Internal Medicine III, Heidelberg, Germany;
²University Hospital of Heidelberg, Department of Cardiac Surgery, Heidelberg, Germany

Introduction: The number of hospitalized patients with severe and advanced heart failure is continuously increasing. In very severe cases the heart rate in these patient is increased due to endogenous sympathetic drive or to necessary positive inotropic pharmacological support. This tachycardia unfavourably affects hemodynamics by shortening of diastole resulting in decreased cardiac output and additionally elevated heart rate is regarded as an independent risk factor. We analysed in a retrospective approach all patients being listed for heart transplantation at high-urgency status (HU) at heart centre Heidelberg in the time from 2004 to 2015 whether a selective heart rate reduction with ivabradine is safe and analysed its impact on hemodynamics.

Methods: This is a single-center, non-interventional, retrospective study. From 2004 to 2015 384 patients have been evaluated for heart transplantation at University-hospital Heidelberg and received an organ or deceased on waiting list. Of those 37 fulfilled patients fulfilled all inclusion criteria (HU heart transplant listing, stable sinus rhythm, heart rate > 70 /min in non-ivabradine treated patients or ivabradine treatment, two invasive hemodynamic evaluations at least 8 weeks apart). 20 patients were pretreated with ivabradine at study inclusion and were continued on ivabradine over the 8 weeks observation period. 17 patients served as controls. Original data from the hospital archive were analysed in a retrospective fashion.

Results: In patients listed in HU status treatment with ivabradine was safe. No adverse events in context with ivabradine treatment occurred during the study period. At first evaluation hemodynamics were favourably affected by ivabradine, as despite lower ejection fraction in the ivabradine treated group cardiac output was similar in both groups at study inclusion. In addition, after 8 weeks ejection fraction worsened in controls compared to study inclusion, whereas a trend towards improvement in the ivabradine treated group was observed. A tendency towards use of ivabradine in sicker patients with regard to ejection fraction was perceived.

Conclusion: Use of ivabradine in advanced heart failure patients appears safe and a tendency towards improved hemodynamics in ivabradine treated patients was observed.

Anti-HLA antibodies prevalence in an advanced heart failure population

A Ayesta Lopez¹; I Sousa Casasnovas¹; P Diez Villanueva²; F Diez Del Hoyo¹; A Alonso Garcia¹; X Li¹; M Martinez-Selles¹; F Fernandez Aviles¹
¹University Hospital Gregorio Marañon, Madrid, Spain; ²University Hospital De La Princesa, Madrid, Spain

Introduction: Anti-HLA antibodies detection is a mandatory test before including a patient in heart transplantation waiting list and can preclude this therapy. The presence of these antibodies has been traditionally related with several risk factors: female sex, transfusions, previous pregnancies, previous cardiac surgery, congenital heart condition, previous circulatory assist device. Nowadays, demographic and clinical characteristics of candidates to cardiac transplantation have changed. In the other hand, newer and more precisely techniques are being used for anti-HLA antibodies detection. Our objective has been to evaluate the prevalence and risk factors associated with anti-HLA antibodies presence.

Material and methods: We included patients with advanced heart failure evaluated for heart transplantation in our centre between June 2010 until April 2015. Basal characteristics, anti-HLA antibodies test results and risk factors were collected. We performed a description of the data and risk factors analysis by logistic regression.

Results: 134 patients were evaluated during the study period. Mean age was 54.43 ± 11.12 years-old, 67.91% were male, 11.45% were smokers, 44.19% suffered from hypertension, 32.06% from diabetes and 38.93% were dyslipemic. According to traditional risk factors, 47.37% had previously received a transfusion, 33.33% had been operated from heart condition, 67.44% had been pregnant, 7.87% had had a circulatory assist device and 5.97% suffered from a congenital heart disease. 11.94% patients had developed HLA antibodies. 68.75% were type I (90.9% PRA $>10\%$) and 50% were type II (100% PRA $>10\%$). 2 patients had developed antibodies without any traditional risk factors. Simple logistic regression analysis related antibodies presence with female sex ($p=0.002$; OR 5.91; CI 95% 1.91- 18.35), previous pregnancy ($p=0.002$; OR 5.57; CI95% 1.86- 16.67) and previous cardiac surgery ($p=0.044$; OR 2.99; CI95% 1.03- 8.68). We did not find statistical relation in patients who had had a circulatory assist device ($p=0.797$), had received previous transfusions ($p=0.064$) nor patients suffering from a congenital heart disease ($p=0.256$). Multivariate logistic regression analysis showed that sex was a confusion variable due to pregnancies and was discarded in the final model: Previous pregnancies (OR 4.302; CI 95% 1.29- 14.42) and previous cardiac surgery (OR 4.005; CI95% 1.19- 13.51) were the variables finally significantly associated with anti-HLA presence.

Conclusion: In our experience, HLA antibodies prevalence in an advanced heart failure population was 11.94%. Its presence was related with previous pregnancies and cardiac surgery.

P899

Genetic variations in end-stage dilated cardiomyopathy patients

PTDC/BIM-MEC/0650/2012

A Sousa¹; P Canedo²; S Leite³; R Pinto³; M Campelo³; S Amorim³; B Moura⁴; JC Machado²; J Silva Cardoso³; E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Institute of Molecular Pathology and Immunology at the University of Porto, Porto, Portugal; ³Sao Joao Hospital, Porto, Portugal; ⁴Regional Military Hospital n°1, Porto, Portugal

Introduction: Dilated cardiomyopathy (DCM) is a major cause of heart transplantation. One of the hypotheses to explain disease progression, despite optimal medical therapy or device implantation, may be the presence of a particular genetic background. Currently, molecular diagnosis of cardiomyopathies, which are characterized by a great clinical heterogeneity, has been facilitated by the accessibility to next generation sequencing (NGS) technology.

Purpose: In this work we aimed to assess genetic background of adult patients with end-stage DCM.

Methods: Adult patients (> 18 years old) that undergone or were in active list for heart transplantation, because of idiopathic or familial DCM, were evaluated. Molecular analysis included the search of mutations in LMNA/C, MYH7, MYBPC3, TNNT2, ACTC1, TPM1, CSRP3, TCAP, SGCD, PLN, MYL2, MYL3, TNNI3, TAZ and LBD3 genes, using PCR technique with direct-sequencing (NGS with at least a 30- fold coverage combined with Sanger sequencing). Pathogenicity was assessed by comparisons with mutations previously described, functional tests and segregations studies.

Results: We included 14 patients, 9 (64%) with criteria of familial DCM; 11 (78%) males, mean age 46 ± 11 years, with mean age at diagnosis of 32 ± 14 years. Mean left ventricle ejection fraction was $20 \pm 8\%$ and mean end-diastolic left ventricular diameter 68 ± 10 mm. Four patients presented left bundle branch block, 7 had an ICD and 3 a CRT device. We identified nine genetic variants in 6 (43%) different patients: 5 in lamina A/C gene, 2 in LBD3 gene, one in TNNT2 gene and one in TCAP gene. New mutations were found in the majority (5/6) of the patients. Two of

the patients with LMNA mutations had also subclinical skeletal myopathy and one evolved to atrial paralysis. Based on family studies, we conclude that one of the variants (TCAP, c.313G > C in exon2, p.Glu105Gln) did not explain familial segregation of the disease.

Conclusion: In our restrict sample of end-stage DCM patients, the identification of genetic variants was not uncommon and allowed genetic screening in some families. The exploration of genes and genes/ambience interactions in larger series will certainly contribute for understanding the dismal heart remodeling process that occurs in a subgroup of DCM patients.

Transition between early and late experience with continuous intravenous morphine for relief of dyspnea in patients with advanced heart failure

S Oishi¹; T Miyata¹; W Fujimoto¹; Y Taniguchi¹; Y Yasaka¹; H Kawai¹

¹Himeji Cardiovascular Center, Himeji, Japan

Background: Palliative care for advanced heart failure is commonly recommended. However, we could not fulfill a demand because of limited evidence and experience.

Objectives: We have experienced continuous intravenous infusion of morphine for relief of dyspnea. We divided years into separate terms, early and late, and compared patients characteristics, dosage of morphine, sedative agents, inotropic agents and others, and effect of morphine among those phase.

Results: Morphine was administered for 42 patients for palliation of dyspnea from 2011 to 2015. Twenty-one patients were divided into two groups each according to the date. In late phase, patients were older than in early phase, however other characteristics of patients were not different between groups. In late phase, respiratory rate was further ameliorated ($p = 0.013$) and symptom was similarly relieved. Sedative agents in addition to morphine for overwhelmingly-stressful general malaise were administered more frequently in late phase ($p = 0.0063$). No patients discontinued morphine due to adverse events.

Conclusion: Low dose morphine was safe and effective. We have to continue evaluating how to use morphine and other drugs in order to appropriately provide palliative care for distressed patients.

	Early	Late	p value

Effect of angiotensin converting enzyme inhibitors and angiotensin II receptor blockers on cardiovascular deaths in patients with and without diabetes mellitus in advanced chronic heart failure

A Alptug Tokatli¹; G Kozdag²; D Ural²; K Karauzum²; I Yilmaz²; O Argan²

¹Golcuk Military Hospital, Kocaeli, Turkey; ²Kocaeli University, Department of Cardiology, Kocaeli, Turkey

Background: Angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) may have different effects on cardiovascular deaths in patients with and without diabetes mellitus (DM) in advanced chronic heart failure.

Purpose: To compare the effect of ACEIs and ARBs on cardiovascular mortality in advanced systolic heart failure in patients with and without DM.

Methods and Results: We analysed the data of 630 patients (mean age: 66 ± 12 years, 231 female, mean ejection fraction (EF): 25 ± 10%) with advanced systolic heart failure. 250 patients (40%) had diabetes mellitus in the study group. 313 patients (49.7%) of the cohort died during a median follow-up duration of 54 months. While 48% of the patients with diabetes died, 44% of patients without diabetes died during the follow-up period ($p = 0.27$). 460 patients were receiving ACEIs and 121 patients were on ARBs therapy. 49 patients did not take either ACEIs or ARBs. 43% of patients with diabetes who were on ACEIs therapy, 65% of patients with

diabetes who were on ARBs therapy and 48% of patients with diabetes who did not take either ACEIs or ARBs therapy died. There was only statistically significant difference between patients with diabetes who were on ACEIs therapy and patients with diabetes who were on ARBs therapy among patients who died during follow-up ($p = 0.005$). There was no impact on survival of taking ACEIs or ARBs in patients without diabetes in advanced chronic heart failure.

Conclusion: Angiotensin-converting enzyme inhibitors reduced the cardiovascular deaths in patients with diabetes in advanced chronic heart failure, whereas ARBs had no benefit on this outcome. Thus, ACEIs should be considered as first-line therapy to limit cardiovascular deaths in this population.

P902

Endomyocardial biopsy through a brachial venous approach.

E Enrique Gutierrez Ibanes¹; M Ventura¹; F Sarnago¹; R Sanz-Ruiz¹;

ME Vazquez¹; A Casado¹; A Rivera¹; E Zatarain¹; J Elizaga¹;

F Fernandez-Aviles¹

¹University Hospital Gregorio Maranon, Cardiology, Madrid, Spain

Introduction: recipients of a heart transplant need to undergo serial procedures of endomyocardial biopsy to rule out rejection. This requires the repeated puncture of central veins, usually the internal jugular or the femoral, which is not completely free of risks, pain and discomfort for the patient. So far, the brachial venous approach has not been considered a routine alternative for endomyocardial biopsy. In our center, we have developed a technique for brachial venous endomyocardial biopsy, which we have implemented as the preferred route. In this article, we describe the technique and the initial clinical experience.

Methods: Between February and October 2015, we developed and implemented the brachial venous approach technique. We registered prospectively the main clinical and procedural variables. Furthermore, we retrospectively recorded all the biopsy procedures performed in our center since 2010. We compared the characteristics of the procedures performed through different routes.

Results: the brachial route was attempted in 63 procedures, and achieved successfully in 62 (98.4%). No complications occurred. Between 2010 and 2015, 322 biopsy procedures were performed in 65 patients. Of them, 56.5% were through the jugular vein, 24.2% through the femoral and 19.3% through the brachial. The jugular procedures needed less fluoroscopy time and dose than the femoral and brachial procedures (fluoro time 2,4 / 5,3 / 6,2 min, $p < 0,01$; fluoroscopy dose 700 / 1473 / 2049 $\mu\text{g}\cdot\text{m}^2$, $p < 0,01$). The femoral procedures were longer than the rest (40 vs 30 min, $p < 0,01$). Brachial procedures were recalled as less painful than jugular or femoral ones (2 / 8 / 9 score on a scale of 1-10; $p = 0,001$). All patients who underwent procedures through two different paths preferred the brachial access.

Conclusion: the venous brachial route is a good alternative to central venous route for endomyocardial biopsy, with high feasibility and safety, and additional patient comfort.

Procedure parameters according to route

	Brachial	Femoral	Jugular	p

Actual condition survey of terminal illness in the advanced heart failure: symptoms and drug utilization during the last two weeks of life

T Taishi Miyata¹; S Oishi¹; Y Taniguchi¹; H Kawai¹; Y Yasaka¹; M Yokoyama¹

¹Himeji Cardiovascular Center, Himeji, Japan

Background: Management and therapy have improved the survival of heart failure (HF) patients. However, many patients progress to advanced chronic HF and death

with variety of symptoms. Recently, palliative and supportive care intervention in advanced heart failure has referred in guidelines for heart failure. On the other hand, reports referred for characteristics and symptoms of the patients which should be intervened during the last few weeks.

Subjects and Methods: We retrospectively investigated the characteristics, symptoms, and drug usage during the last 2 weeks of patients with hospital admission for heart failure and die between November 2012 and October 2014.

Results: We investigated 40 patients (aged 79 ± 11 , 38% males, 33% ischemic etiology) with cardiac death (sudden cardiac deaths: 4 patients) among 841 patients with hospital admission for heart failure. Their last hospital length of stay was 32 ± 28 days and 73% of patients had a history of hospitalization within a year. Noninvasive positive pressure ventilation (NPPV) was used for 5 (13%) patients and endotracheal intubation was performed for 7 (18%) patients during two weeks. Left ventricular ejection fraction (LVEF) was $33 \pm 18\%$, plasma brain natriuretic peptide (BNP) level was 1709 ± 1890 pg/ml, and estimated glomerular filtration rate (eGFR) was 31.0 ± 20.4 mL/min/1.73 m². They complained of breathlessness (55%), fatigue (60%), pain (28%), nausea and vomiting (25%), anxiety (23%), and depression (10%) during last two weeks, respectively. Intravenous inotropic agents were continuously administered for 70% of patients until the last breath, and intravenous morphine was administered for 23% of patients for palliation of breathlessness and pain.

Conclusion: In this study the current situation of terminal phase of advanced heart failure became clinically evident. Appropriate palliative and supportive care was provided for patients based on right assessment of symptoms. Anxiety and depression were possibly underestimated because they tended to be missed without careful observation. Accurate evaluation and treatment including palliative and supportive care were required for the improvement in quality of life of advanced heart failure patients.

P904

Left atrial strain and capillary wedge pressure in patients candidate to heart transplantation

M Cameli¹; FM Righini¹; F Loiacono¹; M Stricagnoli¹; S Sparla¹; S Bernazzali²; M Maccherini²; C Sassi²; A Dokollari²; S Mondillo¹

¹University of Siena, Department of Cardiovascular Diseases, Siena, Italy;

²Department of Cardiovascular Diseases, Heart Transplant Unit, Siena, Italy

Background: Left atrial (LA) deformation analysis by speckle tracking echocardiography (STE) was recently proposed as an alternative approach to estimate LV filling pressures. This study aimed at exploring the correlation of LA longitudinal function by STE and Doppler measurements with direct measurements of LV filling pressures in patients candidate for heart transplantation at baseline and after nitroprusside challenge test.

Methods: 75 hemodynamically stable, end stage heart failure patients who were undergoing right heart catheterization (RHC) were included. Doppler echocardiography and RHC catheterization were simultaneously performed. Echocardiographic measures and STE were obtained as LA peak atrial longitudinal strain (PALS).

Results: LA PALS was inversely correlated with invasively assessed pulmonary capillary wedge pressure ($r = -0.83$; $P < 0.0001$). LA PALS retained this correlation even after nitroprusside challenge test ($r = -0.88$; $P < 0.0001$), indicating patients responder to preload decrease. E/E' showed poor correlation with wedge pressure at baseline and after nitroprusside infusion ($r = 0.24$, $p = ns$; and $r = 0.22$, $P = ns$). Area under the curve optimal cut offs for predicting the wedge pressure > 18 mmHg were for LA PALS 15.0% (AUC:0.91, sensitivity: 97%, specificity: 83%).

Conclusion: LA strain significantly correlate with pulmonary capillary wedge pressure and its changes after nitroprusside challenge test in patients candidate for heart transplantation. It could be considered a good tool for dynamic estimation of LV filling pressures.

ATRIAL FIBRILLATION

P905

Characteristics of heart failure decompensation on atrial fibrillation and on sinus rhythm.

N Koziolova¹; E Polyanskaya¹

¹Medical Academy, Perm, Russian Federation

Aim: to reveal some peculiarities of CHF decompensation course and unfavorable exits risk depending on cardiac rhythm on moment of hospitalization. Methods and materials: 60 patients who had been hospitalized due to CHF decompensation (average age 71.6 ± 11.5 yrs) were examined. They were divided into 2 groups depending on cardiac rhythm on moment of admission. The 1st group consisted of 30 patients with sinus rhythm, and the 2nd group – 30 patients with atrial fibrillation (AF) (12 patients with paroxysmal or persistent form, and 18 with permanent form). All the patients underwent standard clinical examination and observation for 3 months after discharge.

Results: groups were not different in sex, age, comorbidities, main biochemistry, doses of intravenous diuretics and inotropes, RAAS blockers and mineralocorticoid

blockers. Regimens of both anticoagulants and digoxin administration were different with prevalence in 2nd group ($=0.073$ and $=0.026$, respectively). There was significant disparity in LV EF affected by evident decrease: $35.8 \pm 2.7\%$ on sinus rhythm vs $33.9 \pm 3.1\%$ on AF ($=0.014$). Also, stands out the difference in hemoglobin level, which is low in both groups: 106.6 ± 7.7 g/L vs 101.7 ± 6.1 g/L ($=0.011$). Next hospitalizations after 3 months occurred reliably more frequently in the 2nd group: 3.3% vs 30.0% ($=0.044$). Correlation analysis showed that low hemoglobin has influenced on followed hospitalizations for CHF decompensation more than LV EF value ($r = -0.41$, $p = 0.045$ vs $r = -0.60$, $p = 0.102$, respectively).

Conclusion: CHF decompensation with atrial fibrillation proceeds with more evident systolic dysfunction, and anemia as the sign of system impairment, as well as it deteriorates prognosis in term of repeat episodes of CHF decompensation.

P906

Central blood pressure at different pulse wave velocity and atrial fibrillation recurrence in heart failure patients with preserved ejection fraction

I Irina Balabanenko¹; A Shavarov¹; G Kiyakbaev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Atrial fibrillation (AF) is common in heart failure (HF), but few data regarding relationship between arterial stiffness and AF recurrence are available in HF patients with preserved left ventricular ejection fraction (HF-PEF).

Aim: the purpose of this study was to compare AF recurrence rate in patients with HF-PEF and different PWVcf.

Methods: The study included 55 patients (40% men) aged 66 (62; 73) years with mild-to-moderate AH, one year anamnesis of recurrent AF and HF-PEF ($>50\%$). All patients were performed applanation tonometry. Patients were divided into 3 groups: with increased arterial stiffness ($PWV \geq 10$ m/s) and AF recurrence ($n = 19$), with normal arterial stiffness and AF recurrence ($n = 18$) and normal arterial stiffness and without recurrence of arrhythmia during 3 months follow-up ($n = 18$).

Results: Groups were significantly different by age ($p < 0.001$), the risk of thromboembolic events according to CHA2-DS2-VASc ($p = 0.002$), these rates were highest in the group with $PWV \geq 10$ m/s and AF recurrence. Patients with increased arterial stiffness had the highest heart rate (HR, $p = 0.009$), shorter time to return of reflected wave (Tr, $p < 0.001$) and a greater augmentation index (AIx-HR75, $p = 0.02$) with comparable values of both brachial and central SBP and DBP. Peripheral and central pulse pressure (PP and cPP) had significantly lower ranges in patients with normal arterial stiffness and without recurrence of arrhythmia ($p < 0.001$ and $p = 0.006$, respectively). Regression analysis showed positive correlations of AF recurrence with age ($\beta = 0.65$, $p < 0.001$), HR ($\beta = 0.54$, $p < 0.001$), cPP ($\beta = 0.60$, $p < 0.001$), AIx-HR75 ($\beta = 0.66$, $p < 0.001$) and negative relations with Tr ($\beta = -0.48$, $p = 0.001$).

Conclusion: AF recurrence in patients with increased PWV was associated with higher pulse pressure and worse parameters of reflected wave. Reflected wave could have a role in modification of arterial stiffness in patients with $PWV \geq 10$ m/s.

P907

Optimization of warfarin dosing for patients with chronic kidney disease

Z Salpagarova¹; DA Andreev¹; DA Sichev²; SA Suchkova¹; AL Syrkin¹

¹I.M. Sechenov First Moscow State Medical University, of cardiology, Moscow, Russian Federation; ²Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation

Materials and Methods: The study included 238 patients with paroxysmal and persistent atrial fibrillation receiving anticoagulation therapy (warfarin) for at least 1 year before to inclusion in the study. All patients assessed the risk of thromboembolic complications - on a scale CHA2DS2VASS, the risk of bleeding - on a scale of HAS-BLED, and TTR. All patients (100%) had at least two points on the scale CHA2DS2VASS. 93 patients (39%) have a high risk of thromboembolic complications on a scale CHA2DS2VASS, and 105 patients (44%) have the average risk on a scale of HAS-BLED. TTR during the year before the study was 38%. According to MDRD glomerular filtration rate (GFR) was calculated for all patients. GFR of 107 patients (45%) is 60-45 ml / min, GFR of 99 patients (42%) is 44-30 ml / min, GFR of 32 patients (13%) is of less than 30 ml / min. Considering the clinical experience of our clinic, patients with a GFR less than 30 ml / min have been proposed a new algorithm of warfarin dosing, in compare with the classic, which is used in warfarin-dosing.org and other resources. Patients with GFR less than 30 mL / min were considered as patients at high risk of bleeding, and therefore, they held control of the international normalized ratio (INR) 1 every 3 days, but it was recommended to increase the dose of warfarin 1 time in 7 days, despite the low or high INR. At a high INR – cessation of the drug with a further decrease in dose. INR control is carried out every 4-5 days, as the reduction in the INR is slow in this group of patients. Recommended level of INR in this group of patients is in the range from 2 to 2.7. It was estimated large and small bleeding, thromboembolic complications and TTR index. Retrospective data during 1 year and data during research also 1 year were compared.

Results: The amount of bleeding was significantly ($p = 0.019$) prevailed in the group of retrospective analysis. In applying the new algorithm it was mentioned 1 big bleeding (3%) and 4 small bleedings (12%), but in group of retrospective analysis it was

mentioned 5 big bleedings (16%) and 24 small bleedings (75%). Significant difference in the number of thromboembolic complications were not found ($p=0.547$). Statistically significantly TTR was different ($p=0.044$). In the group of retrospective analysis TTR is 32%, in the study group TTR is 51%.

Conclusions: in the application of the recommended warfarin dosing algorithm, patients with chronic kidney disease (GFR less than 30 / min) have statistically significant reduction in both large and small hemorrhages. However, no statistically significant correlation between thromboembolic complications investigated groups. TTR remains within the therapeutic range greater amount of time when using the new algorithm.

P908

Do patients under non-vitamin K oral anticoagulants need to switch to parenteral anticoagulation when admitted for acute decompensated heart failure?

J B Augusto¹; M Borges Santos¹; D Roque¹; M Silva¹; J Castro²; J Sala¹; A Faustino¹; M Branco¹; F Frade¹; C Morais¹

¹Hospital Prof Fernando da Fonseca EPE, Amadora, Portugal; ²Hospital de Cascais, Cascais, Portugal

Background: Patients with both atrial fibrillation (AF) and hospitalization for acute decompensated heart failure (ADHF) often have transient renal function impairment. This may lead to a temporary contraindication to NOAC therapy.

Purpose: We aimed to evaluate the need for NOAC cessation due to renal function impairment in patients admitted for ADHF with non-valvular AF in order to help define a standard approach.

Methods: 2181 consecutive patients with AF who were evaluated in our Emergency Department (ED) in a 12 month period. All patients underwent routine clinical and laboratory exams. We evaluated the degree of renal impairment (peak estimated glomerular filtration rate, eGFR) during hospital stay using Cockcroft-Gault (CG), simplified Modification of Diet in Renal Disease (MDRD), and Chronic Kidney Disease Epidemiology Collaborative (CKD-EPI) equations. An eGFR $\leq 15\text{ mL/min/1.73m}^2$ was used in order to determine the proportion of patients hypothetically requiring NOAC cessation. Additionally we determined the need for dose adjustment for each NOAC (dabigatran, rivaroxaban and apixaban) according to FDA prescribing guidance.

Results: 96 patients were admitted with both non-valvular AF and ADHF (mean age of $77.1 \pm$ standard deviation 9.7 years, 40.6% males). CKD-EPI identified a greater proportion of patients requiring NOAC cessation (12.5%), followed by MDRD (10.4%) and CG (8.0%). Among patients who would discontinue NOAC, 33.3% would experience renal recovery (eGFR $>15\text{ mL/min/1.73m}^2$) according to CKD-EPI, 20.0% using MDRD equation and 14.3% patients according to CG. Dose adjustment would be needed in 65.5% of patients for rivaroxaban, in 40.6% for apixaban and in 33.3% for dabigatran.

Conclusion: Only 1 in 10 patients admitted for ADHF under NOAC therapy for non-valvular AF would have to discontinue NOAC and initiate parenteral anticoagulation, although dose adjustments would be frequently necessary. In patients with 'de novo' severe renal impairment, up to one third would need to switch to vitamin K antagonists at discharge.

P909

Risk of recurrent atrial fibrillation after pulmonary vein isolation- a gender specific approach.

M Graefe¹; J Kaufmann¹; JH Gerds-Li¹; B Pieske²; E Ernst Wellenhofer¹

¹German Heart Center Berlin, Berlin, Germany; ²Charite - University Medicine Berlin, Berlin, Germany

Purpose: Pulmonary vein isolation (PVI) is a standard treatment option in chronic atrial fibrillation (AF). Recurrence of AF (recAF) is an issue, however. Prediction of recAF in patients with paroxysmal AF was related to atrial reservoir function, whereas atrial size has been demonstrated to be a risk factor in permanent atrial fibrillation. We hypothesized that risk of recAF (≥ 3 months after PVI) should be assessed by a stratified approach and investigated the impact of gender on risk prediction.

Methods: We evaluated data sets from 154 consecutive patients (age 61 ± 12 years, 50 females, 69 paroxysmal AF) prior to pulmonary vein isolation (PVI). Transthoracic (transmitral and tissue Doppler, linear parameters and area and volume measurements) and transoesophageal echocardiography (pulmonary vein Doppler) were performed. Data were evaluated for correlation with recAF by Kendall's-tau. Parameters with significant correlation were further evaluated in logistic regression analysis. This was performed by either treating gender as variable or analysis in gender subgroups. Partial validation was performed by bootstrap.

Results: Treating gender as a variable in regression analysis yielded a 62% correct prediction of recAF. If regression modeling was performed in subgroups separately, 70% of recurrences were predicted correctly in either group. This improvement was significant. Moreover, interestingly in females recAF was associated with lower systolic pulmonary vein velocities (PVsys) and smaller end-diastolic diameters (LVEDD), whereas there was no significant difference in 4-chamber end-systolic area (LA-area) and no significant constant in a significant logistic regression model

(-2 Log-Likelihood 43). Model coefficients B (no bootstrap because of limited sample size):

PVsys: -0.130 (-0.027 – 0.233), $p=0.013$; LVEDD: 0.069 (0.0139 – 0.123), $p=0.013$.

On the contrary in males pulmonary vein velocities did not correlate with recAF and LVEDD. In males LA-area and E/E' (E-wave divided by averaged tissue Doppler E-wave) were the best predicting variables in a significant logistic model (-2 Log-Likelihood: 113) including a significant constant. Model coefficients B (bias corrected/bootstrap):

E/E': 0.231 (0.03 – 0.524), $p=0.032$; LA-area: 0.112 (0.027 – 0.218), $p=0.002$; constant: -4.832 (-7.603 – 3.009), $p=0.001$.

Conclusion: Subgroup specific modeling may help to improve risk prediction for recurrence of AF after pulmonary vein isolation. Our results remains to be corroborated by further validation studies. Variations in causal pathology may be reflected by differing associations of outcome with distinct measurement variables. These associations may cancel or be smoothed in aggregated samples. Stratified analysis, although limited by sample size, may provide interesting insights.

P910

Predicting atrial fibrillation in critically ill patients admitted in a general intensive care unit: is BNP really helpful?

F Fernando Montenegro Sa¹; C Ruivo¹; A Antunes¹; C Jesus²; P Viana²; J Morais¹

¹Hospital Santo Andre, Cardiology, Leiria, Portugal; ²Hospital Santo Andre, Intensive Care Unit, Leiria, Portugal

Introduction and objective: In a general intensive care unit (GICU), newly-diagnosed atrial fibrillation (AF) has many different etiologies, and has been associated with a worse prognosis. The correlation between B-type natriuretic peptide (BNP) and AF has been evidenced by some large scale studies, but many questions still remain, especially in regard to such a particular population as the GICU patients. The potential role of BNP as a predictor of AF in this population was investigated.

Methods: The authors (AA) analyzed a consecutive group of 104 patients admitted in a GICU with BNP assessed within the first 48 hours and compared two groups: the group that developed newly-diagnosed AF (wAF, $n=29$) and the group with no AF (noAF, $n=75$). Statistical comparison and binary regression was done to search for differences and predictors of AF.

Results: Mean age was 65.4 ± 16.0 years, with 61.5% of males and a mean APACHE score of 22.8 ± 6.6 . Overall mean BNP was 412.3 ± 663.1 pg/mL. In-hospital mortality was 17.3% ($n=18$). Twenty patients (19.2%) developed signs of heart failure. Mean BNP value was significantly different between the groups: wAF (737.4 ± 197.2 pg/mL) vs. noAF (286.5 ± 41.3); $p=0.033$. After statistical adjustment for age, gender, APACHE score and HF diagnosis, a BNP value >300 pg/mL was an independent predictor for atrial fibrillation (OR = 4.46, IC95: 1.58-12.58, $p=0.005$), with ROC-curve analysis showing a 70.7% specificity and 69.0% sensibility for this cut-off.

Conclusion: Based on the current data BNP seems to be a prognostic marker to predict AF occurrence in critically ill patients admitted in a GICU. More studies with larger populations are needed.

ROC Curve

P911

Cardio-vascular interconnection in patients with decompensated CHF depending on cardiac rhythm.

N Koziolova¹; E Polyanskaya¹

¹Medical Academy, Perm, Russian Federation

Aim: to reveal some peculiarities of cardio-vascular interconnections in patients with decompensated ischemic CHF in the context of different cardiac rhythms. Methods and materials: 92 patients with decompensated ischemic CHF and decreased LV

EF were examined. Patients were divided into 2 groups depending on cardiac rhythm. The 1st group consisted of 60 patients with atrial fibrillation (AF), and the 2nd group – 60 patients with sinus rhythm. All the patients underwent Echo, biochemistry (NT-proBNP and TIMP-1), and sphygmopletismography (VaSera1000, Japan), which showed pulse wave velocities (PWV) in several segments of central and peripheral flow (carotid-femoral PWVcf, aortal PWVao, carotids PWVc). Both groups were equal in swx, age, comorbidities.

Results: severity of CHF symptoms did not differ: CHF functional class was 2.68 ± 0.49 in the 1st group, 2.59 ± 0.40 in the 2nd group ($=0.375$). Decrease of LV EF was indicated in the both groups, but they differed reliably between the groups: $44.71 \pm 11.06\%$ vs $51.3 \pm 2.6\%$ ($=0.001$). Myocardial stress severity (evaluated by NT-proBNP), was harder in patients with AF: 618.4 ± 106.6 pg/mL vs 305.0 ± 151.5 pg/mL, <0.001 . Myocardial collagenolysis activity was also lower in patients with AF: 932.7 ± 15.1 vs 653.5 ± 10.8 , <0.001 . Sphygmopletismography showed significant prevalence of vascular remodeling in patients with CHF and AF, what appeared in decrease of both flow velocity and elasticity, and in increase of arterial stiffness in central and peripheral segments. PWVcf: 11.9 ± 1.7 m/sec vs 10.3 ± 3.02 m/sec ($=0.002$); PWVao: 11.36 ± 5.24 m/sec vs 8.90 ± 3.3 m/sec ($=0.018$); PWVcarotid: 1.19 ± 1.23 m/sec vs 1.68 ± 0.03 m/sec ($=0.003$); CAVI-1: 9.49 ± 1.53 vs 8.47 ± 1.86 ($p=0.006$).

Conclusions: permanent AF in patients with decompensated CHF aggravates arterial remodeling by decrease of collagenolysis activity and by rate- and rhythm-dependent unfavorable ventricular-arterial interaction.

P912

Difference in mortality among digoxin users treated for non-valvular atrial fibrillation with different stages of chronic kidney disease: a nationwide register-based cohort study.

M Maurizio Sessa¹; A Mascolo¹; MP Andersen²; G Rosano³; F Rossi¹; A Capuano¹; C Torp-Pedersen²

¹Second University of Naples, Department of Experimental Medicine, Naples, Italy;

²Aalborg University, Department of Health, Science and Technology, Aalborg, Denmark; ³San Raffaele Pisana Hospital IRCCS, Rome, Italy

Introduction: Changes in renal function due to chronic kidney disease could change digoxin serum concentration. It is well accepted that digoxin benefit/risk ratio is highly related to the dosage and consequently to the serum concentration. Digoxin has a narrow therapeutic window and even small change in dosage could affect the risk of toxicity. Despite the well-known effect of renal function on risk of digoxin toxicity, there is a lack of knowledge regarding the impact of different stages of chronic kidney disease on several clinical outcome (including mortality) in patients with atrial fibrillation treated with digoxin.

Purpose: Considering is not rare to see patients with both conditions as previous studies have found a higher prevalence of patients with both atrial fibrillation and chronic kidney disease compared to the general population, the objective of this study was to investigate the impact of different stages of chronic kidney disease on mortality across non-valvular atrial fibrillation patients treatment-naïve with digoxin.

Methods: All patients with non-valvular atrial fibrillation or atrial flutter as hospitalization diagnosis from January 1, 1997 to December 31, 2012 were extracted through Danish nationwide administrative registries. From this preliminary population were extracted only digoxin treatment-naïve users that have started pharmacological treatment for non-valvular atrial fibrillation in the period. Patients were excluded if they started digoxin in co-administration with other antiarrhythmic drugs. All patients should be diagnosed with non-valvular atrial fibrillation before first digoxin prescription. Using creatinine measurement within 180 days from the first digoxin prescription, the estimated glomerular filtration rate (eGFR) was established for each patient which had creatinine measurement. Based on the results of eGFR, patients were divided into two cohorts, those with eGFR <30 and those with eGFR ≥ 30 ml/min/1.73m². Propensity score was used to match patient with eGFR <30 with 4 patients with eGFR ≥ 30 ml/min/1.73m² for the main confounders and co-administrated drugs. A total of 2740 patients was used; 548 patients with eGFR <30 ml/min/1.73m². Cox proportional hazard analysis was performed to assess differences in all-causes and cardiovascular mortality between the two cohorts. Results. Cox regression analysis showed no statistically significant differences in all-causes and cardiovascular mortality among patients with eGFR <30 compared to those with eGFR ≥ 30 ml/min/1.73m² within both 180 days and 2 years from index date.

Conclusions: The results suggested that eGFR is not a predictor for all-causes and cardiovascular mortality across non-valvular atrial fibrillation patients treatment-naïve with digoxin.

P913

Is body mass index a risk factor for new onset atrial fibrillation in patients with acute coronary syndrome

A Boskovic¹; M Vukmirovic¹; G Nikolic¹; S Vujosevic¹; M Medenica¹; O Orlandic¹

¹CC of Montenegro - Medical Faculty, Podgorica, Montenegro

Purpose: Atrial fibrillation (AF) is a common complication of acute coronary syndrome (ACS) and usually it is associated with an increase in mortality and adverse events. The aim of the study was to evaluate the incidence of AF in patients with ACS and to evaluate if body mass index (BMI) is a risk factor for new-onset AF in patients with ACS.

Methods: We enrolled 600 patients with ACS, 290 patients with STEMI and 310 patients with NSTEMI. At entry, all patients were in sinus rhythm. The AF group included patients with ACS and new onset AF during the hospital course and control group included patients with ACS without AF during the hospital course.

Results: Mean age of patients was 63.6 ± 10.6 years, between them 425 were men and 275 women, mean BMI was 26.8 ± 2.6 kg/m². The incidence of new-onset AF was 8% in the patients with ACS during the hospital course. In AF group there were 48 patients and in control group were 552 patients. We analyzed risk factors for coronary artery disease (CAD) and incidence of AF and found that the patients in AF group were older 69.9 ± 9.4 years versus 63.1 ± 11.4 in control group and with higher BMI (28.0 ± 2.6 kg/m² in AF group versus 26.7 ± 2.6 kg/m² in control group), $p < 0.01$. There was not difference in gender distribution, frequency of smokers, arterial hypertension, hyperlipidemia, diabetes mellitus and family history for CAD between the groups, $p > 0.05$. Multivariable logistic regression analyses showed that from risk factors for CAD older age, OR (95% CI) is 2.37 (1.23-4.58), $p = 0.01$ and increased BMI, OR (95% CI) is 1.17 (1.04-1.33), $p = 0.012$ were independent predictors of new onset AF in the patients with ACS.

Conclusions: The incidence of new-onset AF was 8% in the patients with ACS during the hospital course. The independent predictors of new-onset AF from risk factors for CAD in the patients with ACS were older age and increased BMI.

P914

Efficacy and safety of novel oral anticoagulants in patients with atrial fibrillation and heart failure: a meta-analysis

G Savarese¹; RP Giugliano²; GMC Rosano³; J McMurray⁴; G Magnani²; G Filippatos⁵; LH Lund⁶; B Trimarco¹; P Perrone-Filardi¹

¹Department of Advanced Biomedical Sciences; Federico II University, Naples, Italy, Naples, Italy; ²Brigham and Women's Hospital, TIMI Study Group, Cardiovascular Division, Boston, United States of America; ³St George's University of London, Cardiovascular and Cell Sciences Research Institute, London, United Kingdom; ⁴University of Glasgow, Institute of Cardiovascular and Medical Sciences, BHF Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom; ⁵Attikon University Hospital, Athens, Greece; ⁶Karolinska Institute, Department of Medicine, Cardiology Unit, Stockholm, Sweden

Background: Symptomatic heart failure (HF) has a prevalence of 30% in patients with atrial fibrillation (AF). Patients with HF are older and frailer, have more comorbidity and are at higher risk of both stroke and bleeding, compared with younger patients.

Purpose: To investigate the efficacy and safety of novel oral anticoagulants (NOAC) in patients with AF and HF, in a meta-analysis of all the recent phase III warfarin comparison trials.

Methods: The 4 major clinical trials (ARISTOTLE, ENGAGE AF, RE-LY, ROCKET AF) comparing NOACs to warfarin in patients with non-valvular AF were included. Pre-specified outcomes were the composite of stroke and systemic embolism (SSE), major, intracranial and any bleeding, cardiovascular (CV) and all-cause death.

Results: 55,011 patients were enrolled in 4 trials, 26,384 (48%) with HF and 28,627 (52%) without HF, 27,518 receiving NOACs and 27,493 warfarin [median age 70 years, 36% females, follow-up range: 1.5-2.8 years]. Rates of SSE (RR:0.98 [95% CI:0.90-1.07], $p = 0.68$) and major bleeding (RR:0.95 [0.88-1.03], $p = 0.21$) were comparable in patients with and without HF. HF patients had reduced rates of any (RR:0.86 [0.81-0.91], $p < 0.01$) and intracranial (RR:0.74 [0.63-0.88], $p < 0.01$) bleeding, but increased rates of all-cause (RR:1.70 [1.31-2.19], $p < 0.01$) and CV death (RR:2.05 [1.66-2.55], $p < 0.01$). In HF patients, NOACs, as compared to warfarin, significantly reduced the risk of SSE (RR:0.86 [0.76-0.97], $p = 0.01$), major (RR:0.77 [0.68-0.87], $p < 0.01$), intracranial (RR:0.43 [0.33-0.56], $p < 0.01$) and any (RR:0.88 [0.80-0.98], $p = 0.02$) bleeding, without any significant effect on all-cause (RR:0.94 [0.88-1.01], $p = 0.08$) and CV (RR:0.92 [0.84-1.01], $p = 0.11$) mortality. In patients without HF, NOACs, as compared to warfarin, significantly reduced the risk of SSE (RR:0.77 [0.68-0.87], $p < 0.01$), major (RR:0.88 [0.79-0.97], $p = 0.01$) and intracranial (RR:0.51 [0.41-0.64], $p < 0.01$) bleeding, as well as all-cause (RR:0.85 [0.77-0.95], $p = 0.04$) and CV (RR:0.81 [0.71-0.93], $p = 0.02$) mortality. Rates of any bleeding were numerically lower with NOACs, but this did not meet statistical significance (RR:0.90 [0.80-1.00], $p = 0.054$). Consequently, no difference in the efficacy and safety of NOACs, as compared to warfarin, was detected between patients with and without HF (Pinteraction >0.05 for each).

Conclusions: Patients with AF and HF had increased mortality, but reduced rates of intracranial and any bleeding compared to no-HF patients, with no difference in rates of SSE and major bleeding. NOACs significantly reduced SSE, major bleeding and intracranial haemorrhage in HF patients. No interaction in efficacy and safety of NOACs was observed between AF patients with and without HF.

Right ventricular function and the evolution of echocardiographic parameters in patients with inflammatory cardiomyopathy

J Krejci¹; P Hude¹; E Ozabalova¹; D Sochorova²; D Mlejnek¹; V Zampachova¹; R Stepanova³; L Spinarova²; ¹St. Anne's University Hospital, Masaryk University, Brno, Czech Republic; ²Masaryk University, St. Anne's University Hospital, Brno, Czech Republic; ³St. Anne's University Hospital - ICRC, Brno, Czech Republic

Introduction: The right ventricle (RV) function is considered as an important prognostic predictor in patients with heart failure. According to an earlier study, impaired RV function is negative prognostic marker also in inflammatory cardiomyopathy (ICM).

Objective: Evaluation of the significance of RV function at the time of diagnosis for prediction of echocardiographic parameters evolution in patients with biopsy proven ICM in the 6-month follow-up.

Patients and methods: 64 patients with left ventricular ejection fraction (LVEF) $\leq 40\%$ with biopict findings of > 7 CD3+ cells / mm² and / or > 14 CD45+ cells / mm². They were divided into two groups: 1 / patients with initially preserved RV systolic function and 2/ patients with RV dysfunction. RV dysfunction was defined as the presence of at least two of the three following parameters: RV diameter ≥ 31 mm, s'tri ≤ 10 cm/s and TAPSE ≤ 16 mm. Changes in echocardiographic parameters in 6-month follow-up in both groups were assessed and compared.

Results: In the group 2 (with RV dysfunction, n = 37) LVEF at baseline was lower than in the group 1 (with preserved RV function, n = 27): $21 \pm 7\%$ vs. $29 \pm 7\%$ ($p < 0.001$). Conversely, improvement in LVEF in the group 2 ($21 \pm 15\%$) was more significant than in the group 1 ($12 \pm 13\%$); $p < 0.05$. Improvement in diastolic LV function expressed by the ratio E/e' was more pronounced in the group with RV dysfunction (-6.7 ± 6.6 vs -1.0 ± 4.8 ; $p < 0.001$). Similarly, more significant improvement in other parameters was observed in the group 2: s' and e' mitral annular velocities, LV end-systolic volume, TAPSE, s'tri and RV diameter.

Conclusion: The RV dysfunction at baseline was associated with more significant improvement in majority of evaluated echocardiographic parameters in a group of patients with biopsy-proven ICM.

P916

Septic myocarditis is mainly due to cardiac failure without significant myocardial necrosis

G Vijayaraghavan¹; P T Suhail¹; V R Suresh Kumar¹; ¹Kerala Institute of Medical Sciences, Cardiology, Trivandrum, India

Background: Only few studies incorporating electrocardiography, high sensitive troponin T (hsTnT), N-terminal pro-BNP (pro-BNP) and echocardiography has been conducted in patients with septic myocarditis.

Methods and results: Out of 204 patients with sepsis enrolled, 111 patients satisfied the inclusion criteria and 103 completed the study. Myocardial injury was defined by elevation of hsTnT > 25 pg/ml. Initial hsTnT, pro-BNP and 2D echocardiography were repeated if sepsis progresses. End points were in hospital mortality and left ventricular dysfunction (LVD). Simple sepsis was diagnosed in 45%; 19% had septic shock and 36% developed severe sepsis. Sinus tachycardia was present in 65% and T inversion in inferior leads in 32%. Systolic dysfunction (SD) was present in 42%, diastolic dysfunction (DD) in 21% and 21% had both SD and DD. HsTnT was elevated in 84% of the patients. Both HsTnT and pro-BNP significantly correlated with LVD ($p < 0.001$). Though pro BNP and HsTnT vary in different levels of LVD (table 1). Both levels were lesser in DD than SD. Grade III DD was associated with severe SD. Pro-BNP had significant correlation with pro-calcitonin level ($p < 0.001$) and APACHE II score ($p < 0.001$); HsTnT had significant correlation with APACHE II score ($p < 0.001$). In hospital mortality was 8%. In survivors hsTnT was 158pg/ml and pro-BNP was 6400 pg/ml. In non-survivors hsTnT was 256 pg/ml ($p < 0.047$) and pro-BNP was 21805pg/ml ($p < 0.001$). Pro BNP had better correlation with survival. ROC curve showed that pro-BNP level > 8530 pg/ml signified with mortality (sensitivity-100% and specificity-80%) and HsTnT level > 178 pg/ml correlated with mortality with 88% sensitivity and 71% specificity. Base line creatinine was normal in all our patients; **CONCLUSION:** Pro-BNP value > 8530 pg/ml signified decreased survival with 100% sensitivity. The significant elevation of pro-BNP with minimal elevation of hsTnT indicated that the pathophysiology is mainly myocardial stretch and not myocardial necrosis in sepsis; with full recovery in survivors.

Table 1: distribution of pro-BNP and HsT

ECHOCARDIOGRAPHY	%	Mean pro-BNP(pg/ml)	Mean HsTnT(pg/ml)
Normal	16	2433 (700-4100)	76 (<25-160)
Mild LV SD	11	5481 (3200-9200)	210 (80-360)
Moderate LV SD	13	9608 (5400-16100)	254 (150-480)
Severe LV SD	18	16844 (7200-25000)	268 (148-450)
Grade I DD	8	3132 (1024-5250)	117 (60-220)
Grade II DD	13	6596 (3500-9000)	125 (26-240)

Table 1: distribution of pro-BNP and HsTnT in LVD (*21% had combined LVD)

P917

Left ventricular non-compaction - a magnetic resonance guided clinical and morphological correlation

L Strimbu¹; M I Mihaela Ioana Dregoes¹; I Cote²; R Farcas¹; I Oancea³

¹Heart Institute "Nicolae Stanciu", Cluj-Napoca, Romania; ²Emergency County Hospital, Cardiology, Oradea, Romania; ³"Phoenix" Diagnostic Clinic, Cluj-Napoca, Romania

Introduction: Left ventricular non-compaction (LVNC) is a rare, relatively recently described congenital cardiomyopathy, whose prevalence is continuously rising due to the improved accessibility of modern imaging techniques. It is considered to result from the defective development of the myocardial architecture in the late-stages of embryogenesis and is characterized by a hypertrabeculated myocardial structure. Its pathophysiological and clinical implications are the subject of continuous investigation.

Purpose: The purpose of the study was to establish a correlation between the clinical presentation and the morphological aspect of the left ventricle (LV), as described by the cardiac magnetic resonance imaging (MRI) examination.

Methods: We retrospectively evaluated 35 patients diagnosed with LVNC between Jan 2010 and Jan 2015 based on the echocardiographic Jenni criteria (end-systolic ratio of non-compacted to compacted myocardium above 2). Only patients with the diagnosis confirmed by cardiac MRI, according to the criteria established by Petersen (the diastolic ratio of non-compacted to compacted myocardium greater than 2.3) and Jacquier (trabeculated left ventricular mass above 20% of the total myocardium), were finally included in the study. The medium follow-up period was 3.5 years.

Results: 14 patients were included in the final analysis, with a medium age at diagnosis of 45.5 years. The most common form of presentation was heart failure, followed by ventricular arrhythmias. 64.2% of patients had some form of intra-ventricular conduction disorder, the most frequent being left bundle branch block. Regarding the distribution of the non-compacted myocardium, the lateral wall of the LV was most frequently involved (92.8%), followed by the anterior wall (78.5%), the apex (57.1%) and the inferior wall (42.8%). 78.5% of patients had depressed LV systolic function, defined as an LV ejection fraction below 50%. There was a positive correlation between the extension of the non-compacted myocardium and the severity of the systolic dysfunction. 71.5% of patients had some form of diastolic dysfunction, with an equal distribution between the impaired relaxation and restrictive pattern. During follow-up, there were two readmissions for decompensated heart failure. One patient received an implantable cardioverter-defibrillator for the secondary prevention of sudden cardiac death and one benefitted from cardiac resynchronization therapy. No thromboembolic complications were recorded. There was one fatality, due to massive acute pulmonary oedema.

Conclusions: LVNC is a rare cardiomyopathy, with considerable implications on cardiac function. Echocardiography is considered the standard diagnostic method, but it frequently over- or underestimates the disease prevalence. Therefore, cardiac MRI has become an important tool in confirming the diagnosis. There are still many questions to be answered and a need for more precise echocardiographic diagnosis criteria.

P918

Effects of adaptation to intermittent normobaric hypoxia in the patients with ischemic cardiomyopathy

LV Rachok¹; TA Dubovik¹

¹Republican Scientific and Practical Center of Cardiology, Minsk, Belarus

The purpose of this research was to study the effects of intermittent normobaric hypoxia adaptation (NIHA) in the patients with ischemic cardiomyopathy (ICMP) and chronic heart failure (CHF).

Materials and Methods: Cohort of 90 ICMP patients with HF class II-IV NYHA (n = 45 in the main and control groups) were included into the research. The patients of the main group underwent a 10-days NIHA course before cardiac surgery (CABG).

Results: The initial CHF severity in the both groups was determined by depressed

left ventricle systolic function (LVEF less than 35%) against maladaptive LV remodeling, multiple myocardial perfusion defects with the prevalence of sympathetic activity nervous system (NS) and the changes in the endothelial dysfunction (ED) markers. After NIHA course we revealed the significant decrease in the area of myocardium with slight and moderate hypoperfusion as well as the prevalence of parasympathetic NS activity with reduction in the number of ventricular arrhythmias (VA). It was also marked the significant decrease in the level of the concentration of biochemical ED markers such as endothelin-1, TNF-alpha, interleukin-6, homocysteine and the increase in brachial artery diameter and Gosling's pulsatility index during reactive hyperemia test. The main group patients were characterized with a more favorable recovery during the intra- and early postoperative period after CABG with significantly less frequent of the low cardiac output syndrome with prolonged inotropic support. We also noted EF improvement, significantly less frequent of ventricular fibrillation during artificial circulation and the number of perioperative myocardial infarction with high grade VA.

Conclusion: The use of NIHA course before CABG for the patients with ICMP helps to protect from reperfusion injury and improve the endothelium functional state and microcirculatory processes in the myocardium with reduces the prognostically unfavorable VA after CABG.

P919

Cirrhotic cardiomyopathy-a new entity?

L Lehel Mathe¹

¹ UMPH Clinical Pharmacy Department, Tirgu-Mures, Romania

Liver cirrhosis is associated with a number of secondary cardiovascular changes. New clinical entity, cirrhotic cardiomyopathy (CCM) is already recognized, but still much underdiagnosed. Diagnosis is based on a combination of clinical, echocardiographic and electrocardiographic findings, associated with bioserological markers. The aim of the study was to analyze the incidence and prevalence of these datas in order to obtain an early diagnosis.

Methods: The study group was represented by 53 cirrhotic patients hospitalized in the period January-May 2015 in Tirgu Mures (Romania) County Hospital, Department of Gastroenterology.

Results: The study group consisted mostly of men, 60%, with average age of 59.6 years. 43,75% of the 53 patients met the criteria of cirrhotic cardiomyopathy. These patients had a slightly higher average age, 61.3 years. Etiology was mainly ethanol (60%), but frequently postviral type C (40%). Most patients in the study group were placed in Child B stage of cirrhosis, but in the Child C stage 80% confirmed diagnosis of CCM. Among the most common electrocardiographic signs we can remember chronotropic incompetence with basal tachycardia, disturbed circadian variability and QT prolongation (56.6%). Among the most obvious signs of echocardiographic findings was left atrial dilation (83,21%), the tricuspid reflux (76,47%) and diastolic dysfunction type altered relaxation in 56.66% of patients with CCM.

Conclusions: CCM is relatively common and easily diagnosed new clinical entity, but rarely diagnosed in gastroenterology wards. Cirrhotic cardiomyopathy incidence correlates with the stage of hepatic impairment (Child-Pugh score), particularly by increasing the QTc interval and altered relaxation type diastolic dysfunction.

P920

Endomyocardial fibrosis in Argentina: therapeutic options

RR Favalaro¹; M A Peradejordi¹; L E Favalaro¹; M F Renedo¹; AL Guazzone¹; R D Ratto¹; D O Absi¹; C A Vigliano¹; A M Bertolotti¹

¹ University Hospital Favalaro Foundation, Intrathoracic Transplantation and Heart Failure Division, Ciudad Autónoma de Buenos Aires, Argentina

Introduction: Endomyocardial fibrosis (EMF) is a non-frequent restrictive cardiomyopathy in our country. Its characteristics are fibrotic thickening of the endomyocardium with apex obliteration of one or both ventricles and involvement of the mitral/tricuspid valvular apparatus. Medical treatment is palliative. Objectives To assess the therapeutic options in patients (p) with EMF referred for treatment of this restrictive cardiomyopathy to our Centre.

Material and methods: We analyzed retrospectively 15 p with EMF between 1995 and 2015. Images techniques, clinical and histopathological criteria were used for diagnosis. Continuous variables were expressed as mean \pm SD or median and range and the categorical variables in numbers and percentages. Results Mean age was 44 (3-71) years, 13 p (87%) were female, all Caucasians, 7 p (47%) were from Argentinean Northwest and Mesopotamia provinces (subtropics areas). Three p (3%) had eosinophilia history. At admission, 11 p (73%) were in NYHA FC III-IV; 8 p (53%) presented atrial fibrillation; 4 p (26%) had severe left ventricular systolic dysfunction; 5 p (33%) moderate to severe right ventricular systolic dysfunction; 13 p (87%) moderate to severe mitral regurgitation; 11 p (73%) moderate to severe tricuspid insufficiency and 12 p (80%) developed pulmonary hypertension (mean pulmonary systolic pressure: 59 \pm 29 mmHg). Diagnosis of EMF was confirmed by images and/or pathological tests, confirming 80% (12/15 p) of biventricular compromise. Patients in NYHA FC I-II (4/15, 27%) continued with the medical treatment and clinical follow up. The remaining p on NYHA FC III-IV (73%; 11/15) were eligible either for

surgical treatment or heart transplantation listing. Four of 11 p (27%) on NYHA FC III-IV underwent endomyocardial resection and mitral and tricuspid valve replacement (one p died due to non cardiovascular cause at long term follow up). The rest of the p (7/11; 47%) were listed for heart transplantation due to decompensated heart failure (HF) and cardiogenic shock: 4/7 p (47%) underwent uneventful heart transplantation and 3 p died on waiting list. Conclusion Patients with the diagnosis of EMF in advanced NYHA FC should be consider for endomyocardial resection, valvular repair or replacement surgery when presented clinically compensated. Heart transplantation was the therapeutic choice for p with refractory HF. Due to the high mortality rate while in waiting list, it should be considered the assistance circulatory support as bridge to transplant.

P921

Isolation as a factor predisposing to takotsubo cardiomyopathy

M Budnik¹; J Kochanowski¹; R Piatkowski¹; K Wojtera¹; K

Jablowska-Gorecka¹; M Gaska¹; P Glowacka¹; P Karolczak¹; D Ochijewicz¹; G Opolski¹

¹ Medical University of Warsaw, 1st Department of Cardiology, Warsaw, Poland

Background: Takotsubo cardiomyopathy (TTC) mimics acute coronary syndrome (ACS) and is accompanied by reversible left ventricular wall motion abnormalities. Typically TTC is preceded by acute emotional stress and is also known as "stress cardiomyopathy", "apical ballooning syndrome" or "broken-heart syndrome." The symptoms are similar to ACS. The pathophysiology remains unclear.

Methods: 120 consecutive female patients with TTC were analysed to prove association with stress factor (Table 1) and compared with 120 consecutive female patients with acute myocardial infarction with ST segment elevation (STEMI). All patients had echocardiography and coronary angiography performed.

Results: There were no differences between age, BMI, risk factors like hypertension, diabetes, smoking, hypercholesterolemia, family history in both groups. There weren't differences in comorbidities like: chronic obstructive pulmonary disease, hypothyroidism, stroke, status post hysterectomy, cancer. There weren't differences in drug or alcohol addiction too. The most interesting finding was that pts with TTC were more often lonely- single, divorced or widowed than pts with STEMI. They also more often lived alone. These differences were strongly statistically significant.

Conclusion: It is known that TTC is associated with stress factor. We suppose that not only occurrence of sudden stress is important to develop TTC. Being alone and lack of daily support from loved ones cause that some people may have TTC.

Kind of stress in pts with TTC	
lack of stress factor	10%
psychological stress	67%
physical stress	4,5%
operation	4,5%
exacerbation of chronic disease	12%
head trauma	2%

P922

Cardiac involvement in the two main genotypes of sickle cell disease: specificities of hemoglobin sickle cell compared to sickle cell anemia.

P Guedeney¹; F Lionnet²; A Ceccaldi¹; K Stankovic Stojanovic²; F Laveau¹; M

Duprey¹; A Cohen³; R Isnard¹; N Hammoudi¹; ¹Hospital Pitie-Salpetriere, cardiology, Paris, France; ²Hospital Tenon, hematology, Paris, France; ³Hospital Saint-Antoine, cardiology, Paris, France

Background: Hemoglobin SC (HbSC) and sickle-cell anemia (SCA) are the most frequent genotypes of sickle-cell disease. While SCA cardiac involvement was well characterized, the heart remodeling associated to HbSC was never specifically investigated.

Purpose: Considering the pathophysiological differences of both genotypes the aim of the study was to investigate the cardiac remodeling related to HbSC compared to SCA.

Methods: Using a case-control design, 60 adult HbSC patients (median age 31 years, 25 men) underwent an echocardiography and were compared to 60 SCA patients and 60 controls matched for age and gender. Left ventricular ejection fraction (LVEF), LV mass index (LVMI), cardiac index and peak tricuspid regurgitation velocity (TRV) were measured as recommended. LV filling pressures were assessed using the ratio of early peak diastolic velocities of mitral inflow and annular mitral plane (E/e').

Results: The LVMI was higher in both genotypes compared to controls. However, whereas LV hypertrophy was observed only in 3 (5%) patients with HbSC, this condition was diagnosed in 27 (45%) patients with SCA. While cardiac index and systolic pulmonary pressures were similar in HbSC patients compared to controls, SCA patients exhibited elevated cardiac output and pulmonary pressures. LVEF was similar in the three groups. However, both genotypes had a higher E/e' ratio compared

to controls. In HbSC patients, LVMI, E/e' and TRV were associated to the presence of hypertension and/or obesity comorbidities and not to anemia and hemolysis. In contrast, hematological variables were independently related to cardiac involvement in SCA.

Conclusions: Cardiac phenotype and its correlates are different in HbSC compared to SCA. In HbSC cardiovascular monitoring should focus on patients with non-hematological comorbidities.

P923

Inflammatory and cardiac biomarkers in Takotsubo cardiomyopathy

G Goncalo Neves Pestana¹; M Tavares-Silva¹; C Sousa¹; R Pinto¹; V Ribeiro¹; M Vasconcelos¹; P Bernardo-Almeida¹; MJ Maciel¹; ¹Sao Joao Hospital, Cardiology, Porto, Portugal

Purpose: Takotsubo cardiomyopathy's (TTC) presentation typically mimics the clinical and imaging findings of an anterior wall ST-segment elevation myocardial infarction (MI). Despite a growing knowledge base on this entity, its pathophysiology is still incompletely understood and its diagnosis requires exclusion of MI by coronary angiography. On the contrary, inflammation is known to have a fundamental role in the pathophysiology of MI. Following on this, we compared changes in inflammatory and cardiac biomarkers in both groups.

Methods: We retrospectively analysed the clinical files of patients (pts) with a diagnosis of TTC at our hospital between 2005 and 2015 and of a random sample of pts without known coronary heart disease admitted for anterior MI. Demographic, clinical and laboratory data was collected; the latter included collection of neutrophil count, admission C-reactive protein (CRP), albumin, brain natriuretic peptide (BNP) and maximum troponin I levels. These values were used to calculate BNP/troponin, BNP/left ventricular ejection fraction (LVEF) and troponin/LVEF ratios.

Results: We identified 58 pts with a TTC diagnosis (55 female), with a mean age of 66 years (33 to 88 years), and 21 age-matched MI controls. LVEF on admission was similar between the two groups (mean 38 ± 6 vs $37 \pm 7\%$, respectively).

While values outside the reference range were frequent in all inflammatory parameters analysed, a statistical difference between the two samples was found only for albumin levels, which were lower in TTC pts (35.9 ± 4.8 vs 38.3 ± 2.2 g/L, $p = 0.004$). This difference, however, lost significance after excluding 10 pts diagnosed with TTC during an ongoing hospitalization for other reason.

Regarding cardiac biomarkers, TTC pts had significantly higher brain natriuretic peptide (705 ± 132 vs 198 ± 102 pg/mL, $p = 0.004$) and lower troponin I levels (2.8 ± 0.4 vs 120.4 ± 16.7 ng/mL, $p < 0.001$) when compared to MI controls. BNP/troponin (584.3 ± 951.3 vs 2.2 ± 3.7 , $p < 0.001$), troponin/LVEF ratios (8.8 ± 10.3 vs 367.1 ± 276.0 , $p < 0.001$) and BNP/LVEF (1796 ± 1469 vs 684 ± 1582 , $p < 0.001$) were significantly different as well. Furthermore, on ROC curve analysis, the former ratios showed highly significant power in differentiating TTC and MI: a BNP/troponin ratio > 13.2 identified TTC pts with 99% specificity and 94% sensitivity (AUC = 0.996, $p < 0.001$), while a troponin/LVEF ratio > 70 identified anterior MI pts with 99% specificity and 93% sensitivity (AUC = 0.996, $p < 0.001$).

Conclusions: Common biomarkers are altered in both TTC and MI. However, no statistically significant difference in inflammatory parameters was found between TTC and anterior MI. On the other hand, cardiac biomarkers available in the first 48h of hospitalization were significantly different between the two samples and BNP/troponin and troponin/LVEF ratios actually had significant power in distinguishing both entities.

P924

Cardiac amyloidosis: imaging characterization and prognostic information

M Tavares Da Silva¹; C De Sousa¹; M Vasconcelos¹; F Melao¹; V Ribeiro¹; L Flores²; T Pinho¹; AJ Madureira³; F Macedo¹; MJ Maciel¹; ¹Sao Joao Hospital, Cardiology, Porto, Portugal; ²Sao Joao Hospital, Porto, Portugal; ³Sao Joao Hospital, Radiology, Porto, Portugal;

Purpose: Cardiac amyloidosis (CA) is a challenging diagnosis, with an ominous prognosis. Biopsy remains the gold standard to diagnosis, but imaging techniques have emerged as attractive non-invasive alternatives. Different parameters have been used to predict outcome in these patients (pts). We studied the prognostic significance of clinical, echocardiographic and cardiac magnetic resonance (CMR) parameters in our population of pts with CA.

Methods: Clinical, standard echocardiographic and CMR parameters were collected and analysed in pts with histologically proven amyloidosis and a high suspicion of cardiac involvement. Mortality data was considered as the end-point. Echocardiographic, CMR and clinical variables were evaluated using cox-proportional hazards model. Categorical variables are shown as percentages and continuous are presented as mean \pm standard deviation. A p value less than 0.05 was considered statistically significant.

Results: We enrolled 32 pts with a mean age of 72.59 ± 10.78 years. Heart failure was the presentation form in 59.4%, with a BNP of 1701.26 ± 152.96 pg/mL. Concerning echocardiographic evaluation, the majority (53.1%) had normal left ventricle (LV) ejection fraction (EF) and half had normal right ventricular (RV) systolic function. LV mass index for body surface area (BSA) was increased (248.23 ± 81.77 g/m²)

as well as interventricular septum and posterior wall thickness (14.9 ± 2.80 mm and 13.73 ± 2.82 mm). It was documented elevation in LV filling pressures (E/E' 22.84 ± 6.77) with E/A 1.91 ± 0.93 . Left atrial (LA) volume indexed for BSA was also increased (41.54 ± 10.33 ml/m²) and the majority of pts had pulmonary hypertension (PSAP 42.35 ± 10.73 mmHg). CMR was performed in 14 pts. LV and RV indexed end diastolic volumes were increased (67.23 ± 12.10 and 69.31 ± 14.96 ml/m²). LV EF was slightly decreased ($47.64 \pm 12.11\%$) while RV EF was normal ($49.50 \pm 9.17\%$). Late gadolinium enhancement (LGE) was found in all pts, mainly the diffuse subendocardial pattern (85%). RV and atrial LGE was found in 85% and 50% of pts, respectively. On univariate analysis, the only 1-year mortality predictor was BNP ($p = 0.005$) with a BNP ≥ 768 pg/mL having a sensitivity of 94% and a specificity of 73% to predict 1-year mortality. This group of pts had a mean survival of 5.35 ± 5.34 months.

Conclusion: Echocardiography and CMR are of major importance in the suspicion of cardiac amyloidosis, as they provide important clues to diagnosis. We found biventricular and LA dilation and signs of LV systolic and diastolic dysfunction. Length of survival is strongly associated with BNP compared to echocardiographic or CMR parameters. Moreover, our study indicates that BNP may be used to detect patients at high risk of mortality and help early initiation of aggressive management and treatment.

P925

Clinical significance of giant negative T-waves in patients with takotsubo cardiomyopathy

B Schneider¹; U Desch¹; J Stein¹
¹Sana Kliniken, Luebeck, Germany

Background: Takotsubo cardiomyopathy (TTC) mimics acute myocardial infarction. Electrocardiographic changes include ST-segment elevation during the acute phase and widespread T-wave inversion during follow-up. Some patients develop giant negative T waves ≥ 1 mV resembling those in apical hypertrophic cardiomyopathy (AHCM). This study assessed the frequency and clinical significance of giant negative T waves in patients with TTC.

Methods: Over a 9-year period, we observed 76 TTC patients (69 f, 7m; 70 ± 12 years). By angiography, 45 patients (59%) had apical ballooning (AB) and 31 (41%) mid-ventricular ballooning (MB) of the left ventricle (LV). ECG on admission, at the time of maximal T-wave inversion, before discharge and the daily QTc-interval were compared.

Results: Giant negative T waves ≥ 1 mV were seen in 16/76 patients (21%). All were documented in the precordial leads V2 (n=3), V3 (n=9), V4 (n=10), V5 (n=4) and V6 (n=1). Patient with giant negative T waves were older (75 ± 11 vs 69 ± 12 years, $p = 0.05$) and they had significantly more frequent the apical ballooning variant (88% vs 12%, $p < 0.01$). Time interval from symptom onset to first ECG (7.8 ± 7.7 vs 8.6 ± 8.9 hours, $p = \text{ns}$), heart rate on admission (96 ± 25 vs 87 ± 21 /min, $p = \text{ns}$) and the number of leads with ST-segment elevation on the admission ECG (4.3 ± 1.6 vs 3.8 ± 2.4 , $p = \text{ns}$) were not different in patients with and without development of giant negative T waves. Cardiac markers, LV ejection fraction and LV end-diastolic pressure were comparable in both groups. In patients with giant T there was a trend towards more complications during the acute phase (69% vs 43%, $p = 0.06$).

The maximal QTc interval was significantly longer in patients with giant negative T waves during follow-up (606 ± 70 vs 559 ± 71 msec, $p < 0.02$), however, the occurrence of ventricular arrhythmias and atrial fibrillation was not different. Time to ECG normalization was similar (59 ± 21 vs 68 ± 82 days, $p = \text{ns}$). As assessed by echocardiography, 15/16 patients with giant negative T waves developed wall thickening in the apical area within 2 weeks of presentation with a ratio of apical to posterobasal wall thickness $> 1.5:1$ fulfilling the criteria for AHCM. Cardiac MRI performed in 6 of these 15 patients disclosed myocardial oedema in the apical area. Time to complete normalisation of LV function was significantly longer in patients with giant negative T waves (32 ± 24 vs 20 ± 15 days, $p < 0.02$).

Conclusion: Giant negative T waves ≥ 1 mV in the precordial leads resembling those in AHCM develop in 21% of patients with TTC. They are associated with apical wall thickening due to myocardial oedema, a higher complication rate and a longer time interval to complete normalisation of LV function.

P926

Improved diagnostics and management of Danon disease in the Czech Republic.

M Milos Kubanek¹; A Krebsova¹; L Piherova²; S Kmoch²; M Macek Jr³; T Palecek⁴; V Stara⁵; V Melenovsky¹; J Sikora²; J Kautzner¹

¹Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czech Republic; ²Charles University, 1st Medical School, Institute for Inherited Metabolic Disorders, Prague, Czech Republic; ³Charles University, 2nd Medical School, Department of Biology and Medical Genetics, Prague, Czech Republic; ⁴Charles University of Prague, 1st Medical School, 2nd Internal Department, Prague, Czech Republic; ⁵Charles University of Prague, 2nd Medical School, Department of Pediatrics, Prague, Czech Republic

Introduction: Danon disease (DD) is an X-linked deficiency of LAMP2 protein clinically affecting both males and X-heterozygous females. DD most often presents

as a hypertrophic cardiomyopathy (HCM) with rapid progression to end-stage heart failure (HF).

Purpose and methods: We present an overview of diagnostic strategy, clinical manifestation and management of patients with DD in the Czech Republic.

Results: DD has been diagnosed in five Czech families since 2009. In three families, LAMP2 protein deficiency was identified by skeletal muscle biopsy and/or flow cytometry (FC) in peripheral white blood cells (WBC). Patients from the two remaining families were originally diagnosed with mitochondrial cardiomyopathy or Wilson disease and their DD status was first established by next-generation sequencing (NGS). Pathogenic LAMP2 mutations were confirmed by Sanger sequencing in all patients/families. To validate, LAMP2 protein deficiency was confirmed by FC in all currently living DD patients (4 male and 3 female patients). As a further evidence of practical diagnostic utility, the de-novo mutated female proband was the only affected individual in one of the families tested by FC. Clinical data were available for 6 male (54%) and 5 female (46%) DD patients (2 obligatory heterozygotes not tested for the LAMP2 mutation are included). 8 patients (73%) presented with HCM (including 2 females) and 3 females (27%) with dilated cardiomyopathy. In addition, six males (54%) had mild skeletal myopathy, elevation of aminotransferases and mild cognitive impairment, whereas females had isolated cardiac involvement. Median age at diagnosis of cardiomyopathy was 11 years (6-15). A total of 8 patients (72%) developed HF – median age of HF manifestation was 22 years (19-26) and median age of survival without necessity of heart transplantation (HTx) or ventricular assist device (VAD) was 26 years (20-28). In 5 patients having cardiac resynchronization therapy, we observed a poor response with median time to death, HTx or VAD of 9 months (5-27).

Conclusions: To allow appropriate non-pharmacological treatment of advanced HF early diagnosis of Danon disease can be facilitated by LAMP2 flow cytometry in peripheral WBCs. NGS testing can be suggested as a useful alternative particularly in DD patients/families with atypical clinical phenotypes.

P927

Association of anemia and transfusion with adverse outcomes in 22,991 patients hospitalized with takotsubo cardiomyopathy

DP Kao¹

¹University of Denver, Cardiology, Denver, United States of America

Background: Takotsubo cardiomyopathy (TTCM) is a rare form of acute non-ischemic cardiomyopathy characterized by acute LV dysfunction in a multi-vessel distribution without obstructive coronary artery disease. Due to its rarity, comparatively little is known about predictors of poor outcomes. Anemia and transfusion have been associated with adverse outcomes in other kinds of acute and chronic heart failure. We hypothesize that these factors are associated with poor short-term outcomes in TTCM.

Objective: To describe the association between anemia, transfusion and other risk factors for poor outcomes in TTCM.

Methods: Hospital records from 11 US states were obtained from 2006-2013. All records reporting TTCM (ICD-9 CM code 429.83) were included in the analysis. Anemia, transfusion, and other patient procedures and characteristics were identified using ICD-9 codes and data documentation. A major adverse event (MAE) was defined as death, mechanical ventilation, cardiac arrest, shock, or placement of intraaortic balloon pump. Associations between anemia, transfusion, other patient characteristics and outcomes were determined by chi-square testing and multivariate logistic regression.

Results: In total, 22,991 TTCM cases were identified including 2479 (11%) men and 19327 (89%) women. Where race was reported, there were 15728 (78.6%) white patients, 1916 (9.6%) patients of African Ancestry (AA), 459 (2%) Asian patients, 1687 (8.4%) Hispanic patients and 230 (1.1%) of other or mixed race (2971 race). Anemia was present in 5598 (24%) of patients and 2339 (10%) of all patients received transfusions. Of anemic patients, 1805 (32%) had an MAE compared with 3270 (19%) non-anemic patients ($p < 0.001$). Of patients receiving transfusion, 1133 (48%) had an MAE compared with 3942 (19%) who did not receive a transfusion. In multivariate analysis including age, gender, race, anemia, atrial fibrillation, heart failure, hyperlipidemia, hypertension, mood disorders, intracranial hemorrhage, stroke, and acute renal failure, anemia (OR 1.3, 95% CI 1.2-1.4, $p < 0.001$) and transfusion (OR, 2.4 95% CI 2.1-2.7, $p < 0.001$) remained significant predictors of MAE. Asian patients who have been shown to have worse outcomes in TTCM had significant higher rates of anemia (37%) and transfusion (18%) than non-Asian patients (25% and 10% respectively, $p < 0.001$).

Conclusion: Anemia and transfusion during hospitalisation predict poor outcomes in TTCM.

P928

Clinical profile and outcomes of restrictive cardiomyopathies

J Joffrey Eduardo Lujan Valencia¹; M Chaparro Munoz²; A Recio Mayoral¹; A García Guerrero¹; P Caravaca Perez²; B Prado Gotor¹

¹Virgen Macarena University Hospital, Sevilla, Sevilla, Spain

Background: Restrictive cardiomyopathy (RCM), a heterogeneous group of heart muscle conditions characterized by impairment of ventricular filling during diastole, remains the least common type of cardiomyopathies without uniformly accepted diagnostic criteria. Unlike the other cardiomyopathies that are classified according to morphological criteria, RCM is a functional classification. The clinical profile, therapeutic options and survival outcomes of a cohort of patients with RCM are shown.

Method: We analysed between 2010 and 2015, 15 patients (20 to 95 years old (mean, 64 ± 19 years), 7 females) meeting criteria for RCM the last consensus of the European Society of Cardiology.

Results: Fatigue, dyspnoea on exertion and oedema were the most frequent symptoms at the time of diagnostic. Twelve patients (80%) were in NYHA class ≥ III. Amyloidosis ($n = 9$) was the predominant diagnosis. Other etiologies were: idiopathic ($n = 2$), scleroderma ($n = 1$), glycogenosis type III ($n = 1$), hemochromatosis ($n = 1$) and hypereosinophilic syndrome ($n = 1$). No patient had a myocardial biopsy but biopsies from different tissues were performing to obtain a definitive diagnosis. A cardiac magnetic resonance scan was done in 8 patients supporting the etiologic diagnosis in all cases. Atrial fibrillation was noted in 8 patients (53%). One patient required pacemaker implantation for atrioventricular block. Left ventricle systolic dysfunction was present in 7 patients. In addition to the specific aetiology treatment, all patients received loop diuretics (53% combined with aldosterone antagonists). Among those who received ACE inhibitors ($n = 10$) and beta blockers ($n = 8$), we find his interruption due to poor tolerance of 20% and 50% respectively and one heart transplant was performed with good results. The overall mean follow-up was 3.3 years (median 3.1; range, 0.5 to 4.5 years). Total mortality was 33% due to terminal heart failure in 80% and infection in 20%. In the analytical appreciated that in addition ProBNP, Gamma glutamyl transpeptidase (GGTP) has relation with a poor prognosis and mortality, it is noteworthy that no other liver marker maintained this relationship (including Score Child-Pugh).

Conclusions: Our patients had findings similar to those described in the universal literature, echocardiography was important to evaluate the morphological and functional criteria and cardiac magnetic resonance provided an incremental value in etiologic diagnosis, the conventional treatment may be poor tolerated. The GGTP could be helpful in the prognosis of these patients, but further studies are needed for confirmation.

P929

Biomarkers in idiopathic dilated cardiomyopathy- different predictors of pharmacological reverse remodelling and clinical severity

S M R Sandra Maria Resende Amorim¹; J Rodrigues¹; M Campelo¹; B Moura²; E Martins¹; F Macedo¹; J Silva-Cardoso¹; MJ Maciel¹

¹Sao Joao Hospital, Porto, Portugal; ²Military Hospital, Porto, Portugal

Introduction: Biomarkers in heart failure can play a role, can be related to inflammatory response, to oxidative stress, to myocyte injury, to myocyte stress or to matrix remodelling. Our aim was to see the role of some biomarkers in reverse remodelling (RR) and in clinical severity in pts with idiopathic dilated cardiomyopathy (IDCM). We also try to find association between those biomarkers and echocardiographic measures.

Methods: Prospective study of 50 IDCM pts (28 men, aged 59 ± 10 years, in sinus rhythm, followed for 39 ± 22 months), with ejection fraction <40%. Excluded secondary and reversible causes. At baseline we performed a clinical, bio humoral and echocardiographic evaluation. During follow-up, RR was defined as an increase of 10 units of ejection fraction (EF) and decrease of diastolic left ventricular diameter (LVD) in the absence of resynchronization therapy.

Results: Baseline EF was 25.4 ± 9.8% and LVD/BSA was 34.2 ± 4.5 mm/m². RR occurred in 34% of pts within 17.6 ± 15.6 months. Pts with RR had a final EF of 49.6 ± 7.3% and LVD/BSA of 28.8 ± 2.9 mm/m². RR was associated to lower BNP at the end of follow-up (143.5 ± 137.5 vs 36.9 ± 34.3, $p < 0.01$).

Baseline predictive factors of RR ($p < 0.05$) were: younger age (60.6 ± 8.8 vs 54.7 ± 10.8, $p = 0.04$), smaller LVD/BSA (mm/m²) (35.2 ± 4.1 vs 32.3 ± 4.8, $p = 0.03$), higher RV Tei index (0.46 ± 0.16 vs 0.52 ± 0.32, $p = 0.02$), lower BNP (pg/ml) (163.1 ± 587.7 vs 81.3 ± 198.4, $p = 0.05$), lower levels of adrenalin (pg/ml) (46.2 ± 38.6 vs 29.9 ± 16.8, $p = 0.02$) and renin (U/ml) (228.4 ± 446.7 vs 84.1 ± 90.9, $p = 0.02$). No correlation was found between 25-OH-vit D, CA 125, hs CRP, Lp (a) and reverse remodelling. Pts who presented with poor NYHA class (III-IV) had higher levels of: CA 125 (U/ml) (21.6 ± 58.1 vs 116.0 ± 255.3) cystatin C (mg/l) (0.76 ± 0.16 vs 0.92 ± 0.05), BNP (pg/ml) (257.5 ± 391.0 vs 968.5 ± 950.1) and hs CRP (mg/l) (2.6 ± 3.4 vs 10.9 ± 13.4) ($p > 0.05$). Pts with pulmonary congestion or ankle edema had also higher levels of CA 125, BNP and hsCRP ($p < 0.01$).

CA 125 was correlated to BNP levels ($r = 0.61$), to hs CRP ($r = 0.56$) and uric acid ($r = 0.52$) (all $p = 0.01$). CA 125 correlated with some echocardiographic variables: LA volume/BSA ($r = 0.46$, $p < 0.01$), E/A ratio ($r = 0.60$, $p < 0.01$), pulmonary systolic artery pressure ($r = 0.49$, $p < 0.01$). hs CRP was correlated with LV EF ($r = -0.28$, $p = 0.05$, LV tei index ($r = -0.41$, $p < 0.01$) and with LV diastolic volume/BSA ($r = 0.32$, $p = 0.05$).

Conclusions: RR occurred in one third of IDCM pts, especially in younger pts, with less sympathetic and neuro humoral activation, smaller LVD and better RV function. CA125, BNP, hsCRP were predictors of clinical severity. CA 125 correlated with

measures of diastolic dysfunction and pulmonary pressure, while hs CRP correlated with LV systolic dysfunction. CA 125 correlated with hs-PCR and uric acid, indicating a potential pathogenic link between inflammatory activation and this marker of systemic congestion.

Differential regulation of Receptor for Advanced Glycation End products (RAGE) in ischemic and post-inflammatory dilated cardiomyopathy

Deutsche Stiftung für Herzforschung
SR Simina-Ramona Selezjan¹; F Dahlem¹; M Hohl¹; D Linz¹; AM Tatu¹; S Ewen¹; M Boehm¹; I Kindermann¹

¹Saarland University Hospital, Department of Internal Medicine III, Cardiology, Homburg, Germany

Background: Chronic heart failure is associated with a pro-inflammatory state. Activation of the Receptor for Advanced Glycation End products (RAGE) by its ligands (Advanced Glycation End products (AGEs) like Carboxymethyllysine (CML)) induces inflammatory responses and elicits oxidative stress and cardiac remodelling. The decoy receptor soluble RAGE (sRAGE) comprising only the RAGE-ectodomain and neutralizing RAGE-ligands exerts anti-inflammatory beneficial effects and has been shown to be a prognostic factor for heart failure. The aim of this study was to evaluate plasma and myocardial sRAGE/RAGE/CML expression in ischemic and post-inflammatory chronic heart failure.

Methods: Plasma samples from patients with chronic heart failure (n = 15 ischemic cardiomyopathy ICM, n = 15 post-inflammatory dilated cardiomyopathy DCM) and from age-matched healthy volunteers (controls n = 15) were analyzed for sRAGE and CML by quantitative Western blot. Additionally, myocardial tissue samples from explanted hearts from patients with chronic heart failure (n = 5 ICM; n = 5 DCM) and from non-failing hearts (n = 5) were investigated for RAGE/sRAGE and CML expression by Western blot.

Results: In patients with DCM sRAGE plasma levels were significantly decreased as compared to healthy controls (50% decrease). Additionally, patients with DCM showed increased CML plasma levels (4.2fold increase and 3.6fold increase versus controls and versus ICM), indicating a profound pro-inflammatory dysbalance in DCM. Myocardial RAGE expression was significantly increased in both DCM and ICM patients (3.9fold and 4.5fold increase versus controls). However, in ICM myocardium RAGE increase was counterbalanced by a concomitant 2.7fold sRAGE increase (compared to controls). Contrary to this, in DCM myocardial anti-inflammatory sRAGE was reduced (53% reduction versus controls) and the pro-inflammatory AGE CML was additionally increased (3fold increase).

Conclusions: Chronic heart failure is associated with increased myocardial RAGE expression. However, pro-inflammation is more profound in dilated cardiomyopathy as depicted by reduced myocardial and plasma sRAGE content and increased levels of the AGE Carboxymethyl-lysine. These novel observations might help develop new diagnostic and therapeutic strategies in chronic heart failure.

P931

Insights into mildly dilated cardiomyopathy: temporal evolution and long-term prognosis

M Gigli¹; D Davide Stolfo¹; M Merlo¹; G Barbat¹; F Ramani¹; F Brun¹; B Pinamonti¹; G Sinagra¹

¹University Hospital "Riuniti", Department of Cardiology, Trieste, Italy

Background: Mildly Dilated Cardiomyopathy (MDCM) is a subgroup of dilated cardiomyopathy (DCM) characterized by systolic dysfunction but normal or slightly dilated left ventricle (LV). The characterization and long-term evolution of MDCM are currently unknown.

Purpose: To characterize and assess the long-term natural history of MDCM.

Methods: From 1988 to 2010 we analyzed all DCM patients consecutively enrolled in the Trieste Heart Muscle Disease Registry. MDCM was defined as LV ejection fraction $\leq 45\%$ and index LV end-diastolic volume (LVEDVI) ≤ 70 ml/m² in women and ≤ 89 ml/m² in men. Results. Among a whole population of 638 patients, 226 (35%) fulfilled the criteria for MDCM. They presented features of a less advanced disease at baseline and an overall lower rate of all-cause mortality/heart transplant (D/HTx) in the long-term follow-up (D/HTx at 10 years 15% vs 30%, in MDCM and DCM respectively; $p < 0.001$). However, throughout the follow-up, 55 MDCM patients (24%) evolved in non-MDCM by increasing LVEDVI. Their prognosis consistently worsened approaching that of DCM patients in the long-term. On the other hand, among persistent MDCM patients, restrictive filling pattern (HR 5.30; 95%CI 2.34-12.01 $p < 0.001$) and non-sustained ventricular tachycardia (HR 2.21, IC 95% 1.003-5.11 $p = 0.047$) were independently associated with D/HTx at multivariate analysis.

Conclusions: MDCM identifies a consistent subgroup of DCMs diagnosed at an earlier stage and therefore presenting an apparent better evolution. However, some MDCMs progress towards DCM condition despite adequate medical therapy, whereas among persistent MDCMs those presenting with non-sustained ventricular arrhythmias and restrictive filling pattern were characterized by a very poor long-term outcome.

P932

Improved prediction of major arrhythmic events in patients with unexplained cardiomyopathy who underwent endomyocardial biopsy

M R Mark Hazebroek¹; JJ Merken¹; AM Daniels¹; R Dennert¹; V Van Empel¹; C Knackstedt¹; H Crijns¹; HP Brunner-Larocca¹; S Heymans¹

¹Maastricht University Medical Center, Department of Cardiology, Maastricht, Netherlands

Background: The current ESC guidelines recommend an implantable cardioverter-defibrillator (ICD) in heart failure patients with a low LVEF $< 35\%$ and NYHA-class ≥ 2 . Whether EF and NYHA-class are also ideal predictors of major arrhythmic events (MAE) in patients with unexplained cardiomyopathy (CMP) is not well established. The present study investigated which parameters best predicts MAE and compared it to the predictive value of LVEF and NYHA ≥ 2 .

Objectives: To identify prognostic factors predicting MAE in CMP patients who all underwent endomyocardial biopsy (EMB).

Methods: Within the Maastricht Cardiomyopathy registry, 459 patients with initially unexplained CMP – excluding ischemic, valvular, hypertensive, and congenital heart disease – were enrolled between 2004 and 2015. Patients with a history of ventricular tachycardia (VT) and/or ventricular fibrillation (VF) were excluded. All patients underwent complete work-up including electrocardiography, echocardiography, Holter registration and EMB. Primary endpoint was MAE defined as sustained VT, VF or sudden cardiac death (SCD). Secondary endpoint was event-free survival including all-cause mortality and/or heart transplantation (HTx).

RESULTS: A total of 459 consecutive DCM patients (290 males) were included, mean age of 54 ± 12 yrs, NYHA ≥ 3 in 132 (29%), and LVEF $< 35\%$ in 282 (61%) patients. Increased cardiac inflammation with or without significant viral load (> 500 c/mcg DNA) and significantly increased myocardial fibrosis $> 10\%$ was found in 182 (40%) and 143 (33%) patients, respectively. After median follow-up of 50 [20-75] months, a total of 32 (7%) patients had a MAE (14 SCD & 18 sustained VT/VF). Independent predictors included non-sustained VT (HR 2.18, 95% CI 1.12-4.83, $P = 0.046$), persistent atrial fibrillation (HR 3.16, 95% CI 1.3-7.9, $P = 0.014$), LVEDD (HR 1.08 per mm increase, 95% CI 1.04-1.13, $P < 0.001$) and LVEF $< 35\%$ (HR 3.40, 95% CI 0.7-15, $P = 0.12$). This model was better as compared to LVEF $< 35\%$ and NYHA ≥ 2 (area under the curve (AUC) of 0.80 vs 0.67 (Figure 1, $P = 0.022$). Using all predictors except LVEF $< 35\%$ still showed superiority as compared to ICD indications (Figure 1: AUC 0.79 vs 0.67; $P = 0.041$). EMB-related markers did not further improve the model. Secondary endpoint was reached in 38 (8%) patients (36 deaths & 2 HTx). Independent predictors included older age (HR 1.03, 95% CI 1.01-1.07, $P = 0.038$), longer duration of symptoms (HR 1.01, 95% CI 1.00-1.01, $P = 0.038$), NYHA ≥ 2 (HR 2.01, 95% CI 1.0-3.9, $P = 0.042$) and LVEF $< 35\%$ (HR 4.27, 95% CI 1.3-14, $P = 0.019$).

Conclusion: A better prediction model for major arrhythmic events is found using the presence of NSVT, persistent AF, LVEF $< 35\%$ and LVEDD – even without LVEF $< 35\%$ in the model – as compared to guideline-based LVEF $< 35\%$ and NYHA-class in patients with CMP. In contrast, both LVEF $< 35\%$ and NYHA-class independently predict HTx-free survival, illustrating the importance to differentiate between arrhythmic and heart-failure related outcome.

AUCs for prediction models

Morpho-functional phenotypes of dilated cardiomyopathy due to lamina gene mutation/polymorphism

T Tatiyana Vaikhanskaya¹; LN Sivitskaya²; NG Danilenko²; TV Kurushka¹; OG Davidenko²

¹Republican Scientific and Practical Center "Cardiology", Minsk, Belarus; ²Institute of Genetics and Cytology, National Academy of Science, Minsk, Belarus

Objective of the study was to assess morpho-functional phenotypes in patients with dilated cardiomyopathy (DCM) due to lamina gene mutation/polymorphism.

Methods: The study enrolled 160 patients (pts) with DCM (aged 46 ± 12 ; 70 % male, NYHA 2.7 ± 0.4 ; LVEF $25.8 \pm 8.2\%$). Genetic testing was performed by SSCP and sequencing of exons and intron-exon lamina (LMNA) gene. Genetic finding, data by

SNPs and mutation LMNA gene in DCM

polymorphic locus	nucleotide substitution specifying codon	localization in lamin gene	replacing an amino acid residue in the protein lamin	patients (n)
rs397517894	c.150 C > T	exon 1	Arg50Arg	1
art rs267607571	c.569G > C	exon 3	rg190Pro**	1
rs12117552	c.612G > A	Exon 3	Leu204Leu	2
rs11264442	c.639+56G > T	intron between 3 and 4exons	-	5
rs11264443	c.639+73C > T	intron between 3 and 4exons	-	5
rs538089	c.861 T > C	exon 5	Ala287Ala	16
rs553016	c.1489-41C > T	intron between 8 and 9 exons	-	16
rs267607557	c.1558T > C	exon 9	h520Arg	1
rs57629361	c.1583C > G	exon 9	hr528Arg	1
rs4641	c.1698C > T	exon 10	His566His*	25

Note: * heterozygous carrier replacement s.1698 C > T was detected in 23 patients, homozygous carrier - 2 pts; ** de-novo mutation

EchoCG, ECG/24h-Holter with estimation of QTc dispersion, heart rate turbulence (HRT), microvolt T-wave alternans (mTWA), also age, gender and serum BNP, CPK levels were analyzed.

Results: We genotyped LMNA (SNPs and mutations are represented in Table below); 16/43 (37%) from 43/160 (26,%) pts showed carriage in two and more loci. A positive correlation between missens-mutations (exons 3, 9) and atrioventricular block ($k=0,66$; $p=0.001$), with CPK level ($k=0,61$; $p=0.002$) and muscle disorders ($k=0,52$; $p=0.02$) were revealed. Substitution of nucleotide C to T in codon 566 (exon 10) as result of SNP rs4641 which still codes for Histidine was detected in 25 pts. The LMNA rs4641 T-allele was associated with non-sustained ventricular tachycardia (Spearman $k=0,65$; $p=0.001$), with positive mTWA test ($k=0,64$; $p=0.0001$) and pathological HRT0 ($k=0,53$; $p=0.01$). SNP associated with rs4641 is very important as it is located in splice site at exon 10; alternative splicing at this site leads to the production of either lamin A or C transcripts or protein. The obtained results support the fact this SNP can affect signal transduction processes.

Conclusions: Thus, we consider that T allele rs4641 in LMNA is one of the major genetic risk factor for the pathogenesis of DCM other than mutation in LMNA.

P934

Predictors of cardiac magnetic resonance-assessed reverse remodeling in non-ischaemic dilated cardiomyopathy

G Giuseppe Vergaro¹; L Nesti¹; A Barison¹; C Prontera¹; S Masotti¹; GD Aquaro¹; A Clerici¹; R Poletti¹; C Passino²; M Emdin²; ¹Gabriele Monasterio Foundation, Pisa, Italy; ²Scuola Superiore Sant'Anna, Pisa, Italy

Purpose: Reverse remodeling (R2) in non-ischaemic dilated cardiomyopathy (NIDCM) is associated with reduced morbidity, improved quality of life and survival. There is still scarce knowledge on predictors of R2, relevant for guide to treatment and device implantation. We aimed to identify predictors of R2, assessed by serial cardiac magnetic resonance (CMR) imaging, among several clinical, instrumental and biochemical variables in NIDCM.

Methods: We prospectively enrolled patients with clinical diagnosis of NIDCM, according to the World Health Organization criteria; significant coronary artery disease was excluded by coronary angiography. All patients received a baseline clinical, biochemical (including neurohormones, galectin-3 and ST2) and instrumental characterization, as well as contrast-enhanced CMR. CMR study was performed again 24 months after baseline evaluation. R2 was defined according to three different criteria, all present within literature: 1) > 15% decrease in left ventricular end-systolic volume index (LVESVi) (criterion 1); 2) increase in LV ejection fraction, LVEF, > 10U with a > 10% decrease in LV end-diastolic volume index (LVEDVi) (criterion 2); 3) an increase in LVEF > 10U or a > 10% decrease in LVEDVi (criterion 3).

Results: We recruited 86 patients (males 64%, age 55 ± 15 years, LVEF $38 \pm 10\%$, LVEDVi 118 ± 32 ml/m², LVESVi 75 ± 32 ml/m²). R2 was observed in 48, 26 and 50% of patients, according to criterion 1, 2, 3, respectively. Independent predictors were:

as for criterion 1, absence of diabetes ($p=0.034$), introduction of mineralocorticoid receptor antagonist -MRA- after baseline evaluation ($p=0.032$), greater baseline LVESVi, $p=0.040$; as for criterion 2: MRA introduction ($p=0.028$), higher C-reactive protein ($p=0.017$), and higher baseline LVESVi ($p=0.040$); as for criterion 3, higher baseline aldosterone only ($p=0.044$).

Conclusions: Greater baseline LV volumes and aldosterone levels predict R2, with a possible interaction with MRA therapy. Neurohormonal activation may therefore identify the subset of patients with a more pronounced response to pharmacological neurohormonal antagonism.

P935

Early phase 99Tc-HMDP scintigraphy: a rapid and reliable technique for the diagnosis and typing of cardiac amyloidosis

A Arnault Galat¹; AV Van Der Gucht²; AG Guellich¹; DB Bodez¹; SG Guendouz¹; LH Hittinger¹; JLD Dubois-Randé¹; VP Plante-Bordeneuve³; MM Meignan²; JR Rosso²

¹University Hospital Henri Mondor, Cardiology, Creteil, France; ²University Hospital Henri Mondor, Nuclear medicine, Creteil, France; ³University Hospital Henri Mondor, Neurology, Creteil, France

Background: The usefulness of bisphosphonate-scintigraphy in diagnosing and typing cardiac amyloidosis (CA) has been reported in several studies. However, the procedure is time-consuming and may be regarded as inadequate especially in frail patients.

Objective: To compare accuracy of early (10min) and late (3h) cardiac fixation of 99mTc-HMDP scintigraphy in diagnosing and typing CA.

Methods: 135 patients referred for suspicion of CA were prospectively evaluated using 99mTc-HMDP-scintigraphy. Myocardial tracer accumulation was semi-quantitatively measured and visually scored at early and late phases.

Results: CA was diagnosed in 19 AL (light-chain) and in 33 wt-TTR (wild-type-transthyretin). Among m-TTR (mutated-transthyretin) 33 had CA, 5 had isolated neuropathy without CA and 3 were asymptomatic carriers. 31 patients with LVH (left-ventricle-hypertrophy) and without amyloidosis served as controls. Early 99mTc-HMDP cardiac uptake was found in 68 patients whose late visual score was ≥ 1 . Early uptake was undetectable in all the 57 patients with a null visual score at 3h. Early heart retention was strongly correlated to late heart retention ($r=0.914$, $p<0.0001$). An early 99mTc-HMDP heart/mediastinum ratio ≥ 1.115 predicts a late visual score ≥ 1 which differentiated CA from other causes of LVH (100% sensitivity, 97% specificity). Early heart/mediastinum ratio ≥ 1.210 discriminated TTR-CA from AL with perfect accuracy (100% sensitivity and specificity).

Conclusions: Early phase 99mTc-HMDP-scintigraphy perfectly predicts late phase finding. It is accurate to differentiate TTR-CA from AL and from other causes of LVH. This could be of particular benefit for frail patients and in centres with limited availability of scintigraphy.

Agreement between H/M and visual score

Apical hypertrophic cardiomyopathy: less heart failure symptoms but the same prognosis

C E Carlos Emanuel Correia¹; D Bento²; L Reis³; M Oliveira⁴; R Santos⁵; R Faria⁶; S Leao⁷; B Picarra⁸; L Lopes⁹

¹Hospital Sao Teotónio, Viseu, Portugal; ²Faro Hospital EPE, CARDIOLOGY, FARO, Portugal; ³University Hospitals of Coimbra, Coimbra, Portugal; ⁴Alto Ave Hospital Center, Guimaraes, Portugal; ⁵Hospital Centre do Tamega e Sousa, Penafiel, Portugal; ⁶Centro Hospitalar Medio Ave, Famalicão, Portugal; ⁷Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁸Hospital Espírito Santo de Evora, Evora, Portugal; ⁹Hospital Garcia de Orta, Almada, Portugal

Introduction: Apical hypertrophic cardiomyopathy (ApHCM) is the less frequent form of HCM. Despite described as benign, the natural history is less known.

Aim: Comparison between ApHCM vs asymmetrical or concentric HCM concerning clinical, ECG and genetic characteristics.

Methods: Retrospective, multicentre study including all HCM patients from ten hospitals. We compared clinical characteristics, genetics, ECG and 24 hours Holter between patients with ApMCH and patients with concentric or asymmetrical HCM.

Results: We included 476 HCM patients: 73 with ApHCM and 403 with concentric or asymmetrical HCM. Mean age 65 ± 15 years for ApHCM vs 62 ± 15 years ($p=0.045$). Mean follow up of six years. Patients with ApHCM had less dyspnea (45% vs 59%, $p=0.034$) and more angina (30% vs 17%, $p=0.009$). Genetic study was positive in 39% of patients in both groups. Mutations in TNNI3 gene were more frequent in ApMCH (14.3% vs 0.7%, $p<0.001$). In 12 lead ECG atrial fibrillation (18% vs 10%, $p=0.045$), left ventricular strain pattern (64% vs 42%, $p<0.001$), ST segment depression (29% vs 15%, $p=0.002$) and negative T waves (68% vs 34%, $p<0.001$) were more frequent in patients with ApHCM. 24h Holter revealed more frequently supraventricular tachycardia in patients with ApHCM.

No differences were found in the other variables tested including ventricular arrhythmias, stroke or death in the follow up.

Conclusions: This large multicentre study showed that ApHCM patients had more frequently symptoms of angina and less frequently dyspnea. TNNI3 mutations were more frequent. The ECG of patients with ApHCM has more frequently left ventricular strain pattern, negative T waves and ST segment depression. Despite more supraventricular arrhythmias on 24h Holter, there were no differences in ventricular arrhythmias, stroke or death in the follow up. Despite clinical and ECG differences, with found similar prognosis in patients with ApHCM and concentric or asymmetrical HCM upon a follow up of six years.

P937

Nt-proBNP and high sensitive troponin in Friedreich ataxia's cardiopathy

L Legrand¹; C Maupain¹; ML Monin²; A Tataru³; M Komajda¹; A Durr²; R Isnard¹; F Pousset¹

¹Hospital Pitie-Salpetriere, Assistance Publique-Hôpitaux de Paris, Institut de cardiologie, Paris, France; ²Hospital Pitie-Salpetriere, Assistance Publique-Hôpitaux de Paris, Fédération de Génétique, Paris, France; ³Hospital Pitie-Salpetriere, Institut du cerveau et de la moelle épinière, Paris, France

Background: Friedreich Ataxia (FRDA) is the most common autosomal recessive neurodegenerative ataxia, resulting of mitochondrial disorder, caused by repetition of GAA expansion in frataxin gene. Hypertrophic cardiopathy is associated with FRDA and is known to be the first cause of death. Patients have abnormal ECG without acute coronary syndrome symptomatology. Cardiac biomarkers, high sensitive (hs) troponin and Nt-proBNP could be useful for the management of these patients.

Purpose: To establish the role of high sensitive troponin and Nt-proBNP plasma levels in the diagnosis and prognosis of cardiopathy in FRDA.

Methods: From december 2012 to january 2015, 76 genetically confirmed Friedreich ataxia's patients were included in our Hospital and had a cardiac evaluation: clinical examination, ECG 12 leads, echocardiography and plasma level of hs troponin and Nt-proBNP.

Results: Patients were aged of 38 ± 12 years, (mean \pm standard deviation). 4 patients had palpitations, 2 dyspnea and no patients had chest pain. 89% had negative T waves on the ECG. 2 groups of patients were defined according to cardiac hypertrophy (Henrys'Nomogram). 37 patients had hypertrophy and 39 patients had no hypertrophy. Patients with hypertrophy were younger: 34 ± 10 years versus 42 ± 14 years, and age at onset of the disease was earlier 15 ± 6 years versus 21 ± 15 years. Myocardial wall thicknesses were respectively 12.6 ± 1.7 mm versus 10.2 ± 1.2 mm for septum wall thickness and 11.3 ± 1.5 mm versus 9.4 ± 1 mm for posterior wall thickness. Left ventricle ejection fraction were normal and not different between the two groups. High sensitive troponin t was higher in the group with hypertrophy: 22 ± 21 ng/L versus 10 ± 7 ng/L, $p<0.01$. Value of Nt-proBNP was similar in the 2 groups: 104 ± 170 ng/L versus 64 ± 122 ng/L. In multivariate analysis, hs troponin increases with interventricular wall thickness, $p<0.01$. A number of 12 patients had Nt-proBNP > 125 ng/L: 42% experienced atrial fibrillation and 17% heart failure.

Conclusion: High sensitive troponin could be a diagnostic marker of hypertrophic cardiomyopathy in FRDA patients. Nt-proBNP is associated with cardiac events and could be rather a prognostic marker in these patients. Follow up studies are needed to study the evolution and the prognostic value of these biomarkers.

P938

Predictors of heart failure on hypertrophic cardiomyopathy - a portuguese multicenter study

AC Ana Catarina Gomes¹; P Azevedo²; H Antunes³; L Reis⁴; K Domingues⁵; P Magalhaes⁶; R Santos⁷; B Picarra⁸; O Azevedo⁹

¹Hospital Garcia de Orta, Cardiology, Almada, Portugal; ²Hospital de Braga, Cardiology, Braga, Portugal; ³Sao Teotónio Hospital, Cardiology, Viseu, Portugal; ⁴University Hospitals of Coimbra, Cardiology, Coimbra, Portugal; ⁵Hospital of Santarem, Cardiology, Santarem, Portugal; ⁶Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal; ⁷Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal; ⁸Hospital Espírito Santo de Evora, Cardiology, Evora, Portugal; ⁹Alto Ave Hospital Center, Cardiology, Guimaraes, Portugal

Introduction: Hypertrophic cardiomyopathy (HCM) may lead to the development of heart failure. Little is known about the predictors of heart failure in HCM. Aim: To identify predictors of heart failure in patients with HCM.

Methods: A Portuguese multicenter study involving 10 hospital centers and including all patients diagnosed with HCM. We evaluated demographic, clinical, genetic, electrocardiographic, echocardiographic and cardiac magnetic resonance data. We determined the factors that were associated with the development of heart failure and then conducted a multivariate analysis to establish the independent predictors of heart failure in patients with HCM.

Results: We included 476 patients with HCM. Heart failure was present in 56.5% of patients. In patients with HCM, the factors associated with the development of heart failure were female gender (53.4% vs 27.7%, $p<0.001$), older age (66 ± 14 vs 58 ± 16 years, $p<0.001$), hypertension (17.8% vs 9.7%, $p=0.011$), presence of angina pectoris (22.3% vs 15%, $p=0.044$), history of surgical miectomy (5.2% vs 0%, $p<0.001$) and atrial fibrillation on clinical presentation (14.4% vs 7%, $p=0.011$). Patients with HCM and heart failure had higher frequency of death in the 6 years of follow up (3.7% vs 0.5%, $p=0.020$). In the multivariate analysis, older age ($p=0.002$) was identified as an independent predictor of heart failure in HCM.

Conclusion: Heart failure is a common complication of HCM. The development of heart failure in patients with HCM was associated with female gender, older age, hypertension, presence of angina pectoris, history of surgical miectomy and atrial fibrillation on presentation. Older age was identified as independent predictor of heart failure in patients with HCM.

Factors associated with medication adherence of elderly patients with chronic heart failure

VN Larina¹; DG Karpenko¹; MG Golovko¹

¹ The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation

Understanding the factors associated with medication adherence over time is important for the prevention of disease progression and good outcomes among patients with heart failure. However, little is known regarding the factors associated with medication adherence among elderly patients with heart failure and osteoporosis.

The objective of this study was to analyze the factors associated with medication adherence of elderly patients with chronic heart failure and osteoporosis in primary care.

Methods: Fifty-three outpatients suffering from NYHA class II-III CHF (40 F, 13 M, aged 60 - 88 years) due to ischemic heart disease and/or arterial hypertension entered the study. All patients had clinical, laboratorial evaluation, ECG, Echo CG measurements. Validated questionnaire Morisky-Green Test is being used to evaluate adherence to treatments. Bone mineral density (BMD) in the lumbar spine (L1-L4) and femoral neck (FN) were examined using dual-energy X-ray absorptiometry (DXA). BMD was expressed by T-score. All patients were under optimal HF therapy based upon the HFA guidelines. Statistical analysis was made using software packages SPSS 16.0. Results. Osteoporosis (T-score < -2.4 SD) was present in 33 (62.3%) patients (29 F, 4 M; group 1) and absent in 20 (37.7%) patients (11 F, 9 M; group 2). Patients of both groups were similar by age, NYHA class, hemodynamic parameters, atrial fibrillation and arterial hypertension cases. Diabetes mellitus was found in 45% patients with osteoporosis and in 18.2% patients without osteoporosis, $p=0.036$. MMLVI was 111.1 ± 5 g/m² in patients with osteoporosis and 122 ± 6.0 g/m² - without osteoporosis, $p=0.038$. Blood concentration of N-proBNP was 1418.5 ± 170.1 pg/ml in patients with osteoporosis, 228.6 ± 179.5 pg/ml - without osteoporosis, $p=0.001$. Patients with osteoporosis had higher rates of past bone fractures compared to those without osteoporosis, $p<0.001$. Adherent to treatments was 14 (42.4%) patients with osteoporosis and 9 (45%) - without osteoporosis. Morisky-Green Test mean score was 3.3 ± 0.7 in patients with osteoporosis and 3.25 ± 0.8 - without osteoporosis. There was correlations between high medication adherence and systolic BP ($p<0.001$, $r=-0.44$), diastolic BP ($p=0.04$, $r=-0.27$) and past osteoporotic bone fractures ($p=0.039$, $r=0.46$).

Conclusion: Medication adherence was similar in two groups of elderly HF patients and correlated with disease severity (due to N-proBNP) and past osteoporotic bone fractures. Our finding raises the fact that osteoporosis fractures could be a mere marker of disease severity and it should become a routine additional assessment of HF outpatients' adherence to medical treatment

P940

Renal denervation as a supportive treatment to chronic heart failure

P Paivi Pietila-Effati¹; M Hoglund¹; T Paana²; A Nabb¹; E Matila¹; MJ Koistinen¹
¹ Central Hospital of Vaasa, Cardiology, Vaasa, Finland; ² Satakunta Central Hospital, Cardiology, Pori, Finland

Introduction: Heart failure (HF) is a syndrome in which an abnormal cardiac function causes symptoms and signs of inadequate blood flow and oxygen delivery to the metabolizing tissues. The prevalence of HF in developed countries is increasing with the age and varies from 1-2% in the whole population to over 10% in the group of ≥ 85 years old. The costs of HF in Germany are between 3417€ to 5576€ per patient per year and are rising with the progression of the disease. The medication and device therapy should be addressed to slow and prevent worsening of HF. Cardiac resynchronization therapy (CRT) reduces annual mortality from 18.9% to 10.5% in patients who have severely depressed ejection fraction ($EF \leq 35\%$). However, all the patients do not respond equally to CRT. 25-45% of the patients are non-responders and one of the greatest challenges is to improve the prognosis and the quality of life in this group. Renal sympathetic overactivation is present in chronic systolic heart failure and predicts adverse outcome. Sympathetic overdrive can effectively be reduced by renal denervation in patient with drug-resistant hypertension. Reach-Pilot trial demonstrated that renal denervation can safely be performed to patients with chronic systolic heart failure.²

Purpose: The aim of this study is to examine renal denervation (RDN) as a complementary treatment to optimal medical therapy and CRT to the non-responders for CRT.³

Methods: There are 13 patients who are non-responders for CRT with the criteria NYHA III-IV symptoms in spite of optimal medical therapy and CRT, the lack of reverse remodelling in left ventricle (LV), unchanged or worsened EF after CRT and walking distance in 6 minute walking test (6MWT) <400m with dyspnoea as a walking limiting symptom. All patients are > 18 years old. Patients were openly divided in two groups according to waiting list. Seven patients received RDN soon after signing of informed consent and six patients received RDN six months after signing informed consent. The follow-up will last two years. The primary end points are mortality, changes in 6MWT, th size of LV, EF and the quality of life measured by EQ-5D. The secondary end point is change in P-Pro-BNP. The group of early denervation and the group of late denervation will be compared to each other. The study will last until year 2017.

P941

Heart failure and the risk of perioperative cardiovascular complications in noncardiac surgery

O Sherbanov¹; N Nadia Stancheva²; T Nedeva¹; SN Tisheva²
¹ MHAT, Russe, Bulgaria; ² University Hospital Georgi Stranski, Pleven, Bulgaria

Background: History of heart failure (HF) is an independent predictor for increased cardiovascular risk in noncardiac surgery. The incidence of HF among the European population varies from 0.4 to 2%, and it increases with age, the same way as the rate of noncardiac surgery increases with age.

Methods and

Results: A survey of the hospital stay of 561 surgically treated patients in the departments of general surgery in the University hospital of Pleven and multiprofile hospital for active treatment Rousse in the period 2012-2013 was performed. One hundred and sixty two patients (28.9%) had history and clinical manifestation of HF in the past or at the moment of hospitalization. All the patients were evaluated for different cardiovascular complications – hypertensive crisis, long lasting hypotension requiring administration of catecholamines, anginal pain, acute coronary syndrome, newly registered rhythm and conduction disorders, pulmonary thromboembolism, sudden cardiac death, acute or acutely decompensated chronic HF, acute manifestation of cerebrovascular disease, as well as death of any reason. The incidence of perioperative cardiovascular complications in patients with HF was 37.7% against 19.3% for the patients without HF. Thus the probability for complications in patients with history and / or clinical data for HF at admission was evaluated /OR=2.53; 95% CI=1.69-3.78 ($p<0.001$). The concrete cardiovascular complications which increased the risk for HF patients turned out to be: newly registered ventricular rhythm disorders / $p=0.007$ /, sudden cardiac death / $p=0.024$ /, acute or acutely decompensated chronic HF / $p<0.001$ / and overall death / $p=0.004$ / . Additional analysis showed that the longer the history of HF and the higher the NYHA functional class of HF the higher the risk of perioperative cardiovascular complications. Thus a patient with one year history of HF has a 15% risk of perioperative cardiovascular complications, while a more than 5 year history of HF the risk increases to 57.6%, OR=4.66; 95% CI=2.27-9.58 ($p<0.001$). Similar are the results concerning the functional class of HF – complications were seen in 18.2% of the patients with NYHA class I, while in NYHA class III complications were registered in 66.7% of the patients, OR=7.21; 95% CI=3.5-14.86 ($p<0.001$).

Conclusions: With means of cross tabulation and univariate analysis we proved that both the presence and duration of HF as well as the NYHA functional class of HF /acute and chronic/ have great importance for the occurrence of perioperative cardiovascular complications in non cardiac surgery.

P942

Contrast-induced nephropathy in a population with acute myocardial infarction and diabetes mellitus

C Carina Arantes¹; G Abreu¹; C Quina-Rodrigues¹; S Fonseca¹; J Martins¹; C Braga¹; C Vieira¹; A Salgado¹; S Rocha¹; J Marques¹
¹ HOSPITAL DE BRAGA, BRAGA, Portugal

Introduction: Contrast-induced nephropathy (CIN) often complicates the invasive coronary procedures, appearing to associate with an adverse prognosis in acute myocardial infarction. In patients (P) with diabetes mellitus (DM), seems to be an intensification of oxidative stress and renal hypoxemia induced by contrast, making this population at increased risk of CIN.

Aim: To determine the prevalence of CIN after primary angioplasty in P with DM, the factors associated with its occurrence and its prognostic impact.

Methods: Retrospective study based on 250 P with DM admitted for ST-segment elevation myocardial infarction (STEMI) for 5 years. P requiring chronic peritoneal or hemodialysis treatment and cardiogenic shock at admission were excluded. CIN was defined by an elevation in creatinine values (cr) ≥ 0.5 mg/dl 48 hours after angioplasty and there were determined 2 groups. We evaluated the occurrence of in-hospital death and at 6 months.

Results: The prevalence of CIN was 10.4% and these patients were older ($p=0.009$). There were no differences in demographic characteristics. The volume of contrast (VC) used was similar between the groups, but the ratio VC/eGFR was higher in P with CIN ($p=0.007$). P with CIN had more frequent anemia ($p=0.008$), left ventricular systolic dysfunction ($p=0.001$) and heart failure (HF) ($p<0.001$). The presence of anemia ($p=0.03$), eGFR <60ml/min and HF at admission ($p=0.009$) were predictors of CIN. The in-hospital mortality and at 6 months was higher in G1 (23.1% vs 4.5%, $p<0.001$ and 34.6% vs 8.0%, $p<0.001$), although the presence of CIN does not persist as an independent predictor of these events.

Conclusion: It is central to identify early P of higher risk in order to avoid side effects of therapy. In our population, the presence of anemia, eGFR <60 ml/min and HF are CIN predictors. Although the CIN is associated with an adverse prognosis, was not a predictor of mortality, remaining the doubt that this is only a marker of clinical severity.

P943

Is there any benefit of early revascularization in patients with non-ST-elevation myocardial infarction and kidney disease?

A Andre Correia¹; M Neto¹; B Silva¹; J Monteiro¹; D Pereira¹¹Hospital Funchal, Funchal, Portugal

Introduction: Kidney Disease (KD) is common amongst patients with non-ST-elevation myocardial infarction (NSTEMI) and it is associated with higher morbi-mortality. Due to renal impairment, the percutaneous coronary intervention (PCI) is sometimes deferred. It is still not consensual when is the best time to perform PCI in these patients.

Purpose: Evaluate the outcomes of early versus late PCI in patients with KD, admitted for NSTEMI.

Methods: Single-center registry of 552 consecutive NSTEMI patients, with moderate or severe KD (evaluated by Glomerular Filtration Rate $< 60 \text{ ml/min/1.73m}^2$) measured by the Cockcroft-Gault formula (previous validated for our population), between the years 2010-2014. Patients submitted to conservative therapy were excluded from this study. They were divided in 2 groups according to the moment PCI was performed, after NSTEMI was diagnosed. Group A: patients submitted to PCI $\leq 24 \text{ h}$ ($n=241$); Group B: patients submitted to PCI $> 24 \text{ h}$ ($n=311$). Groups were compared regarding mortality rate and a primary composite endpoint (re-MI, stroke, and cardiovascular mortality) at one year follow-up.

Results: Group A was younger ($A=72.10 \pm 10.2$ vs $B=76.0 \pm 8.9$, years; $p < 0.01$). They had less history of arterial hypertension ($A=70.5\%$ vs $B=79.4\%$; $p < 0.05$), Diabetes Mellitus ($A=24.0\%$ vs $B=35.2\%$; $p < 0.01$), heart failure ($A=5.8\%$ vs $B=14.8\%$; $p < 0.01$) and myocardial infarction ($A=16.2\%$ vs $B=28.3\%$; $p < 0.01$).

At admission, Group A had higher glomerular filtration rate ($A=43.3 \pm 11.7$ vs $B=40.9 \pm 13.5$, ml/min/1.73m^2 ; $p < 0.05$) and inferior prevalence of Killip Class > 1 ($A=13.5\%$ vs $B=25.3\%$; $p < 0.01$).

During hospitalization, they had lower Killip Class > 1 at 72h ($A=17.3\%$ vs $B=26.8\%$; $p < 0.05$), cardiogenic shock ($A=8.7\%$ vs $B=15.8\%$; $p < 0.01$) and ischemic arrhythmias ($A=12.2\%$ vs $B=21.6\%$; $p < 0.01$). They were less medicated with intravenous diuretics ($A=25.8\%$ vs $B=34.0\%$; $p < 0.05$). At 1-year follow-up, Group A had an inferior mortality rate ($A=20.3\%$ vs $B=29.6\%$; $p < 0.01$) and primary composite endpoint ($A=23.2\%$ vs $B=34.4\%$; $p < 0.01$).

Conclusion: In this real-world cohort of patients with kidney disease, performing percutaneous coronary intervention in the first 24h after the setting of NSTEMI was beneficial, as patients showed long-term survival.

P944

A simple depression screening tool and its association with outcomes in Asian patients with heart failure

M R Michael Macdonald¹; SN Tan¹; S Lee¹; DM Yang¹; Y Cao¹; XY Chua¹; KL Tong¹; KT Leong¹¹Changi General Hospital, Cardiology, Singapore, Singapore

Background: Few studies have examined the prevalence of depression and its association with outcomes in Asian patients with HF. The Patient Health Questionnaire-9 (PHQ-9) is a simple screening tool to evaluate depressive symptoms. PHQ-9 has never been evaluated in an Asian population with HF. Purpose Our aim was to compare the characteristics and outcomes of HF patients with and without depression as defined by the PHQ-9. Methods This was a prospective study enrolling consecutive patients hospitalised with HF to a tertiary centre in Singapore between 2010-2013. All patients were invited to take the PHQ-9 on admission. Depression was defined by PHQ-9 ≥ 5 or question 9 positive. Patient characteristics on admission and 1 year outcomes were collected. A t-test was used to compare means, a z-test for proportions and logistic regression to examine the independent association of PHQ-9 with outcomes. Results 1450 consecutive patients were screened with the PHQ-9 questionnaire. 15.4% had depression. Depressed patients were younger (64 v 70 years, $p < 0.05$), had a lower LVEF (32 v 35% , $p < 0.05$) and were more likely to have symptoms of paroxysmal nocturnal dyspnea (42 v 31% , $p < 0.05$) and orthopnea (66 v 52% , $p < 0.05$) on admission. Patients with depression had higher rates of HF hospitalisation at 30 days and 1 year, and death or CV hospitalization at 1 year. Depression (as defined by PHQ-9) was an independent predictor of death or CV hospitalisation at 1 year: OR 1.59 (1.13-2.2, $p = 0.008$). Conclusion-Depression as defined by PHQ-9 is common in Asian patients with HF. The PHQ-9 questionnaire is a simple tool that can be used to screen for patients at high risk of adverse events. Further studies examining interventions for depression in this population are warranted.

Characteristics and outcomes

	Not depressed (PHQ-9 <5) (n = 1227)	Depressed (PHQ-9 ≥ 5 or question 9+ve) (n = 223)	p-value
Female (%)	39.5	39.0	n.s.
Ischemic heart disease (%)	69.3	65.5	n.s.
Previous stroke (%)	16.2	15.7	n.s.
Hypertension (%)	74.2	68.6	n.s.
Diabetes (%)	52.6	56.5	n.s.
NTproBNP (pg/ml)	4034	4419	n.s.
HF admission 30days (%)	6.5	10.8	$p < 0.05$
HF admission 1 year (%)	31.2	43.0	$p < 0.05$
Death or cardiovascular admission 30 days (%)	11.1	14.9	n.s.
Death or cardiovascular admission 1 year (%)	49.9	59.6	$p < 0.05$

Impact of diabetes mellitus in the predictive value of heart failure biomarkers

M De Antonio¹; J Lupon¹; N Alonso¹; J Barallat¹; M Domingo¹; E Zamora¹; C Diez-Lopez¹; J Santesmases¹; C Pastor¹; A Bayes-Genis¹¹Germans Trias i Pujol University Hospital, Badalona, Spain

Background: Diabetes mellitus (DM) entails a worse prognosis in heart failure (HF) patients. DM usually carries an increased atherosclerotic load and also a low-degree inflammation status. The use of biomarkers for HF risk stratification is growing. Biomarkers of different pathophysiological processes have been successfully used in predicting the risk of death in HF patients. Whether DM interferes their stratification ability is not completely elucidated. Objective: We sought to explore whether a panel of biomarkers have different prognostic value in patients with HF based on the presence or absence of DM.

Patients and methods: 1069 patients were included in the study (age 66.2 ± 12.8 years, 72% male, 51% of ischemic aetiology, mean LVEF $33.5\% \pm 13.3$, 36% with DM). Serum concentrations of NT-proBNP ($n=1030$), high-sensitivity troponin T (hs-TnT) ($n=803$), ST2 ($n=814$), Galectin 3 ($n=811$), high-sensitivity C reactive protein (hs-CRP) ($n=773$) and Neprilysin ($n=1069$) were measured in consecutive ambulatory HF patients followed during 4.9 ± 2.8 years (6.6 ± 2.3 for alive patients). All-cause and cardiovascular deaths were the primary end-points.

Results: 534 patients died during follow-up, 283 of them from cardiovascular causes. As expected, mortality was higher in diabetic patients (57.7% vs. 45.6%, $p < 0.001$). NTproBNP ($p = 0.07$), hs-TnT ($p < 0.001$) and Galectin-3 ($p < 0.001$) serum concentrations were higher in diabetic patients. We found no interaction between the majority of the biomarkers and DM in the prediction of risk of all-cause or cardiovascular death: NTproBNP, $p = 0.98$ and $p = 0.66$ respectively; hs-TnT, $p = 0.39$ and $p = 0.78$ respectively; Galectin-3, $p = 0.78$ and $p = 0.96$ respectively; hs-CRP, $p = 0.19$ and $p = 0.90$, respectively (after excluding those patients with very high levels due to other diseases); and Neprilysin, $p = 0.98$ and $p = 0.19$ respectively. However, ST2 significantly interacted with DM for all-cause death ($p = 0.02$) and cardiovascular death ($p = 0.03$). HR for ST2/10 were 1.27 [95%CI 1.16-1.40], $p < 0.001$ and 1.23 [95%CI 1.09-1.39], $p = 0.001$ for all-cause and cardiovascular death, respectively in diabetic patients; and 1.53 [95%CI 1.35-1.73], $p < 0.001$ for all-cause death and 1.64 [95%CI 1.31-2.05], $p < 0.001$ for cardiovascular death in non-diabetic patients.

Conclusions: We did not find an interaction between DM and NTproBNP, hs-TnT, Galectin-3, hs-CRP and Neprilysin in the prediction of risk of all-cause or cardiovascular death in a long-term follow-up of a cohort of ambulatory patients with HF. However ST2, a significantly predictor for both all-cause and cardiovascular death together in diabetic and also non-diabetic patients, conferred an appreciably higher risk in the non-diabetic patients.

P946

Comparative long term effects of Nebivolol and Carvedilol in hypertensive heart failure patients

G Marazzi¹; G Caminiti¹; G Campolongo¹; B Sposato¹; R Massaro¹; C Vitale¹; G M C Giuseppe M C Rosano¹; M Volterrani¹¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Background: Beta-blockers improve left ventricular (LV) systolic function and prognosis in chronic heart failure (CHF) patients, but their different pleiotropic properties may influence their cardiovascular effects.

Aim This study compared the effects of long term treatment with nebivolol versus carvedilol on left ventricular ejection fraction (LVEF), in hypertensive CHF patients. Secondary endpoints were to assess the effect of the two beta-blockers on exercise capacity and clinical outcome.

Methods: 160 hypertensive CHF patients, LVEF < 40% and in NYHA class I, II or III were randomly assigned to receive nebivolol or carvedilol for 24 months. At baseline and at the end of treatment, all patients underwent clinical evaluation, echocardiogram and 6-minute walking test.

Results: Compared with baseline values LVEF increased by a similar extent in the carvedilol (C) and nebivolol (N) groups (C: from 36.1% (SD 1.5) to 40.9 (SD 1.9) $p < 0.001$; N: from 34.1% (SD 1.8) to 38.5% (SD 2.2) $p < 0.001$). Heart rate, NYHA class decreased significantly in both groups, while the 6-minutes walk distance (6MWT) increased (C: from 420 m (SD 104) to 490 m (SD 115) $p < 0.001$; N: from 421 m (SD 118) to 487 m (SD 138) $p < 0.001$). During 24 months 21 (26%) of carvedilol recipients and 18 (22%) nebivolol recipients had cardiac events, including 3 and 4 deaths, respectively.

Conclusion: In the long-term, nebivolol and carvedilol appear to be similarly effective in the treatment of hypertensive CHF patients.

³Harefield Hospital, London, United Kingdom

Introduction: It has been suggested that comorbidities drive myocardial dysfunction and remodeling in heart failure with preserved ejection fraction (HFpEF). We hypothesized that comorbidities determine whether a patient develops HFpEF or HF with reduced EF (HFrEF).

Purpose: To evaluate the contribution of comorbidities to the development of HF phenotype, HFpEF or HFrEF.

Patients and methods: 1019 consecutive HF patients (age 71.7 ± 12.3 years, male 56.9%, mean LVEF $42.8 \pm 14.4\%$, HFpEF 46.6%) referred to the outpatient HF Clinic of a tertiary University Hospital were screened for major HF comorbidities, from January 2014 to December 2015.

Results: The prevalence of major HF comorbidities was: hypertension 72.3%; myocardial infarction 39.8%; atrial fibrillation 26.2%; diabetes 21.3%; chronic obstructive pulmonary disease 13.6%; obesity 39.4%; chronic kidney disease 18.9%; anemia 28.2%. Univariable and multivariable logistic regression analyses demonstrated that only hypertension, myocardial infarction, obesity and diabetes determined the HF phenotype (HFpEF or HFrEF) (Table), with an area under the curve of 0.90 (Figure).

Conclusion: Hypertension, myocardial infarction, obesity, and diabetes were the only determinants of the HF phenotype. The contribution of other comorbidities was not significant.

Variable	Odds ratios* (95% CI)	P value
Hypertension	9.43 (5.85, 15.17)	< 0.0001
Myocardial infarction	0.06 (0.04, 0.09)	< 0.0001
Obesity	3.24 (2.23, 4.69)	< 0.0001
Diabetes	0.57 (0.37, 0.90)	0.01

*Higher odds for: i) HFpEF, if OR > 1.0; ii) HFrEF, if OR < 1.0

Long-term prognosis of patients with moderate to severe sleep apnea with preserved left ventricular systolic function and systolic dysfunction after myocardial infarction

O Ludka¹; R Stepanova²; B Fischerova²; T Kara³; J Spinar¹

¹University Hospital Brno, Masaryk University, International Clinical Research Center, Department of Internal Medicine and Cardiology, Brno, Czech Republic;

²St. Anne's University Hospital, Faculty of Medicine, Masaryk University, International Clinical Research Center, Brno, Czech Republic; ³Division of Cardiovascular Diseases, Department of Internal Medicine, Mayo Clinic and Foundation, Minnesota, United States of America

Purpose: Sleep apnea (SA) has a high prevalence in patients after myocardial infarction (MI). While SA might be a modifiable risk factor, recent data suggest that SA is severely underdiagnosed in patients after MI. There is a limited evidence about long-term prognosis of patients with moderate to severe sleep apnea with preserved (PEF) and reduced (REF) left ventricular ejection fraction after MI. We therefore prospectively investigated differences in the prognosis of these two groups of patients.

Methods: We prospectively studied 782 consecutive patients admitted to the hospital with the diagnosis of acute MI. The study was conducted in two tertiary care institutions, where primary percutaneous coronary intervention (PCI) is the standard of care in the treatment of acute MI. All subjects underwent sleep evaluations using a portable diagnostic device after at least 48 hours post-admission, provided they were in stable condition. Patients were followed for median follow-up of 44 months.

Results: Almost all patients (98%) underwent urgent coronary angiography and 91% of patients underwent primary PCI. 175 (22.4%) patients had technically inadequate limited sleep studies (less than 4 h recording time or inability to score study due to excessive artifact). We therefore analyzed the data from 607 patients who had good quality sleep study records. SA was present in 63% of patients after MI with PEF and in 72% of patients with REF (LVEF < 45%), $p = 0.05$. Moderate to severe SA was present in 33.1% of patients after MI. There was a higher total mortality in REF (21.7%) than in PEF (10.6%) patients after MI in the group of moderate to severe SA, $p = 0.033$. Independent predictors of mortality according to the multivariate analysis were type 2 diabetes mellitus (OR 5.003, 95% CI 1.968 to 12.717, $p = 0.001$), history of previous MI (OR 4.633, 95% CI 1.832 to 11.718, $p = 0.001$), age (OR 2.326, 95% CI 1.417 to 3.819, $p = 0.001$) and apnea index (OR 1.216, 95% CI 1.023 to 1.445, $p = 0.027$).

Conclusion: MI patients with moderate to severe SA and left ventricular systolic dysfunction had worse long-term prognosis than those with preserved systolic function. Whether treatment of SA after MI will significantly improve outcomes in these patients remains to be determined.

P949

Prevalence, severity and prognostic value of sleep apnea syndromes in cardiac amyloidosis

D Diane Bodez¹; A Guellich¹; M Kharoubi¹; A Covali-Noroc²; JL Dubois-Randé¹; JP Lefaucheur²; V Plante-Bordeneuve³; S Adnot²; L Boyer²; T Damy¹

¹University Hospital Henri Mondor, Department of Cardiology, Creteil, France;

²University Hospital Henri Mondor, Department of Physiology, Creteil, France;

³University Hospital Henri Mondor, Department of Neurology, Creteil, France

Background: Sleep disordered breathing (SDB) occurs frequently in heart failure and is a marker of bad prognosis but its prevalence and consequence are unknown in cardiac amyloidosis (CA).

Purpose: Our aims were to assess prevalence, severity and prognosis value of SDB in the three main CA types i.e., light-chain (AL), transthyretin-related familial (m-TTR) or senile (WT-TTR).

Methods: Patients consecutively referred for CA diagnosis work-up underwent a night polygraphy. SDB was defined as apnea-hypopnea index (AHI) $\geq 5/h$. Multivariate analysis was used to identify predictors of major cardiovascular events (MACE) defined as death, heart transplantation and acute heart failure.

Results: Seventy CA patients were included (31 AL, 22 m-TTR, 17 WT-TTR). The mean (SD) age and LVEF were 71 ± 12 years and $49 \pm 13\%$ and median(IQR) NT-proBNP was 3932pg/ml (1607;7028). The prevalence of SDB was 90% without difference between amyloidosis types. SDB was central in 27% and obstructive in 73%. AL had less frequent severe SDB compared to m-TTR and WT-TTR ($p = 0.015$) but higher time with $\text{SaO}_2 < 90\%$ ($p = 0.037$). After 7.5 (2.8; 14.9) months of follow-up, 49% patients experienced MACE. Time with nocturnal $\text{SaO}_2 < 90\%$ were the only independent predictor of MACE with a threshold time superior to 30min indicating bad prognosis (Log-rank X2: 8.01, p -value = 0.005). Determinants of time with nocturnal SaO_2 were NYHA and logNTproBNP but not AHI. Conclusion. Prevalence of SDB is high (90%) in CA population, most having an obstructive pattern. Nocturnal time spent with oxygen saturation less than 90% was an independent prognosticator of bad outcome and determined by heart failure severity.

P950

Anaemia and the cardiorespiratory adaptation to exercise in chronic heart failure

E Vigano¹; C Bonino¹; V Guida¹; C Torlasco¹; A Faini¹; S Caravita¹; A Villani¹; G Malfatto¹; G Parati¹

¹Ospedale Auxologico San Luca, Cardiology, Milan, Italy

Introduction: Anaemia (AN) in chronic heart failure (CHF) leads to worse symptoms and prognosis. Since haemoglobin (Hb) is implicated in O₂ and CO₂ transport, the presence of AN may be associated with more severe derangement in the control of ventilation (VE) during exercise.

Purpose: to evaluate the effect of AN on cardiopulmonary response to exercise in CHF.

Methods: We analysed 60 CHF patients (ejection fraction $\leq 45\%$) on optimized therapy who consecutively performed a cardiopulmonary exercise test between 2014 and 2015. AN was defined according to WHO criteria (women: Hb < 12.0 ; men < 13.0 g/dL).

Results: 41 patients (68%) had AN. Demographics and echocardiography were similar in AN and non-AN. AN presented more advanced NYHA class, higher serum creatinine and higher prevalence of atrial fibrillation. At peak exercise, they had lower oxygen uptake (VO₂) and lower heart rate (HR) than non-AN, while respiratory quotient did not differ. Exercise-induced hyperventilation, defined by the slope between VE and carbon dioxide production (VCO₂), as well as the prevalence of exercise oscillatory breathing (EOV) did not differ between the two groups. NYHA class ($r = -0.483$; $p < 0.001$), creatinine ($r = -0.382$; $p = 0.003$), peak VO₂ ($r = 0.371$; $p = 0.04$) and peak HR ($r = 0.303$; $p = 0.019$) were all related to Hb values.

Conclusions: in our population, AN is associated with a more impaired functional capacity but not with worse ventilatory control during exercise. Somehow counter-intuitively, limitation in AN seems to be secondary to chronotropic incompetence more than to a reduction in the delivery/peripheral extraction of O₂.

Prognostic significance of anemia in patients with chronic heart failure

LJ Ljilja Music¹; N Bulatovic¹

¹Clinical Center of Montenegro, Podgorica, Montenegro

The aim of our study was to determine the prevalence of anemia in patients with chronic heart failure (CHF), the impact of anemia on quality of life, a correlation between the severity of CHF and anemia, the relationship between the severity of anemia and left ventricular function, the impact of anemia on the length of hospitalization.

Methods: The study included 205 patients with CHF. To assess the quality of life of patients we used Minnesota Living With Heart Failure Questionnaire - MLWHFQ. Standard echocardiography examination was performed. The functional capacity of patients was assessed by the six minute walk test (6MW). Results We examined 109 men and 96 women, 62.67 ± 8.38 years old, the average duration of CHF was 37.7 months. The anemia was diagnosed in 25.4% patients. There was a significant difference in the values of MLWHFQ ($p < 0.01$), significantly higher in patients with anemia. Analysis of variance showed statistically significant difference in average values MLWHFQ in according NYHA class in both groups. By comparing the two groups of patients examined on the basis of the distance traveled during the 6MW was found highly statistically significant ($p < 0.01$). Patients with anemia had bigger dimensions of left ventricle and lower ejection fraction. Severity of mitral regurgitation was significantly higher in patients with anemia and CHF ($p < 0.01$). Patients with anemia required significantly longer hospital treatment ($p < 0.01$). Predictor factors for death during the period of 6 months follow-up after hospitalization in patients with CHF were hematocrit and serum creatinine. Our study showed that anemia is a common co-morbidity in patients with CHF and requires more aggressive treatment.

P952

Anemia and low haemoglobin levels are associated with worse functional status in patients with chronic heart failure: results from TREAT HF

S Eraslan¹; H Kaya²; Y Yuksel Cavusoglu¹

¹Eskisehir Osmangazi University, Eskisehir, Turkey; ²Cumhuriyet University, Cardiology, Sivas, Turkey

Purpose: Anemia has been demonstrated to be prevalent in patients with heart failure (HF) and associated with worse clinical outcomes. NYHA functional class has also been known to be a strong marker of poor prognosis. TREAT HF (Turkish Research Team-HF) data were analyzed for the assessment of any association of anemia or haemoglobin levels with NYHA functional class categories in patients with chronic HF and reduced ejection fraction (HFrEF).

Methods: TREAT HF is a network which undertakes multicenter, national, observational studies designed to evaluate HF patient's clinical characteristics and current treatment modalities. 924 patients with the diagnosis of chronic HFrEF and > 18 years of age who had haemoglobin measurement were included in this analysis. Anemia was defined as a haemoglobin level < 13 g/dL in men and < 12 g/dL in women. Out of 924 patients, 113 patients (12.2%) were in NYHA class I, 409 patients (44.2%) in NYHA class II, 356 patients (38.5%) in NYHA class III and 46 patients (5%) in NYHA class IV. Patients with recent acute coronary syndromes, severe hepatic or renal dysfunction, severe chronic obstructive pulmonary disease, hematological disease, ongoing systemic inflammatory conditions, cancer, hyper-/hypothyroidism and pregnant women were excluded from the study.

Results: Anemia was found in 437 patients (47.3%) in our study population. Mean haemoglobin level was 12.6 ± 2.1 g/dL in the study population, 13.2 ± 1.9 g/dL in those with NYHA class I, 12.9 ± 2.0 g/dL in those with NYHA class II, 12.2 ± 2.2 g/dL in those with NYHA class III and 11.4 ± 2.2 g/dL in those with NYHA class IV and overall, mean haemoglobin levels were found to gradually and significantly reduce across NYHA functional class categories ($p = 0.001$). Anemia was found in 40 patients (35.4%) in those with NYHA class I, 163 patients (39.9%) in those with NYHA class II, 200 patients (56.2%) in those with NYHA class III and 34 patients (73.9%) in those with NYHA class IV and overall, the prevalence of anemia was also found to gradually and significantly increase across NYHA functional class categories ($p < 0.001$). There was no significant difference between NYHA I and NYHA II in terms of the incident of anemia ($p = 0.446$) while patients with NYHA IV showed significantly higher prevalence of anemia when compared patients with NYHA III, NYHA II or NYHA I ($p = 0.015$, $p = 0.001$ and $p = 0.001$, respectively). Also significantly more patients with NYHA III have had anemia as compared to those with NYHA II ($p = 0.001$).

Conclusions: These results suggest that anemia and low haemoglobin levels are associated with worse functional status in patients with HFrEF.

P953

Comparison of the effect of EPO treatment and intravenous iron treatment by patients in chronic heart failure with anaemia.

K Kamala Zahidova¹; FA Guliyev¹

¹The Azerbaijan State Advanced Training Institute for Doctors, Baku, Azerbaijan

Purpose. The aim of investigation were to study the effect of intravenous (iv) iron sucrose (Venofer) and metoxipolyethylen glycol epoietin beta (MEB) in patients with CHF with anemic syndrome.

Material and methods: 63 patients with NYHA class II-IV CHF and LVEF 40 % or less with anemia and hypererythropoietinemia or hyporerythropoietinemia were obtained. Mean age of patients 67.9 ± 8.5 years. The level of Hb was $\text{Hb} < 11$ g/dl and iron deficiency (ID) was diagnosed at serum ferritin 30-99 $\mu\text{g/l}$ or 100-299 $\mu\text{g/l}$, if the transferrin saturation (TSAT) < 20 %. It should be noted that patients with absolute ID. Echocardiographic indices of LV systolic and diastolic function and RV function, 6 minute walked distance and plasma NT pro BNP, erythropoietin (EPO), ferritin, TSAT were assessed at baseline and posttreatment. 63 patients

with anemic CHF were obtained and were randomly into two groups. I groups included 33 patients were treated with treatment of iv Venofer in dose either as 5 iv bolus injections of 100-200 mg iron per dose or as a fast high-dose infusion at baseline and of II groups included 30 patients were treated with percutaneous MEB in dose 50 IU in day in one month in follow-up 6 months. Control groups included 31 patients in CHF II-IV class without anemia. The level of Hb 12.63 ± 0.9 g/dl, EPO- 14.19 ± 3.45 IU, serum ferritin- $147.9 \pm 19.2 \pm \mu\text{g/L}$, NT pro BNP- 1739 ± 145.3 pg/ml, TSAT $> 20\%$, LVEF-40% or less, 6-minute walking test - 340 ± 65 meters. Results. The treatment patients with anaemic CHF with ID and hypereritropoietinemia of Venofer there was a significant increase Hb (to 10.32 ± 0.18 g/dl to 10.8 ± 0.22 g/dl) ($p < 0.001$), decrease EPO- 36.7 ± 14.8 IU to 13.1 ± 2.8 IU ($p = 0.194$), increase ferritin $88.4 \pm 14.9 \mu\text{g/L}$ to $150.2 \pm 25.5 \mu\text{g/L}$ ($p < 0.05$), TSAT $> 20\%$, NT pro BNP decrease 2505.4 ± 136.3 pg/ml to 1886.4 ± 192.7 pg/ml ($p < 0.001$), LVEF increase $35.8 \pm 1.6\%$ to $37.4 \pm 1.6\%$ ($p = 1.292$) a significant NYHA class from 3.4 ± 0.2 to 2.2 ± 0.3 ($p < 0.05$), a longer endurance on exercise testing from 243 ± 34 to 384 ± 75 meters ($p < 0.01$). But the treatment patients with anaemic CHF without ID and hypereritropoietinemia of MEB there was a significant increase Hb (to 9.36 ± 0.32 g/dl to 10.4 ± 0.32 g/dl) ($p < 0.001$), increase EPO 1.3 ± 0.4 IU to 32.8 ± 5.7 IU ($p < 0.01$), increase ferritin 158.4 ± 20.8 to $160.5 \pm 22.2 \mu\text{g/L}$ ($p = 0.3$), increase TSAT $< 20\%$ to TSAT $> 20\%$, NT pro BNP decrease 1816.5 ± 145 pg/ml to 991.6 ± 142.9 pg/ml ($p < 0.001$), LVEF increase $39.4 \pm 1.6\%$ to $44.4 \pm 1.7\%$ ($p < 0.05$) a significant NYHA class from 3.4 ± 0.2 to 2.2 ± 0.3 ($p < 0.05$), a longer endurance on exercise testing from 243 ± 34 to 384 ± 75 meters ($p < 0.01$). Conclusion. Therefore the treatment patients with anaemic CHF with hypereritropoietinemia of Venofer there was a significant increase Hb, ferritin, TSAT $> 20\%$, a longer endurance on exercise testing and decrease the level of NT pro BNP. The treatment patients with anaemic CHF and hypereritropoietinemia of MEB there was a significant increase Hb, EPO, LVEF and decrease NT pro BNP, NYHA class, 6-minute walking test.

Oral iron therapy with polysaccharide iron complex may be useful in increasing ferritin level at short time in patients with dilated cardiomyopathy

N Naderi¹; A Amiri¹; A Amin¹; S Taghavi¹; M Maleki¹

¹ Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, Iran (Islamic Republic of)

Introduction: It has been shown that iron therapy improves symptoms, exercise capacity and quality of life in HF patients with reduced ejection fraction. Polysaccharide-iron complex (PIC) is an oral iron supplement which allows the iron to be absorbed intact through the small intestine without coming into contact with the upper GI tract. In this study we aimed to investigate if oral PIC is effective in increasing ferritin level in dilated cardiomyopathy patients with absolute iron deficiency and what is the incidence GI side effects.

Methods: Thirty patients with a diagnosis of non-ischemic dilated cardiomyopathy were recruited according to the following inclusion criteria; LVEF equal or less than 35%, NYHA function class of I-III and serum ferritin level less than 100 microgram/lit. For all study participants one capsule of Feramax-150 (BioSyntPharmalnc) was prescribed on daily basis for 12 weeks. The study variables (table 1) were measured at baseline and after 12 weeks. All patients were asked to report any GI side effect they may have.

Results: A total of 30 patients (12 male) with a diagnosis of non-ischemic dilated cardiomyopathy were included. The mean (SD) of age was $43.2(13.4)$ years. The mean of LVEF was 23 % (between 10-35%). The mean (SD) of ferritin level was $48.8(27.7) \mu\text{g/L}$ at baseline. After 12 weeks treatment with feramax-150 the mean (SD) of ferritin level increased to $69.9(42)$ which was statistically significant ($P < 0.001$). There was also statistically significant increase in 6 MWT and decrease in pro-BNP level after 12 weeks treatment with Feramax-150 (Table 1). No one of patients showed gastrointestinal side effects.

Conclusion: PICs would be a good and well-tolerated medicine in the treatment of iron deficiency in patients with heart failure.

Iron deficiency predicts respiratory muscle weakness in men with heart failure with reduced ejection fraction

Supported by the National Science Centre (Poland) grant allocated on the basis of the decision number DEC-2012/05/E/NZ5/00590

M Tkaczyszyn¹; M Drozd¹; K Węgrzynowska-Teodorczyk²; I Flinta³; W Banasiak⁴; P Ponikowski⁵; EA Jankowska¹

¹Wrocław Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wrocław, Poland; ²University School of Physical Education of Wrocław, Faculty of Physiotherapy, Wrocław, Poland;

³Wrocław Medical University, Department of Physiology, Wrocław, Poland; ⁴Military Hospital, Cardiology Department, Centre for Heart Diseases, Wrocław, Poland;

⁵Wrocław Medical University, Department of Heart Diseases, Wrocław, Poland

Introduction: Dysfunction of respiratory muscles constitutes an important pathophysiological feature of heart failure (HF) and contributes to decreased exercise capacity in these patients. Preserved iron status is essential for effective functioning of muscle tissue, and therefore iron deficiency (ID) could potentially contribute to respiratory myopathy in patients with HF.

Methods: We evaluated respiratory muscle strength, exercise capacity and systemic iron status in 51 male outpatients with stable HF with reduced ejection fraction (HFrEF) (age: 64 ± 11 years; NYHA class I/II/III: 35/49/16%; ischaemic aetiology: 82%; all with LVEF $\leq 40\%$). None of them was diagnosed with asthma or COPD. Respiratory muscle function was assessed as maximal inspiratory pressure (MIP) at the mouth using a portable device (the average value of 5 measurements). We also assessed spirometry parameters (percentage of predicted value, the average value of 3 tests), i.e. forced vital capacity (FVC), forced expiratory volume in 1 second (FEV1) and peak expiratory flow (PEF). Exercise capacity was evaluated using a 6-minute walking test distance (6MWD). ID was defined as serum ferritin $< 100 \mu\text{g/L}$ or serum ferritin 100-299 $\mu\text{g/L}$ with transferrin saturation (TSAT) $< 20\%$.

Results: Mean MIP, FVC, FEV1 and PEF were 74 ± 23 cm H₂O, $101 \pm 26\%$, $89 \pm 28\%$, and $66 \pm 27\%$, respectively. MIP was reduced in men with higher NT-proBNP ($r = -0.31$, $p = 0.03$), but was not related to NYHA class, aetiology of HF or BMI, and there was a trend towards lower MIP in older patients ($p = 0.056$). Spirometry parameters correlated neither with the severity (NYHA class, NT-proBNP) nor aetiology of HFrEF (all $p > 0.16$). Age was not associated with spirometry parameters, whereas subjects with lower BMI had greater FVC ($r = -0.44$, $p = 0.001$) and there was a trend towards higher FEV1 in these patients ($p = 0.059$). Patients with ID had lower MIP than subjects without ID (67 ± 20 vs. 83 ± 23 mm H₂O, $p = 0.02$), without any differences in spirometry parameters. In a two-variable linear regression model, both ID and anaemia independently predicted lower MIP ($\beta = -0.29$, $p = 0.03$; and $\beta = -0.28$, $p = 0.04$; respectively), and similar associations were also seen in a model comprising serum ferritin (but not TSAT) and haemoglobin. After the adjustment for haemoglobin and NT-proBNP, lower ferritin remained an independent predictor of lower MIP ($\beta = 0.35$, $p = 0.01$). Spirometry parameters were lower in subjects with anaemia (FVC: $r = -0.28$; FEV1: $r = -0.35$; PEF: $r = -0.43$; all $p < 0.05$), but correlated neither with ID nor serum ferritin. Importantly, in studied patients with HFrEF, lower MIP was an independent predictor of lower 6MWD after the adjustment for NT-proBNP and NYHA class ($\beta = 0.40$, $p = 0.004$).

Conclusions: In men with HFrEF respiratory muscle weakness correlates with ID and predicts decreased exercise capacity. Respiratory muscle dysfunction due to ID can partially explain decreased exercise capacity in iron-deficient men with HF.

P956

Kynurenine levels correlated with depression, functional capacity, and muscle performance in heart failure patients

the European Commission under the FP7

M Konishi¹; N Ebnar¹; J Ishida¹; M Saito¹; A Emami¹; M Rodrigues Dos Santos¹; A Sandek¹; J Springer¹; S D Anker¹; S Von Haehling¹

¹University Medical Center Göttingen, Göttingen, Germany

Background: Lower functional capacity in heart failure (HF) patients is considered to be multifactorial, where depression and skeletal muscle wasting may play some roles. Recently, exercise-induced degradation of kynurenine (a metabolite from essential amino acid tryptophan) in skeletal muscle has been reported preferentially affecting for maintaining resilience against psychological stress and depression.

Methods and Results: We assessed serum kynurenine levels in 249 HF patients (mean age; 67 ± 11 years, 21% women) and 45 non-HF patients who participated in the Studies Investigating Co-morbidities Aggravating Heart Failure (SICA-HF). Kynurenine levels were higher in 173 HF patients with reduced ejection fraction (EF) and 76 patients with preserved EF than 45 non-HF patients (3.5 ± 1.5 , 3.4 ± 1.3 , and $2.4 \pm 1.1 \mu\text{mol/L}$, respectively, $p < 0.001$). In HF with reduced EF, kynurenine levels had inverse correlation with handgrip (Pearson's $r = -0.26$, $p < 0.01$), peak O₂ consumption ($r = -0.29$, $p < 0.01$), and 6-min walk distance ($r = -0.23$, $p < 0.01$), and had positive correlation with parameters of kidney/liver function and depression assessed by questionnaire. No correlation was observed between kynurenine and muscle mass. In multivariable logistic regression analysis, kynurenine could identify those with lower peak O₂ consumption (below median; 17.2 ml/min/kg) even after

the adjustment by age, gender, and body mass index (odds ratio; 1.36, 95% confidence interval 1.02-1.81, for 1 $\mu\text{mol/L}$ increase in kynurenine, $p=0.04$).

Conclusions: Kynurenine may have some roles linking depression, functional capacity, and muscle performance in HF. Further analysis assessing prognosis or implication in treatment would be warranted.

Relationship between skeletal muscle mass and cardiac function during exercise in chronically ill older adults

M Msamitsu Sugie¹; K Harada¹; M Nara²; H Fujimoto¹; T Takahashi³; S Kyo¹; H Itoh¹

¹The Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology, Department of Cardiology, Itabashi, Japan; ²Ochanomizu University, Department of Physical Therapy, Bunkyo, Japan; ³Tokyo University of Technology, Department of Physical Therapy, Ohta, Japan

Introduction: The clinical interrelationship between skeletal muscle and cardiac function remains unknown. The aim of the study is to investigate the relationship between skeletal muscle mass and cardiac functional parameters in older adults during cardiopulmonary exercise testing (CPET).

Methods: Sixty-eight chronically ill older adults were enrolled. The participants consisted of 22 men and 46 women (mean age, 78 years; range, 52-97 years). Cardiac functional parameters during exercise were assessed using the CPET. Skeletal muscle mass index (SMI) was calculated from the appendicular lean mass, which was measured with dual-energy X-ray absorptiometry, divided by height in square centimeters. We divided the subjects into two groups based on their SMI as follows: men with SMI ≥ 7.0 kg/m² and women with SMI ≥ 5.4 kg/m² (Preserved-SMI group); or men with SMI < 7.0 kg/m² and women with SMI < 5.4 kg/m² (Reduced-SMI group). These criteria were derived from the Asian Working Group for Sarcopenia.

Results: There were significant positive correlations between SMI and peak VO₂ ($r=0.609$, $p<0.001$), and between SMI and peak VO₂/HR ($r=0.691$, $p<0.001$). However, only peak VO₂/HR was significantly different between the Preserved-SMI group and the Reduced-SMI groups in both sexes. Multiple linear regression analyses showed that SMI was the only independent determinant of peak VO₂/HR after adjusting for potential confounders.

Conclusions: Peak VO₂/HR, an index of stroke volume at peak exercise, was strongly associated with skeletal muscle mass. This result showed for the first time that reduced skeletal muscle mass might affect the impaired cardiac function during exercise, which might be the case with older patients with heart failure and preserved ejection fraction.

¹Mediterranean Institute for Transplantation and High Specialization Therapies (IsMeTT), Palermo, Italy

The aim of our study was to evaluate the role of the NT-proBNP and hs-TnI in the prognosis stratification of HF. We studied 226 patients affected by chronic HF with EF $< 35\%$, whose 9 (3 heart transplant recipients and 6 lost to follow up). During the last follow up 69 clinical events were recorded, of which 53 hospitalizations for acute HF and 16 cardiovascular deaths (19% of the overall population). Baseline acute levels of NT-proBNP and hs-TnI were higher in dead patients, was related to this clinical event ($p=0.001$). Kaplan Meier analysis demonstrated that concentrations of NT-proBNP > 1250 pg/ml are predictors of reduced survival ($p=0.0003$). We assessed by univariate Cox analysis that, unlike hs-TnI, an increase of 500 Units of NT-proBNP were related to a relative risk of cardiovascular death of 22.4% ($p<0.001$); similar results at the univariate logistic regression. As regard the second study end point (hospitalization for acute HF), in hospitalized patients serum levels of NT-proBNP and hs-TnI were higher than health patients (in particular: NT-proBNP > 1250 pg/ml, hs-TnI > 0.009 ng/ml); we demonstrated through regression analysis a significant correlation between an increase of the risk of hospitalization and serum concentrations of both biomarkers ($p<0.001$). Applying the statistical illness-death model, we observed 122 transitions: 53 from health to illness (transition 1), 53 from illness to health (transition 3) and 16 from health to death (transition 4). None transition from illness to death (transition 2) verified, because all patients hospitalized were discharged home (Fig.1). We demonstrated, through Cox model, that a statistical correlation existed between an increase of 500 Units of NT-proBNP, compared to baseline, and the risk of transition both from health to illness (HR 1.278, $p<0.001$, IC 1.215-1.343) and from health to death (HR 1.234, $p<0.001$, IC 1.124-1.356); we were not able to evaluate the role of this biomarker to favour transition from illness to health (transition 3) because of the lack of its serum values at discharge. We studied also the composite of CV mortality and hospitalization; we demonstrated that high serum levels of

NT-proBNP were correlated to an increased risk of composite endpoint, unlike hs-TnI. Stratifying our population according to the serum levels of NT-proBNP and hs-TnI, we found that the risk of CV death combined to hospitalization was significantly associated with concentrations of NT-proBNP and hs-TnI respectively major than 1250 pg/ml and 0.009 ng/ml; we obtained similar results through univariate Cox analysis. The independent prognostic role of NT-proBNP was then confirmed by multivariate regression.

In our study NT-proBNP represents a strong predictor of cardiovascular outcomes: an increase of 500 Units of NT-proBNP is correlated to an increase of the relative risk of cardiovascular death and it influences the "transition" from the state of health to the state of illness/death.

P959

Acute cardio-renal syndrome: the role of inferior vena cava collapse

ER Makeeva¹; NR Nurdinova²; LL Chuvalov³

¹Central City Clinical Hospital of Ulyanovsk, cardiology, Ulyanovsk, Russian Federation; ²Health Center Perspective, Family medicine, Ulyanovsk, Russian Federation; ³Ulyanovsk State University, Ulyanovsk, Russian Federation

The size and shape of the inferior vena cava (IVC) is correlated with central venous pressure (CVP) and intravascular volume status. Lung ultrasound with counting B-lines is a simple way to assess extravascular lung water. We assume that in patients with acute decompensated heart failure (ADHF), not only were with venous congestion strongly associated with renal perfusion, but also renal function impairment.

Purpose: To determine the interaction between the inferior vena cava collapse as a noninvasive ultrasound method of CVP assessment and counting B-lines and the risk of acute kidney injury (AKI) of patients with ADHF.

Methods: A prospective observational cohort study of patients admitted for ADHF. We enrolled 62 patients (69% male) with a mean age of 62 years. The main cause of ADHF was a combination of coronary artery disease and arterial hypertension - 36 (58%). AKI was diagnosed and classified according to the KDIGO Recommendations (2012). According to the Recommendations on pre-hospital and early hospital management of acute heart failure (2015) we carried out bedside thoracic ultrasound for signs of interstitial oedema and abdominal ultrasound for assessment of inferior vena cava diameter. Result: Acute cardiorenal syndrome (CRS type 1) was diagnosed in 33 (53%) patients with ADHF. On the basis of the AKIN staging system, 23 (70%) patients were classified as stage 1, 9 (27%) as stage 2, and 1 (3%) as stage 3. Patients needing replacement renal therapy were not found. Mean age was similar between both (63.3 (SD 11.9) in the development cohort, 61.5 (SD 11.7) in the validation cohort. In general, patients with ADHF and AKI during the first day of hospitalization had larger diameter of IVC (18.9 ± 5.4 mm vs. 14.7 ± 5.3 mm resp., $p=0.05$) and variations of IVC diameter were significantly lower (12.4 ± 4.7 mm vs. 7.2 ± 4.7 mm resp., $p=0.01$). Subsequently, during the 7th day of therapy of patients with ACS type 1 diameter IVC remained larger (21.2 ± 5.2 mm. vs. 13.1 ± 5.7 mm resp., $p=0.01$), and the value of collapse IVC became lower compared with patients with ADHF without AKI (13.1 ± 9.2 mm vs. 5.5 ± 5.3 mm resp., $p=0.04$). By the 10th day of intensive medical therapy diameter IVC correlated with the presence of AKI ($r=0.73$; $p=0.02$). Optimal cutoff points for predicting AKI were 8.7 mm for IVC collapse (sensitivity 73%, specificity 69%). Receiver operator curves demonstrated area under the curves of 0.77 for IVC collapse. The study showed no interaction between the count of B-lines and the risk of AKI.

Conclusion: Study showed that AKI affected 1% of patients with ADHF. Majority of patients (70%) had AKI stage 1. Development AKI when CRS type 1 may be associated increased venous congestion leading to renal dysfunction. Increasing CVP, IVC diameter and reducing IVC collapse leads to the AKI development of patients with ADHF. The study showed no interaction between the count of B-lines and the risk of AKI.

Prognostic effect of dynamic renal function in chronic heart failure: is kidney more than a surrogate marker of cardiac function?

J Mascarenhas¹; O Laszczynska²; M Severo²; F Fries³; P Bettencourt³; J Pimenta³; A Azevedo⁴

¹Hospital Center Vila Nova Gaia, Porto, Portugal; ²Institute of Public Health of the University of Porto, EPIUnit, Porto, Portugal; ³Sao Joao Hospital, Internal Medicine, Porto, Portugal; ⁴Faculty of Medicine University of Porto, Department of Clinical Epidemiology, Predictive Medicine and Public Health, Porto, Portugal

Background: Chronic kidney disease (CKD) is a frequent comorbidity in heart failure (HF), associated with increased mortality. The prognostic value of dynamic kidney function is largely unknown.

Purpose: We evaluated the effect of longitudinal variation of renal function in all-cause mortality among ambulatory HF patients.

Methods: We retrospectively analyzed data from 560 HF patients with left ventricular systolic dysfunction followed for a median of 25.1 months at an outpatient HF

clinic. Demographics and comorbidities were abstracted from clinical records. Kidney function was assessed by estimated glomerular filtration rate (eGFR) and was categorized into three classes based on KDIGO guidelines. Extended Cox models were performed to study the association between dynamic changes in eGFR and death.

Results: Patients' median age was 70.0 years, 70% were men, 46% had ischemic etiology and the majority had moderate to severe LVEF. Half of the patients had CKD. Comorbidities were more prevalent in these patients. The eGFR declined about 12 mL/min/1.73m² over 5 years. After adjustment for baseline eGFR, time-varying eGFR had a marginally significant dose-dependent association with death [hazard ratio (HR)=1.26, 95% confidence interval (95%CI): 0.93-1.71; HR:1.37, 95%CI: 0.93-2.01, for eGFR between 30 to 60 and under 30 mL/min/1.73m², respectively]. The prognostic value of dynamic eGFR was totally explained by baseline comorbidities, indicators of HF severity and drugs (adjusted HR=1.1, 95%CI: 0.79-1.54; HR=1.16, 95%CI: 0.75-1.79, for eGFR 30-60 and <30 mL/min/1.73m², respectively).

Conclusion: Dynamic kidney function is not independently related to poor prognosis. Rather than directly affect survival, renal impairment is probably a surrogate marker of HF severity.

P961

Correlation of laboratory biomarkers with echocardiographic parameters in patients with cardiorenal syndrome

B Leskovaar¹; T Furlan¹; B Kljucsek¹; A Adamlje¹; M Lainscak²

¹Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia;

²Celje General Hospital, Department of Cardiology, Celje, Slovenia

Background: Cardiorenal syndrome is associated with higher morbidity and mortality than in isolated chronic heart or kidney disease. NT-proBNP is a biomarker of heart failure that is currently used in all heart failure patients, though the number of studies concerning the use of biomarkers in diagnosing heart failure in chronic kidney disease patients is limited.

Purpose: We evaluated associations between biomarkers and echocardiographic parameters in patients with chronic heart failure and chronic kidney disease in hemodialysis program.

Methods: We included all patients with heart failure currently treated with chronic hemodialysis in our center. Echocardiography imaging was performed in all patients (LVEF, VTI, Sm, Em, E/A, E/Em) and blood samples were analysed for NT-proBNP, troponin T and iPTH. We evaluated the possible correlations between echocardiographic parameters and biomarkers with multiple regression analysis.

Results: We enrolled 22 patients with concurrent end-stage kidney disease and chronic heart failure (50% men, mean age 65.5 ± 11.7 years, mean NT-proBNP 1425 ± 1226 pg/ml, mean LVEF 57.1 ± 13.0%, 45% with HFrEF). Higher troponin T was the most important prognostic factor of lower LVEF (Pearson=-0.637, p=0.001; R²=0.406, F(1,20)=13.69, p=0.001), lower VTI (Pearson=-0.678, p=0.000; R²=0.459, F(1,20)=16.98, p=0.001), lower Sm (Pearson=-0.576, p=0.003; R²=0.331, F(1,20)=9.91, p=0.005) and higher E/A (Pearson=0.700, p=0.000; R²=0.490, F(1,20)=19.20, p=0.000). NTproBNP was a statistically significant prognostic factor of lower Em (Pearson=-0.489, p=0.010; R²=0.239, F(1,20)=6.30, p=0.021) and higher E/Em (Pearson=0.644, p=0.001; R²=0.415, F(1,20)=14.18, p=0.001). Indirect PTH was a statistically significant but not a prognostic factor of lower VTI and lower Sm. None of the tested laboratory or echocardiographic parameters were associated with heart failure hospitalizations in previous two years, but low VTI was a prognostic factor of longer hospital stay due to heart failure in same period (Pearson=-0.526, p=0.006; R²=0.277, F(1,20)=7.66, p=0.012).

Conclusions: Troponin T demonstrated better associations with echocardiographic parameters than NT-proBNP in patients with chronic heart failure and chronic kidney disease in hemodialysis program.

Acute cardiorenal syndrome in decompensated heart failure: impact on outcomes after hospital discharge in Brazil.

P P M Spinetti¹; E F Salles¹; L L Perruso¹; P D Maia¹; P Ferreira¹; L A Feijó¹; M I Garcia¹; S X Xavier¹; A S Sousa¹

¹Federal University of Rio de Janeiro (UFRJ), Cardiology, Rio de Janeiro, Brazil

Background: Acute cardiorenal syndrome (ACRS) is associated with poorer in hospital prognosis in patients with decompensated heart failure (DHF). There is no general agreement on its impact on outcomes after hospital discharge.

Objectives: To assess the association between ACRS and mortality after hospital discharge and readmission due to DHF and to compare the impact of ACRS in any moment during admission with the impact of persistent ACRS.

Methods: Patients admitted for DHF in a university hospital, between 01/01/06 and 12/31/11, were included in a cohort study. Deaths after discharge were identified through record linkage with the State of Rio de Janeiro mortality database. ACRS was defined as an absolute increase in serum creatinine ≥0.3mg/dL during hospitalization. ACRS was stratified in intermittent when creatinine levels

decreased until discharge and persistent when levels remained increased until discharge. The study excluded patients who had less than two creatinine measurements during hospitalization. Kaplan-Meier curves were built for overall survival and rehospitalization-free survival and were compared using the log-rank test. Cox multivariate analysis was used to assess the independent prognostic value of ACRS compared to outcomes after hospital discharge.

Results: Data from 395 patients showed that 53.3% were men, with mean age of 64 ± 14 years, 83.15% had systolic dysfunction and 37.6% ischemic etiology. ACRS incidence was 43.3%, being persistent in 22.3% of patients. The median follow-up time was 25.6 months (minimum of 12 and maximum of 83.9). Mortality after hospital discharge was 67.9% and hospital readmission rate for DHF was 41.4%. The accuracy of deaths search was 99.44%. Persistent ACRS was associated with mortality after discharge in uni- and multivariate analysis (OR1.52, 95% CI 1.12 to 2.08, p=0.008). There was no association between ACRS and readmission regardless of the definition used.

Conclusion: Persistent ACRS is associated with higher mortality after hospital discharge. ACRS is not associated with readmissions due to DHF.

Survival after discharge and CRS

P963

The heart failure and kidney injury in elderly patients with IE

EO Kotova¹; T S Getiya²; AS Pisaryuk¹; PV Lazarev¹; JL Karaulova¹; GK Kiyakbayev¹; V L Filatov²; V S Moiseev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation;

²M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Purpose: To study the features of heart failure and kidney injury in elderly patients with infective endocarditis (IE).

Material and methods: 80 patients (50 men) with IE (Duke 2015) were included, of which the elderly (≥60 years) were 54 (43.2%) patients (group 1), young adults (group 2) — 26 (20.8%). The anamnesis, echocardiogram, renal function (GFR, proteinuria, microscopic hematuria, serum Cystatin C, urinary KIM-1), heart failure (NYHA) rates and NT-proBNP levels, acute kidney injury (AKI, KDIGO 2012) and mortality rates were evaluated. Early AKI was defined as AKI at the moment of admission to the hospital, AKI developed during hospitalization was considered as late AKI. Results. The median age in group 1 was 73 [66-79], in group 2 — 42 [32-52] years. Concomitant diseases were more common in group 1 than in group 2: hypertension [50 (92.6%) vs. 11 (42.3%), p<0.05], atrial fibrillation [25 (46.3%) vs. 3 (11.5%), p<0.05], coronary artery disease [22 (40.7%) vs. 3 (11.5%), p<0.05], cerebral infarction [20 (37.0%) vs. 3 (11.5%), p<0.05] and diabetes mellitus [13 (24.1%) vs. 4 (15.4%), p<0.05]. Groups did not differ in incidence of secondary forms, subacute IE. Median left ventricular EF in groups were comparable [53.8 ± 8.7 (28-72) vs. 58.3 ± 7.1 (39-72), p>0.05]. Heart failure occurred more frequent in group 1 than in group 2 [45 (83.3%) vs. 16 (61.5%), p<0.05], that was consistent with higher values of NT-proBNP — 3103 [1091-4890] pg/ml vs. 2030 [301-3499] pg/ml, p<0.05. The median GFR in group 1 was 47.9 [31-58] ml/min, in group 2 — 77.0 [45-91] ml/min (p<0.05). AKI in group 1 were more common than in the group 2 [29 (53.7%) vs. 12 (46.2%), p<0.05] and was presented by early AKI [6 (11.1%) vs. 3 (11.5%), p>0.05] and late AKI [23 (42.6%) vs. 9 (34.6%), p<0.05]. Laboratory changes in urine also prevailed in group 1 [45 (83.3%) vs. 17 (65.4%), p<0.05] and was presented by proteinuria [39 (72.2%) vs. 17 (65.4%), p<0.05] and hematuria

[28 (51.9%) vs. 9 (34.6%), $p < 0.05$]. Elderly patients had significantly higher levels of serum Cystatin C – 3.1 [2.3–3.9] vs. 2.0 [1.8–2.4] pg/ml ($p < 0.05$), KIM-1 in urine – 2.6 [2.5–2.8] vs. 1.6 [1.4–1.8] ng/ml ($p < 0.05$). Mortality in the group of elderly was 2.5 times higher than in the young adults group [21 (38.9%) to 4 (15.4%), $p < 0.05$]. Conclusion. IE in elderly patients is characterized by frequent association with comorbidities, heart failure (mainly III–IV FC) and AKI, by increased levels of NT-proBNP, Cystatin C, KIM-1, and by higher mortality rate.

The relationship between renal resistance index values and worsening of renal function

C Rizzo¹; F Monitillo¹; M Leone¹; MS Lattarulo¹; D Grande¹; P Terlizze¹; A Doronzo²; G Citarelli³; MM Ciccone⁴; M Iacoviello⁴

¹University of Bari, School of Cardiology, Bari, Italy; ²F Ferrari Hospital, Cardiology Unit, Casarano, Italy; ³San Paolo Hospital, Cardiology Unit, Bari, Italy; ⁴Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

Background: Arterial Renal Resistance Index (RRI) is a Doppler measure, which reflects abnormalities in renal blood flow, which can be determined by structural and functional abnormalities of kidneys. The aim of this study was to verify the association between RRI values and worsening renal function (WRF) in a group of chronic heart failure (CHF) outpatients.

Methods: We enrolled 266 patients (Age 64 ± 14 years, 79% males, NYHA class 2.2 ± 0.7 , left ventricular ejection fraction, LVEF, $33 \pm 9\%$) in stable clinical conditions and in conventional therapy. All patients underwent a clinical evaluation, a routine chemistry and an echocardiogram. Peak systolic velocity and end diastolic velocity of a segmental renal artery were obtained by pulsed Doppler flow and RRI was calculated. WRF was defined as an increase in serum creatinine of ≥ 0.3 mg/dl associated with a change $> 25\%$ or a decrease in GFR $> 20\%$ at 1 year follow-up.

Results. During follow-up, thirty-four (13%) patients showed WRF. RRI was associated with WRF at univariate analysis (OR: 1.13; 95%CI: 1.07–1.20). In a multivariate forward stepwise regression model including the other univariate predictors, i.e. age, high diuretic dose, GFR-EPI, log NT-proBNP, CVP > 5 mmHg and acute decompensated heart failure within 1 year, only RRI (OR: 1.09; 95%CI: 1.03–1.16; $p: 0.005$) and CVP > 5 mm Hg (OR: 2.62; 95%CI: 1.04–6.63; $p: 0.041$) remained significantly associated with WRF. As shown in Figure 1A, a progressive increase of relative and absolute creatinine changes was observed in subgroups of patients with greater RRI values as well as an increase in the risk of WRF occurrence (Figure 1B). At ROC curve analysis, the RRI showed an AUC of 0.74 (95% CI 0.67–0.82) for WRF occurrence. The best cut-off of RRI was 70 (sensitivity 91%; specificity 50%).

Conclusions: Quantification of arterial renal perfusion provides a new parameter whose greater values are independently associated with a progressive increase of the risk of WRF in CHF outpatients, thus helping to better define the risk of cardiorenal syndrome progression.

P965

Serum cystatin C is associated with left ventricular hypertrophy and impaired left ventricular relaxation in patients with stage 2 or 3 chronic kidney disease

J Jun Iwasaki¹; S Sakuragi²; K Enkoh¹; T Takamura¹; H Kobayashi¹

¹Onomichi municipal hospital, cardiology, Onomichi, Japan; ²Iwakuni Clinical Center, Cardiology, Iwakuni, Japan

Background: In this cross-sectional study, we aimed to determine the associations between serum cystatin C levels and structural and functional cardiac changes in patients with stage 2 or 3 chronic kidney disease (CKD).

Methods and Results: We enrolled 429 consecutive patients (aged 24–97 years) with CKD stage 2 or 3 and left ventricular (LV) ejection fraction (LVEF) $> 40\%$. Echocardiographic parameters, including LV mass index (LVMI), early diastolic mitral annulus velocity (e' velocity), left atrial volume index (LAVI), and N-terminal of the prohormone brain natriuretic peptide (NT-proBNP) were measured. Patients were categorized into quartiles according to serum cystatin C levels. Cystatin C was associated with LAVI ($p = 0.0055$), LVEF ($p = 0.0432$), LVMI ($p = 0.0409$), e' ($p = 0.0051$), E/e' ($p = 0.0027$), and log-transformed NT-proBNP ($p < 0.0001$) according to multivariate linear Regression analysis, after adjustment for confounding factors including creatinine-based estimated glomerular filtration rate (eGFR_{creat}) and urinary albumin to creatinine ratio. Incidence of eccentric and concentric hypertrophy increased

with increasing cystatin C (Q1, 38%; Q2 49%; Q3, 51%; Q4, 66%, $p = 0.0008$), mainly because of increasing concentric hypertrophy (Q1, 30%; Q2, 39%; Q3, 39%; Q4, 51%, $p = 0.0187$).

Conclusion: A high serum cystatin C is strongly associated with structural cardiac abnormalities such as LVH and left atrial enlargement, impaired LV relaxation, and an increased NT-proBNP, independently of eGFR_{creat} in patients with stage 2 or 3 CKD.

P966

Primary prevention of anthracycline-induced subclinical cardiotoxicity in breast cancer

WB Chung¹; SM Seo¹; BJ Chae²; BJ Song²; HJ Youn¹

¹The Catholic University of Korea, Division of Cardiology, Department of Internal Medicine, Seoul, Korea Republic of; ²The Catholic University of Korea, Department of Surgery, Seoul, Korea Republic of

Introduction: There is no effective method for prevention of anthracycline-induced cardiotoxicity.

Purpose: To investigate the preventive effect of concomitant administration of candesartan or carvedilol in the anthracycline-induced subclinical cardiotoxicity.

Methods: 110 patients from prospective registry (Pros) for prediction and prevention of chemotherapy induced cardiotoxicity in breast cancer of our institution were selected. All patients were administered candesartan or carvedilol concomitantly with doxorubicin contained chemotherapy. 85 patients from retrospective registry (Retros) of breast cancer of our institution were selected for control. Both group evaluated cardiac function by transthoracic echocardiography (TTE) before chemotherapy for baseline and followed up at least twice during chemotherapeutic period. The incidence of subclinical cardiotoxicity (SC) was evaluated.

Results: Intervals between TTE evaluation was 12 ± 1 weeks in Pros, but intervals between TTE in Retros was rather irregular. Left ventricular ejection fraction (LVEF) of Pros showed no change during follow up, however, LVEF of Retros showed gradual decrement (Table 1). Incidence of SC was higher in Retros (Table 2). Number of SC with mild LV dysfunction (LVEF $< 55\%$) was higher in Retros.

Conclusion: Concomitant administration of candesartan or carvedilol with chemotherapy can reduce incidence of SC and prevent aggravation of LV dysfunction of SC developed patients.

P967

Assessment of atrial and ventricular electromechanical delay, as a cardiotoxicity parameter in patients with trastuzumab chemotherapy for breast cancer patient.

J-H Jung-Hyun Choi¹; JH Choi¹; BW Kim¹; TJ Hong¹; ¹Busan National University Hospital, Busan, Korea Republic of

Backgrounds: The atrial electromechanical delays(AEMD) and ventricular electromechanical delays(VEMD) on echocardiography was noninvasive indicator of atrial and ventricular conduction delay. We hypothesized that cardiotoxicity of Trastuzumab may affect to cardiac conduction disorder and it maybe occur before significant decrease in LVEF and evaluated AEMDs and VEMDs before and after trastuzumab chemotherapy in breast cancer patients.

Methods: The breast cancer patients who underwent chemotherapy with Trastuzumab from 2011 to 2015 in a national university hospital were selected. Among this patients, Total 57 pateints have 6 \pm 2 month follow up echocardiography after chemotherapy, and we analyzed this echocardiographic parameters compared with baseline echocardiography. Left and Right VEMDs was defined as the time intervals from initiation of QRS wave of electrocardiography(ECG) to the initiation(LVEMDi, RVEMDi) and peaks(LVEMDp, RVEMDp) of left and right ventricular outflow tract time-velocity integrals on pulse wave(PW) doppler echocardiography. AEMD was defined as the time interval between the onset of ECG P wave and the initial(AEMDi) or peak a' wave(AEMDp) on the medial mitral annular tissue Doppler velocity curve(TDI) or PW Doppler at the mitral valve inflow level. We also measured GLS(global longitudinal strain), known as parameter of early predictor of cardiotoxicity in patients receiving cancer therapy. We compared these echocardiographic parameter between before and after 6 months trastuzumab chemotherapy with other echocardiographic parameters. Paired t-tests were used to compare all parameter at 6month with baseline.

Results: There were significant elongation of time in RVEMDi, RVEMDp, LVEMDi, LVEMDp, AEMDi at TDI, and AEMDp at TDI between baseline and after 6month follow up echocardiographic data (RVEMDi, 90.31 ± 20.11 vs. 97.09 ± 19.34 , p value = 0.04, RVEMDp, 220.81 ± 35.57 vs. 237.40 ± 34.91 , p value < 0.001 , 84.77 ± 14.83 vs. 95.91 ± 18.31 , p value = 0.009, LVEMDp, 179.18 ± 26.60 vs. 199.82 ± 26.01 , p value = 0.004, AEMDi at TDI, 57.88 ± 15.71 vs. 63.50 ± 13.73 , p value = 0.001, AEMDp at TDI, 114.02 ± 19.84 vs. 119.84 ± 18.94 , $p = 0.001$). Particularly, LVEMDi and LVEMDp showed an increase of 10% or more. GLS average was also changed after trastuzumab chemotherapy, but mean difference was very small(GLS average, -16.15 ± 3.69 vs. -15.10 ± 3.64 , p value = 0.044) LVEF was significant statistical difference between baseline and 6 month follow up echocardiographic data, but both data was in normal value, this results was no clinical significance. (62.55 ± 2.98 vs. 60.16 ± 3.64 , $p < 0.001$)

Conclusion: AEMDs and VEMDs was a good parameter to early detect of Trastuzumab cardiac toxicity in breast cancer patients before LV systolic dysfunction occurred. Especially, LVEMDi and LVEMDp showed great difference at 6 months follow up after initiation of trastuzumab chemotherapy.

Purpose: Even though chemotherapy-induced cardiotoxicity is one of the commonest side-effects of anthracyclines, it is unclear whether hospital-based clinicians routinely ensure thorough diagnostic, management and cardiac specialist referral of oncology patients.

P968

Relationship between left ventricular diastolic stiffness, trastuzumab, and cardiac function and toxicity

M Arao¹

¹ Tokyo Metropolitan Matsuzawa Hospital, Department of Internal Medicine, Tokyo, Japan

Purpose: Trastuzumab (T) can induce reversible cardiac dysfunction and an increase in left ventricular mass (LVM). This study investigated the utility of diastolic wall strain (DWS) to assess diastolic stiffness (DS) in patients treated with T.

Methods: We studied 157 consecutive breast cancer patients (all females; mean age, 57.1 ± 10.8 years) who received T for more than 6 months. These patients were categorized into the following two groups: DWS ≤ 0.63 (group A; mean age, 56.8 ± 10.8 years; n = 79) and DWS > 0.63 (group B; mean age 57.4 ± 11.3 years; n = 78). Echocardiography was performed before and after administration of T, and the following parameters were calculated: left atrial diameter (LAD); LV diameter in diastole/systole (LVDd/s); LV end-diastolic volume (LVEDV); LV end-systolic volume (LVESV); interventricular septal thickness in diastole/systole (IVSTd/s); posterior wall thickness in diastole/systole (PWTd/s); LV ejection fraction (LVEF); ratio of early to late ventricular filling velocity (E/A); mitral annulus velocity (e'); E/e'; Tei index (TI); relative wall thickness (RWT); DWS (DWS = (PWTs - PWTd)/PWTs); LVM; LVM index (LVMI); diameter of the inferior vena cava (IVC); pulmonary artery systolic pressure (PASP); LV end-diastolic pressure (LVEDP); and systolic blood pressure (BPs). Data were then compared between the two groups.

Results: Symptomatic heart failure was observed in five cases. Overall, no significant changes were observed in the indices of cardiac function, including IVSTd, PWTd, E/A, e', RWT, and IVC. After treatment with T, significant increases were observed in LAD, LVDd/s, LVED(S)V, E/e', TI, LVM, LVMI, PASP, LVEDP, and BPs (p < 0.001) and significant decreases were observed in IVSTs (p < 0.05), PWTs, LVEF, and DWS (p < 0.001). In both groups, no significant changes were observed in IVSTd, IVSTs, E/A, e', and IVC, and significant increases were observed in LVDd, LVDs, LVEDV, LVEDVI, LVESV, LVM, LVMI, and BPs. Further, significant decreases were observed in LVEF and DWS. With regard to indices of cardiac function, including LAD, E/e', T-I, PASP, and LVEDP, significant increases were observed only in group A. Furthermore, a significant decrease was observed in RWT only in group A.

Conclusion: Administration of T resulted in an increase in DS with LV diastolic dysfunction, a tendency towards eccentric hypertrophy with an increase in LVM, and heart failure with reduced ejection fraction. The tendency for LV diastolic dysfunction and eccentric hypertrophy was more common in patients with lower DWS than in those with higher DWS before treatment with T.

Forgotten but not forgiven: current practices in surveillance and prevention of anthracycline-induced cardiomyopathy

J Ferreira-Martins¹; E Welving¹; O Stewart¹; R Marcus¹

¹ King's College Hospital, London, United Kingdom

Methods: retrospective review of cardiac function investigations, management and follow-up practices of patients with diffuse large B-cell lymphoma (DLBCL) undergoing anthracycline-based chemotherapy between 2010 and 2015.

Results: Sixty-seven patients with DLBCL received anthracycline-based chemotherapy (34 males, 33 females; average age 59.7 ± 15.3 years). Forty-seven patients (70.1%) underwent echocardiography prior to chemotherapy, only 19 patients (28.8%) underwent subsequent evaluation of cardiac function after receiving anthracyclines. Eleven patients (16.4%) did not receive any form of imaging surveillance either prior or after treatment. Twelve patients (18%) were referred to a cardiology specialist either during or after treatment. Pre-existing cardiovascular comorbidities were significantly more prevalent in patients receiving cardiac review such as hypertension (66.7 vs 25.5%, p < 0.05), diabetes (33.3 vs 9.1%, p < 0.05), dyslipidaemia (41.7 vs 12.7%, p < 0.05) and coronary artery disease (33.3 vs 5.5%, p < 0.05). Current or prior smoking history did not differ (41.6 vs 41.8%, p > 0.05). Importantly, cardiology specialist review led to a significantly higher proportion of patients undergoing follow-up assessments by echocardiography (91.7 vs 27.8%, p < 0.0001), receiving heart failure therapies angiotensin-converting enzyme inhibitors/angiotensin receptor antagonists (75.0 vs 9.4%, p < 0.0001) and beta-blockers (58.3 vs 9.4%, p < 0.005).

Conclusion: There is still a significant under-referral in the assessment, management and follow-up of cardiac function in patients undergoing well recognized cardiotoxic chemotherapies. These results suggest that there is substantial opportunity for early detection and management of chemotherapy-induced cardiomyopathy by promoting a stronger collaboration between oncologists and cardiologists. This approach has had a positive and significant impact on the implementation of post-chemotherapy cardiac surveillance practices and instigation of evidence-based heart failure treatments, known to prevent or reverse anthracycline-induced cardiomyopathy.

P970

The outcome of hypertensive patients with diastolic dysfunction under doxorubicin therapy assessed by echocardiography

R M Christodorescu¹; M Trofenciu²; D Darabantiu²; M Puschita²; S Mercea²; A Mihuta²; A Pop-Moldovan²

¹ University of Medicine Victor Babes, Timisoara, Romania; ² Vasile Goldis Western University, Arad, Romania

Premises and objectives: Potential life-threatening cardiac toxicity limits the dose of doxorubicin. Echocardiography is the standard noninvasive method for monitoring the patients on chemotherapy. The purpose of this study was to assess the outcome in hypertensive oncological patients with diastolic dysfunction and to identify potential risk factors associated with early induced doxorubicin cardiotoxicity.

Material and method: The study group consisted of 50 consecutive hypertensive patients (P) with oncological pathology on doxorubicin chemotherapy and 25 control hypertensive P. A Siemens Acuson X300 unit was used for echocardiographic measurements. The data recorded included: demographics, clinical and echocardiographic measurements, (Table 1). In all 50 P data collection and follow-up were

done in outpatient and cardiology department prior to treatment, 6 w after initiation of treatment and at 6 m. Statistical analysis was made using paired t test for patient data and unpaired t test for comparison between the control and study group.

Results: There were no significant differences between control and study P regarding demographic parameters. The study P had a poorer hypertension control, LV hypertrophy and diastolic dysfunction and at 6 weeks and 6 months showed

echocardiographic evidence of SAVS. One-year mortality was 6% for OP- and 19% for NON-OP. Any cause hospitalization (at least an overnight stay) this year was in days and incidence rate per million patient years (IR): 2364 (46) and 362 (142) for OP and NON-OP, respectively. Number (IR) of any cause hospitalization (3 times or more) was for OP 39 (0,8) and 15 (5,8) for NON-OP (p=0,08). Table displays paired analyses for additional outcomes.

Table 1

Parameters	Control (n = 25)	Baseline (n = 50)	6 weeks (n = 50)	6 months (n = 50)	P value
Age (years)	55.0 ± 7.9	56.9 ± 11.9	56.9 ± 11.9	56.9 ± 11.9	0.396
Males (n)	13 (52%)	23 (46%)	23 (46%)	23 (46%)	0.478
SBP (mmHg)	138.9 ± 12.9	147.0 ± 24.7	149.0 ± 12.6 (0.5)	151.0 ± 11.2(0.2)	0.003*
DBP (mmHg)	78.6 ± 10.3	89.4 ± 12.3	91.2 ± 9.7 (0.3)	92.8 ± 11.2 (0.1)	0.0004*
EF (%)	66.8 ± 12.9	58.6 ± 14.5	57.3 ± 12.5 (0.7)	54.7 ± 13.2 (0.1)	0.001*
E/A	1.3 ± 0.4	0.98 ± 1.21	0.97 ± 1.11 (0.9)	0.95 ± 2.3 (0.9)	0.001*
IVRT (ms)	79.9 ± 17.4	100.8 ± 27.9	101.2 ± 22.4 (0.8)	102.0 ± 25.9 (0.7)	0.001*
LVMI (g/m ²)	64.4 ± 19.0	86.4 ± 36.1	87.2 ± 28.2 (0.9)	88.3 ± 37.8 (0.8)	0.006*

* Statistically Significant; SBP - Systolic blood pressure; DBP - diastolic blood pressure; EF - ejection fraction; IVRT - izovolumic relaxation time; LVMI - left ventricular mass index. Data are expressed as mean followed by " ± " mean standard deviation (SD).

an decrease in EF and deterioration of diastolic function, without reaching statistical significance (table 1).

Conclusions: The hypertensive P treated with doxorubicine have a good cardiovascular prognosis at 6 months. There is, however, a tendency of deterioration in diastolic and probably in systolic LV function. Therefore a more intensive additional echocardiographic follow-up at, 3 months would be more appropriate.

VALVULAR HEART DISEASE (DIAGNOSIS, MANAGEMENT AND INTERVENTIONAL THERAPIES)

P971

Comparing one-year outcomes beyond mortality in operated versus non-operated patients with severe aortic valve stenosis.

A Auensen¹; Al Hussain¹; J Bye¹; M Hansen¹; RS Falk²; KI Pettersen¹; L Gullestad¹

¹University of Oslo, Faculty of Medicine, Department of Cardiology, Oslo, Norway;

²Oslo University Hospital, Centre for biostatistics and Epidemiology, Oslo, Norway

Introduction: Aortic valve replacement (AVR) improves survival and quality of life in patients with severe aortic valve stenosis (SAVS). Few clinical studies compare outcomes beyond mortality-rates in operated versus non-operated patients.

Purpose: To compare functional- cognitive- and morbidity-outcomes in the year following AVR or not in patients with SAVS. Method Of 480 patients with SAVS evaluated for AVR, 351 had surgical- and 38 transcatheter-AVR (OP), while 91 were declined operation (NON-OP). At inclusion and one year follow-up, we obtained data on Six-Minute Walk test (6MWT), New York Heart Association-scale (NYHA) and Canadian Cardiovascular Society-scale (CCS). Cognitive function was assessed by the mini-mental state examination (MMSE). Questionnaires and medical records provided information on home situation, level of independence and hospitalizations.

Results: Mean (SD) age was 74 (10) and 81 (9) years, and gender (% women) was 41 and 52 for OP and NON-OP, respectively. At inclusion, all patients had

Conclusion: The present study demonstrates that aortic valve replacement for severe aortic stenosis is associated with improved functional outcome, while being declined AVR is associated with high mortality, more hospitalizations, unaltered functional status and a tendency to loss of independence.

P972

Comparing one-year patient reported outcomes (PROs) in operated versus non-operated patients with severe aortic valve stenosis (SAVS)

A Auensen¹; Al Hussain¹; KI Pettersen¹; L Gullestad¹

¹University of Oslo, Faculty of Medicine, Department of Cardiology, Oslo, Norway

Introduction: Advancements in surgical techniques make high risk and progressively older patients with SAVS eligible for aortic valve replacement (AVR). Current guidelines emphasize the importance of improving PROs as an outcome after AVR.

Purpose: To compare PROs at inclusion and one year for operated versus non-operated patients with SAVS.

Method: Of 480 patients with SAVS evaluated for AVR, 351 had surgical- and 38 transcatheter-AVR (OP), while 91 were declined operation (NON-OP). We collected data on SF-36v2; Physical-(PCS) and Mental-(MCS) Component Summary, EuroQol-5 Dimensions (EQ-5D), visual analogue scale (EQ-VAS), and Hospital Anxiety and Depression Scale (HADS).

Results: Mean (SD) age was 74 (10) and 81 (9) years, and 41 and 52 % were women for OP and NON-OP patients, respectively. Physical- and general health increased for OP patients, while anxiety decreased. In the NON-OP group there was a tendency towards decreased physical health. Table displays paired analyses of selected PROs.

Conclusion: Aortic valve replacement improves PROs assessed as perception of overall health and physical health, and reduces anxiety in patients with SAVS. Patients with SAVS declined for operation tend to experience a decrease in physical health over a one-year period. Our results advocate AVR in patients with SAVS.

new insights into cardiac functional status after MitraClip: the role of cardiopulmonary exercise test

G Salerno¹; M Di Maio²; M Cappelli Bigazzi²; R Bianchi²; MT Palladino²; P Calabro²; F Valente¹; C Maiello³; G Limongelli¹
G Pacileo¹; ¹Heart Failure Unit, Second University of Naples, AO dei Colli-Monaldi Hospital, Department of Cardiology, Naples, Italy; ²Second University of Naples - Monaldi Hospital, Department of Cardiology, Naples, Italy; ³ AO dei Colli-Monaldi Hospital, Heart Transplant Unit, Naples, Italy

Background: Whereas haemodynamic and echocardiographic studies suggest clinical benefits after MitraClip system in advanced heart failure (HF) patients, there are limited data on changes in functional capacity evaluated by cardiopulmonary exercise test (CPET).

Purpose: to assess the functional status in HF patients undergoing MitraClip using CPET and to evaluate whether preoperative echocardiographic data could predict the effects of this therapy.

Methods: Out of 46 patients undergoing MitraClip at our institute, 23 performed a maximal symptom-limited bicycle CPET with ramp protocol, transthoracic echocardiography (TTE) and clinical assessment before and after 6 months from the procedure. All patients (mean age 61.9 ± 8 years, 72.7% males) were affected with severe left ventricle (LV) systolic dysfunction (mean LV ejection fraction, LVEF 24 ± 7.9%) in optimal HF medical therapy. 7 were in waiting list for heart transplantation, the others were judged not eligible from HF team because of multi-organ failure or relative contraindications. 75% of patients were implanted with implantable cardioverter defibrillators (ICDs), 57% of whom received CRT-D. The main mechanism of MR was functional (FMR 87%; ischaemic 45.2%; no-ischaemic 41.9%). Baseline functional status was poor: 85% in NYHA Class III/IV, mean VO₂max 10.58 ± 3 ml/Kg per min (43.6 ± 9.4% of predicted value, p.v.), mean slope VE/VCO₂: 37.24 ± 8.7, mean work rate 63 ± 25 Watt (47.8 ± 14.1 % of p.v.). Results MitraClip significantly reduced MR from 3+/4+ to 1+/2+ in 94% of cases (p < 0.0001), increased LVEF from 24 ± 7.9% to 28.5 ± 7.0% (p < 0.001), decreased pulmonary systolic pressure (Δ PAPs ~10 mmHg; p value < 0.005), with a substantial clinical benefit (97% of patients in NYHA Class III/IV, improved to I/II Class; p < 0.0001) at 6 month follow up. On the contrary, among CPET parameters only the exercise capacity improved after MitraClip (Δ Watt % ~7.4; p = 0.02). Among pre-procedural TTE parameters, evaluated at multiple linear regression analysis, only tricuspid annular plane excursion (TAPSE), resulted significantly related to the improvement of the maximum workload achieved at CPET (p = 0.022).

Conclusions: MitraClip resulted in a little increase of exercise capacity without any functional or ventilatory efficiency improvement in our patients at 6 months follow-up. TAPSE resulted the only TTE parameter able to predict exercise response at CPET after MitraClip. Further analysis of this cohort are needed to reveal the correlations among CPET parameters and haemodynamic/echocardiographic findings able to explain the clinical benefits of this therapy beyond NYHA Class.

Introduction: Tricuspid regurgitation (TR) is an acquired valvular abnormality that is most frequently encountered during the evaluation of left heart valve disease. Uncorrected significant TR during mitral valve surgery can result in inferior early and late outcomes due to progression of TR and underlying right heart failure. The purpose of this study was to report the clinical characteristics of patients undergoing tricuspid annuloplasty.

Methods: It was a retrospective study that included 91 patients who underwent Tricuspid annuloplasty in a Tunisian tertiary cardiovascular center. Clinical and echocardiographic data of patients who underwent Tricuspid annuloplasty were recorded.

Results: Ninety-one patients underwent tricuspid annuloplasty for TR as part of their cardiac surgical procedure. De-Vega annuloplasty was performed in 46 patients and ring annuloplasty in 45 patients. Tricuspid annuloplasty was associated to mitral replacement in 59 patients (64.8%), to aortic replacement in 3 patients (3.3%) et to a mitro-aortic replacement in 26 patients (28.6%). The mean age of the study population was 43.58 ± 12.56 years. The female gender was predominant (72.8%). Six patients (6.5 %) had a history of percutaneous mitral balloon valvuloplasty and 17 patients (18.6 %) had previous left-sided valvular surgery. The comparison of preoperative clinical characteristics showed no significant difference between the 2 groups of patients (Ring annuloplasty versus De-Vega annuloplasty).

Conclusion: TR is an important condition which is associated with adverse clinical outcomes. Based on numerous trials and registries, concomitant surgical repair of TR at the time of mitral valve surgery should be considered the current. It is important to select patients for tricuspid annuloplasty during operative management of left-sided valvular heart disease to improve outcomes.

Long-term follow-up of mitral stenosis after percutaneous mitral balloon valvuloplasty treatment. inoue versus balt single balloon technique

I P Ivana Borges¹; ECS Peixoto²; RTS Peixoto¹; RTS Peixoto²; AAB Aragao¹; VF Marcolla¹

¹Policia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; ²Fluminense Federal University, Rio de Janeiro, Brazil

Percutaneous mitral balloon valvuloplasty (PMBV) has emerged as an alternative to surgical treatment for mitral stenosis. Objective: This study aimed to demonstrate that mitral balloon valvuloplasty (MBV) with the Balt single balloon (BSB) has similar outcome and long-term follow-up (FU) than MBV performed with the Inoue worldwide accepted technique.

Methods: From 1987 to 2013 a total of 526 procedures were performed, being 312 with a FU, 56 (17.9%) with Inoue balloon (IB) and 256 (82.1%) with BSB.

¹Hedi Chaker University Hospital, Cardiology department, Sfax, Tunisia; ²Habib Bourguiba University Hospital, Anesthesia department, Sfax, Tunisia; ³Habib Bourguiba University Hospital, Cardiovascular and thoracic surgery department, Sfax, Tunisia

The mean FU in IB group was 33 ± 27 (2 to 118) and 55 ± 33 (1 to 198) months, p < 0.0001. Univariate analysis (UA) and multivariate Cox analysis (MVA) were utilized to determine independent predict variables of survival and event free survival (EFS) in both techniques groups. The major events (ME) were death, cardiac surgery and new MBV.

Results: In IB and BSB groups there were, respectively: female 42 (75.0%) and 222 (86.7%); mean age 37.3 ± 10.0 (19 to 63) and 38.0 ± 12.6 (13 to 83) years, p = 0.7138; sinus rhythm 51 (91.1%) and 215 (84.0%), p = 0.1754; echo score (ES) 7.6 ± 1.3 (5 to 10) and 7.2 ± 1.5 (4 to 14) points, p = 0.0528; echo mitral valve area (MVA)

pre-MBV 0.96 ± 0.18 and 0.93 ± 0.21 cm², $p = 0.2265$; post-MBV mean MVA (Gorlin) were 2.00 ± 0.52 and 2.02 ± 0.37 cm², $p = 0.9554$; MBV dilatation area 6.09 ± 0.27 and 7.02 ± 0.30 , $p < 0.0001$. At the end of the FU, there were in IB and BSB groups, respectively: echo MVA 1.71 ± 0.41 and 1.54 ± 0.51 cm², $p = 0.0552$; new severe mitral regurgitation in 5 (8.9%) and 17 (6.6%) patients, $p = 0.5633$; new MBV in 1 (1.8%) and 13 (5.1%), $p = 0.4779$; mitral valve surgery in 3 (5.4%) and 27 (10.4%), $p = 0.3456$; deaths 2 (3.6%) and 11 (4.3%), $p = 1.000$; cardiac deaths 1 (1.8%) and 9 (3.5%), $p = 1.000$; ME 5 (8.9%) and 46 (18.0%), $p = 0.1449$. In UA and MCA the BSB or IB technique do not predict survival or EFS. The independent risk factors to survival (MCA with 2 models with 5 and 6 variables) were: age < 50 years ($p = 0.016$, HR = 0.233, 95% IC 0.071 - 0.764), ES ≤ 8 ($p < 0.001$, HR = 0.105, 95% IC 0.34 - 0.327), MBV dilatation area ($p < 0.001$, HR 16.838, 95% IC 3.353 - 84.580) and no mitral valve surgery in the FU ($p = 0.001$, HR 0.152, 95% IC 0.050 - 0.459). Independent risk factors to EFS: no prior commissurotomy ($p = 0.012$, HR = 0.390, 95% IC 0.187 - 0.813) and post-MBV MVA ≥ 1.50 cm² ($p = 0.001$, HR = 7.969, 95% IC 3.413 - 18.608).

Conclusion: MBV with BSB and IB were equally efficient, there were similar survival and EFS in the FU. Independent predictors of survival were: age < 50 years, ES ≤ 8 points, MBV dilatation area > 7 mm² and no mitral valve surgery in the FU. Independent risk factors of EFS were no prior commissurotomy and post-MBV MVA ≥ 1.50 cm².

Background: Successful surgery for valvular heart disease prolongs life and generally improves symptoms and cardiac function. Nevertheless, myocardial dysfunction and health-related quality of life (HRQoL) impairment may persist and worsen post-operatively.

Purpose: We hypothesized that long-term nonsteroidal anabolic magnesium orotate might help improve symptoms and HRQoL after valve replacement.

Methods: 100 patients [aged 56.2 ± 3.5 years; 62% males; 68% NYHA class III, 32% NYHA class II; 35% concomitant SCAD, 18% CABG; median (IQR) 6-min walk distance (6-MWD) 348 (152-442) m; mean (SE) left ventricular ejection fraction (LVEF) 55.6 (2.4)%] 2-4 weeks after conventional aortic ($n = 58$) or mitral ($n = 42$) valve replacement by mechanical prostheses (38% due to degenerative, 32% rheumatic, 13% myxomatous, 11% congenital valve diseases and 6% infective endocarditis) were randomized 1:1 to receive either optimal standard therapy or magnesium orotate 500 mg t.i.d. added to conventional treatment. Efficacy endpoints included changes from preoperative baseline in 6-MWD, NYHA functional class, echo-parameters, heart failure hospitalizations and all-cause mortality. HRQoL was assessed by the Short Form (SF-36 v.1) Health Survey.

Results: There were no significant differences between magnesium orotate and control groups at baseline. Patients reported poor postoperative HRQoL. At month 12, patients receiving magnesium orotate ($n = 50$) had a mean increase in 6-MWD of 191 m ($p < 0.0001$); control patients ($n = 50$) had a mean 6-MWD increase of 135 m ($p < 0.001$), with a control-adjusted difference of +56 m ($p = 0.022$). NYHA status improved by two classes in 48% of magnesium orotate versus 32% of controls ($p = 0.028$), by one class in 52% versus 68% ($p = 0.028$). Magnesium orotate delayed the time to clinical worsening ($p = 0.0063$) and reduced the heart failure admissions ($p = 0.0042$). Improvements were noted in control-adjusted changes in supraventricular ($p = 0.0027$) and ventricular arrhythmias ($p = 0.035$) and in postoperative heart remodeling, e.g. in mean LVEF (+4.8%; $p = 0.0018$), left ventricular end-diastolic diameter (-6.3 mm; $p = 0.0012$), and end-systolic diameter (-3.9 mm; $p = 0.0038$). Combination therapy with magnesium orotate was well tolerated. In both groups, SF-36 scores substantially rose after follow-up. Magnesium orotate patients had significant higher improvements in HRQoL over time compared to controls. One patient died in the control group ($p = 0.63$).

Conclusion: Long-term magnesium orotate treatment for patients with mechanical aortic/mitral valve prostheses improves symptom status, cardiac function and HRQoL. This study provides the evidence that the metabolically acting agent magnesium orotate may be a new additional therapy for patients after proceeding with surgical valve replacement.

Percutaneous mitral valvuloplasty with balt single balloon. long-term follow-up of 25 years.

I P Ivana Borges¹; ECS Peixoto²; RTS Peixoto¹; RTS Peixoto²; AAB Aragao¹; VF Marcolla¹

¹Polícia Militar do Rio de Janeiro, Rio de Janeiro, Brazil; ²Fluminense Federal University, Rio de Janeiro, Brazil

Introduction: Percutaneous mitral balloon valvuloplasty has been proven to be an effective and safe method for treatment of patients with severe mitral valve stenosis and single balloon is a less expensive technique to perform the procedure of mitral balloon valvuloplasty. **Objective:** To evaluate the long-term follow-up (FU) of mitral balloon valvuloplasty (MBV) with Balt single balloon (BSB) technique and to determine independent predictors of survival and event-free survival (EFS). **Method:** From 1987 to 12-31-2013, 526 procedures of MBV were performed, 404 (77.1%) with BSB. There were 256 procedures with long-term FU. Balloon diameter: 25 mm in 5 procedures, 30 mm in 251; mean dilatation area: 7.02 ± 0.30 cm². FU was 156 ± 144 months. Multivariate Cox analysis to determine IPS and EFS.

Results: Mean age: 38.0 ± 12.6 (13 to 83) years, 222 (86.7%) female gender, 215 (84.0%) sinus rhythm, echo score (ES) 7.2 ± 1.5 (4 to 14) points and echo mitral valve area (MVA) pre-MBV 0.93 ± 0.21 cm². Mean pre and post-MVA (Gorlin): 0.90 ± 0.20 and 2.02 ± 0.37 cm², respectively ($p < 0.001$). Success (MVA ≥ 1.5 cm²): 241 (94.1%) procedures. Mean pulmonary artery pressure pre and post-MBV: 27 ± 10 and 20 ± 7 mmHg, respectively. Three (1.2%) patients began the FU with severe mitral regurgitation (SMR). At the end of FU 119 (46.5%) patients were in NYHA functional class (FC) I; 70 (27.3%) in FC II; 53 (20.7%) in FC III; 3 (1.2%) in FC IV; 11 (4.3%) deaths; 17 (8.2%) patients with SMR; 20 (4.7%) were submitted to a new MBV; 27 (10.5%) to mitral valve surgery and 70 (26.3%) without any medicine. Independent predictors of survival were: ES ≤ 8 points ($p < 0.001$, HR 0.116, 95% IC 0.035-0.384), age ≤ 50 years old ($p = 0.011$, HR 0.203, 95% IC 0.059-0.693) and absence of mitral valve surgery in the FU ($p = 0.004$, HR 0.170, 95% IC 0.050-0.571). Independent predictors of EFS were: absence of prior commissurotomy ($p < 0.002$, HR 0.318, 95% IC 0.151-0.667), female gender ($p = 0.036$, HR 0.466, 95% IC 0.229-0.951) and MVA post-MBV ≥ 1.50 cm² ($p < 0.001$, HR 0.466, 95% IC 4.884-28.457).

Conclusions: Success in 94% of procedures. At the end of follow-up (25 years) only 4.3% of mortality. The independent predictors of survival were: ES ≤ 8 points, age ≤ 50 years old and absence of mitral valve surgery in the FU. Independent predictors of EFS were: absence of prior commissurotomy, female gender and MVA post-MBV ≥ 1.50 cm².

Early hemodynamic improvement after percutaneous mitral valve repair evaluated by noninvasive pressure-volume analysis

D Daniel Laval¹; L Segura Schmitz¹; J-C Reil¹; SH Schirmer¹; M Boehm¹; U Laufs¹

¹Saarland University Hospital, Department of Internal Medicine III, Cardiology, Homburg, Germany

Purpose: Mitral regurgitation represents a volume load on the left ventricle (LV) leading to congestion and symptoms of heart failure. This study aimed to investigate the early hemodynamic changes after successful percutaneous mitral valve repair (MVR) with catheter-based clip implantation.

Methods and Results: 46 consecutive patients with symptomatic high-grade mitral valve insufficiency (mean age, 72 years; 54 % men) were prospectively included. 70% of patients had secondary mitral regurgitation. Noninvasive pressure-volume loops were reconstructed from echocardiography with simultaneous blood pressure measurements. MVR reduced left ventricular (LV) end-diastolic volume index from 87 ± 41 ml/m² to 80 ± 40 ml/m² ($p < 0.0001$). End-systolic volume index was 55 ± 37 ml/m² before versus 54 ± 37 ml/m² after repair ($p = 0.52$). Hence total stroke volume decreased from 60 ± 23 ml to 49 ± 16 ml ($p < 0.0001$), as did ejection fraction ($41 \pm 14\%$ to $37 \pm 13\%$, $p = 0.002$) and global longitudinal strain ($-11 \pm 4.9\%$ vs. $-9.1 \pm 4.4\%$, $p = 0.0001$). Forward stroke volume and forward cardiac output remained constant (43 ± 12 ml vs. 42 ± 11 ml and 3.2 ± 0.9 l/min vs. 3.4 ± 0.8 l/min, respectively). Parameters of LV contractility (end-systolic elastance, peak power index) and measurements of afterload (arterial elastance, end-systolic wall stress, total peripheral resistance) were similar before and after MVR. Total mechanical energy assessed as pressure-volume area decreased

(10,903 ± 4,410 mmHg x ml vs. 9,124 ± 2,968 mmHg x ml, $p = 0.0007$) due to a reduced stroke work (5,546 ± 2,241 mmHg x ml vs. 4,414 ± 1,412 mmHg x ml, $p < 0.0001$).

Conclusions: Noninvasive pressure-volume analysis shows that percutaneous mitral valve repair preserves left ventricular contractility and forward cardiac output while unloading the left ventricle through reducing the end-diastolic volume. Mitral valve repair is associated with a reduced total myocardial work and an economized cardiac function.

Long-term outcomes after transcatheter aortic valve implantation with the CoreValve prosthesis in the first patients

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; AJ Dominguez-Franco³; MF Jimenez-Navarro³; JH Alonso-Briales³; JM Hernandez-Garcia³; E De Teresa-Galvan³

¹Department of Cardiology, Malaga, Spain; ²Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Little is known about long-term outcomes following TAVI. Previous reports of transcatheter aortic valve implantation (TAVI) have focused on short- and mid-term outcomes; however, long-term durability of transcatheter heart valves and long-term clinical outcomes are unknown. The aim of this study was to evaluate clinical and hemodynamic outcomes 5 years after TAVI.

Methods: Between April 2008 and December 2010, 144 patients underwent TAVI for the treatment of severe symptomatic aortic stenosis with the CoreValve prosthesis. **Results:** the mean age and euroSCORE were 79.6 ± 6.4 years and 20.8 ± 14% respectively. Mean aortic valve gradient decreased from 50.8 ± 16 mmHg to 8.8 ± 4 mmHg after TAVI, to 11.3 ± 9 mmHg at 4 years and 19.7 ± 12 mmHg at 5 years (p for post-TAVI trend 0.03). Mean aortic valve area increased from 0.62 ± 0.19 cm² to 1.61 ± 0.4 cm² after TAVI to 1.47 ± 0.27 at 4 years and 0.98 ± 0.4 cm² (p for post-TAVI trend 0.01). Mean left ventricular ejection fraction increased from 62.8 ± 14 mmHg to 67.1 ± 10 mmHg after TAVI, to 60.7 ± 8 mmHg at 4 years and 53 ± 16 at 5 years (p for post-TAVI trend 0.001). Late mortality after a mean of 52.1 ± 26 months was 44.4% and in only 15 p was cardiovascular mortality. Survival rates at 1 to 6 years were at 88.8%, 75.6%, 72.2%, 61.8%, 50.57% and 45.5% respectively. At 5 years, 2 patients had severe prosthetic valve dysfunction (severe stenosis and moderate transvalvular regurgitation). Median survival time after TAVI was 3.55 years (95% confidence interval [CI]: 3.26 to 3.84), and the risk of death was significantly increased in patients with stroke (adjusted hazard ratio [HR]: 29.9; (95% CI: 3.4 to 262), $p = 0.002$ and new-onset atrial fibrillation HR 3.53; (95% CI 1.54 to 8.11) $p = 0.003$.

Conclusions: Our study demonstrated favourable long-term outcomes after TAVI. Signs of prosthetic valve failure were observed in 1.4% of patients.

Clinical screening for pacing induced cardiomyopathy is not enough

CN Iorgulescu¹; ST N Bogdan¹; DA Radu¹; AI Deaconu¹; A Nastasa¹; S Iancovici¹; D Zamfir¹; V R-G Vatasescu Radu-Gabriel¹

¹Clinic Emergency Hospital, Bucharest, Romania

Background: Prolonged pacing from the right ventricular apex (RV) is associated with left ventricular (LV) dyssynchrony leading to progressive left ventricular dysfunction and increased morbidity and mortality. Currently the diagnosis is based on development of heart failure symptoms.

Purpose: The aim of this study is to analyze the efficiency of clinical screening for pacemaker induced cardiomyopathy.

Methods: We analysed retrospectively the patients upgraded in our center from conventional pacemaker to biventricular device for pacing induced cardiomyopathy between the years 2010-2013. The diagnosis was based upon questioning for heart failure symptoms during pacemaker follow up visits. Symptomatic patients performed cardiac echo and were upgraded to a CRT device if LVEF was lower than 35%. We excluded from our group those patients with abnormal LVEF at the initial implant, patients with ischaemic cardiomyopathy or significant valvular disease. The 32 patients were divided in two groups – a group of 16 patients with LVEF at diagnosis ≤ 25% and a group of 16 patients with LVEF > 25% at diagnosis. Echocardiographic and clinical follow up was performed at one year after the implant in all patients.

Results: Average duration between the initial implant and diagnosis was 51,7 months. NYHA class, age comorbidities and symptom duration did not differ significantly between groups. Patients with LVEF ≤ 25% (average 16,37%) had an increase to 29,5% while those with LVEF > 25% (average 31,05%) reached an LVEF of 47,64% at one year. LVEF > 25% was associated with normalisation of LV systolic function (LVEF > 45%) at one year after CRT upgrade ($p < 0,05$).

Conclusions: LVEF > 25% at diagnosis was a predictor of normalized systolic function at one year after CRT. Using heart failure signs and symptoms for screening half

of the patients had LVEF ≤ 25% at diagnosis, showing the need for better screening strategies.

P981

Reducing heart failure mortality through remote nursing telemonitoring

M Michela Barisone¹; A Bagnasco¹; G Aleo¹; G Catania¹; MP Zanini¹; L Sasso¹

¹University of Genoa, Genoa, Italy

Introduction: Heart failure is often the result of the clinical evolution of several common diseases such as ischaemic heart disease, arterial hypertension, and cardiomyopathy, with an incidence of 2 million cases per year in the world, 470,000 in Europe, and 66,000 in Italy. Heart failure is the most frequent cause for hospitalization in older people. The use of Health Technology Assessment, pacemakers and defibrillators has rapidly increased in the last decade following clinical advances. Implanted heart devices play an important role in monitoring heart failure. Telemonitoring systems enable to check at any time current and previous data produced by the implanted devices, for an early detection of arrhythmia or incipient anomaly of the stimulation or heart defibrillating system. Purpose To identify to what extent telemonitoring affects survival rates and patient adherence to follow up. Methods From June 2014 to October 2015, out of a total of 65 patients with an implanted cardiac defibrillator and an initial diagnosis of heart failure, 40 accepted to participate in this study. One of our nurses educated and trained the patients, entered the data into the website, reviewed and screened transmitted data, and identified any critical cases, and if necessary contacted a physician specialized in arrhythmia, keeping in contact with the patient and checking adherence to treatment through the reports received. Six months after patient enrolment, a semi-structured interview was conducted to study how patients perceived the quality of this service. Results Telemonitoring enabled to identify 84% of the adverse clinical events and intervene immediately for urgent cases and on average within three days for other cases. Patients expressed high levels of acceptance and satisfaction, positively perceived monitoring, and their quality of life improved. The control group after one year presented a higher incidence of adverse events (27.5%) than the intervention group (18.9%). We received 211 transmissions, and avoided 51 outpatient consultations. Telemonitored patients presented lower mortality rates (3.4% vs. 8.7%). Conclusion The data that emerged from this study, despite the small size of our sample, confirmed the data reported by guidelines and the most important studies in this area. Remote follow up performed using implanted devices ensure an early detection of any clinical events or device malfunctions, a 50% reduction of inappropriate shocks, a better quality of life, better compliance and patient satisfaction.

P982

Two ways for measuring B-type natriuretic peptide, either from capillary blood or venous sample. a comparison of diagnostic accuracy in patients with chronic heart failure in NYHA classes I-III

R De Vecchis¹; C Ariano²

¹Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy;

²Neurorehabilitation Unit, Clinica "S.Maria del Pozzo", Somma Vesuviana, Italy

Background: In recent years, several systems have been implemented to achieve quick and non-invasive measurements of B-type natriuretic peptide (BNP). Among them, a detection system with very innovative properties has been patented, consisting in a one-step immunoassay that uses biotinylated anti-BNP monoclonal antibody and streptavidin-coated magnetic solid-phase particles to attract the immune binding of latex particles coupled with horseradish peroxidase and a monoclonal antibody fragment. It represents the most recent advancement in its field and is termed here as Heart Check (HC) BNP test, so as not to include in the report any trademark symbol, according to the rules and regulations governing the present submission. This system is a rapid point of care immunoassay (POC), projected for measuring BNP directly from a capillary whole blood sample.

Purpose: This study aimed at comparing the analytical and clinical performances of this new POC with our reference method, namely the lab-based test Architect system which obtains the BNP measurement from plasma derived from venous blood sample, subsequently treated with ethylenediaminetetraacetic acid (EDTA).

Methods: 111 patients with stable chronic heart failure (CHF) referring to two cardiac rehabilitation centers were enrolled from December 2013 to January 2015. These patients were subjected to a simultaneous capillary (HC) and plasma (Architect system) BNP measurements. Clinical and analytical performance of HC were assessed and compared to the reference method. Results Capillary BNP showed a good correlation with the reference method ($r = 0.94$, $p < 0.0001$), although the values diverged when BNP was higher than 1500 pg/mL. Indeed, the HC had a relatively poor precision and the coefficient of variability was 10.1% and 18% for low and high controls, respectively. However, both methods showed similar diagnostic performances in discriminating the patients with heart failure in NYHA class I from those belonging to NYHA classes II-III, with values of area under the curve (AUC) of 0.983 and 0.984, respectively, and equivalent sensitivity, specificity, and positive and negative likelihood ratios.

Conclusions: The HC BNP test is a good POC able to provide reliable information

about the hemodynamic status of CHF patients, especially of those belonging to NYHA classes I-III.

P983

Trend of echocardiographic parameters in pediatric patients with Berlin Heart EXCOR LVAD: a prospective observational study

A Arianna Di Molfetta¹; R Iacobelli¹; S Filippelli¹; A Toscano¹; S Morelli¹; G Ferrari²; MG Trivella²; A Amodeo¹

¹Bambino Gesù Childrens Hospital, Pediatric Cardiology and Cardiac Surgery, Rome, Italy; ²Italian National Research Council, Institute of Clinical Physiology, Rome, Italy

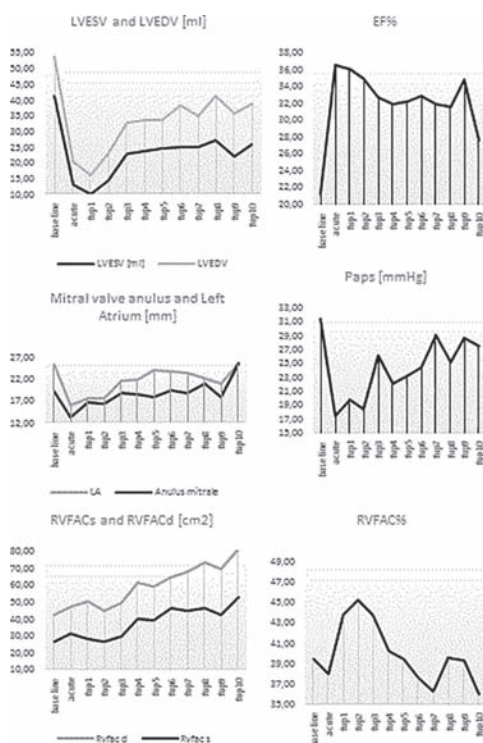

Background: LVAD is an important treatment for bridging pediatric patients to heart transplant or to heart recovery assuring an adequate cardiac output and the left ventricular unloading.

Purpose: This work aim at evaluating the trend of echocardiographic parameters in pediatric patients undergoing Berlin Heart EXCOR LVAD.

Methods: Data of Children implanted from 2013 to 2015 were prospectively collected before the LVAD implantation and at the monthly follow-up till the LVAD explantation.

Results: 12 patients were enrolled. 9 patients (75%) were affected by an idiopathic dilated cardiomyopathy, 2 patients (17%) by a non compacted left myocardium and 1 patient (8%) by a restrictive cardiomyopathy. At the implantation, average patients age and weight were 13.1 ± 11.1 months and 7.2 ± 3.7 Kg, respectively. Average LVAD staying was 226 ± 104 days. Six patients (50%) were successfully transplanted, one (8%) was weaned from the LVAD, three (25%) died for a major neurological complication and two (17%) are still on LVAD. Left ventricle was significantly unloaded by the LVAD with a statistically significant reduction in left ventricular end diastolic volume (LVEDV) ($p_{\text{acute}}=0.0001$, $P_{\text{fup1}}=0.0004$, $p_{\text{fup2}}=0.0006$, $p_{\text{fup3}}=0.02$, $p_{\text{fup4}}=0.03$, $p_{\text{fup5}}=0.05$), Left ventricular end systolic volume (LVESV) ($p_{\text{acute}}=0.0003$, $P_{\text{fup1}}=0.0003$, $p_{\text{fup2}}=0.0003$, $p_{\text{fup3}}=0.03$, $p_{\text{fup4}}=0.04$) and a statistically significant improvement of left ventricular ejection fraction (EF) ($p_{\text{acute}}=0.01$, $P_{\text{fup1}}=0.02$, $p_{\text{fup2}}=0.02$). However, after the initial unloading, the LVESV and LVEDV increase and the EF decreases. A similar trend is shown by the left atrial size, mitral valve annulus, mitral regurgitation and right ventricular pressure (Paps). Right Ventricular Fractional Area Change (RVFAC) is initially improved by the LVAD. However, right ventricular end systolic (RVFACs) and end diastolic (RVFACd) area and tricuspid valve annulus showed a progressively increment and then the RVFAC decreases.

Conclusion: Berlin Heart EXCOR LVAD could successfully bridge patients till the heart transplantation. However, results show that the left ventricular unloading provided by the LVAD in the short term follow up decreases in time resulting in both left and right ventricular dilatation.

Trend of Ecocardiographic Data

P984

Ventricular assist devices do not treat ventricular arrhythmias. Significant morbidity persists after implantation

A Aggeliki Gkouziouta¹; D Miliopoulos¹; G Karavolias¹; E Bousoula¹; A Kostopoulou¹; E Livanis¹; G Theodorakis¹; S Adamopoulos¹

¹Onassis Cardiac Surgery Center, Athens, Greece

Purpose: Left Ventricular assist devices (LVADs) have emerged as a life saving treatment option for patients with advanced heart failure. Despite robust left ventricular unloading, the right ventricle remains unsupported and susceptible to hemodynamic perturbations, including those from ventricular arrhythmias (VAs). Little is known about the epidemiology and influence of sustained VAs on outcomes in patients with VADs.

Methods: We retrospectively reviewed and analyzed data from all consecutive patients receiving a continuous flow VAD at our hospital from October 2003- December 2015. Patient demographics, medical therapies, and outcomes were recorded. Descriptive statistics were generated and multivariable logistic regression was used to assess the independent association of clinical variables on post-implant VAs.

Results: Thirty – five patients underwent the implantation of left ventricular assist devices. Fifteen out of 35 patients (43%) had sustained VAs after VAD. The majority with post-implant VAs were male (95%), had history of HTN (55%) and hyperlipidemia (30%), and had non-ischemic cardiomyopathy (75%). Compared with patients who did not experience VAs after VAD, patients with post-VAD VAs more often had pre-VAD VAs (67% v. 20%), an ICD (86% vs. 43%), and appropriate ICD discharge prior to mechanical circulatory support (44.4% v. 12.5%). The length-of-stay during implant hospitalization was similar regardless of post-VAD VAs, but those with VAs had twice the rate of rehospitalization (2.8 v. 1.6 admissions/patient) and required more anti-arrhythmic medications (2.3 v. 0.6 antiarrhythmics/patient). Post-VAD VAs were often refractory to medical therapy, requiring electrical cardioversion in the majority of cases (75%). Using multivariable logistic regression, only history of prior VAs was found to be associated with the development of post-VAD VAs.

Conclusions: VAs following VAD implantation are often refractory to conservative therapy and are associated with frequent hospital readmissions. Since only pre-implant ventricular tachycardia was associated with post-VAD VAs, arrhythmia burden may have a significant impact on future outcomes. Additional study should focus on utilizing arrhythmia burden to optimize patient selection for VAD.

P986

Right ventricular failure and left ventricular assist device: a 14-year, single-centre experience.

M Cottini¹; A Montalto¹; R Gherli¹; A Pergolini¹; M Lo Presti¹; V Polizzi¹; P Lilla Della Monica¹; F Musumeci¹

¹San Camillo Forlanini Hospital, Rome, Italy

Background: Right Ventricular Failure (RVF) is life-threatening complication after 20-50% of the implantation of a LVAD and contributes to increase postoperative morbidity and mortality. This complication has a poor prognosis and is generally unpredictable. RVF may often need temporary mechanical assistance and is most commonly associated with TVR.

Purpose: To study institutional experience over 14 years in LVAD implantation, to investigate effectiveness of TV annuloplasty in reducing the weaning time from temporary RV mechanical support in patients with mild-to-moderate TVR.

Methods: We evaluated our institution's LVAD database and analyzed all patients who received a LVAD as a bridge to transplant (BTT) or destination therapy (DT) from 2002 to 2015. We identified 64 patients, of which 54 were implanted as BTT (84.4%) and 10 received the device as DT (15.6%)

Results: The mean age was 54 ± 7.3 years, 79% were males, the INTERMACS medium level was 3.25 ± 0.45 . The 17.2% of the patients ($n=11$, Group A) required a temporary magnetically levitated rotary pump to support the RV without tricuspid annuloplasty (RVSWI 5.2 ± 3.1 , PCWP 25.2 ± 5.2 mmHg, SVR 1611 ± 2950 dyne/sec/cm-5/m2, PVR 244 ± 90 dyne/sec/cm-5/m2). In 9 patients (14.1%, Group B), temporary RV support was combined by TV annuloplasty (RVSWI 6.1 ± 3.5 , PCWP 24.4 ± 4.5 mmHg, SVR 1591 ± 270 dyne/sec/cm-5/m2, PVR 254 ± 110 dyne/sec/cm-5/m2). We compared the outcome of 2 groups of patients. They were similar regarding preoperative risk variables. Incidence of RHF after LVAD is successful weaning from mechanical RV support occurred in 9 patients in group A (81%) and 8 patients in group B (88%). Weaning time, need of inotropic support, time of recovery were significantly shorter for group B as compared to that of group A (9 ± 2.1 days group B versus 21.1 ± 8.1 days group A: $p < 0.001$; 7.8 ± 0.9 patients of group B versus 25 ± 2.6 patients of group A: $p = 0.002$; 29.4 ± 4.5 days group B versus 61.8 ± 1.8 days group A: $p = 0.004$). Also, data of Group B evidenced a reducing of the early postoperative complications (such as dialysis, perioperative mortality, revision for bleeding) and less time of recovery in ICU (Table 1).

Conclusion: Our single-centre experience suggests that the associated procedure LVAD implantation and TV annuloplasty, in patients with TVR at least mild-moderate grade, may reduce the mechanical and pharmacological support as well as recovery time, risk of infections and costs of hospitalization.

¹Center of Cardiovascular and Transplant Surgery, Transplantology, Brno, Czech Republic

Background: Continuous-flow left ventricle assist device (CF-LVAD) implantation has become the therapeutic standard for management of advanced heart failure patients awaiting heart transplantation (HTx) as a bridge-to-HTx. The aim of our study was to determine association between LVAD device type and short-term outcomes following the HTx.

Patients and methods: We retrospectively analyzed a total of 23 patients, who underwent LVAD implantation at our institution between 1/2009 and 6/2015. 11 patients received the type HM II, 12 type HW. There was no statistical difference between the two groups in age, gender, BMI, diagnosis and pulmonary vascular resistance. They were all transplanted from the urgent order. The only significant difference between the two groups was the time on the waiting list, in the group of the HMII it was in average 342 days compared to 166 days in the HW group ($p=0.039$). There were no significant differences in following donor characteristics: age, gender, cause of death, BMI, EF of left ventricle and cold ischemia time.

Results: The average duration of extracorporeal circulation was in the HMII group 163 minutes, in HW 170 minutes ($p=0.902$), blood losses were 1836 ml versus 1946 ml ($p=0.224$), the need for implantation of ECMO 2 versus 1, renal failure with hemodialysis 4 versus 5 ($p=1.0$). The incidence of failure of wound healing 2 versus 3 ($p=1.0$), the incidence of acute rejection grade 1B and higher 5 versus 3 ($p=0.40$), length of stay in the ICU was 21 days versus 18 days ($p=1.0$) and total duration of hospitalization after HTx 37 versus 39 days ($p=0.926$). Survival according to Kaplan Meier was significantly different in favour of HW group: the one and three year survival was 100%, compare to HMII group 64% and 55% respectively.

Conclusions: According to our pilot results, in patients undergoing HTx from different types of implanted LVADs there was no significant difference in the incidence of postoperative complications and in length of hospitalization. However, based on out limited sample data, patients transplanted from HW device support had a statistically significantly better survival.

P988

Iron deficiency in patients with ventricular assist devices - how common is it?

C Charles Butcher¹; M Mcgarvey²; G Karagiannis²; M Hedger²; O Dar²; A Simon²; JGF Cleland³; N Banner²; A Suarez-Barrientos²

¹Harefield Hospital, Cardiology, London, United Kingdom; ²Harefield Hospital, Transplant, London, United Kingdom; ³Imperial College London, London, United Kingdom

Introduction: Patients with ventricular assist devices (VAD) often suffer from bleeding events, multiple or persistent infections and develop acquired Von Willebrand Disease, which may all contribute to iron deficiency (ID). Traditionally, ID is associated with decreased haemoglobin, microcytosis and a low serum ferritin (FER). However, FER increases in response to inflammation, which may render it unreliable in patients with cardiac disease. An alternative method of assessing ID is transferrin saturation (TSAT).

Purpose: We sought to assess the prevalence of ID and anaemia in a population of VAD patients.

Methods: Blood iron profiles, with associated full blood count, renal function and C reactive protein (CRP) were retrospectively collated.

Results: From 77 patients (median age 48, IQR 41-56; 67 men) who had a VAD implanted between 2007 and 2015, 212 relevant blood samples taken after VAD implantation were available. Median length of VAD support was 439 days (IQR 266-808). For all samples, median (IQR) TSAT was 12 (8-17) and FER was 74 (29-195); 27 (34%) patients had at least one TSAT <20%, 59 (75%) had at least one FER <100ug/L and only 20 (25%) had at least one FER >300ug/L. At one year, Hb was <10g/dL in 25 patients, 10-12g/dL in 35 patients, 12-14g/dL in 12 patients and >14g/dL in 5 patients. Indices suggesting ID were common in all Hb categories. TSAT but not FER declined as Hb fell. RDW, eGFR and LDH were similar in each Hb group. Conclusion VAD patients are often anaemic and most fulfill criteria for ID regardless of Hb category. In this population, FER may be acting as an inflammatory marker rather than a measure of ID. TSAT may be a more reliable marker of both absolute and functional ID in this clinical setting. Further studies are needed to assess the clinical relevance and importance of correcting ID in this population.

Ventricular energetics in pediatric LVAD patients: a retrospective clinical study

A Arianna Di Molfetta¹; G Ferrari²; R Iacobelli¹; S Filippelli¹; A Antonio¹

¹Bambino Gesù Childrens Hospital, Pediatric Cardiology and Cardiac Surgery, Rome, Italy; ²Italian National Research Council, Institute of Clinical Physiology, Rome, Italy

Background: The continued decline in donor hearts' availability prolonged the LVAD support duration and leads to an increased interest in the use of LVAD as a bridge to heart recovery in pediatrics. Left and right ventricular energetic parameters were proposed in literature to evaluate ventricular unloading and recovery.

Purpose: The aim of this study is to estimate the trend of right and left ventricular energetic parameters in pediatric patients implanted with LVAD.

Methods: Echocardiographic data of 12 pediatric LVAD patients implanted from December 2013 to December 2015 were retrospectively analyzed at the baseline, in the acute phase after the LVAD implantation and at the monthly follow ups till the LVAD explantation. Data were used to estimate left and right ventricular energetic parameters.

Results: A significant relationship between the left and right ventricular energetic parameter trends along all the study period has been found. Left ventricular end systolic pressure-volume relationship (LVEmax) showed a statistically significant improvement till the follow-up of two months ($p=0.002$) and then it progressively decreases. Left attero-ventricular coupling (LAVC) significantly decreases after the LVAD ($p=0.04$) and right attero-ventricular coupling (RAVC) decreases in the short term follow up. Left ventricular external work (LVEW), potential energy (LVPE) and pressure-volume area (LVPVA) decrease at the short term follow up and then increase progressively. The right ventricular external work (RVEW), potential energy (RVPE) and pressure-volume area (RVPVA) increase after the LVAD implantation. Finally the left (right) cardiac mechanical efficiency (LVCME and RVCME) is improved (decreased, $p=0.02$) by the LVAD.

Conclusion: The trend of energetic variables shows that the benefits provided by the LVAD could decrease over time. A continuous and patient tailored LVAD parameter programming could contribute to prolongue LVAD benefits. The introduction of energetic parameters could lead to a more complete evaluation of LVAD patients outcome which is, typically, a multiparametric process.

Ventricular Energetic Trends

P990

Value of BNP monitoring in patients with left ventricle mechanical circulatory support in outpatient care.

M Marketa Hegarova¹; I Malek¹; V Melenovsky¹; Z Dorazilova¹; J Maly²; I Netuka²; J Pirk²

¹Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czech Republic; ²Institute for Clinical and Experimental Medicine, Department of cardiovascular surgery, Prague, Czech Republic

Background: Implantation of left ventricle assist devices (LVAD) can be lifesaving procedure for eligible patients with terminal heart failure. Early identification of complications during post LVAD outpatient care using BNP levels monitoring has not been well documented.

Purpose: The aim of our study was evaluation of BNP as a marker of severe clinical events in patients with LVAD Heart Mate II (HM II) in outpatient care.

Methods: We analysed BNP levels in patients with HM II implanted as a bridge to transplant from 02/08 to 6/15 in our institution who were discharged from hospital to outpatient care, n = 109. In all patients we evaluated the most increased BNP level during follow-up ("BNP max") and we calculated the percentage change in relation to BNP level prior to implantation ("% BNP before") and to the lowest one ("% BNP min"). To each BNP max level we assigned any clinical event (0 = no clinical event, 1 = hypervolemia without need of parenteral therapy, 2 = arterial hypertension with mean BP ≥ 100 mmHg, 3 = less severe infection, 4 = severe infection, 5 = heart failure without pump dysfunction, 6 = pump dysfunction according to echo and angiography findings). We divided patients into 3 groups by the severity of clinical events, Group A (clinical event 4, 5, 6) = serious, Group B (clinical event 1, 2, 3) = not serious and Group C (0 = no clinical event). We compared mean BNP max levels of Groups A, B, C one another. Consequently we used ROC analysis to identify the strongest predictors of any event and the serious one.

Results: In Group A we included 16 pts (with event 4 = 7 pts, 5 = 4 pts, 6 = 5 pts), in Group B 34 pts (with event 1 = 14 pts, 2 = 11 pts, 3 = 9 pts) and in Group C 59 pts. There was statistically significant difference in log of mean "BNP max" between A and B Groups p = 0.001, A and C p < 0.001 and B and C p < 0.001 (Tukey-Kramer

test). Using ROC analysis we found "% BNP before" as the strongest predictor of the serious event. The cut off point was increased BNP level amounting $\geq 40\%$ of BNP level before HM II implantation with 100% sensitivity and 81% specificity. Using ROC analysis we identified "%BNP min" as the strongest predictor of any event (Groups A+B) with cut off point 167% with sensitivity 92% and specificity 85%.

Conclusion: Our findings showed that BNP monitoring is an important part of post LVAD outpatient care. High sensitivity and specificity of BNP changes allow identification of clinical events with need for further diagnostic and therapeutic interventions. Of special importance is BNP monitoring ability to reveal life threatening situations. Furthermore we believe that this approach could decrease frequency of visits in outpatient VAD departments in stable pts.

P991

RESPIRATE-2 project: a co-management telemedicine-based programme between hospital (HF clinic) and field (general practitioner) for ICD-CRTD heart failure patients. final results

P Rocca¹; P Neri²; L Viscardi¹; A Locatelli²; MT Villa²; M Pisoni¹; G Maiorana¹; V Giudici¹

¹Bolognini Hospital, Cardiological Rehabilitation, Seriate, Italy; ²Bolognini Hospital, Department of Cardiology, Seriate, Italy

Background: The effectiveness of telemedicine and Remote Monitoring (RM) in heart failure is not established. RM systems can transmit device data and clinical data (for e.g. Transthoracic impedance, Heart Rate Variability, Physical Activity). Today these data are managed only by HF specialist or Electrophysiologist (EP). RespiRATE-1 was a pilot-project about Remote Patient Management (RPM) that involved HF specialist, EP (Hospital HF Clinic) and general practitioners (GP) (Outpatient Clinic). The aim of this Project was to create a network between the hospital and the field. RespiRATE-2 followed the same program but involved a greater number of GP and was supported by the local healthcare business of Bergamo.

Purpose: the primary aim of this project is to develop, implement, and test the feasibility and efficacy of RPM program (telephone support, network care and device-assisted monitoring) co-managed by HF specialist and GP.

Methods: HF specialist and GP used a common remote access technology and followed agreed simple flow-charts, in order to view and to share clinical and device data and to plan diagnostic or therapeutic actions if necessary (increase diuretic's dosage, prescribe blood tests or X-rays, etc.). A teleconsultation between patient and HF Clinic (physician or nurse) or Outpatient Clinic (GP) was allowed, if necessary.

Results: 10 GP were trained about HF management and RPM. 6 transmissions (tx) per pt was scheduled on a monthly basis from June 2014 to November 2014 and Alert tx was activated. GP was the first clinical data reviewer. Clinical actions, if needed, were shared by HF specialist and GP, following agreed flow-chart. During the study we reported: -60 scheduled transmissions, all co-managed by GP and HF specialist, with no need for pt's hospital access. -7 Alert Tx: 3 of these due to ICD shock on VF, that required patient's hospitalization; 4 of these due to fluid accumulation, all managed by GP in Outpatient Clinic. The use of RPM technology was perceived positively by patients and physicians.

Conclusions: A remote HF patient co-management with GP seems to be feasible but requests clear and simple flow-chart. The acceptance by patients and primary physicians is necessary for the implementation of RPM via implantable electronic devices as part of the out-patient HF-care program.

P992

Heart failure risk status and medical management: Insights from the TRIAGE-HF trial.

Medtronic

S A Virani¹; V Sharma²; M Mc Cann²; J Koehler²; B Tsang³; S Zieroth⁴

¹University of British Columbia, Vancouver, Canada; ²Medtronic, Minneapolis, United States of America; ³Southlake Regional Health Centre, Newmarket, Canada; ⁴University of Manitoba, Winnipeg, Canada

Background: TRIAGE-HF was a Canadian prospective observational post-market study to evaluate the performance and clinical usability of the heart failure risk status (HFRS) feature on CareLink. HFRS is a Health Canada approved integrated diagnostic tool. HFRS is based on existing commercially available device diagnostic parameters and is a dynamically updated tool to assess individual patient risk (low, medium or high) of having a heart failure (HF) hospitalization in the next 30 days.

Purpose: One of the TRIAGE-HF study objectives was to correlate HFRS burden with participant's medical management. Since prescription of mineralocorticoid receptor antagonists (MRA) in HF is a marker of advanced disease, we hypothesized that MRA prescription will be associated with less modifiable HFRS scores despite optimal HF care in TRIAGE-HF.

Methods: TRIAGE-HF enrolled 100 patients with systolic HF implanted with a Medtronic high performance device and followed at 3 Canadian HF centers. Study follow-up was up to 8 months. The sum of HFRS scores from 30 days

prior to both the baseline and study exit visits was computed. The data were summarized for each visit (baseline and study exit) by the presence or absence of MRA treatment. All patients included in the analysis received background therapy with beta-blockers and ACE-inhibitors/angiotensin receptor blockers or nitrates/hydralazine. Non-parametric testing was used to compute p-values within and between groups.

Results: 69% of patients remained in the same medication group at study entry and exit. HFRS scores improved over the study period in both groups and this achieved statistical significance in those patients who were not treated with an MRA ($p=0.03$). HFRS scores were higher at study entry and exit in MRA treated patients (see Table 1).

Conclusions: In the TRIAGE-HF study, HFRS was high in both MRA and non-MRA groups at baseline and improved over the study duration. This decrease was large and statistically significant only in the non-MRA group. This may be due to more advanced HF in MRA treated patients, which is more difficult to impact even with optimal HF care.

Table 1: HFRS and MRA Use

				no MRA		MRA		p-value	
Baseline	Mean (SD)	Median (IQR)		1.59 (1.29)	1.25 (0.80-1.76)	1.99 (2.39)	0.99 (0.79-1.87)		0.68
Exit	Mean (SD)	Median(IQR)		1.19 (0.87)	1.07 (0.73-1.41)	1.49 (1.31)	1.08 (0.79-1.49)		0.51
Difference	Mean (SD)	Median (IQR)	p-value	-0.39 (1.51)	-0.13 (-0.60, 0.10)	0.03	-0.49 (2.21)	-0.06 (-0.93, 0.43)	0.60

Correlation between pulmonary pressure and thoracic impedance measured by remote monitoring devices

G Perego¹; G Malfatto¹; A Villani¹; FM Brasca¹; M Oldani¹; E Bressan¹; R Brambilla¹; G Parati²

¹Italian Institute for Auxology IRCCS, Cardiology, Milan, Italy; ²University of Milan-Bicocca, Milan, Italy

Background: The increase in ventricular filling pressures is considered the first event causing acute decompensation in Chronic Heart Failure (CHF). Neurohormonal activation would then take place and, finally, peripheral and pulmonary edema would cause symptoms of overt acute heart failure. Left ventricular filling pressure can be estimated from diastolic Pulmonary Artery Pressure (dPAP) and monitored by means of telemetric sensors; pulmonary congestion is associated to reduction of Thoracic Impedance (TI), which can be monitored remotely by ICDs. The purpose of our study was to investigate the temporal relationship between sustained variations of left ventricular filling pressures and pulmonary congestion.

Methods: 11 CHF patients (Age 71 ± 9 ; EF 27 ± 4 ; NYHAIII) with ICDs measuring TI were implanted with a PAP sensor. TI was measured daily and transmitted automatically every 15 days. PAP was transmitted daily; for three months CHF specialists were blinded to PAP and no medical intervention was guided by PAP. We defined: TI as decreasing and dPAP as increasing, when their value was lower or higher than the average of the previous week; a decrease or increase period when TI or PAP had been decreasing or increasing for three or more days

Results: we received 691 PAP transmissions (compliance 77%). 7 patients suffered from 1.82 ± 2.64 episodes of mild AHF requiring therapy adjustment. There were no hospitalizations. We recorded 35 TI decrease periods and 47 dPAP increase periods. Most (74%) TI decrease periods were "subthreshold", i.e. not associated to impedance alert conditions, according to the algorithms of the ICDs. dPAP increases preceded TI decreases by 6.83 ± 3.1 days. A weak, though significant, correlation between the increase of dPAP and the decrease of TI recorded 7 days later was observed ($R=0.22$; $p<0.001$). The association of 1) increasing PAPd and 2) PAPd absolute value > 22 mmHg was evaluated as a predictor of decrease of TI taking place 7 days later: specificity was 59%, sensitivity 42%, PPV 36%; NPV 65%.

Conclusions: Our observations confirm the strict correlation between filling pressure and pulmonary impedance. dPAP increase is associated TI decrease, occurring about 1 week later, mainly subthreshold, possibly indicating subclinical pulmonary congestion. It can be hypothesized that PAP and TI remote monitoring may be combined for more reliable and timely early detection of impending AHF.

P994

HF-RADD; Early experience of risk monitoring in ambulatory heart failure patients using device-reported parameters

P Black¹; C Cassidy¹; A Seed¹

¹Lancashire Cardiac Centre, Blackpool, United Kingdom

Introduction: The majority of heart failure (HF) risk assessment tools apply models of care based on population studies rather than predicting acute, possibly preventable, events in individuals. A number of variables have been associated with worsening HF. An integrated diagnostic algorithm, considering the combined impact on risk of

a number of such HF variables monitored by implantable cardiac device provides us with opportunity to monitor dynamic risk in individual patients even remotely. It has been shown that a patient at 'high' risk by this algorithm faces nine times the risk of hospitalisation at that time.

Purpose: To consider the feasibility of providing a clinical response for all patients with cardiac device reporting 'high' risk status. To consider the opportunity for intervention and the feasibility of a prospective study of the impact of such intervention.

Methods: The Cardiac rhythm management (CRM) team applied an integrated diagnostics algorithm to HF patient data sent by remote download as part of routine device surveillance. They monitored reported risk. Patients at 'high' risk were referred to the HF team at that point. The HF team reviewed the clinical status of all those patients by telephone. Intervention was offered to those with symptom change. No additional visits were arranged unless indicated in response to condition change. Treatment change was delivered via pacing clinic, specialist HF teams or primary care physicians.

Results: Over 1 year, 762 remote downloads were considered (381 patients, assessed remotely twice/year). 37 patients were monitored by another study and therefore excluded. 22/762 downloads reported 'high risk'. 19/22 patients reported worsening HF symptoms prompting intervention, 13/19 were referred to local HF team, 5/19 to their primary care practitioner, 1 to cardiologist for management of new arrhythmia. 9/19 had resulting medication change. 3/22 patients reviewed by telephone were asymptomatic and therefore had no action.

Conclusion: The Integrated diagnostics algorithm is a means of focusing clinical teams on a patients' current risk of event. It highlights change in condition for which intervention might prevent clinical deterioration, perhaps optimising resource utilisation. We are able to report that only a small proportion of HF patients with device, face such a change at any one time. Specialist response is feasible. In our organisation closer collaboration between CRM and HF teams has been welcomed by both. We have now activated real time device alerts in all patients and are offering clinical review as a 'high alert' is reported. We are collecting data prospectively in order to better describe the reasons for an alert, the opportunity for intervention and with control group are considering the impact of such intervention on outcome. We are expanding the population to include neighbouring HF centres managed by different specialist teams.

P995

Influence of biventricular pacing on clinical status and left ventricular diastolic parameters in patients with preserved ejection fraction after radiofrequency AV node ablation. Case series.

R Roman Marchenko¹; A Kozlov¹; S Durmanov¹; N Makarova¹; O Popilkova¹; V Bazilev¹; R Babukov¹

¹Federal Hospital of Cardiovascular Surgery, Penza, Russian Federation

Introduction: After radiofrequency AV node ablation and implantation of conventional pacemaker some patients present with clinical picture of diastolic heart failure with preserved left ventricular systolic function. We observed several patients with described problem who were undergone upgrade to CRT procedure.

Materials and methods: Three patients with preserved systolic function were included into study (table 1). As the criteria of assessment the following parameters were used: early diastolic myocardial velocity - e' and E/e' ratio. In all patients left ventricular endocardial lead was optimally implanted into lateral left ventricular wall. Follow-up was conducted after 1, 3 and 6 months after the procedure. **Results.** All the patients initially had 100% right ventricular pacing with QRS duration 180-200 msec, signs of left ventricular diastolic dysfunction, which was reflected in delayed early diastolic myocardial velocity and increased E/e' ratio. After CRT upgrade QRS duration decreased by 60-70 msec and was 130-140 msec. In all patients we observed increase of distance of six minute walk test, increased quality of life score. Early diastolic myocardial velocity increased by 1-2 cm/sec, E/e' ratio decreased by 1-3. Ejection fraction increased by 6-8%, left ventricular end diastolic volume decreased by 10-20 ml and remained the same in third patient. Mitral regurgitation degree decreased in 2 patients and did not change in one patient.

Conclusion: CRT upgrade is one of the possible methods of management of left ventricular diastolic dysfunction in patients with implanted conventional pacemaker, clinical picture of heart failure and preserved ejection fraction.

Table 1. Patient data.

Sex	Age, yrs	BMI	EF, %	QRS, msec	Quality of life score	Six minute walk test, meters	Mitral regurgitation
female	66	44	62	180	78	147	moderate
male	69	38	57	200	61	145	moderate
male	66	33	55	200	58	294	moderate

BMI - body mass index, EF - ejection fraction

Optimization of interventricular delay with contrast echocardiography in end-stage heart failure patients with biventricular pacing

D Clemente¹; M Di Mauro¹; A Falcone¹; S Romano¹; M Penco¹; G Tonti¹

¹University of L'Aquila, University of L'Aquila, L'Aquila, Italy

Background: More than 25% of patients with cardiac resynchronization therapy (CRT) are not-responders. By now few is known about features predicting CRT success. In this scenario, the optimization of interventricular delay has not been widely assessed so far, as predicting variable for CRT responding.

Methods: 13 patients with end-stage heart failure on ICD-CRT underwent to contrast echocardiography after a mean time of 4.7 years. During contrast injection interventricular (IV) delay was modified according to following protocol: left ventricular (LV) stimulation was anticipated 20, 40 and 60 msec with respect to right ventricular (RV) stimulation and vice versa. At every modification, 3 cardiac cycles echocardiographic clips were recorded. Then offline analysis of LV vortex was performed using a dedicated software (HyperFlow version 6.2, AMID s.r.l.) to evaluate the best configuration to achieve a physiological flow direction (from basis to apex and then to left ventricular outflow tract). To corroborate our hypothesis we evaluated the patient's quality of life using Kansas City Cardiomyopathy Questionnaire. Pro-BNP was also estimated both before modifying pacing configuration and one month afterwards.

Results: In 5 patients no change of ventricular pacing features were needed. Conversely, in 8 patients IV delay was changed according to offline vortex analysis. We found a decrease in end diastolic ventricular diameters as well as a contractile function an improvement of ejection fraction (EF) (respectively end diastolic left ventricle diameter 65 ± 9 vs 64 ± 7 and EF 30 ± 11 vs 32 ± 8). One month after CRT modification pro-BNP values was significantly reduced (1438 vs 1123 , $p = 0.04$).

Conclusion: This is a pilot study aimed to verify the possible clinical use of intraventricular vortex examination in order to find the best interventricular delay to optimize CRT and increase the rate of responders. A further analysis with a larger cohort of study is mandatory to confirm this initial findings.

P997

Usefulness of cardiac resynchronization therapy in elderly patients: predictors of response at long term follow up

S Briongos Figuero¹; M Cortes²; J Benezet-Mazuecos²; JA Palfy²; A Romero²; A Garcia²; M Lopez²; A Garcia²; R Munoz-Aguilera¹; J Farre²

¹University Hospital Infanta Leonor, Cardiology, Madrid, Spain; ²Foundation Jimenez Diaz, Cardiology, Madrid, Spain

Background: proportion of elderly patients included in studies of cardiac resynchronization therapy (CRT) is low. Therefore response to CRT has not been well studied in this population. We aimed to determine useful predictors of response to CRT in elderly patients (≥ 75 years old).

Methods: A total of 49 patients (mean age 79.2 ± 2.9 years; 79.6% men) undergoing CRT implantation between June 2006 and October 2014 were included. Response was defined if patients met a composite endpoint (alive status, improvement in NYHA class ≥ 1 and no need for HF admission).

Results: At implantation, mean functional class (FC) was 2.4 ± 0.8 , left ventricular ejection fraction (LVEF) was severely impaired (mean 23.4 ± 6.7 %) and left ventricle was severely dilated (mean end diastolic diameter 60.4 ± 6.6 mm). Heart failure was due to non-ischemic cardiomyopathy in 25 patients. Population was under optimal medical treatment (Beta blockers: 87.5%; ACEI (angiotensin-converting enzyme inhibitors)/ARB (angiotensin II receptor blockers): $64.6/27.1$ % respectively and aldosterone antagonists: 68.8%). Left bundle branch block (LBBB) was present in 67.3% of the overall population, and mean QRS duration was of 155.4 ± 25 ms. After 37.1 months of follow-up, 68% of patients remained alive and both average FC (2.1 ± 0.9) and LVEF (30.8 ± 13.7 %) were improved. A total of 17 patients (35.4%) met the clinical endpoint. Response to CRT was more frequently observed in more symptomatic patients (mean FC in responders 2.7 ± 0.4 Vs 2.3 ± 0.7 in non-responders; $p = 0.049$) and in those with LBBB ($p < 0.005$). After multivariable analysis, both functional class (HR 3.4; 95% CI 1.02-11.45) and LBBB (HR 8.5; 95% CI 1.03-70.10) emerged as predictors of clinical response in elderly patients.

Conclusion: response to CRT was seen in 35.4% of elderly patients (≥ 75 years), which is slightly less than in general population. Two reliable predictors of positive

response emerged: poorer functional class and LBBB were found to be useful markers after long-term follow up. These factors can be used to select those elderly candidates to CRT more suitable to obtain a positive response.

P998

real world on CRT in a colombian heart failure clinic

C I Clara Ines Saldarriaga¹; C Gallego²; C Gonzalez²; C Delgado²; E Canas²

¹Cardiovascular Clinic Santa Maria, University of Antioquia cardiology department, Medellin, Colombia; ²Cardiovascular Clinic Santa Maria, universidad pontificia bolivariana, Medellin, Colombia

Cardiac resynchronization therapy has been shown to improve outcomes in heart failure. Patients enrolled in clinical trials are highly selected and do not represent the real-life scenario.

Objective: To evaluate the response to resynchronization therapy in NYHA class, echocardiographic criteria, hospitalizations and survival after 6 months follow-up.

Methods: Retrospective observational analytical cohort.

Results: 96 patients were included, 59.4% were male, 31.3% of patients had non-ischemic and 68.8% ischemic heart disease. The mean ejection fraction was $18.9\% \pm 7.1\%$. The functional class before the implant was: NYHA I 4.2%, NYHA II 31.3%, NYHA III 52.1% and NYHA IV 12.5%. 90.6% had left bundle branch block on with a QRS of $152\text{ms} \pm 21.4\text{ms}$. There were no cases of death or cardiac transplantation at six months, 53.1% of the patients were free of hospitalizations after implant, 62.5% improved the NYHA class, the mean ejection fraction improvement was $29.2\% \pm 13.6\%$ and 22.9% decreased ventricular diameters.

Conclusions: response to cardiac resynchronization therapy in our real life scenario is closer to reported in literature, mainly in the improvement of NYHA and the number of hospitalizations. All patients with CRT must be followed in a heart failure clinic to get the best results of this therapy.

P999

The correlation between six minute walking test distance and noninvasive cardiac output measurements before and after cardiac resynchronization therapy optimization

S Serkan Yukse¹; M Yenercag¹; M Coksevim¹; O O Seker¹; O Yilmaz¹; M Sahin¹

¹Ondokuz Mayıs University, Faculty of Medicine, Department of Cardiology, Kurupelit-Samsun, Turkey

Background: Optimization is performed in patients unresponsive to cardiac resynchronization treatment (CRT) to increase the effectiveness of treatment. Six minutes walking test (SMWT) is a practical test and commonly used test to evaluate the clinical response to optimization. CRT devices are programmed to achieve the highest cardiac output during optimization by echocardiography and other methods as well. In this study; we aimed to compare the relationship between SMWT distance and cardiac output values measured by different methods before and after CRT optimization.

Methods: Fifty non-responder patients were enrolled in the study. Patients were divided into two groups. In group 1, cardiac output values were measured by non-invasive cardiac output measurement (NICOM) device and optimizations were performed. In group 2, cardiac output measurement and optimization were performed by conventional echocardiographic methods. Both groups performed SMWT before and after optimization and the correlation between cardiac output values and SMWT distance were investigated.

Results: After the optimization, SMWT distances revealed significant increase in both groups (244 ± 62 m vs. 254 ± 61 m and 235 ± 39 m vs. 261 ± 5 m, $p < 0.05$). In Group 1, pre-optimization SMWT distance and cardiac output values showed moderately positive significant correlation ($r = 0.460$, $p = 0.021$). In this group, postoptimization values again showed a good positive significant correlation ($r = 0.557$, $p = 0.004$). In Group 2, no significant correlation was observed in SMWT distances and cardiac output values before and after optimization ($r = 0.094$ vs. $r = 0.347$, $p > 0.05$).

Conclusion: Results of this study showed that NICOM based cardiac output measurement and optimization is practical, reliable and not operator dependent

method compared to echocardiography. Additionally, cardiac output values measured by NICOM device showed stronger correlations with SMWT distances. Therefore NICOM method can be used as an alternative for CRT optimization in selected patients.

P1000

Galectin 3 predicts improvement in LV volumes after Cardiac Resynchronisation Therapy

SJ Chua¹; C Ajaero¹; B Assadi-Khansari¹; A McGavigan²; JD Horowitz¹; DT Ngo¹; AL Sverdllov¹

¹University of Adelaide, Queen Elizabeth Hospital, Adelaide, Australia; ²Flinders Medical Centre and Flinders University, Cardiology, Adelaide, Australia

Background/Introduction: Cardiac Resynchronisation Therapy (CRT) is commonly used in the management of patients with chronic systolic heart failure (CHF). However, up to 30-50% patients with severe CHF who receive CRT derive no benefit. The exact mechanisms underlying this phenomenon are poorly understood and there are no well-established biomarkers to predict the response to CRT. It has been suggested that fibrosis, as occurs in most forms of CHF, may play a role in determining the response to CRT. Galectin 3 is a soluble β -galactoside-binding lectin that has regulatory roles in fibrosis, inflammation and tissue repair. Several recent clinical studies have reported an association between circulating galectin 3 levels and cardiac remodeling as well as adverse clinical outcomes in patients with CHF. However, the association between baseline galectin 3 levels and response to CRT in severe CHF has not been established.

Purpose: To investigate the relationship between baseline plasma galectin 3 levels and physical performance and reverse remodeling in patients undergoing CRT implantation.

Methods: 28 patients (aged 71.2 ± 9.4) with predominantly severe CHF (70% NYHA class III or IV) and planned CRT irrespective of the aetiology of heart failure were studied. Transthoracic echocardiogram (TTE), 6-minute walk test (6MWT), maximum oxygen uptake (VO₂ max) and blood collection for routine biochemistry, NT pro-BNP and galectin 3 levels were performed prior to and 6 months post-CRT implantation. Galectin 3 levels were assayed with commercially available ELISA kits. Univariate analyses were performed to investigate the relationship between the measures of physical performance (6MWT and VO₂ max), echocardiographic measures of response to CRT (LVESV and LVEDV) and baseline galectin 3 levels. Multivariate analyses were then performed to establish the independent baseline predictors of these parameters.

Results: On univariate analyses, baseline galectin 3 levels were inversely correlated with baseline and end-of-study 6MWT ($p = 0.002$), VO₂ max ($p = 0.003$) and improvement in LVESV ($p = 0.01$) and LVEDV ($p = 0.02$). On multivariate analyses, galectin 3 remained the only independent predictor of the improvements in LVESV ($p = 0.015$) and LVEDV ($p = 0.02$), while galectin 3 ($p = 0.03$) and NYHA class ($p = 0.01$) were independent predictors of baseline VO₂ max after adjustment for age, gender, NT pro-BNP and NYHA class.

Conclusion: Plasma galectin 3 levels predict poor baseline status and are the inverse predictor of response to CRT implantation in patients with severe symptomatic CHF. Thus, galectin 3 is a promising biomarker of physical performance and response to CRT, potentially being a surrogate for myocardial fibrosis.

CRT survey II

C Camilla Normand¹; K Dickstein¹; C Linde²; G Hindricks³; A Auricchio⁴; C Stellbrink⁵; G Filippatos⁶; J Cleland⁷; F Ruschitzka⁸; N Bogale¹

¹Stavanger University Hospital, Cardiology, Stavanger, Norway; ²Karolinska University Hospital, Cardiology, Stockholm, Sweden; ³Leipzig University Hospital, Cardiology, Leipzig, Germany; ⁴Cardiocentro Ticino, Cardiology, Lugano, Switzerland; ⁵Bielefeld Hospital, Cardiology, Bielefeld, Germany; ⁶University of Athens, Cardiology, Athens, Greece; ⁷Imperial College London, Cardiology, London, United Kingdom; ⁸University Hospital Zurich, Cardiology, Zurich, Switzerland

Background/Introduction: CRT reduces mortality and morbidity in patients with heart failure with electrical dyssynchrony and therefore receives strong recommendations in current guidelines. However, despite these recommendations and the expanding indications for CRT, the increase in the rate of CRT has been modest across Europe. Therefore, actions to increase the awareness of the indications for CRT as well as to increase both the quality and level of care for follow-up over EHRA countries are needed.

Purpose: The two ESC associations, EHRA and HFA have designed the CRT Survey II, which is an 8 month snapshot Survey created to describe clinical practice regarding implantation of CRT devices in a broad sample of hospitals in ESC member countries. It should reflect changes in clinical practice due to the substantial modifications in ESC device guideline recommendations by both the HFA and EHRA Methods Patients enrolled are both those with new implantations of a CRT-P/CRT-D and upgrades. There is a one-time, site description questionnaire completed by each site. This information gathered by this questionnaire describes the organisation of

the device programme for each site and provides information useful for assessing health resource utilisation. The second and patient related electronic case report form (eCRF) is completed at each enrolment. This eCRF includes patient demographics, aetiology of heart failure, pharmacological therapy, ECG morphology and QRS duration, indication for CRT implantation, procedural details, complications, discharge status, and follow-up plans. CRT Survey II began collecting data on 1st October 2015, is currently operating in > 40 countries and should complete data collection by June 2016. Conclusion This pan-European Survey hosted by two ESC Associations will collect essential data permitting national and international benchmarking of clinical practice with regard to CRT. The data collected should provide information relevant for assessing healthcare resource utilisation, help to identify the major obstacles to implementation of CRT therapy and thus create a basis for enhancement of therapy access. Ultimately, we hope that the results will serve to increase CRT implementation for appropriate heart failure patients in Europe.

DISEASE MANAGEMENT PROGRAMMES

P1002

Acute heart failure in three disease management programs, retrospective study in colombia

Novartis Colombia S.A.

C I Clara Ines Saldarriaga¹; C Plata²; A Buitrago³; E Karpf⁴; G Montoya⁴; M Quijano⁴; E Salguero⁵; T Lozano⁵

¹Cardiovascular Clinic Santa Maria, University of Antioquia cardiology department, Medellin, Colombia; ²Dime clinica neurocardiovascular, Heart failure, Cali, Colombia; ³Fundacion Santa Fe de Bogota, heart failure, Bogota, Colombia; ⁴Novartis de Colombia S.A, Pharmacoeconomy, Bogota, Colombia; ⁵Consultores SAS, research, information and quality, bogota, Colombia

Introduction: Acute heart failure is a major public health problem. However, there is little information on the clinical characteristics, management patterns and outcomes of patients with acute heart failure (AHF) in Latin America.

Purpose: To describe the demographics, clinical profile, comorbidity, treatment, use of resources in hospitalization, and mortality in a population of AHF patients treated in three Colombian institutions with comprehensive disease management programs from 2012 to 2014.

Methods: A retrospective descriptive study in which medical records were reviewed. The information was consolidated using a standard software tool, and analyzed by basic central tendency statistical measures

Results: The results are presented based on the sample size (n) for each of the variables. Demographics: 408 patients, 181 women, 227 men, age (67 ± 16 years). Clinical Profile: reduced function 79% (n=330), preserved function 21% (n=330), etiology of heart failure: n=288 [ischemic 45%, valvular 19%, non-ischemic dilated 7%, hypertrophic 2%, chagasic 1%, others 72%], blood pressure n=407 [systolic 122 ± 22 mmHg, diastolic 72 ± 14 mmHg], heart rate 79 ± 21 (n=407), main NYHA at the time of admission 57% NYHA III (n=260), main NYHA upon discharge 53% NYHA II (n=171), LVEF 36.4 ± 17.7 (n=393), creatinine 1.4 ± 1.4 mg/dl (n=384), BUN 32.1 ± 17.2 (n=193), BNP 2366.4 ± 5546.5 (n=181), positive troponin 25% (n=150). Comorbidity: hypertension 65% (n=392), diabetes 64% (n=408), coronary artery disease 37% (n=406), atrial fibrillation, 26% (n=337), anemia 23% (n=314), chronic kidney failure 19% (n=200), COPD 18% (n=403), stroke 9% (n=269), previous hospitalization for AHF 48% (n=266). Treatment: ACE inhibitors 23% (n=383), ARB 36% (n=381), beta blockers 52% (n=383), diuretics 53% (n=314), digitalis 5% (n=314). In-hospital treatment: Inotropes [levosimendan 7% (n=408), dobutamine 6% (n=325), milrinone 3% (n=326)] Vasopressors n=326 [dopamine 3%, norepinephrine 18%] Diuretics [IV 48% (n=318), PO 47% (n=198)]. Use of resources: hospital bed days 11 ± 16 (n=268), ICU days ± 8 (n=268). Mortality: General death 11% (n=189), cardiovascular death 13% (n=182).

Conclusions: The study population is a high-risk population with a high profile of comorbidities, with an elevation of biomarkers and advanced functional class. However, hospital stay, ICU stay and mortality are similar to those reported in the literature. These data suggest that the comprehensive treatment right from the acute phase of decompensation promotes a proper use of resources and an optimum management in accordance with the guidelines.

P1003

In patients with systolic dysfunction, what does being young imply?

V Veronica Angela Rial Baston¹; R Dalmáu Gonzalez-Gallarza¹; A Castro Conde¹; P Meras Colunga¹; FJ Irazusta Cordoba¹; O Gonzalez Fernandez¹; AM Iniesta Manjavacas¹; CA Alvarez Ortega¹; Z Blazquez Bermejo¹; JL Lopez-Sendon¹

¹University Hospital La Paz, Cardiology, Madrid, Spain

Background and objectives: Patients (P) with systolic dysfunction benefit from close monitoring, such as that provided in cardiac rehabilitation programs (CRP). We aimed to determine whether age influences their results or their efficacy.

Methods: We studied a cohort of 509 P. with low ejection fraction (EF) (EF < 51%) referred to a CRP between 2006 and 2014. The reason for inclusion was a recent

acute coronary syndrome (93.6%) or heart failure (4.8%). EF was calculated using the Simpson method at the beginning of the program and before the end of it. Functional status was evaluated with a treadmill exercise test. The CRP lasted for six weeks and included supervised exercise training twice a week. According to the age, P. were classified in two groups: P. under the age of 50 (n=378, 74.3%) and P. over 50 (n=131, 25.7%). We compared their baseline characteristics, functional status improvement and achievement of program's targets.

Results: Mean age was 42.76 years (range: 29-49) and 62.98 (range: 50-86) respectively; 88.6% (451 P) were male. Hypertension (53.7% vs 32.1%, $p < 0.01$) and diabetes (27.3% vs 16.9%, $p = 0.018$) were more prevalent in the over-50 group, whereas smoking was more frequent among young P. (45.6% vs 79.4%, $p < 0.01$). There were not significant differences in the prevalence of dyslipidemia or obesity. The rates of prescription of ACE inhibitors (80.9% vs 81.9%, $p = 0.81$), betablockers (94.1% vs 96.1%, $p = 0.40$), aldosterone antagonists (51.1% vs 55.1%, $p = 0.43$) or ivabradine (8.9% vs 10.2%, $p = 0.65$) did not differ between both groups, although there is a trend toward a more common use of diuretics in older P. (17.7% vs 11%, $p = 0.075$). Considering only P. with moderate or severe systolic dysfunction (EF $< 40\%$), young P. showed better functional status (9.19 vs 11.40 METs, $p < 0.01$) and greater exercise capacity increase during the CRP (3.22 vs 3.88 METs increment, $p = 0.05$), despite no significant differences were found in EF improvement (11.70% vs 12.41% increase, $p = 0.632$). Targets were achieved in the same proportion in both groups: HbA1c $< 7\%$ (72.7% vs 72.2%, $p = 0.96$), LDL < 70 mg/dL (50.8% vs 45.2%, $p = 0.44$), smoking cessation (82.1% vs 77.4%, $p = 0.37$) and abdominal perimeter (96.99 cm vs 98.89 cm, $p = 0.16$).

Conclusion: Although age does not influence medical treatment or goals of a CRP, young P. with systolic dysfunction represent a group of growing importance who get the maximal benefit from these programs thanks to a greater improvement in functional status. Moreover, a long-standing correction of young patients' lifestyle is mandatory in order to improve their outcomes.

P1004

The impact of the multidisciplinary team approach on early mortality and acute cellular rejection after heart transplantation

R Hulin¹; M Schmidhauser¹; J Regamey¹; N Pilon²; M Pascual²; S Rotman³; C Banfi⁴; P Tozzi⁵; P Meyer⁶; JP Antonietti⁷

¹University Hospital Centre Vaudois (CHUV), Department of Medicine, Cardiology, Lausanne, Switzerland; ²University Hospital Centre Vaudois (CHUV), Centre de Transplantation d'Organes, Lausanne, Switzerland; ³University Hospital Centre Vaudois (CHUV), Pathology, Lausanne, Switzerland; ⁴Geneva University Hospitals, Cardiac Surgery, Geneva, Switzerland; ⁵University Hospital Centre Vaudois (CHUV), Department of Cardiac Surgery, Lausanne, Switzerland; ⁶Geneva University Hospitals, Department of Cardiology, Geneva, Switzerland; ⁷University of Lausanne, Lausanne, Switzerland

Background: In 2008, the University Hospital of Lausanne established the multi-disciplinary Heart Transplantation (HTx) team to improve quality of respective pre- and postoperative care. This study investigates its impact on mortality and morbidity early post-transplant. Methods and

Results: A total of 140 patients underwent HTx between 2000-8/2014 with 66 patients operated between 2000-2007 and 74 thereafter. Mean age was 53.5 years (IQR 47.3-59.8 years), 80% were males, donor/recipient gender mismatch was 38.3%, length of in-hospital stay was 34 days (IQR 26-61 days), donor age was 41 years (IQR 26-51 years); characteristics were not different between groups. In HTx recipients of 2008-2014, dilated cardiomyopathy of non-ischemic origin was less prevalent (43.2 vs 63.6%; $p = 0.024$), assist device treatment was more frequent (24.3 vs. 9.1%; $p = 0.030$). Cardiovascular risk factors, burden of comorbidity, and baseline hemodynamic, clinical, and echocardiographic parameters were not different between groups. In-hospital and 1-year all-cause mortality (ACM) was lower in HTx recipients of 2008-2014 (22.2 vs. 16.2%; 25.8% to 18.9%, respectively; $p = 0.4711/0.4708$). Diabetes mellitus was a predictor of in-hospital and 1-year ACM in patients operated 2000-2007, acute cellular rejection (ACR) of \geq moderate grade was associated with in-hospital mortality in 2000-2007 but not in 2008-2014; mean individual grade of ACR was lower in 2008-2014 (0.2 vs. 0.65; $p < 0.0001$).

Conclusion: The multidisciplinary HTx team approach increased the number of HTx recipients and increased quality of care in HTx with a lower mean ACR grade within the first year post-transplant, improved treatment of risk factors, and non-significant decrease of in-hospital and 1-year ACM.

P1005

Coding of acute decompensated heart failure admissions and patient enrolment in a disease management programme

C Casey¹; B Travers²; R O Hanlon²; K McDonald²

¹St Vincent's University Hospital, Cardiology Department, Dublin, Ireland; ²Heart Failure Unit, St. Michael's Hospital, Dun Laoghaire, Dublin, Ireland

Background: Acute decompensated heart failure (ADHF) contributes to about 5% of all emergency hospital admissions and 27% of the total cost of all hospitalisations.

Disease management programmes are well established as the optimal management strategy for patients discharged following an acute decompensation of heart failure. Coded hospital discharge data is an important information source for research and health planning services.

Purpose: We sought to evaluate all admissions coded as ADHF- to assess how many of these patients were enrolled in a heart failure disease management programme (DMP) and to look at reasons for not enrolling patients. We also sought to identify any coding errors.

Methods: We obtained a list of all admissions to an acute tertiary hospital coded as a primary diagnosis of ADHF for a four month period. We then compared this to a list of ADHF patients identified and followed by our heart failure unit from the same hospital and same time period. We reviewed the medical records of the patients that were "missed"- i.e. not followed by our heart failure unit and investigated into the reasons for same.

Results: A total of 95 patients were coded as having a primary diagnosis of ADHF. Of these 62% were enrolled in a DMP. The reasons for not enrolling were: 1. Incorrect coding- a total of 7.37% were inappropriately coded as primary ADHF admissions although the admission was unrelated to ADHF 2. RIP on admission 3. Patients were dialysis dependent 4. Geographical- living too far from the heart failure unit 5. Heart failure was a secondary rather than primary diagnosis 6. Not referred to the heart failure team 7. Significant comorbidity or poor compliance impacting on ability to engage with the programme A further 6 patients were identified as having had an admission with primary ADHF during that period and not coded as same.

Conclusions: This highlights the level of inappropriate coding of hospital admissions which can lead to an inaccurate estimation of the burden of ADHF admissions and unreliable calculation of length of stay for ADHF admissions. It also gives insight into the activity of the heart failure unit and the patients most appropriate for a disease management programme.

P1006

Heart failure patient post discharge follow up by phone calls by nurse call center 24/7/365

N Nekane Murga Lizagaachevarria¹; A Azcona Lucio¹; R Roca Castro²; S Resino Santamaria¹; A Lozano Bahamonte¹; B Gomez Bravo³; P Castro Arroyo¹; A Laskibar Asua¹; G Fernandez Penalba¹

¹Hospital de Basurto, Bilbao, Spain; ²Osakidetza, Consejo Sanitario, Bilbao, Spain; ³Osakidetza, Osarean, Bilbao, Spain

Purpose: Since June 2013 the hospital guidelines at discharge in Heart Failure (HF) patients include a 72h follow up phone call and an appointment within the next 8-10 days at their GP's clinics. We try to evaluate the utility of the phone call in detecting patients' care needs and early signs of decompensation. Method The phone call is carried out by a pool of nurses in a call centre working 24/7. This call centre has the ability to arrange and modify appointments with GP's and/or community nurses according to the results obtained in that phone call. These appointments can be scheduled at patient's homes, avoiding the need to travel depending on the patient situation. The 72h follow up phone call allows nurses to registrar the results in the patient's notes (electronic health record), information which can be accessed and shared by GP's and also Dr's in the hospital setting. These nurses know the medication the patient is on. This 72h phone call consists on 8 questions which depending on the answer given will determine different actions, as per protocol. • Correct answers: Advice regarding, diet, exercise, weight and indications to take the medications prescribed correctly. • Adherence or knowledge problems: New appointment with the Nurses in the community to see the patient in their homes in the next 24-48h. • Symptoms or drug side effects: Nurses arrange an appointment with their GP's to see the patient in their homes in the next 24-48h. • Severe symptoms of Congestive Heart Failure: Nurses will contact emergency services. Nurses also remind the patient of their next scheduled appointment to see their GPs.

Results: Average age 80 years of age and 48% were women. 60% of patients with preserved ejection fraction. We have performed 600 phone calls: 35% generated an appointment with their nurses in community as aspects of adherence to treatment and self caring habits needed reinforcing. 22% required an early appointment with their GP due to medication side effects or weight gain. 9% required emergency services due to dyspnea at rest or temperature and no specific actions were performed after 32% call phones.

Conclusions: Problems related to adherence to treatment were the ones that generated most alarms. The 72h follow up phone call helps us to improve patient adherence after discharge. This 72h follow up phone call guideline allows us to detect early warning signs of decompensation in HF and signs of the no compliance of their treatment and as a result, schedule early appointments with their Dr's or activate emergency services upon severity of symptoms.

P1007

Verification of guidelines-adherent medical therapy in patients with sinus rhythm hospitalised due to worsening of heart failure

Y Lopatin¹; A Grebennikova¹; H Sisakian²; H Hayrapetyan³; Z Pagava⁴; A Chesnikova⁵; N Koziolova⁶; T Abdullaev⁷; S Berkinbayev⁸; A Rakisheva⁹

¹Volgograd State Medical University, Volgograd Regional Cardiology Centre, Volgograd, Russian Federation; ²Yerevan State Medical University Hospital 1: University Cardiology Clinic, Yerevan, Armenia; ³Erebouni Medical Center, Yerevan, Armenia; ⁴Tbilisi State Medical University (TSMU), Tbilisi, Georgia Republic of; ⁵Rostov State Medical University, Rostov-on-Don, Russian Federation; ⁶Perm State Medical Academy, Perm, Russian Federation; ⁷Specialized Cardiology Center of the Republic of Uzbekistan, Tashkent, Uzbekistan; ⁸Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan

Background: Hospitalization of patients with heart failure (HF) is a good opportunity to re-evaluate patient care including optimizing present and planning future management. The aim of our study was to analyze medical management in patients with sinus rhythm hospitalized due to worsening of HF, who were included in an ongoing Optimize Heart Failure Care program.

Methods: The Optimize Heart Failure Care program is an international, multi-center patient support program based on pre-discharge patient education, pre- and post-discharge check-lists over a period of 12 months. This analysis included data collected over 3 months from 317 patients (mean age 62.9 ± 0.6 years, 70% male) with sinus rhythm hospitalized due to worsening of HF, NYHA II-IV (mean 2.81 ± 0.03), left ventricular ejection fraction (LVEF) $<40\%$ (mean $31.1 \pm 0.5\%$), mean systolic/diastolic blood pressure $128.6 \pm 1.3/80.8 \pm 0.7$ mm Hg and mean heart rate (HR) 85.1 ± 1.0 bpm.

Results: The prescription rate of angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs), beta-blockers (BBs) and mineralocorticoid receptor antagonists (MRAs) before discharge from hospital were 92.4%, 82.6% and 90.5%, respectively. Diuretics and digoxin were recommended in 98.8% and 17.7% of patients with HF, respectively. However, despite high baseline HR, ivabradine was prescribed in 25.5% of patients with HF only. Interestingly, baseline HR in this group of patients was significantly higher than in patients who did not receive ivabradine (91.2 ± 1.7 bpm vs. 83.4 ± 0.9 bpm, $p < 0.05$). There were no differences in terms of age, sex, NYHA functional class, LVEF between the groups of patients receiving and not receiving ivabradine. Thus, ivabradine was prescribed in patients with excessively high HR only. On the other hand, ivabradine therapy was characterized not only with good safety, but also with a significant reduction of the rate of repeated hospitalizations after 3 months of follow-up (3.7% versus 17.7% in patients without ivabradine therapy, $p < 0.05$).

Conclusion: Despite the high adherence among cardiologists to prescribing neurohumoral antagonists and diuretics in patients hospitalized due to worsening of HF, additional efforts are needed in order to improve the adherence to HR lowering therapy with ivabradine.

P1008

NT-proBNP guided care versus standard care for heart failure in outpatient setting

A Kisko¹; L. Dernerova¹; N. Kishko²; L. Frajtova³

¹University in Presov, Faculty of Health Care, Presov, Slovak Republic; ²Sekcov Polyclinic, Presov, Slovak Republic; ³Reiman Faculty Hospital with Polyclinic, Heart Centre, Presov, Slovak Republic

It remains unclear whether treating chronic heart failure (HF) in outpatient setting based on the follow-up with serial NT-proBNP evaluation would be associated with better outcomes compared to standard follow-up alone. The goal of the study was to evaluate whether patients (pts) with HF would benefit from NT-proBNP guided care (GC), compared to standard care (SC) with LVEF but not NT-proBNP serial controls in outpatient setting. In a prospective single-centre trial, 186 subjects (age: 63 ± 12 years, man/female: 90/96, LVEF: $<40\%$, mean $29 \pm 10\%$) with NYHA class II-IV due to left ventricular systolic dysfunction were randomized 1:1 to receive SC for HF or GC (NT-proBNP evaluation on regular basis at each visit) with a goal of keeping pts compensated longer reducing numbers of hospitalizations and lowering the biomarker plasma levels. The primary endpoint was total hospitalization events in both groups compared using generalized estimating equations. Secondary endpoints included effects of the each type of care on LVEF and NT-proBNP levels at the end of follow-up. Echocardiographer making the assessment of LVEF was blinded of NT-proBNP levels.

Through a mean follow-up period of 18 ± 2 months, GC significantly improved hospitalization-free survival compared with SC (68 events vs. 110 events, HR = 0.71; 95% CI 0.55–0.98; $P = 0.04$). Kaplan-Meier curves demonstrated significant differences in time to first hospitalization event, favouring GC ($p = 0.02$). No age and sex interactions were found, with elderly pts (age ≥ 65) benefitting similarly from GC as younger subjects (age <65). Although there was no significant difference in LVEF improvement at the end of follow-up in both groups neither in interaction ($32 \pm 8\%$ in SC group, $p = 0.2$ vs. $36 \pm 9\%$ in GC group, $p = 0.3$, interaction $p = 0.5$), the mean NT-proBNP levels, achieved at the end of follow-up period in GC group were significantly lower against those in SC group ($1,254 \pm 480$ ng/l vs $3,824 \pm 560$ ng/l, $p = 0.01$).

NT-proBNP-guided therapy can improve long-term hospitalization-free survival of HF pts versus standard therapy in outpatient setting. Possibly, this attributes to on time and appropriately intensified complex HF medication based on the dynamic changes in serial NT-proBNP measurements. It argues, that individually tailored and

targeted, but not "blind" due to symptoms or LVEF results carpet bombing with drugs, approach is appropriate for HF pts in outpatient setting.

DRUG THERAPY, OTHER

Efficacy of trimetazidine on functional capacity in symptomatic patients with moderately reduced or left ventricular dysfunction and CAD: a subgroup analysis of the VASCO trial

C Vitale¹; I. Spoletini¹; W. Malorni¹; P. Perrone-Filardi²; G. M. C. Giuseppe M. C. Rosano¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy; ²Federico II University Hospital, Naples, Italy

Trimetazidine (TMZ) is a metabolic agent of proven efficacy in improving functional capacity in patients with angina, in monotherapy or combined with beta-blockers. VASCO was a 12-week multicentre randomised double-blind controlled trial aimed to assess the anti-anginal efficacy and safety of modified-release TMZ (TMZ 70 mg/d, TMZ 140 mg/d) on top of background therapy with beta-blockers in patients with coronary heart disease. The trial demonstrated that TMZ is effective in improving total exercise duration (TED) measured by the treadmill exercise stress test (ETT) in symptomatic angina patients. Therefore, we conducted a retrospective subgroup analysis of the VASCO trial, aimed at further investigating the efficacy of the two doses of TMZ on TED and time to 1-mm ST segment depression (T1), in the subgroup of symptomatic patients with moderately reduced or impaired left ventricular function. TED significantly increased both in the group allocated to TMZ 140 mg/d than placebo ($p = 0.004$), and in the group allocated to TMZ 70 mg/d than placebo ($p = 0.01$). These improvements were dose-dependent with a greater TED variation observed in TMZ 140 mg/d than in TMZ 70 mg/d. In conclusion this post-hoc analysis of the VASCO study confirms the effectiveness of TMZ in improving exercise capacity in patients with moderately impaired and in patients with left ventricular dysfunction and coronary artery disease.

P1010

Pharmacological treatment of chronic heart failure during cardiac resynchronization therapy

J. Laukaitiene¹; A. Krivickiene¹; D. Rinkuniene¹

¹Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: Cardiac resynchronization therapy (CRT) is associated with improved morbidity and mortality in patients with chronic heart failure (HF). Optimal medical therapy also plays an important role for CHF patients prognosis and quality of life.

Purpose: To evaluate pharmacological treatment changes of HF patients during 1-year follow-up of CRT.

Methods: We evaluated 85 consecutive HF patients pharmacological treatment during 1-year follow-up of CRT. Medication consumption data were assessed before CRT, at the time of hospital discharge following CRT implantation and 1-year follow-up visit. Statistical analysis was performed using SPSS version 21.0.

Results: Beta-blockers were used in 81.2% of patients before CRT, consumption increased after CRT implantation (96.5% at 1-year follow-up visit) ($p < 0.002$). Angiotensin-converting enzyme inhibitors (ACEI) or angiotensin receptor blockers (ARB) consumption and dose didn't change statistically significant during study. The average dose of spironolactone changed statistically significant comparing spironolactone dose before CRT with the discharge from the hospital period ($p = 0.02$). The use of diuretics was significantly higher after CRT device implantation, compared with period before CRT from 62.4% to 84.7% - at discharge and at 1-year follow-up visit ($p < 0.001$), but doses of torsemide hasn't changed statistically significant, comparing the period before CRT with both, hospital discharge ($p = 0.5$) and 1-year follow-up periods ($p = 0.8$). Cardiovascular medications consumption was significantly lower before CRT 4.6 ± 2.1 , compared with discharge 5.6 ± 1.8 ($p < 0.001$) and follow-up 5.5 ± 1.8 ($p < 0.001$) periods.

Conclusions:

1. Beta-blockers, ACEI and diuretics were the most frequently used medications.
2. Beta-blockers consumption increased after CRT implantation.
3. The use of diuretics was significantly higher after CRT device implantation, but average dose of the loop diuretic after CRT remained almost the same.
4. Cardiovascular medications consumption was significantly lower before CRT.

P1011

Effect of levosimendan on left and right ventricular function in patients with acute and chronic heart failure: a review of echocardiographic studies

FM Righini¹; D. Menci¹; M. Losito¹; R. Navarri¹; M. Cameli¹; R. Favilli¹; S. Mondillo¹; S. Lunghetti¹

¹University of Siena, Department of Cardiovascular Diseases, Siena, Italy

Background: Levosimendan infusion induces a rapid improvement in haemodynamic parameters in patients with congestive heart failure (HF) with maximal effects occurring 1-3 days after starting the infusion, but the effects are sustained for up to at least a week, thanks to its long-lived metabolite, OR-1896. According to the recent ESC guidelines, i.v. infusion of levosimendan may be considered to reverse the effect of beta-blockade if beta-blockade is thought to be contributing to hypoperfusion (Class IIb, Level of Evidence C). In the recent literature, there has been interest in the use of i.v. levosimendan in chronic advanced HF, also for planned repetitive use to potentially avoid acute decompensation and frequent rehospitalisation.

Purpose: To summarize current knowledge on the effects of levosimendan therapy on the echocardiographic indexes of systolic and diastolic left ventricular (LV) and right ventricular (RV) function and to present future prospects for the effects of this drug on myocardial deformation studied by a newer echocardiographic technique of speckle tracking echocardiography (STE).

Methods: We reviewed all the previous studies published so far about the effects of levosimendan in patients with acute and chronic heart failure on echocardiographic parameters of systolic and diastolic biventricular functions.

Results: Echocardiographic studies have shown improved LV and RV systolic and diastolic function in HF; levosimendan therapy produced beneficial effects via the improvements in left ventricle ejection fraction (LVEF), mitral annular plane systolic excursion (MAPSE), the E/A ratio, early diastolic transmitral flow peak wave/early diastolic tissue Doppler velocity (E/e') ratio, LV wall stress and left atrial performance.

Conclusion: Levosimendan has shown positive effects in a range of conditions requiring inotropic support, not only on LV impairment but also on RV dysfunction which often complicates advanced LV HF.

Two drugs comparison of bisoprolol in efficiency influence on the heart rate from a position of pharmacoeconomics

El Tarlovskaya¹; T Chudinovskikh²

¹Nizhny Novgorod State Medical Academy, internal Medicine, Nizhny Novgorod, Russian Federation; ²Kirov State Medical Academy, Kirov, Russian Federation

Objective: To compare the efficiency of two drugs bisoprolol (original and generic) on the effects on heart rate (HR). To perform clinical and economic analysis with using the method of "cost-effectiveness" (CER).

Materials and methods: 60 patients with coronary artery disease (CAD) were studied. Patients of group A received the original bisoprolol, patients in group B - generic. All patients were matched for baseline dates ($p > 0.05$). Treatment correction was performed on the 3rd and 14th day. Target HR was considered as 60 b.p.m or less. Ivabradine (Coraxan, Servier, France) was administrated to main therapy in the cases of target HR absence and there was not opportunity to increase the dose of beta-blockers (BAB). BAB dose was picked individually with focusing on HR, blood pressure level, tolerance and efficacy. HR was evaluated on electrocardiogram at baseline and after 6 weeks therapy. Cost/efficiency was calculated as $CER = DC/Ef$, where CER is cost-effectiveness result; DC - direct costs; Ef- therapy efficiency.

Results: Significant HR reduction ($p < 0.05$) was in both groups by 6 therapy weeks. However, it was found that the original bisoprolol decreases HR more significantly in comparison with the generic in assessing the degree of HR ($\Delta\%$ HR). In group A $\Delta\%$ HR was $16.55 \pm 7.55\%$, in group B $12.5 \pm 7.5\%$ ($p < 0.05$). Ivabradine was administrated to 4 patients (13.3%) in the group A, in group B to 7 patients (23.3%). The treatment cost for HR reduction on 1 heart beat was 48.46 rubles in group A, in group B - 69.40 rubles during 6 weeks therapy.

Conclusion: It is more efficiently to use the original bisoprolol in patients with CAD from the pharmacoeconomic analysis.

How many patients with chronic heart failure will be eligible for LCZ696 in the community?

P Pierpaolo Pellicori¹; A Urbinati¹; P Shah¹; A Macnamara¹; S Kazmi¹; R Dierckx¹; JGF Cleland¹; AL Clark¹

¹University of Hull, Department of Academic Cardiology, Hull, United Kingdom

Background: LCZ696 is a new class of agent for the treatment of heart failure (HF) but it is unknown how many patients might be eligible for treatment with it in clinical practice. The product is licensed for use in patients with symptomatic chronic heart failure with reduced ejection fraction (HFrEF); there are few contra-indications other than pregnancy. However, the PARADIGM clinical trial required that patients tolerated enalapril 10mg bd and had an elevated NT-proBNP (≥ 600 ng/L or ≥ 400 ng/L if hospitalized in prior 12 months).

Methods: Between 2001 and 2014, all patients referred to a community HF clinic with suspected HF were enrolled in a prospective observational study.

Results: Of 6131 referrals, 1,980 patients had HFrEF, of whom 1,396 had NTproBNP measured concurrently and would have been eligible for LCZ696 according to its license. However, only 379 patients were on target doses of ACE-I or ARB at baseline and, of these, only 45% ($n = 172$) fulfilled the PARADIGM criteria; lack of limiting symptoms (32% in NYHA I) and NT-proBNP < 600 ng/L (49%) were the commonest

reasons for exclusion. At 4 and 12 month follow-up visits, only a few new patients became eligible for LCZ 696 (22 and 13 patients, respectively). When the analysis was expanded to patients with HFREF on any dose of ACE-I or ARB at the baseline visit ($n = 1,144$), 570 patients were potentially suitable for LCZ696 treatment, but the number fell to 360 when restricted only those already receiving beta-blockers.

Conclusions: The number of patients who require switching from LCZ696 will depend greatly on whether clinicians follow the licensed indication or the PARADIGM inclusion criteria. We await with interest the ESC guidelines on this issue.

The ACEi switchback study

Servier

N Nadia Giannetti¹; P Farand²; M Rajda³; C Michel¹; R Sheppard¹; G Moe¹; F Tournoux⁴

¹McGill University, Medicine, Montreal, Canada; ²Sherbrooke University, Sherbrooke, Canada; ³QE II Health Sciences Center, Halifax, Canada; ⁴University of Montreal, medicine, Montreal, Canada

Background/Introduction: ACE inhibitors (ACEi) have been studied extensively in the treatment of heart failure (HF) and have been shown to be beneficial in all its stages. Studies with the use of ARBs in chronic HF have not shown the equivalent results of ACEi trials. However, many patients are on ARB pharmacotherapy and some patients appear to have never been treated with an ACEi. Registry data have shown very few patients had absolute contraindications to ACEi. Guidelines recommend ACEi first line to treat HF as they reduce morbidity and mortality, hence all HF patients should be on ACEi therapy unless clear contra-indications exist.

Purpose: To assess among patients on ARBs the percentage of these patients who are truly ACEi-intolerant by determining the percentage who will tolerate a switch to an ACEi.

Methods: HF patients with indication for ACEi but on an ARB (no absolute contraindication to ACEi) were enrolled from 6 HF clinics in Canada. These patients had LVEF $\leq 35\%$, NYHA class I-IV, treated with beta-blockers as well as followed in HF clinic and stable for > 3 months (except diuretic dose). Patients with documented intolerance with prior ACEi use, were excluded candidates from this study. Enrolled patients were switched from ARB to ACEi (perindopril); dosage was determined by ARB dosage. Patients were instructed to watch for ACEi side effects and given a contact to call in the event of side effects. Perindopril was stopped if abnormalities in renal function ($> 25\%$ change in creatinine value), kalemia (> 5.2 mmol/L) or important adverse events occurred. The primary end-point was medication tolerance recorded at 3-6 months post-switch. Patients who continued on ACEi beyond 3 months were considered a positive SwitchBack patient. Results 65 HF patients were enrolled from the 6 HF clinics. 48 patients were included in the preliminary analysis. 71% of the patients analyzed were tolerating Perindopril at 3-6 months post-switch. The main reason for intolerance to perindopril at 3-6 months was cough.

Conclusion: These preliminary results are showing that most HF patients who were on ARB were not true ACEi-intolerant as once switched back on the ACEi perindopril, they were tolerating the drug after 3 months.

Assessment of the understanding of a standardized medication plan by patients with chronic heart failure

German Federal Ministry of Health ref. no. 2514ATS001

L Botermann¹; K Monzel²; K Krueger¹; C Eickhoff¹; A Wachter²; C Kloft³; U Laufs²; M Schulz¹

¹ABDA - Bundesvereinigung Deutscher Apothekerverbände, Department of Medicine, Berlin, Germany; ²Saarland University Hospital, Department of Internal Medicine III - Cardiology, Angiology and Intensive Care Medicine, Homburg/Saar, Germany; ³Institute of Pharmacy, Freie Universitaet Berlin, Department of Clinical Pharmacy and Biochemistry, Berlin, Germany

Background/Introduction: A medication plan (MP) template has been implemented by national law as part of the German Action Plan for Medication Safety issued by the Federal Ministry of Health. The MP depicts all medicines taken including active ingredient, brand name, strength, form, dosage, unit, instructions for use, and indication. However, patients' understanding of a MP has never been explored in detail.

Purpose: To evaluate the understanding of the national MP in $n = 50$ patients with the diagnosis of chronic heart failure (CHF) compared to $n = 40$ general internal medicine (GIM) patients, each taking ≥ 5 drugs regularly.

Methods: We developed an "Evaluation Tool to test the handling of the Medication Plan" (ET-MP) that rates patients' medication management skills from 0-100%. The ET-MP is based on an individual test providing the patient with a standardized MP listing 6 drugs with different morning/noon/afternoon/at bedtime doses. Patients were asked to fill a pillbox according to the MP for 2 days. The pillboxes were photographed and both days rated by the ET-MP. The cut-off, distinguishing if patients understand the medication regimen, was set at 90%. For the CHF patients, we also tested for signs of depression (PHQ-9), level of selfcare (EHFScB-9), and impaired cognitive function (Mini-Cog). The study was approved by the local ethics committees.

Results: Both cohorts were comparable with a mean (\pm SD) age of 69 ± 13 years and they took 8 ± 3 drugs chronically. 53% were male, 33% lived alone. The CHF patients (78% NYHA I/II, LVEF $51 \pm 14\%$) had a lower level of education ($p = 0.004$). The mean (\pm SD) ET-MP Score for the CHF cohort was $78 \pm 23\%$ and $86 \pm 19\%$ for the GIM patients ($p = 0.16$). 38% of the CHF patients achieved a score $>90\%$ compared to 50% of the GIM cohort ($p = 0.29$). Overall, we found a moderate correlation between the score and the level of education ($r = 0.45$) and age ($r = -0.46$), both $p < 0.001$, but not living alone ($p = 0.19$). Cognitive impaired CHF patients (46%) achieved a lower score ($p = 0.03$). Signs of depression (PHQ-9 ≥ 10 : 26%) or a lower level of self-care behaviour (EHFScB-9 scale $<$ median) were not associated with a lower score.

Conclusions: The ET-MP is suitable to explore CHF patients' understanding of a medication plan (MP) but less than 50% reached a score $>90\%$. Higher age (>75 y) and lower level of education (<10 y) but not the diagnosis of CHF per se correlate with lower medication management skills. Apart from providing a written MP, a significant number of CHF patients might benefit from further counselling and continuous care e.g., via weekly prepared dosing-aids.

P1016

Pre-hospital treatment of acute heart failure - vasodilators in combination with diuretics or diuretics alone?

M Felsoci¹; J Svoboda²; S Littnerova³; J Parenica¹; J Spinar¹

¹University Hospital Brno, Department of Cardiology and Internal Medicine, Brno, Czech Republic; ²University Hospital Brno, Emergency Medical Service of the South-Moravian Region, Brno, Czech Republic; ³Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic

Background: The most common drugs used in patients with acute heart failure (AHF) are intravenous loop diuretics. The combination of drugs with vasodilatory action (nitrates) with diuretics (furosemide) is very challenging and especially data from early administration in pre-hospital setting are poor.

Purpose: We have investigated whether adding of intravenous nitrate to furosemide in pre-hospital area has additional effect on short and mid-term outcome in patients with suspicion for AHF.

Methods: We used data from CARE PRE-H registry (aCute heARt failure in PRE-Hospital care), multi-centric observational study performed by 21 ambulance teams of the emergency medical system in a region with the total population of 1.17 million inhabitants. During the study period between January 2010 and December 2011 overall 1118 patients with suspected AHF were enrolled. Propensity score method was used to compare balanced population of 211 patients treated with intravenous nitrate (isosorbide dinitrate, glyceryl trinitrate) in addition to furosemide, to 211 patients receiving furosemide alone. Assessed were 30-day up to 3-year overall mortality.

Results: Compared populations (nitrates and furosemide vs. furosemide alone) were balanced (with no statistically significant difference) in terms of age (78.0 vs. 79.0

Conclusion: Pre-hospital administration of intravenous nitrate when added to loop diuretic furosemide did not significantly changed outcome of patients with suspected AHF, nevertheless trend for lower mortality rates and need of tracheal intubation in these patients was observed. These findings require further research in larger studies.

P1017

Dose reduction and contraindication of the novel oral anticoagulant in patients with heart failure and reduced ejection fraction during a follow-up of 27 month. Data from CORONA Trial

A Pozzi¹; NM Hawkins²; PS Jhund³; MC Petrie³; JJV McMurray³

¹Di Circolo Hospital, Cardiologia 2, Varese, Italy; ²University of British Columbia, Cardiology, Vancouver, Canada; ³Cardiovascular Research Centre of Glasgow, Glasgow, United Kingdom

Aim: The non-vitamin K antagonist oral anticoagulants (NOACs) exhibit varying degrees of renal elimination. Their dose should be altered by renal function. Patients with heart failure (HF) often have fluctuating renal function. We estimated the need for dose adjustment in patients with HF using data from the Controlled Rosuvastatin Multinational Trial in Heart Failure (CORONA)

Methods: We calculated creatinine clearance using Cockcroft-Gault formula in 779 patients with AF at baseline, 15 and 27 months. The proportion of patients requiring NOAC dose reduction or discontinuation was estimated according to EU prescribing guidance.

Results: The estimated proportion of patients requiring dose reduction at baseline and during follow-up according to EU guidance was respectively: apixaban 9.7% and 9.3%, dabigatran 26.3% and 5.5%, rivaroxaban 34% and 17% and edoxaban both 35% and 16%. US guidance yielded similar proportions in reductions for all NOACs except dabigatran, for which 3.7% and 7.5% of patients would need dose reduction. With the exception of EU guidance for dabigatran and US for edoxaban, the NOACs are only contraindicated with creatinine clearance less than 15 ml/min, which was rare in this trial population.

Conclusion: Renal function is often impaired and fluctuates in patients with HF, necessitating NOAC dose reduction. The proportions of patients requiring dose reduction varying substantially between the different NOACs. Physicians should carefully consider renal function when prescribing NOACs and ensure adequate monitoring of renal function

A novel oral partial adenosine A1 receptor agonist for the treatment of heart failure: safety and tolerability in healthy volunteers pretreated with beta-blocker

W Dinh¹; A Voors²; H Delesens³; R Heineig⁴; F Kramer¹; A Kretschmer⁵; M Jensen⁴; M Gheorghide⁶

¹Bayer Pharma AG, Global Drug Discovery, Clinical Sciences, Experimental Medicine, Wuppertal, Germany; ²University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands; ³Bayer Pharma AG, Research & Clinical Sciences Statistics, Wuppertal, Germany; ⁴Bayer Pharma AG, Clinical Sciences, Clinical Pharmacology, Cardiovascular and Hematology, Wuppertal, Germany; ⁵Bayer Pharma AG, Global Drug Discovery, Global Biomarker Research, Wuppertal,

Germany; ⁶Northwestern University Feinberg School of Medicine, Center for Cardiovascular Innovation, Chicago, United States of America

Introduction: Activation of adenosine A1 receptors (A1R) is a key mechanism for protecting the heart from injury and energetic imbalance in various pathophysiological conditions like heart failure (HF). The development of A1R agonists for HF is supported by encouraging preclinical evidence in animal models. However, therapy with a full A1R agonist is limited by side effects, notably higher degree AV blocks, in particular with the concomitant use of beta-blocker. A partial A1R agonist might overcome these undesired effects, while preserving the beneficial potential. This is the first study to investigate the safety and tolerability of BAY 1067197, a novel oral partial A1R agonist, in healthy subjects pretreated with beta-blocker.

Methods: 11 male healthy volunteers (mean age 33 ± 8 years) were pretreated with 95mg metoprolol-succinate (MS) alone for 6 consecutive days followed by a co-administration of placebo on day 7 and a single dose of 50mg BAY 1067197 at day 8. Blood samples were collected for safety monitoring and pharmacokinetics. Standard ECG, 48h Holter ECG and vital signs were monitored. Results After co-administration of BAY 1067197, all subjects' Holter ECG recordings were interpreted as normal by a central ECG reader. The heart rate (HR) measured over 1 minute was slightly lower following MS+BAY 1067197 vs. MS+placebo (HR -1.1 beats/min, $p=0.06$, ANCOVA), whereas the PR interval corrected for HR was not significantly different ($p \geq 0.13$, ANCOVA). No changes in blood pressure (BP) were observed in the BAY 1067197 treatment arm. BAY 1067197 co-administration had no effects on MS exposure. Conclusion The novel partial A1R agonist BAY 1067197 was safe and well tolerated following a single oral dose co-administered with a beta-blocker. Notably, no higher degree AV block, relevant decreases in HR or BP were observed. We conclude that co-administration of BAY 1067197 with a beta-blocker does not increase the risk of AV blocks in healthy volunteers. The development of a partial A1R agonist may overcome the undesired effects of a full A1R agonist on AV conduction. The safety of co-administration with a beta-blocker needs to be confirmed in patients with HF and for longer treatment duration.
