Introduction: Left ventricular noncompaction (LVNC) is characterized by excessive and prominent myocardial trabeculations associated with deep recesses. The clinical spectrum is very wide, including ventricular arrhythmias and sudden cardiac death (SCD). Algorithms for SCD stratification are lacking, especially in those with preserved ejection fraction. 123I-MIBG imaging evaluates sympathetic nervous system function and has been shown to lead to better risk stratification in heart failure and coronary artery disease, with lower heart/mediastinal ratio (HMR) and higher myocardial washout rate (WR) being associated with worse outcome. The use of 123I-MIBG imaging in LVNC has not been systematically studied.

Purpose: We aimed to evaluate cardiac adrenergic activity in LVNC patients and compare it to dilated cardiomyopathy (DCM) patients and respective family members.

Methods: We evaluated 6 patients with LVNC and no left ventricular dysfunction (LVD), 10 with LVNC+LVD, 27 with DCM and 14 family members of DCM patients, with no LVD (unknown genetic background). For 123I-MIBG imaging anterior projection planar images of the thorax were obtained, 20min and 4h after intravenous administration of 370 MBq of 123I-MIBG (early and late images). HMR and WR were calculated twice by 2 independent blinded observers; the final result was the mean of the average of each operator.

Results: Patients with isolated LVNC presented the highest late HMR (2.11 ± 0.24 vs 1.65 ± 0.15 vs 1.74 ± 0.27 vs 1.93 ± 0.15 , $p=0.000$) and the lowest WR (22.5 ± 11.6 vs 39.9 ± 10.4 vs 42.6 ± 11.5 vs 31.8 ± 9.3 , $p=0.000$) compared to patients with LVNC+LVD, DCM and no LVD, respectively. Early HMR results did not present significant differences, although there was a trend in the same direction of late HMR results. Only 17% of patients with isolated LVNC presented abnormal results of WR (> 30%) comparing with 80%, 85% and 64% of patients with LVNC+LVD, DCM and no LVD, respectively. However, when analyzing 123I-MIBG parameters according to the presence of LVNC in patients with and without LVD (isolated LVNC vs no LVD / LVNC+LVD vs DCM), we found no significant differences.

Conclusion: In our group of patients, 123I-MIBG imaging indexes were not significantly affected by the presence of LVNC, beyond left ventricular ejection fraction. Additionally, in LVNC patients with no LVD, we found markers of better cardiac adrenergic activity than in family members of DCM patients, a result that warrants further investigation.

Sympathetic cardiac activity evaluated by 123I-MIBG scintigraphy in left ventricular non-compaction patients

A Sousa¹; T Faria²; A Oliveira²; T Pinho²; T Vieira²; M Campelo²; J Silva Cardoso²; F Rocha Gonçalves¹; J Pereira²; E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Sao Joao Hospital, Porto, Portugal

Introduction: Left ventricular non-compaction (LVNC) is an increasingly recognized cardiomyopathy, characterized by a distinctive spongy appearance of the myocardium. The clinical presentation is very heterogeneous and includes heart failure, thromboembolic events, conduction disturbances, supraventricular or ventricular arrhythmias and sudden cardiac death (SCD). Cardiac 123I-MIBG scintigraphy evaluates adrenergic activity and has been shown to be related with outcomes in heart failure and ischemic coronary artery disease, with lower heart/mediastinal ratio (HMR) and higher myocardial washout rate (WR) being associated with worse prognosis. However, the usefulness of 123I-MIBG cardiac uptake imaging in the setting of LVNC has not been systematically studied.

Purpose: We aimed to evaluate cardiac adrenergic activity, using 123I-MIBG imaging, in LVNC patient.

Methods: We evaluated 16 patients (50% men, mean age 47 ± 17 years) with LVNC, assessed by cardiac magnetic resonance (CMR), which underwent 123I-MIBG cardiac uptake imaging. For 123I-MIBG scintigraphy, anterior projection planar images of the thorax were obtained 20 minutes and 4 hours after intravenous administration of 370 MBq of 123I-MIBG (early and late images). HMR and WR were calculated twice by 2 independent blinded observers, with the final results being the mean of the average of each operator.

Results: Mean early and late HMR and WR were 1.81 ± 0.21 , 1.82 ± 0.29 and $33.4 \pm 13.6\%$, respectively. Ten patients presented left ventricular (LV) dysfunction (mean ejection fraction and LV end-diastolic volume of $36 \pm 8\%$ vs $66 \pm 4\%$, $p=0.000$, and $123 \pm 35\text{mL}$ vs $90 \pm 15\text{mL}$, $p=0.067$, respectively). There was no significant differences in the age of patients of both groups 53 ± 17 vs 38 ± 14 years, $p=0.093$, in patients with and without LV dysfunction, respectively. Early and late HMR were significantly lower in patients with LV dysfunction (1.71 ± 0.18 vs 1.97 ± 0.16 , $p=0.011$ and 1.65 ± 0.15 vs 2.11 ± 0.24 , $p=0.000$, respectively) and WR was higher (39.9 ± 10.4 vs 22.5 ± 11.6 , $p=0.008$). Late HMR was correlated with age ($r=-0.502$, $p=0.047$) and both late HMR and WR were correlated with LVEF ($r=0.686$, $p=0.005$; $r=-0.688$, $p=0.005$, respectively) and BNP levels ($r=-0.635$, $p=0.036$; $r=0.661$, $p=0.027$, respectively).

Conclusion: In our group of LVNC patients, the presence of LV dysfunction was associated with sympathetic denervation, usually present in severe forms of heart failure. Late HRM and WR were associated with other prognostic factors such as left ventricular ejection fraction and BNP. These findings are in accordance with those found in other forms of cardiomyopathies/heart failure conditions.

P1021

Potential prognostic role of chromogranin a in patients with systolic heart failure: correlation with plasma levels of natriuretic peptide and left ventricular function

A Autieri¹; A Corti¹; G Fragasso¹; B Colombo¹; M Gemma¹; R Spoladore¹; F Maranta¹; A Margonato¹

¹San Raffaele Hospital (IRCCS), Milan, Italy

In patients with chronic heart failure plasma chromogranin A (CgA) concentrations are increased and represent an independent prognostic indication of mortality. Recently the measurement of some CgA fragments has been set up in our Institute: compared to intact CgA, single fragments seem to yield a different pathophysiological role in different diseases. In this study the potential correlation between plasma concentration of CgA and its dosable fragments with ejection fraction (EF) and proBNP plasma levels in patients with systolic heart failure was evaluated. 77 patients (54 males, age 72.5 ± 10 years) with systolic heart failure (EF<45%) (24 post-ischemic) were studied. Patients were NYHA class I (10 patients), class IIA (30 patients), class IIB (21 patients), class III (16 patients), on optimal therapy with β -blockers, ACE-inhibitors/ARBs, diuretics and, if necessary, anti-aldosterone drugs and digoxin. In all patients one blood sample was collected in basal conditions and proBNP, CgA and its fragments (non processed CgA or Cg439, Cg436, Cg373, Cg76, fragments lacking C-terminal or FRs, Cg439+Cg436, total CgA, N-terminal fragmentation index, C-terminal fragmentation index, and Cg373/Cg439 and Cg373/Cg76 ratios) were measured. On the basis of the recognised effect of PPI therapy and aging on CgA plasma levels (and the effect of aging on proBNP plasma concentration), age (in years) and PPI therapy (as a dichotomic variable) have been inserted as control variables in each model. proBNP showed significant associations with basal levels of Cg76 (0.156, p -value<0.001), FRs (0.118, p -value=0.031), total CgA (0.107, p -value=0.038), C-terminal fragmentation index (-0.017, p -value=0.040) and Cg373/Cg76 ratio (-0.076, p -value=0.005). Unlike proBNP, no CgA fragment but Cg373/Cg439 ratio (-0.022, p -value=0.020) was significantly associated with EF. In conclusion, total CgA plasma levels are significantly associated with proBNP, but not with EF. Considering the significant association

between proBNP and EF, the non-significant correlation between the absolute levels of CgA fragments and EF suggests that the evaluation of CgA and its fragments could be an independent and complementary marker to proBNP, as it is probably released through pathophysiological mechanisms which are different from other well-known mechanical and neuro-humoral phenomena involved in heart failure onset and progression.

P1022

Subclinical hypothyroidism(SCH) as a risk factor in elderly patients with chronic heart failure(CHF) -still a challenge for clinical practice

D Toporan¹; CS Stamate¹

¹University of Medicine Carol Davila, Emergency Hospital St. Pantelimon, Bucharest, Romania

Background: Subclinical hypothyroidism (SCH), defined as an isolated elevation of thyroid-stimulating hormone (TSH) levels ($>5.0\text{mIU/L}$) with a normal free thyroxine (fT4) level, became a common disorder, with a strong impact on the cardiovascular diseases outcome. The prevalence of SCH is relatively high, ranging from 4% to 20% in the adult population, more often in women and elderly people.

Purpose: This study was undertaken to assess the prevalence of SCH in elderly with chronic heart failure (CHF) and the relationship between SCH and clinical, biomolecular, echocardiographic and echovascular parameters.

Methods: Data were collected on 874 patients, aged >65 years (mean age 73 years), women 63%, admitted to our hospital with the clinical syndrome of CHF. The New York Heart Association (NYHA) heart failure classification on admission was: 62% of patients had class IV, 25% had class III criteria and 13% met class II. Exclusion criteria were: known previous thyroid diseases, amiodarone therapy, atrial flutter and fibrillation. Among the analyzed cases, 52% had heart failure (HF) resulting from coronary artery disease, 11% had HF attributable to valve disease, 9% had a dilated cardiomyopathy and 28% had HF as a result of arterial hypertension. In each patient measurement of ejection fraction (EF) was performed by the quantitative 2D(biplane Simpson) method and all cases underwent pulsed-wave Doppler examination of mitral inflow for diastolic evaluation, as well as carotid artery intima-media thickness measurements. Based on TSH level, patients were divided into two groups: group I, with SCH and CHF (10.8%), comprised 94 cases and group II, without SCH (89.2%), comprised 780 cases. The correlations were performed using Student's t-test. Results. Patients in group I were, compared with those in group II, older, more often women, had higher body mass index, higher prevalence of diabetes, higher systolic blood pressure, higher levels of serum lipids and higher serum creatinine values ($p < 0.05$). The CHF and SCH were associated more frequently with class III and IV NYHA and with a lower EF, compared with group with normal TSH ($p < 0.001$). Also, patients in group I had a higher index of intima-media thickness of carotid artery and more atheroma plaques "at risk".

Conclusions: The presence of SCH (10.8% in our study) was associated for sure with a worse status of patients in CHF, but SCH could represent a potentially modifiable risk factor. The current determination of TSH threshold levels for the treatment of SCH remained a clinical controversy and the decision to treat or not to treat a SCH patient with CHF is still a challenge for clinician, in the light of known risk of hormonal replacement therapy.

Mid-regional pro atrial natriuretic peptide predicts increase in cardiac output during submaximal exercise in patients with heart failure.

The Research Fund, Rigshospitalet, Denmark. The Heart Center Research Foundation, Rigshospitalet, Denmark

L. Balling¹; J. Hartvig Thomsen²; E. Wolsk²; C. Hassager²; S. Boesgaard²; J.P. Goetze¹; F. Gustafsson²

¹Rigshospitalet - Copenhagen University Hospital, Department of Clinical Biochemistry, Copenhagen, Denmark; ²Rigshospitalet - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark

Background: Mid-regional pro-atrial natriuretic peptide (MR-proANP) is produced and secreted from the atria as a result of atrial distention in heart failure (HF). The association between MR-proANP and invasive hemodynamic parameters during exercise in patients with HF is unknown.

Purpose: The purpose was to investigate the association of MR-proANP and invasive hemodynamic measures during submaximal exercise.

Methods: Patients with chronic HF with a left ventricular ejection fraction (LVEF) $<45\%$ performed a submaximal exercise test on a supine exercise bike. The individual submaximal exercise level was determined as 50% of the maximal workload during maximal exercise testing one week prior. All patients underwent right heart catheterization with measurement of invasive hemodynamic parameters at rest and during submaximal exercise. Blood levels of MR-proANP were measured at rest and during exercise. MR-proANP was logtransformed for analyses.

Results: A total of 18 patients (89% male) were included (mean age 53 ± 12 , mean LVEF $23 \pm 8\%$, mean VO_2max 18 ± 5 l/kg/min, mean submaximal workload was 52 ± 18 Watts). Pulmonary capillary wedge pressure (PCWP) increased from rest

(15 ± 8 mmHg) to submaximal exercise: (34 ± 11 mmHg) ($p < 0.05$). The increase in cardiac index (CI) from rest to submaximal exercise was 2.3 ± 0.5 L/min to 4.0 ± 1.3 L/min ($p < 0.05$). Levels of MR-proANP also increased from rest to submaximal exercise: 180 ± 114 pmol/L vs. 238 ± 142 pmol/L ($p < 0.05$). There was an inverse correlation between resting log(MR-proANP) and increase in cardiac index (CI) from rest to submaximal exercise ($r^2 = 0.41$, $p = 0.004$). Log(MR-proANP) was also correlated with resting pulmonary capillary pressure (PCWP) ($r^2 = 0.37$, $p = 0.007$), but there was no association between log(MR-proANP) and PCWP during peak exercise ($p = 0.09$). Increase in CO during exercise was also associated with resting PCWP ($P = 0.005$). NT-proBNP was not associated with CI or PCWP at rest or during exercise in this study ($p > 0.05$).

Conclusion: A low blood level of MR-proANP predicts a greater increase in cardiac output during submaximal exercise in patients with chronic HF. In systolic HF, MR-proANP is a predictor of resting PCWP, and hereby further predicts cardiac reserve during submaximal exercise.

Association: Cardiac Index and MR-proANP

Renin-angiotensin-aldosterone system stimulation in different stages of heart failure with reduced ejection fraction

P Petra Nijst¹; FH Verbrugge²; P Martens¹; PB Bertrand¹; M Dupont¹; W Mullens¹

¹Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium; ²University Hospitals (UZ) Leuven, Leuven, Belgium

Background: Renin-angiotensin-aldosterone system (RAAS) stimulation in heart failure (HF) with reduced ejection fraction (HFrEF) is detrimental through cardiac remodeling and water/salt retention. Cardiac function, hemodynamic alterations and HF therapies influence RAAS hormones.

Aims: This study aims to describe RAAS activation during different stages of HFrEF and assesses their prognostic role.

Methods and Results: In 72 acute decompensated HFrEF patients (ADHF), 78 stable chronic HFrEF patients and 53 patients with HF with normalized ejection fraction (HFNEF), venous blood samples and hemodynamic parameters were obtained. Subjects were prospectively followed up to 30 months. RAAS hormones (plasma renin activity (PRA) and serum aldosterone) are significantly lower in ADHF compared to stable HFrEF and HFNEF patients (all $p < 0.05$) (Table 1). Volume status, blood pressure and HF medication seem to play an important role (all $p < 0.05$). High PRA levels are associated with worse outcome in acute ADHF, which does not hold true in stable HFrEF or HFNEF (Figure 1). There is a trend to lower PRA levels in HFNEF patients compared to stable HFrEF ($p = 0.06$, not presented in table) which could not be accounted for by medication use or hemodynamic factors between these two groups.

Conclusion: High RAAS activity in stable HFrEF and HFNEF patients is not associated with worse outcome in contrast to patients with ADHF. During acute decompensation the RAAS system remains appropriate responsive and is downregulated. In HFNEF patients RAAS activity declines possibly due to the reversal of cardiac abnormalities.

Longitudinal left ventricular strain in type 1 diabetes children

I Ihnen Zairi¹; K Mzoughi¹; R Bensaid¹; S Kamoun¹; F Benmouss¹; S Fennira¹; S Kraiem¹

¹Habib Thameur Hospital, cardiology, Tunis, Tunisia

Introduction: Diabetic cardiomyopathy is a new entity, defined as a form of heart failure with preserved LVEF, observed in diabetic patients, in the absence of coronary artery disease, hypertension and significant valvular heart disease. Application of a new echocardiographic tool, the 2D Strain is being evaluated. The aims of our study were to investigate the global longitudinal Strain (GLS) of the left ventricle (LV) and of the right ventricle (RV) and to determine the correlations between GLS and metabolic control evaluated by HbA1c. **Methods:** It was a retrospective study of 24 children with type 1 diabetes. The conventional echocardiographic parameters and GLS were studied. These data were compared to the measured parameters in 20 healthy children matched for age and sex.

Results: The mean age was 11,13 ± 0,54 years. The mean duration of diabetes was 7 years ± 0,54. Mean HbA1c was 8,79% ± 0,25. LVEDD was 41,8 ± 0,84 mm and LVESD was 26,33 ± 0,73 mm. LVEF was preserved with an average of 67,88 ± 1,18%. E/A ratio was 4,4 ± 2,08. The TDE was significantly shorter in the diabetic group (146,54 ms ± 3,69 Vs 161,42 ms ± 2,38 for the control group, p = 0,005). E/E' ratio was significantly higher in the diabetic group compared with the control group (6,72 ± 0,33 Vs 5,21 ± 0,15, p = 0,0011). RV function was preserved in the diabetic group: TAPSE was 20,33 ± 0,26 mm and S' Wave was 14 cm / s ± 0,002. The study of myocardial deformation showed a significant decrease in the GLS of diabetic patients compared to healthy subjects (-18,53% ± 0,5 Vs -25,52% ± 0,37, respectively; p < 0,001). RV longitudinal strain was preserved (-26,31% ± 0,51). No correlation was found between the GLS of the LV and the HbA1c (r = 152, p = 0,477).

Conclusion: Myocardial deformation analysis by Strain 2D can detect subclinical impairment of LV systolic function. It is an early marker of diabetic cardiomyopathy. It has a contributive value for screening early cases and for optimizing therapeutic management and consequently codifying the subsequent monitoring strategy.

P1026

Biventricular remodelling after pregnancies complicated by HELLP syndrome

R Orabona¹; E Edoardo Sciatti²; E Vizzardi²; I Bonadei²; A Valcamonica¹; M Metra²; T Frusca³

¹University of Brescia, Maternal-Fetal Medicine Unit, Department of Obstetrics and Gynecology, Brescia, Italy; ²University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy; ³University of Parma, Department of Obstetrics and Gynecology, Parma, Italy

Background: Haemolysis, Elevated Liver enzymes and Low Platelets (HELLP) syndrome is a rare condition which can superimpose to pre-eclampsia (PE). PE is characterized by left ventricular subclinical alterations persisting after pregnancy. Nothing is known about similar consequences after HELLP syndrome.

Purpose: To evaluate biventricular function in patients with previous pregnancies complicated by HELLP syndrome, and to compare it to PE and healthy controls.

Methods: 50 women with a history of HELLP syndrome, 50 with a previous PE and 50 controls were examined from 6 months to 4 years after delivery. Left ventricular (LV) dimensions, volumes, ejection fraction (LVEF) and mass were measured. Right ventricular (RV) tricuspid annular plane systolic movement (TAPSE) and fractional area changing (FAC) were sampled. Diastolic filling (E/A and E/E' ratios) and tissue Doppler imaging were evaluated for both ventricles and myocardial performance index was calculated.

Results: HELLP group showed an earlier gestational age at delivery if compared to PE alone. LV concentric hypertrophy was present only in the HELLP group. LV concentric remodeling was identified also in the PE group together with consequent diastolic dysfunction (altered E/E' ratio) and reduced LVEF. Regarding RV parameters, only FAC and E/E' were slightly impaired in the HELLP group while the others were similar to controls.

Conclusion: The significant overlap among data related to women with a history of HELLP syndrome and those with previous PE alone seems to suggest that these disorders represent variations of the same pathophysiologic process. However early onset of HELLP syndrome may lead to a more severe cardiovascular remodelling after delivery.

P1027

Speckle tracking echocardiography analysis of the left ventricular function in young athletes

S Charfeddine¹; S Mallek¹; M Jabeur¹; F Triki¹; D Abid¹; R Hammami¹; L Abid¹; S Kammoun¹; ¹Hedi Chaker University Hospital, Cardiology department, Sfax, Tunisia;

Introduction: In addition to the 2D standard echocardiographic parameters, the assessment of left ventricular (LV) function in young athletes is currently possible by deformation parameters (strain or speckle tracking echocardiography (STE)). The aim of this study was to assess the role of 2 D-STE for better characterize the heart performance in young athletes.

Patients and methods: Thirty-three footballers and 20 healthy untrained subjects were included in the study. The systolic LV function was evaluated by 2D conventional echo parameters, Doppler method and 2D-STE.

Results: The STE demonstrated a different pattern of LV deformation in the 2 study groups. A significant lower LV global longitudinal strain (GLS -20.68 ± 2.05 versus -22.99 ± 2.32 %, p < 0.001) and higher radial and circumferential strains have been found in the young athletes as compared with controls. A significant relationship between the GLS values and LVED (r = 0.299, p = 0.03) and LVMi was also reported in athletes.

Conclusion: STE could detect early changes in the LV systolic function. Deformation parameters showed a different pattern of LV mechanics in young footballers versus controls.

Role of echocardiography and cardiac sonographer in outpatient evaluation for heart failure

S Serena Leombruni¹; A Posteraro¹; A Granatelli¹; CMP Biscosi¹; E Proietti¹; V Rizzello¹; MT Calandro¹; S Brunetti¹; C Coletta²; C Autore²
¹S. Giovanni Evangelista Hospital-Tivoli, Cardiology Unit, Rome, Italy; ²Sapienza University of Rome, Dept. of Clinical and Molecular Sciences, Rome, Italy

1. Heart failure (HF) is a complex syndrome due to structural or functional heart diseases that make heart unable to fill and/or pump at normal filling pressures. The definition of accurate diagnostic settings for its recognition is crucial for patients' management.

2. The aim of this study is to show the feasibility and usefulness of a focused echocardiographic examination performed by cardiac sonographer during the clinical evaluation of patients referred to an outpatient program dedicated to HF.

3. Between September and October 2015 68 patients (68% males, average age 74 years) were referred to the outpatient program dedicated to HF. For each patient we obtained clinical and instrumental data (age, sex, risk factors, symptoms, blood pressure, heart rate -HR, oxygen saturation, electrocardiogram) and an echocardiographic examination performed by a cardiac sonographer (level 1 of competence in echocardiography according to American Society of Echocardiography - ASE recommendations). The echocardiographic acquisition was limited to a minimal data set of 12 images (frames and loops). It was focus to obtain the following parameters: left ventricle (LV) dimensions, ejection fraction (EF; Simpsons' rule) and filling pressure estimation (E/A ratio, DTE, E/E' ratio), right ventricle (RV) systolic function (TAPSE), pulmonary artery systolic pressure (PASP) estimation (using tricuspid regurgitation peak pressure gradient and inferior cava vein dimensions and breath excursion). The images and the preliminary report performed by the sonographer were sent to a DICOM server and immediately evaluated by the cardiologist (level 2 of competence in echocardiography according to ASE recommendations) on his workstation.

4. According to clinical and echocardiographic data, 24 patients were not enrolled into the outpatient program dedicated to HF.

Forty-four patients (66% males, average age 75 y) were enrolled into the program. Only 60% of them was in sinus rhythm and echocardiographic examination shown a LVEF ≤50% in 68% (46,6% 40-50%, 46,6% 30-40% and 6,8% <30%), increased LV filling pressure in 93,2% (slightly 19,5%, moderately 61% and severely 19,5%), reduced RV systolic function (TAPSE ≤17 mm) in 18,2% and increased PASP in 38,6%. Only 7 patients shown bidimensional and Doppler signs of valve (mitral or aortic) disease and were referred to the Echo-Lab to perform a standard examination. The mean duration of echocardiographic examination performed by the sonographer was of 12 minutes and the mean global duration of the clinical outpatient evaluation was not significantly prolonged (35 minutes).

5. The echocardiographic evaluation performed by cardiac sonographer during the clinical evaluation of patients, referred to an outpatient program dedicated to HF is feasible, allows immediate information about structural and functional cardiac parameters useful for patients' management and avoids to refer all the patient to the Echo-Lab with evident economic advantages.

P1029

The study about 4D LV strain according to the changes of preload

CS Chan Seok Park¹; JW Roh¹; JS Cho¹; HS Ahn¹; HJ Youn¹

¹Catholic University Medical College, Seoul, Korea Republic of

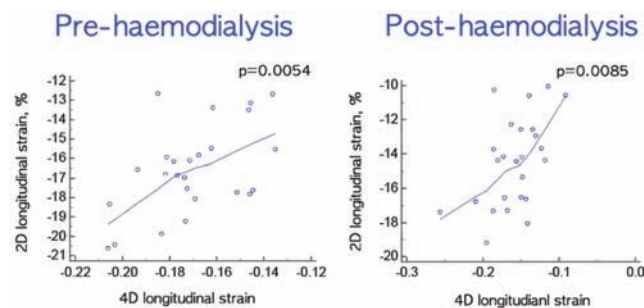

Purpose: Various peak strain values from 4D full volume image are novel indicator of left ventricular function. In this study, we investigated various 4D strain values to examine the effect of preload reduction in end-stage renal disease patients who were undergoing regular hemodialysis.

Methods: 56 subjects who underwent transthoracic echocardiography including 4D full volume image acquisition of left ventricle before and after haemodialysis were enrolled. Peak systolic longitudinal, circumferential, radial and area strain values were obtained from left ventricular 4D full volume image. (Table) All the values were significant decreased after preload reduction. 2D longitudinal strain values were also calculated from 25 subjects. And they were well correlated with the longitudinal strain values obtained from 4D image. (Figure)

Conclusion: 4D strain values are reliable parameter for left ventricular function. They can be more easily obtained from just one image. However, they are not preload-independent just like other conventional left ventricular systolic parameters.

Strain values from 4D speckle tracking

	pre-haemodialysis	post-haemodialysis	p values

Ventricular-vascular coupling after pre-eclampsia

R Orabona¹; E Edoardo Sciatti²; E Vizzardi²; I Bonadei²; A Valcamonica¹; M Metra²; T Frusca³

¹University of Brescia, Maternal-Fetal Medicine Unit, Department of Obstetrics and Gynecology, Brescia, Italy; ²University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy; ³University of Parma, Department of Obstetrics and Gynecology, Parma, Italy

Background: Ventricular-arterial coupling (VAC) is a major determinant of left ventricular function and energy transfer to the aorta. Pre-eclampsia (PE) is associated to subsequent higher cardiovascular risk and development of arterial stiffness and heart failure.

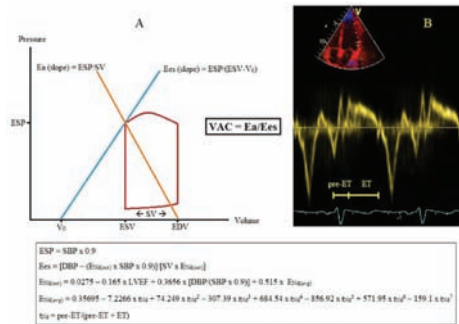

Purpose: To evaluate VAC few years after pregnancies complicated by PE.

Methods: 30 non-pregnant women with a previous singleton pregnancy complicated by early-onset (EO) PE, 30 by late-onset (LO) PE and 30 controls with a previous uncomplicated pregnancy underwent an echocardiographic evaluation 6 months to 4 years after delivery. Women with cardiovascular risk factors,

ongoing medical therapy, hypertensive or nephrologic or immunologic disorders were excluded. VAC was defined as the ratio between aortic elastance (Ea) and left ventricular end-systolic elastance (Ees), assessed by the echocardiographic single-beat method. Multivariate regressions were run to test the association between gestational age (GA) at PE onset and VAC parameters, after correcting for blood pressure and uterine artery pulsatility index at diagnosis of PE and for birth weight.

Results: VAC was normal in the whole study cohort. Ea and Ees were altered significantly more in the EOPE group than both LOPE and controls. Ea, Ees and VAC were independently associated with GA, after correcting for blood pressure and uterine artery pulsatility index at diagnosis of PE and for birth weight.

Conclusions: VAC as a marker of cardiovascular performance is maintained normal few years after pregnancies complicated by PE. Nevertheless, its single components (Ea and Ees) showed subclinical alterations principally in the EOPE group. This findings support the greater risk of cardiovascular diseases which affects these women later in life.

P1031

Clinical and prognostic relationships of pulmonary artery to aorta diameter ratio in patients with heart failure. A cardiac magnetic resonance imaging study.

A Urbinati¹; P Pierpaolo Pellicori²; J Zhang²; A Joseph²; P Costanzo²; E Lukaschuk²; A Capucci¹
JGF Cleland²; AL Clark²; ¹Marche Polytechnic University of Ancona, Ancona, Italy; ²University of Hull, Department of Academic Cardiology, Hull, United Kingdom

Background: The main pulmonary artery (PA) distends as a consequence of raised pulmonary artery pressure. Its diameter, and the ratio to the aorta diameter, might provide prognostic information in patients with chronic heart failure (CHF).

Methods: Patients with CHF and control subjects undergoing cardiac magnetic resonance imaging (CMRI) were evaluated. The main PA diameter and the transverse axial ascending aorta (Ao) diameter at the level of bifurcation of the main pulmonary artery were measured. The maximum diameter of both vessels was measured through the cardiac cycle and the PA/Ao ratio was calculated.

Results: 384 patients (mean age 69 years, mean left ventricular ejection fraction 40%, median amino terminal pro-brain natriuretic peptide (NT-proBNP) 1010 (IQR: 448-2262) ng/l) and 38 controls were included. Controls and patients with CHF had similar maximum Ao and PA diameters, and PA/Ao ratio. During a median follow up of 1759 days (998-2269), 181 patients with HF were hospitalised for HF or died. Neither PA diameter nor PA/Ao ratio predicted outcome in univariable analysis. In a multivariable model, only age and NT-pro BNP were independent predictors of adverse events.

Conclusions: the PA/Ao ratio is not a useful method to stratify prognosis in patients with heart failure.

P1032

Hybrid SPECT/CT imaging in patients with heart failure and coronary artery diseases

M Kostkiewicz¹; W Szot²; A Lesniak Sobelga¹; P Podolec¹
¹Institute of Cardiology, Jagiellonian University, John Paul II Hospital, Dpt Cardiovascular Diseases, Krakow, Poland; ²John Paul II Hospital, Dept of Nuclear Medicine, Krakow, Poland

Background: SPECT-CT is a hybrid technique whereby simultaneous non-invasive functional information about myocardial perfusion obtained by SPECT and anatomical information about the coronary arteries using CT is obtained. A hybrid SPECT-CT scanner can be used in heart failure patient with coronary heart diseases. In this kind

of imaging CT could correct the limitations of SPECT, and SPECT corrects limitations of CT.

Material and Methods: 48 patients (mean age 52.5 ± 10.1 years, 48.4% male) with stable symptoms of angina and mean ejection fraction < 35% assessed by echocardiography, were prospectively included in this study. Hybrid SPECT/CT was performed prior to conventional coronary angiography. Hybrid analysis was performed by combined interpretation of SPECT and CT images. The sensitivity, specificity, positive (PPV), and negative (NPV) predictive values were calculated for SPECT, CT, and hybrid SPECT/CT comparing with coronary angiography. Ejection fraction, regional wall motion, and regional wall thickening measured by echocardiography was compared with GSPECT parameters. Results Significant CAD was demonstrated in 32 patients (67%). SPECT had a sensitivity of 83%, specificity 72%, CT had a sensitivity of 100%, specificity 62%. Hybrid analysis of SPECT and CT improved the overall performance: sensitivity, specificity for the presence of significant CAD in heart failure pts to 96, 95% respectively. Conclusions Hybrid SPECT/CT is fast, complete and easy to obtain. It could diagnose or exclude coronary artery disease and identify coronary risk in patients with heart failure.

P1033

Characterization of patients with diffuse aneurysmatic coronary artery disease by non-dimensional shape analysis and wall shear stress

E Ernst Wellenhofer¹; U Kertzscher²; K Affeld²; B Pieske²; L Goubergrits²
¹German Heart Center Berlin, Berlin, Germany; ²Charité - University Medicine Berlin, Berlin, Germany

Purpose: Aneurysmatic coronary artery disease (ANCAD) is a descriptive diagnosis based on local or diffuse ectasia of several coronary vessels. Patients with ANCAD may have poor prognosis due to early myocardial infarction resulting in heart failure. We evaluated whether a previously published classification model discriminating ANCAD by quantitative measures based on 3-D reconstruction and flow simulation in right coronary arteries may be validated in left coronary arteries of the same patients.

Methods: Patients with ANCAD (n=6; age: 50 ± 10 y, 1 f), with CAD ruled out by angiography (controls) (n=8; age: 53 ± 14 y, 5 f) and with CAD without ectasia (n=9; age: 59 ± 10 y, 3 f) with long-term follow-up (20 years) were selected by review of coronary angiograms performed between 1990 and 1994. Left and right coronary arteries were 3-dimensionally reconstructed from biplane angiograms by a validated method. Numerical flow simulations based on Navier Stokes equations in an appropriately refined mesh were performed. A previously published classification approach based on non-dimensional shape analysis and wall shear stress statistics was applied.

Results: There was fair agreement between the classifications irrespective whether it was applied to right or left coronary arteries. The three patients with different classification related to selected coronary vessel are identified by a red circle in the left part of the figure. Discriminant function 1 characterizes the "aneurysma factor" and function 2 reflects negative remodeling.

Conclusion: The novel classification approach based on non-dimensional shape analysis and wall shear stress statistics is a promising diagnostic tool to identify aneurysmatic coronary artery disease that should be further investigated. This could probably be easily done with CT data. Of particular interest is, whether the severity of disease or prognostic impact might be reflected by the discriminant functions.

Discriminant function

BIOMARKERS

P1034

Diagnostic and prognostic accuracy of galectin-3 for acute heart failure

T Mueller¹; A Gegenhuber²; M Haltmayer¹; B Dieplinger¹
¹Convent of the Brothers of Mercy Hospital Linz, Department of Laboratory Medicine, Linz, Austria; ²Hospital Bad Ischl, Department of Internal Medicine, Bad Ischl, Austria

Background: The biomarker galectin-3 has been included in the 2013 ACCF/AHA guideline for additive risk stratification of patients with acute and chronic heart failure (HF). However, it remains unclear whether galectin-3 may be useful as an aid for the diagnosis of heart failure.

Purpose: To compare head to head the diagnostic and prognostic capabilities of galectin-3 and B-type natriuretic peptide (BNP) for HF in an emergency setting.

Methods: We studied 251 consecutive patients with dyspnoea as a chief complaint presenting to an emergency department. The diagnosis of HF was based on the Framingham score for HF plus echocardiographic evidence of systolic or diastolic dysfunction. All-cause mortality was assessed at one year. We measured plasma concentrations of galectin-3 and BNP by two commercially available assays from Abbott Diagnostics. The diagnostic and prognostic accuracies of galectin-3 and BNP were assessed by receiver operating characteristic (ROC) curve analysis.

Results: Of the 251 patients, 137 had dyspnoea attributable to acute HF and 114 had dyspnoea attributable to other reasons. BNP had a higher area under the curve (AUC) for the diagnosis of HF (0.91; 95% CI, 0.87-0.95) than galectin-3 (0.57; 95% CI, 0.51-0.64). Galectin-3 did not add to the diagnostic capability of BNP. Cut-off values with the highest diagnostic accuracies were 295 ng/L for BNP (sensitivity, 80%; specificity, 86%), and 26 ng/mL for galectin-3 (sensitivity, 41%; specificity, 75%). Of the 137 patients with acute HF, 41 died and 96 survived during follow up. The AUC of BNP for the prediction of one-year all-cause mortality in HF patients (0.72; 95% CI, 0.63-0.79) was not different from the AUC of galectin-3 (0.70; 95% CI, 0.62-0.78). A statistical model combining the predictive values of both biomarkers did not improve the prognostic capabilities of each analyte. Cut-off values with the highest prognostic accuracies were 925 ng/L for BNP (sensitivity, 68%; specificity, 69%), and 33 ng/mL for galectin-3 (sensitivity, 54%; specificity, 88%).

Conclusions: In this study, galectin-3 and BNP were equally useful for the prediction of one-year all-cause mortality in patients with acute HF. However, in contrast to BNP, galectin-3 was not useful as an aid in the diagnosis of acute HF in short of breath patients presenting to an emergency department.

P1035

Serum concentrations of tumor markers carbohydrate antigen 125 (CA 125) in acute heart failure - clinical implications

N Nenad Ratkovic¹; VD Vranes Danijela¹; OS Obradovic Slobodan¹; SM Sipic Miodrag¹; TL Torbica Lidija¹; AR Andjelka Ristic¹; DD Dragan Dincic¹

¹ Military Medical Academy, Clinic of Emergency Internal Medicine, Belgrade, Serbia;

Introduction: Serum CA 125 is elevated in patients with congestive heart failure.

Objective: To examine the relationship between Ca 125 with different clinical presentations of acute heart failure (AHF).

Methods: In 86 patients who were hospitalized with AHF, the serum concentration of Ca 125 and BNP was measured 48-72 hours after hospitalization.

Results: Ca 125 is positively correlated with serum concentration of BNP, and negatively with EF. In patients with pleural effusions (47) Ca 125 is higher than in those without (121.7 ± 108.4 U / ml, vs. 24.1 ± 12.1 U / ml, $p < 0.001$), patients with dilated right ventricle (RV) (53) had higher of Ca 125 than those without (139.0 ± 102.2 / mL vs. 20.8 ± 14.9 U / ml, $p < 0.001$). Patients with Acute pulmonary edema (20) have lower values than those with no AHF (66) (25.3 ± 10.5 U / ml vs. 131.4 ± 98.0 U / mL), patients with atrial fibrillation (29) had higher Ca 125 than those without (107.3 ± 101.7 U / ml vs. 22.2 ± 14.9 / ml, $p < 0.001$).

Conclusion: CA 125 is a good indicator of heart failure, particularly volume overload at the right ventricle decompensation

P1036

Predictors of length of stay of heart failure hospitalizations in heart failure patients with normal and reduced left ventricular ejection fraction

J Jufen Zhang¹; JGF Cleland²; P Shah¹; T Nikolaidou¹; P Pellicori¹; AL Clark¹

¹ University of Hull, Hull, United Kingdom; ² Imperial College London, London, United Kingdom

Background and aims: Factors associated with the length of hospital stay (LoHS) for patients with decompensation of chronic heart failure (HF) with normal and reduced left ventricular ejection fraction (HfPEF and HFrEF) have not been well described.

Methods: Demographic measurements, symptoms and signs, and standard blood tests were collected routinely from patients referred with suspected heart failure to a community heart failure service between 2000 and 2013. For this analysis, hospitalizations resulting in death were excluded. HF was defined as a clinical diagnosis confirmed by an NT-proBNP > 400 ng/L; patients were classified as HfPEF and HFrEF if their LVEF was above or below 40%. A multivariable model was developed to identify variables associated with a total of LoHS for HF > 7 days in the 5 years following enrolment. Pre-specified variables were: age, sex, body mass index (BMI), NYHA class, systolic BP, NT-proBNP, creatinine, haemoglobin, sodium, QRS, heart rate, sinus rhythm, COPD and diabetes.

Results: Of 4,055 patients with suspected HF evaluated with a follow-up of at least

5 years after first NT-proBNP measurements, 1,091 patients had HfPEF and 1,274 had HFrEF. Of patients with HfPEF, the median age was 77 (IQR: 72-83) years, 591 (54%) were men and 305 (28%) were in NYHA class III/IV. Of patients with HFrEF, the median age was 79 (IQR: 73-84) years, 944 (74%) were men and 469 (37%) were in NYHA class III/IV. The patients with HFrEF had a total of 5,141 hospitalizations over the following 5 years, of which 2,947 lasted > 24 hours, 1,274 of these were for HF and 444 (35%) lasted > 7 days. The patients with HfPEF had a total of 4,720 hospitalizations over the following 5 years, of which 2,527 lasted > 24 hours, 776 of these were for HF and 303 (28%) lasted > 7 days. 628 patients with HFrEF and 518 patients with HfPEF died within 5 years; 388 patients with HFrEF and 403 patients with HfPEF survived 5 years without a HF hospitalization (>= 24 hours). For HfPEF, a total LoHS for HF > 7 days over 5 years was associated with increasing NT-proBNP, BMI, age, NYHA class, and decreasing haemoglobin and sodium and presence of COPD. For HFrEF, only increasing age (odds ratio (OR): 1.02 (95% CI: 1.01-1.03)), NYHA class (OR: 1.52 (1.17-1.97)), and diabetes (OR: 1.47 (1.10-1.97)) were associated with a total of LoHS for HF > 7 days.

Conclusions: Patients with HFrEF are more likely to have a total of LoHS for HF > 7 days than those with HfPEF. Older age and more severe heart failure predict longer LoHS.

P1037

CT-pro-endothelin-1 in heart failure patients with reduced and preserved ejection fraction - useful or waste of resources? MOLITOR substudy.

S Apostolovic¹; D Dragana Stanojevic¹; R Jankovic-Tomasevic¹;

D Djordjevic-Radojkovic¹; S Salinger-Martinovic¹; S Dakic¹; S Obradovic²;

E Tahirovic³; S Radenovic³; HD Dungen³

¹ Clinic for Cardiovascular Diseases, Nis, Serbia; ² Military Medical Academy of Belgrade, Belgrade, Serbia; ³ Charite - Campus Virchow-Klinikum, Department of Internal Medicine-Cardiology, Berlin, Germany

Introduction: N-terminal-pro-brain natriuretic peptide (NT-proBNP) has a diagnostic and prognostic role in heart failure (HF). The role of CT-pro-endothelin-1 (CT-pro-ET-1) in HF is unclear. Endothelin-1 increases with the rise of right ventricle systolic pressure (RVSP).

Purpose. The goal was to investigate the change of NT-proBNP and CT-proET-1 in patients with reduced and preserved left ventricle ejection fraction (HFrEF/HfPEF) one year after hospital admission due to acute HF.

Methods. We included 168 patients with acute HF, age 68.18 ± 9.9 years, 70.8% being males, 83.7% with HFrEF.

Results. CT-proET-1 in HfPEF patients was $122.1(86.4-143.8)$ at admission and $92.34(72.3-106.46)$ pmol/L after 1 year ($p=ns$). NT-proBNP at admission and 1 year after was $1501(1018-1948)$ / $854.4(388.6-1460)$ pg/mL, $p=0.046$. In HFrEF patients, CT-proET-1 at admission and after 1 year was $112.7(80.9-191.6)$ / $95.13(78.29-127.61)$ pmol/L, $p=ns$, while NT-proBNP was $3414.5(1578.5-10989.5)$ at admission and $1017.6(437.05-2581)$ pg/mL after 1 year ($p=0.002$). The difference was found among patients with HFrEF and HfPEF in NT-proBNP values measured at admission ($p < 0.01$). Left ventricle ejection fraction significantly changed in HFrEF patients during 1 year (33.47 ± 10.77 vs. $29.91 \pm 9.08\%$, $p < 0.001$), while in patients with HfPEF it was not the case (51.38 ± 8.8 vs. $54.04 \pm 6.7\%$). SPDK did not change significantly in HfPEF and HFrEF patients during 1 year (28.56 ± 15.03 vs. 30.56 ± 22.83) / (35.72 ± 17.7 vs. 33.39 ± 15.34 mmHg).

Conclusions: NT-proBNP was higher in patients with HFrEF and was significantly reduced after 1 year in all patients. CT-proET-1 did not change as well as RVSP during 1 year in all our patients. CT-proET-1 could be the indicator of pulmonary hypertension in HF. However, its role in this setting is yet to be determined.

P1038

The evaluation of early risk of lymphoproliferative diseases after heart transplantation: important but underutilized

The work was supported by the Ministry of Health of the Czech Republic (Grant number: AZV MZ 15-27579A).

A Jabor¹; J Franeкова²; P Secnik Jr²; P Lavrikova²; L Hoskova³; E Pokorna⁴

Methods, Prague, Czech Republic; ³ Institute for Clinical and Experimental

Medicine (IKEM), Cardiology Department, Prague, Czech Republic; ⁴ Institute for

Clinical and Experimental Medicine (IKEM), Department of Organ Harvesting and

Transplantation Databases, Prague, Czech Republic

Introduction: Post-transplant lymphoproliferative diseases (PTLD) are one of the most frequent and severe complications after transplantation (Tx) with 40-70% mortality. There were 13 definitive diagnosis of PTLD in 603 patients after heart Tx (HTx). Monoclonal gammopathy (MG) is an independent risk factor of PTLD. Conventional tests for the detection of MG and/or polyclonal activation of the immune system include electrophoresis (PE) and immunofixation (IFE) of serum and urine proteins; the measurement of free light chains (FLC) is another option. However, these tests are usually not included in the guidelines for the management

of patients after HTx. Purpose To describe the common practice in the use of screening methods for PTLTD risk. Methods Retrospective study: We searched the laboratory database for serum and urine PE and IFE in patients after Tx. We compared number of patients screened for MG with data from our institution transplant register. Pilot prospective study: 80 patients (67 men, 13 women, aged 21-68, median 52 years) after HTx (2010 – 2012, 4 sequential serum samples were obtained from each patient: before HTx and at 9th, 18th and 24th month after HTx). Serum and urine PE, IFE, and FLC were determined in an accredited laboratory using Sebia and Binding Site systems. Results The retrospective study is described in Table 1 (study 2005 - 2015). Pilot prospective study: No positive result (PE and/or IFE) was found in any of the 80 pts before HTx. Within 2 years, 2 pts developed MG, 6 pts biconal gammopathy and 3 pts developed oligoclonal gammopathy. The FLC determination revealed 12 pathologies before HTx and 18 pathologies within 2 years after HTx. Conclusions Screening for MG is protocol-based in patients after liver Tx, but only rarely ordered in other Tx patients (based on clinicians' judgment). The significant number of pathologies and more intensive immunosuppressant therapy after HTx encourage the screening use of PE and IFE together with FLC measurement. The utility of this regimen will be assessed in our prospective study.

Table 1. PE and/or IFE results

Organ	No. of Tx	No. of Pts.	No. of MG screenings (%)	No. of pathologies before (%)	No. of pathologies after (%)

Bio-humoral determinants of early LV dysfunction in patients with stable angina.

C Caselli¹; C Prontera²; V Lorenzoni³; R Ragusa³; S Del Ry¹; A Clerico³; M Emdin²; J Knuuti⁴; SR Underwood⁵; D Neglia²

¹Institute of Clinical Physiology of CNR, Pisa, Italy; ²Fondazione Toscana Gabriele Monasterio, Pisa, Italy; ³Scuola Superiore Sant'Anna, Pisa, Italy; ⁴Turku University Hospital, Turku, Finland; ⁵Imperial College London, London, United Kingdom

Background: In patients with stable coronary artery disease (CAD) LV function can be impaired as a result of repetitive myocardial ischemia. It is not known whether circulating biomarkers of atherosclerosis/ischemia are associated with early LV functional impairment in these patients.

Purpose: To evaluate whether particular biohumoral profiles are related with LV systolic function in patients with stable angina.

Methods. Clinical, functional and imaging data were collected in 362 patients (212 males, 150 females, mean age 60 ± 9 years) with stable angina and suspected CAD enrolled in the Evaluation of Integrated Cardiac Imaging (EVINCI) study. All patients underwent baseline echocardiography measurements to assess LV function, stress imaging to detect myocardial ischemia (SDS > 2) and coronary computed tomography angiography (CTA) to assess the presence of obstructive CAD (>50% stenosis of a major coronary vessel). Only patients with LVEF ≥ 50% were included in this substudy. Biohumoral profile involved 39 markers associated with atherosclerosis/ischemia including lipid/glucose, inflammatory and cardiac specific markers.

Results: LVEF was 60 [55-66] %, median [25-75 percentiles]. Myocardial ischemia was present in 90 patients (25%), obstructive CAD in 112 (31%), and myocardial ischemia + obstructive CAD in 46 (13%). At multivariate analysis including age, sex, cardiovascular risk factors, medical treatment, CTA and stress imaging results, high levels of adiponectin (Coefficient: -0.044 ± 0.01 (SE), p < 0.0001) and low levels of HDL cholesterol (0.055 ± 0.02, p = 0.0167) were predictors of lower LVEF independently of the presence of myocardial ischemia and/or obstructive CAD.

Conclusions: Adiponectin and HDL cholesterol are associated with low-normal systolic LV function in patients with stable angina independently of the presence of myocardial ischemia and obstructive CAD.

P1040

Elevated parathyroid hormone is associated with left ventricular remodeling in elderly patients with mild to moderate chronic kidney disease

S Satoru Sakuragi¹

¹Iwakuni Clinical Center, Department of cardiology, Iwakuni, Japan

Background: Parathyroid hormone (PTH) plays an important role in bone metabolism. Aging and chronic kidney disease is recognized as an important factor associated with elevation in PTH. Although elevated PTH was associated with cardiovascular mortality, the association of PTH and left ventricular

remodeling in elderly patients with mild to moderate kidney disease has not been elucidated.

Methods and results: 238 patients over 65 years with CKD stage 2 or 3 were examined (101 male, 75 years). Subjects with LV dysfunction (LVEF < 50%), atrial fibrillation and advanced chronic kidney disease (eGFR < 15 ml/min/1.73m²) were excluded. Patients were divided into two groups according to intact PTH level: below 65pg/ml (normal PTH, n=201) and above 65pg/ml (high PTH, n=37). High PTH groups had lower creatinine-based estimated GFR (57 ± 15 vs 63 ± 13 ml/min/1.73m², p < 0.05) and higher cystatin C level (1.21 ± 0.44 vs 1.01 ± 0.30 mg/L, p < 0.01). In echocardiography, high PTH group had lower e (5.3 ± 1.6 vs 5.9 ± 1.7 cm/sec, p < 0.05), higher E/e (16.1 ± 21.9 vs 11.5 ± 3.6, p < 0.01) and higher LVMI (119 ± 28 vs 107 ± 30 g/m², p < 0.05). The intact PTH was significantly associated with LVMI, even after adjustment for confounding factors. Also, high PTH group had high prevalence of LVH in multivariable logistic regression analysis. Conclusion In elderly patients with mild to moderate CKD, higher level of parathyroid hormone is associated with left ventricular remodeling, which may cause cardiovascular event in these patients.

P1041

Differences in biochemical and genetic biomarkers in patients with heart failure of various etiologies

A Bielecka-Dabrowa¹; A Sakowicz²; M Misztal³; T Pietrucha²; J Rysz⁴; M Banach¹

¹Department of Hypertension, Chair of Nephrology and Hypertension, Medical University of Lodz, Lodz, Poland; ²Medical University of Lodz, Department of Medical Biotechnology, Lodz, Poland; ³University of Lodz, Chair of Statistical Methods, Faculty of Economics and Sociology, Lodz, Poland; ⁴Medical University of Lodz, Department of Nephrology, Hypertension and Family Medicine, Lodz, Poland

Purpose: To evaluate whether biomarkers reflecting pathophysiological pathways and selected single nucleotide polymorphisms differ between patients (pts) with heart failure (HF) with different etiologies.

Methods: 110 pts with HF (mean age 63 years, 69% males) were involved, including HF pts with preserved ejection fraction (HFpEF, n=51) with hypertensive origin, HF pts with reduced ejection fraction (HFrEF) with ischemic aetiology (ICM) (n=32) and HFrEF with dilated cardiomyopathy (DCM) (n=27). Functional polymorphisms were selected from six candidate genes: CYP27B1, NOS3, IL-6, TGF beta, TNF alpha, PPAR gamma. We also assessed the levels of selected HF biomarkers and performed echocardiographic examinations.

Results: Higher concentrations of TNF alpha were observed in pts. with hypertensive HFpEF compared to pts. with DCM (p=0.008). Pts. with HFpEF had higher concentrations of TGF beta 1 compared to pts. with DCM and ICM (p=0.0001 and p=0.0003, respectively). Compared to HFpEF and ICM pts., subjects with DCM had significantly higher values of syndecan 4 (p=0.03 and p=0.0001, respectively), cardiotrophin (p=0.02 and p=0.0003, respectively), and PIIINP (p=0.0008 and p=0.04, respectively). For the NOS3 -786 C/T rs2070744 polymorphism in DCM there were significantly more CT heterozygotes than in ICM and HFpEF. The only biomarkers distinguishing HFpEF vs HFrEF were TGF beta 1 and syndecan 4. The higher levels of syndecan 4 were connected with HFrEF and higher levels of TGF beta 1 were found in HFpEF.

Conclusions: Inflammation mediated through TNF alpha and TGF beta 1 may represent an important component of an inflammatory response that partially drives the pathophysiology of HFpEF. NOS3 -786 C/T rs2070744 polymorphism in DCM may serve as a marker for more rapid progression of heart failure. Finally, the only biomarkers independently distinguishing HFpEF and HFrEF are syndecan 4 and TGF beta 1.

Multivariate logistic regression

Groups	Variable	OR	95%CI for OR	p-value
Lower limit	Upper limit			
DCM	constant	x	x	x

P1042

The factors associated with heart failure hospitalization rates in heart failure patients with normal and reduced left ventricular ejection fraction

J Jufen Zhang¹; JGF Cleland²; P Pellicori¹; P Shah¹; T Nikolaidou¹; AL Clark¹

¹University of Hull, Hull, United Kingdom; ²Imperial College London, London, United Kingdom

Background and aims: limited information from epidemiological studies on the causes and frequency of heart failure (HF) hospitalizations for patients with normal (HFnef) and reduced (HFref) left ventricular ejection fraction exist. We explored these issues in a large, epidemiologically-representative cohort enrolled in a single regional centre which was also the sole provider of expert HF care.

Methods: Demographic measurements, symptoms and signs, and standard blood tests were collected routinely from patients referred with suspected heart failure to a community heart failure service between 2000 and 2013. Hospitalizations with admission and discharge on separate days were included (lasting ≥ 24 hours); for this analysis, hospitalizations resulting in death were excluded. Only patients with HF confirmed by an NT-proBNP > 400 ng/l were included and divided into those with an LVEF below (HFref) or above (HFnef) 40%. A multivariate model was developed to identify the variables associated with HF hospitalization rates within 5 years follow-up for each group. Pre-specified variables included were: age, sex, body mass index (BMI), NYHA class, systolic BP, NT-proBNP, creatinine, haemoglobin, sodium, QRS, heart rate, sinus rhythm, COPD and diabetes.

Results: Of 4,055 patients with a follow-up of at least 5 years after first NT-proBNP measurements, 1,091 had HFpEF and 1,274 had HFref. Of patients with HFpEF, the median age was 77 years (IQR: 72-83), 591 (54%) were men, and 305 (28%) were in NYHA class III/IV. Of patients with HFref, the median age was 79 years (IQR: 73-84), 944 (74%) were men, and 469 (37%) were in NYHA class III/IV. HF hospitalization rates in HFpEF and HFref were 10.0 and 13.2 per 100 patient-years, respectively. For both HFpEF and HFref, the risk of ≥ 1 HF hospitalizations in the following 5 years was associated with increasing NT-proBNP, NYHA class and age and with decreasing systolic BP, sodium and with a diagnosis of diabetes. For patients with HFpEF, only increasing BMI and decreasing haemoglobin added to this model. For patients with HFref, no other variable added information unless NT-proBNP was excluded, in which case both creatinine and haemoglobin did.

Conclusions: Patients with HFref have a higher rate of HF hospitalizations compared to those with HFpEF. Variables that predict HF hospitalization rates are similar regardless of cardiac phenotype.

P1043

Soluble ST2 and vitamin D, a potent deleterious interaction for the heart

D Damien Gruson¹; B Ferracin¹; S Ahn¹; M Rousseau¹

¹Saint-Luc University Clinics, Brussels, Belgium

Background: The increase of circulating soluble ST2 (sST2) levels is related to cardiac remodeling, fibrosis and to Heart Failure (HF). Recently, the regulation of the production of ST2 by vitamin D was demonstrated. A growing body of evidence is supporting the role of vitamin D and parathyroid hormone (PTH) in cardiac remodeling and worsening HF. These elements raise therefore the question of potential interrelations between vitamin D and mediators of fibrosis and inflammation such as sST2.

Purpose: Our objectives were therefore to determine the potential interrelation between sST2, 25(OH)D, 1,25(OH)2D and PTH levels in HF patients with reduced ejection fraction and to compare their prognosis value for cardiovascular death over a long-term follow-up.

Methods: One hundred HF patients with reduced left ventricular ejection fraction (mean age: 66 ± 14 years; males $n=78$; females $n=22$; NYHA II-IV; etiology: ischemic $n=67$, dilated cardiomyopathy $n=33$; mean left ventricular ejection fraction (EF): $23 \pm 6\%$) were included. The primary outcome was cardiovascular death. Circulating levels of sST2, NT-proBNP, 25(OH)D, 1,25(OH)2D and PTH(1-84) were determined with immunoassays.

Results: Increased sST2, PTH(1-84) and NT-proBNP concentrations were significantly related to NYHA classes ($p < 0.001$). The decreased levels of 1,25(OH)2D was related to NYHA classes but not to 25(OH)D. Levels of sST2 were significantly correlated with EF, 25(OH)D, 1,25(OH)2D, PTH(1-84) and NT-proBNP. In multiple regression analysis including age, EF, eGFR, 25(OH)D, 1,25(OH)2D, PTH(1-84), NT-proBNP, and the 1,25(OH)2D/PTH(1-84) ratio, the independent determinants of sST2 levels were NT-proBNP, 25(OH)D and 1,25(OH)2D. In univariate COX analysis, sST2, NT-proBNP, 1,25(OH)2D, PTH(1-84) and the 1,25(OH)2D/PTH(1-84) ratio were predictive of CV death in HF patients. The areas under the ROC curves were 0.70 for sST2, 0.71 for the 1,25(OH)2D/PTH(1-84) ratio, 0.68 for 1,25(OH)2D, 0.65 for PTH(1-84) and only 0.54 for 25(OH)D. In a backward stepwise multivariate Cox analysis only sST2, NT-proBNP and the 1,25(OH)2D/PTH(1-84) ratio remained significantly associated with CV death.

Conclusions: Our results suggest the potential interrelation between sST2 and the vitamin D / PTH(1-84) axis in patient with HF. Like sST2, the ratio between 1,25(OH)2D and PTH(1-84) is also a strong predictor of CV death. Our study might also open additional therapeutic perspectives through vitamin D or calcitriol supplementation.

P1044

The association between BDNF levels and survival and prognosis in patients with decompensated heart failure

H Hasan Ali Barman¹; PROF Keles Ibrahim¹

¹Istanbul University, Cerrahpasa Faculty of Medicine, Cardiology, Istanbul, Turkey

Introduction: The aim of this study is investigate the prognostic value and role of the BDNF levels in hospital and short term follow-up in patients with decompensated systolic heart failure

Methods and Materials: We examined 125 patients with decompensated heart failure that have NYHA III-IV functional capacity and left ventricle systolic dysfunction (EF < 35) between the period of February 2013- March 2015. The control group consisted of 40 healthy volunteers who had no known history of cardiac disease. We measured serum NT pro-BNP and BDNF levels of patients and control subjects with ELISA method. In present study was aimed to examine the association of BDNF levels with primary endpoints including death and rehospitalization after at least six-month follow-up. We also pointed to examine the value of BDNF in secondary endpoints (in-hospital arrest, major arrhythmia, cardiorenal syndrom, mechanical ventilator, coronary care need, inotropic support).

Results: One variable analysis suggested that there is an significant association between BDNF levels and clinical status generate primary and secondary endpoints in patients with decompensated HF. However multiple variable analysis with Cox-regression analysis determined that increasing NT-proBNP (OR:1.071, 95% CI 1.01-1.13) were independent variable but the association between BDNF levels and survival was lost its significance. On the other hand, multiple variable analysis determine factors that affect the "time to rehospitalization" showed that increasing NT-proBNP (OR:1.004, 95% CI 1.002-1.006), decreasing BDNF level (OR:9.077, 95% CI 1.99-41.4) were independent factors.

Discussion: Serum BDNF levels were lower in hospitalized patients with decompensated HF than healthy individuals. Our results suggest that serum BDNF level is a independent prognostic factor to determine the "time to rehospitalization" in hospitalized patients with decompensated systolic HF. Unlike NT-proBNP, it is not found serum BDNF level is an independent prognostic factor to determine survival.

Cox regression rehospitalization

	β	p	OR	95.0% CI for Exp(B)

Role of NT-proBNP evaluations in risk stratification of patients with heart failure within one year follow-up

F A Immordino¹; C S Vella¹; G Evola¹; B Lo Sasso²; M Ciaccio²; S Novo¹

¹University Hospital Paolo Giaccone, Department of Internal Medicine and Cardiovascular Diseases, Chair and Division of Cardiology, Palermo, Italy;

²University of Palermo, Department of Biopathology and Medical Biotechnologies, Palermo, Italy

Background: Ability of N-terminal-pro-B-type natriuretic peptide (NT-proBNP) to stratify risk in patients with heart failure (HF) is well established. Repeated measurements however, seem improve the risk stratification.

Purpose: We prospectively investigated the prognostic value of NT-proBNP levels and their changes during hospitalization in patients with HF. Method: We enrolled 135 patients with echocardiographic and clinical criteria of HF. 67 have HFrEF (EF ≤ 40%) while 68 have HFpEF (EF > 40% and abnormalities in E/e' ratio and/or increased left atrial volume). NT-proBNP was titrated within 24 hours from admission and at discharge. Median follow-up was 12 months. At census we administered the Minnesota Living with Heart Failure questionnaire to define their quality of life (QoL). Primary outcomes were mortality and the combined end-point of HF readmission and mortality. The evaluations were done in different ways: adding individual titrations, through percentage changes and classifying patients into categories of risk based on changes across threshold levels.

Results: NT-proBNP at discharge have the higher prognostic power for mortality (HFrEF 26.8% deceased: C-Index 0.85 $P < 0.0001$; HFpEF 14.7% deceased: C-Index 0.76 $P = 0.0004$) and combined end-point (HFrEF: C-Index 0.84 $P < 0.0001$; HFpEF: C-Index 0.67 $P = 0.01$). In multivariate Cox analysis it appears the most powerful and independent prognostic factor (HFrEF all $P \leq 0.02$; HFpEF all $P \leq 0.03$) and increases hazard ratio of models with only titrations at admission. The percentage changes stratify the risk only for mortality (χ^2 12.44 $P = 0.001$) conversely, categorical risk stratification shows a prognostic role for all outcomes (all log-rank $P < 0.0001$) and provides independent prognostic informations when threshold values are specific for HFrEF or HFpEF compared to titrations. The categorical analysis seems define different profiles of QoL at 12 months census in patients still alive ($P < 0.0001$). NT-proBNP at admission correlates with days of hospitalization ($P = 0.0002$).

Conclusions: Levels of NT-proBNP at discharge have the highest prognostic value in inpatients subject with HF but a categorical classification based on repeated measurements and changes across threshold values of NT-proBNP specific for type of HF may be an independent strategy of risk stratification and may define differences in QoL in these patients.

P1046

ST2 in heart failure- a prognostic marker

J Jamshed Dalal¹; A Digrajkari¹

¹Kokilaben Dhirubhai Ambani Hospital, cardiology, Mumbai, India

Introduction: ST2 (growth STimulation expression gene 2), a member of the interleukin family, has emerged as a novel biomarker in patients with heart failure (HF). It acts as a trigger for fibrosis and the cascade of events leading to cardiac remodelling. The heart is subjected to greater stress in the presence of high levels of soluble ST2, leading to cellular death and tissue fibrosis, reduced cardiac function, and increasing the rate of disease progression. While Brain Natriuretic Peptide (NTpro-BNP) is more useful for diagnosis of HF, ST2 is of particular value in prognostication. Patients with ST2 > 35 ng/ml are documented to have a 2.8x higher risk of adverse outcomes within 30 days. Good response of ST2 to therapy is associated with a better future course of the disease.

Purpose: To study and correlate ST2 biomarker release with NTpro-BNP, left ventricular ejection fraction (LVEF) and other parameters at the time of admission in patients presenting with heart failure in a single tertiary centre.

Methods: 150 patients, 93 males and 57 females who presented with clinical evidence of cardiac failure were evaluated with echocardiography and estimation of NTpro-BNP, ST2 and other blood investigations at time of admission. Patients were divided into four groups: GROUP A: 49 patients with ST2 < 35ng/dl (normals), GROUP B: 60 PATIENTS with ST2 between 35 to 100ng/dl and GROUP C: 41 patients with ST2 between 100 to 200ng/dl or more.

Results: Overall there was a correlation of ST2 with age, renal dysfunction and diabetes. There was also a significant correlation of ST2 with NTpro-BNP. Overall ST2 did not correlate with LVEF and 30% of HF patients on admission had normal ST2. However 43% of patients with ST2 over 100ng/dl had LVEF less than 30% compared with 26% when ST2 was normal. On follow up after discharge, no patient with normal ST2 (Group A) died, whereas 5 deaths and one cardiac transplant occurred in the abnormal groups put together (B, C and D). No difference was seen within groups B, C and D, suggesting any high value was associated with poorer prognosis.

Conclusion: Though there is a correlation between ST2 and NTpro-BNP values, ST2 is a better biomarker for risk stratification but not for diagnosis of HF. In this study, 30% of patients had normal ST2 levels on admission confirming this. ST2 was able to identify amongst HF patients those who had a poorer prognosis, as seen from the greater number of deaths in the high ST2 groups in this study. Correlation of high ST2 values with increasing age, renal dysfunction and diabetes in this study, could be a factor in poorer prognosis. We are closely following our patients for further clinical events and biomarker changes.

Biomarkers of cardiac damage in elderly people

C Claudio Galli¹; R Valle²; S Valverde³; F Gessoni³; L Valle²; G Collura²; S Favero¹; G Gessoni³

¹Abbott Diagnostics, Medical Scientific Liaison Europe, Roma, Italy; ²Civil Hospital, Cardiology, Chioggia, Italy; ³Civil Hospital, Laboratory, Chioggia, Italy

Introduction and aims: Chronic cardiac damage and heart failure represent the major cause of illness and death among elderly people. Since clinical signs and symptoms may be mild or even absent circulating biomarkers are of increased importance and utility for prognosis. Recently, high sensitive assays for cardiac troponin and specific markers for fibrosis have become available and we aimed to evaluate those in an apparently healthy population of elderly Italian people.

Patients and methods: A single plasma sample was taken after informed consent from 130 elderly persons (age > 65 years) living in hospices and with no overt signs of heart disease. Samples were tested by Vitros for cardiac troponin I (TnI) by a contemporary assay and by ARCHITECT for high sensitive (hs) TnI and also for BNP and Galectin-3, a fibrosis biomarker. Common tests for kidney function were also performed. Results. The mean age was 85.6±7.6 years with no significant differences between females (n=96) and males (n=34). Troponin I was detectable in 19 cases (14.6%) by the contemporary assays and in 124 (95.4%) cases by the hs assay; by the latter, measurable levels ranged from 2 to 110 ng/L and values exceeding the expected 99th percentile were found in 13.5% of females vs. 5.9 % of males ($p < 0.01$). BNP and Galectin-3 levels exceeded the respective thresholds in 33.8% and 13.8% cases, respectively, with no gender differences. Mean creatinine levels were significantly higher in subjects with raised Galectin (1.70±0.77 umol/L) than in those with normal Galectin (1.06±0.39 umol/L) irrespective of BNP levels. An impaired renal function was detected in 6/9 subjects (66.7%) with both BNP and Galectin elevation (66.7%) compared to 30/121 (24.8%) of the other ($p < 0.05$).

Conclusions: Our observation confirms that cardiac troponin is detectable by hs assays in almost all individuals, especially in elderly individuals that undergo a more active cardiac remodeling. The functional and structural biomarkers of heart failure are often altered in this population and reflect the general worsening of cardiac function in the late stages; whether the increase of the fibrosis biomarker is cause of consequence of the worsening of renal function is still to be investigated.

P1048

Clinical significance of growth differentiation factor-15 in patients with acute decompensated heart failure

R Jankovic-Tomasevic¹; SU Pavlovic²; T Jevtovic-Stoimenov³; S Apostolovic¹; D Stanojevic¹; I Jovanovic³; G Koracevic¹; D Djordjevic-Radojkovic¹; D Penjaskovic⁴

¹Clinical Center of Nis, Cardiovascular Clinic, Nis, Serbia; ²Clinical center of Serbia, Belgrade, Serbia; ³University of Nis, Nis, Serbia; ⁴General Hospital Sremska Mitrovica, Sremska Mitrovica, Serbia

Purpose: Growth differentiation factor-15 (GDF-15) is emerging prognostic biomarker in various cardiovascular diseases. There is scarce information about it in patients with acute heart failure. The aim of our study was to determine the long-term prognostic value of GDF-15 in patients with acute decompensated heart failure (ADHF).

Methods: One hundred and seven consecutive patients (median age 70 [interquartile range, IQR: 60-73.5]; 36% women), hospitalized for ADHF, were examined. The primary and secondary end-points were to determine the differences in mortality and rehospitalization due to heart failure after two years, depending on the GDF-15 plasma level. Twenty-five healthy people of a similar age were in control group.

Results: The patients with ADHF had a significantly higher level of GDF-15 on admission (median 3481 [IQR: 2113-5090]), than the subjects in the control group (887.5 [IQR: 763.75-960.25] ng/L). A high GDF-15 level on admission remained a significant predictor for adverse outcome, shown by a multivariable regression analysis (hazard ratio [HR], 3.69; 95% confidence interval [CI], 1.58-13.53, $p < 0.05$), together with B-type natriuretic peptide ($p < 0.05$). A Kaplan-Meier curve analysis showed a significantly higher probability of death and heart failure rehospitalization in patients with higher levels of GDF-15. The highest mortality rate had patients with both GDF-15 and BNP levels above the median on admission.

Conclusion: The elevated GDF-15 value on admission was strong predictor of an adverse clinical outcome regarding mortality and HF rehospitalization 2-years after the initial hospitalization in patients with ADHF.

P1049

Calculated colloid osmotic pressure as an independent risk factor of mortality in chronic heart failureJ T Niedziela¹; B Hudzik¹; P Rozentryt¹; N Niedziela²; A Ociessa¹; J Nowak¹; M Gasior¹¹Medical University of Silesia, 3rd Department of Cardiology, SMDZ in Zabrze, Katowice, Poland; ²Medical University of Silesia, Department of Neurology, SMDZ in Zabrze, Katowice, Poland

Introduction: Colloid osmotic pressure (COP) is determined by blood proteins and plays a pivotal role in the fluid balance between extra- and intravascular compartments. COP is associated with fluid shifts between compartments, which may result in the edema appearance. In critically ill patients COP was found to be a predictor of survival. Calculated COP (cCOP) based not only on plasma albumin (A), but also globulin (G) concentration, was found to be better correlated with measured COP than plasma albumin level itself.

Purpose: The purpose of this study was to assess the predictive role of cCOP in stable patients with heart failure with reduced ejection fraction (HFrEF) in 1-year follow-up.

Methods: Patients with stable HFrEF (without any clinical signs of congestion) treated in the heart failure outpatient clinic were included into the study. The cCOP was calculated using the Hoeffs equation: $cCOP = A \times (1.058 \times G + 1.063 \times A + 3.11)$. The cCOP was divided into quartiles. The probability of 1-year survival were compared between the groups using log-rank test. The multivariate survival analysis using COX's regression model adjusted for age, sex, LVEF, peak VO₂, NT-proBNP levels, HF etiology and duration was performed. The forward regression was applied for 1-year follow-up.

Results: There were 999 patients included into the study; age 52.8 ± 10.4 years, 13% of them were women, EF $24.3 \pm 6.9\%$, mean NYHA class 2.6 ± 0.7 ; NT-proBNP 2502 ± 2992 pg/mL and mean cCOP 28.85 ± 3.6 mmHg. In the unadjusted survival analyses, the trend toward differences in 1-year mortality between the groups was found (log-rank $p=0.07$). In the multivariate Cox model the Q4 of cCOP was associated with higher 1-year mortality than Q1 of cCOP.

Conclusion: In stable HFrEF patients the higher cCOP is an independent predictor of 1-year mortality. The effect of cCOP changes during albumin supplementation may be an interesting aim of further prospective studies.

Thyroid-stimulating hormone -predictor of long term mortality in heart failure with reduced ejection fractionA Anca Breha¹; C Delcea¹; CA Buzea¹; A Dima¹; RA Popescu¹; M Dobranici¹; I Daba¹; AR Dan¹; C Baicus¹; GA Dan¹¹Colentina University Hospital, Bucharest, Romania

Introduction: Thyroid hormones exert important effects on cardiac structure and function. Both hypo- and hyperthyroidism could induce heart failure. However, data

regarding the clinical significance of thyroid-stimulating hormone (TSH) levels alone as a predictor of mortality in patients with HF with reduced ejection fraction (HFrEF) are sparse.

Purpose: We aimed to assess the value of TSH levels as a predictor for mortality in HFrEF patients.

Methods: We have retrospectively included patients with HFrEF aged over 18 years admitted to our clinic from January 1st to July 31st 2012. Acute coronary syndromes, pulmonary embolism, clinical manifest hypo- or hyperthyroidism, and in-hospital mortality were considered exclusion criteria. TSH levels were measured in all patients, while free T4 values were determined on individual basis. Survival was assessed at 3 years after hospital discharge for each subject.

Results: Our study group consisted of 150 patients with a mean age of 72.71 ± 10.31 years, of which 82 (54.7%) patients were female. Median (minimum; maximum) TSH levels were 1.855 (0.005; 95.76) uIU/ mL. 18 (12%) patients had increased TSH levels (> 4.2 uIU/ mL) and 5 (3.33%) had decreased TSH levels (< 0.27 uIU/ mL). 3-year all-cause mortality was 28.7% for all group. Surviving patients had lower median TSH values of 1.65 (0.016; 52.53) compared to 2.27 (0.005; 95.76) in non-survivors, $p=0.0138$. Mortality increased with TSH value tertile from 10 (19.23%) patients in the first tertile to 20 patients (40.00%) in the highest tertile (p for trend = 0.0239). Patients in the highest TSH tertile had a fatality OR of 2.2 (95% CI 1.05 - 4.58), $p=0.033$ compared to the rest of the sample. In ROC curve analysis, TSH predicted 3-year all-cause mortality with an AUC of 0.629 (95% CI 0.529 - 0.729), $p=0.014$. No correlation with mortality was found for decreased TSH levels.

Conclusion: TSH levels are correlated to survival in HFrEF patients, higher values indicating worse prognosis. We therefor emphasize the importance of thyroid function assessment in all heart failure patients.

P1051

Serial troponin assessment in the early phase of hospitalization for acute heart failure to identify high risk patientsR Zymliński¹; M Sokolski²; J Biegus²; P Siwolowski¹; J Todd³; J Estis³; S Florey³; EA Jankowska⁴; W Banasiak¹; P Ponikowski²¹Centre for Heart Disease - Clinical Military Hospital, Wrocław, Poland; ²Wrocław Medical University, Department of Heart Diseases, Centre for Heart Disease - Clinical Military Hospital, Wrocław, Poland; ³Singulex, California Inc. 1701 Harbor Bay Parkway Alameda, CA 94502, United States of America; ⁴Wrocław Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wrocław, Poland

Background: New sensitive assays for cardiac troponins (Tn) are able to detect very low Tn concentrations. However, clinical interpretation of these findings, outside of acute coronary syndrome, remains unclear.

Purpose: The aim of the study was to interlink different patterns of Tn leak (measured with ultrasensitive assay) with clinical characteristics and outcomes in patients hospitalized with acute heart failure (AHF).

Methods: Ultra-sensitive cardiac TnI (us-TnI) was measured on admission, after 24, and after 48 hours using new diagnostic platform - immunoassay for plasma cardiac TnI by Single Molecule Counting technology (Singulex, USA). The following pattern of usTnI was defined as confirming 'myocardial damage' occurring early during AHF: A. usTnI above the 99th upper reference limit either at baseline or after 24 hours without significant (> 20%) decrease in subsequent samples or B. a significant (> 20%) increase from baseline in 24 and 48 hours. Remaining patients were classified as having 'no myocardial damage' usTnI pattern.

Results: We analyzed 91 patients with AHF (age: 64 ± 12 years, 79% men, 24 % AHF de novo) among whom 30 (33%) met the criteria for 'early myocardial damage'. These patients had on admission: lower systolic blood pressure (124 ± 29 vs 140 ± 36 , mmHg), more often peripheral oedema (60% vs 34%), higher levels of NTproBNP (7116 [4893-14955] vs 4670 [2209-7980], pg/mL), creatinine (1.39 [1.20-1.75] vs 1.07 [0.90-1.30], mg/dL), urea (72 [49-100] vs 46 [37-58], mg/dL) and more common history of chronic heart failure (90% vs 69%) (all $P < 0.05$). During hospital stay 13 % from 'early myocardial damage group' required inotropic therapy and 3.3% pts died (vs 5% and 1.6% in the remaining patients). During 1-year follow-up cardiovascular mortality was significantly higher in patients with 'early myocardial damage' (40% vs 18%, $p=0.023$; test log-rank: $p=0.032$).

61734. Table

All-cause mortality	Model 1 (OPTIMAL)*	Model 2 (MAGGIC)#	CV mortality	Model 1 (OPTIMAL)*	Model 2 (MAGGIC)#
	p	HR (95% CI)†	p	HR (95% CI)†	p
log PICP µg/L	0.008	2.1 (1.2-3.6)	0.05	1.8 (1.0 -3.2)	0.006
log CITP µg/L	0.003	1.9 (1.2-2.8)	< 0.0001	2.3 (1.4-3.7)	0.012
log PICP/CITP	0.200	0.8 (0.6-1.1)	0.057	0.7 (0.4-1.0)	0.55

*model 1 including: age, gender, endsystolic volume, serum creatinine, hemoglobin. # model 2 including: age, gender, diabetes, previous HF, smoking, NYHA class, EF, ACE/ARB, betablockade, BMI, systolic blood pressure, serum creatinine. †Hazard ratios (HR) and confidence intervals (CI) for all-cause and cardiovascular mortality per 1 log unit change.

Conclusion: The pattern of us-TnI characterizing 'early myocardial damage' in patients hospitalized with AHF is associated with worse clinical status and poor outcome. Serial evaluation of us-TnI during early phase of hospitalization for AHF may be useful to identify high risk patients.

P1052

BNP and PCT utility in the management of acute heart failure patients with or without infections

I Lalle¹; G Adducchio¹; L Magrini¹; F Travaglino¹; G Salerno²; P Cardelli²; S Di Somma¹

¹Sant' Andrea Hospital, Emergency Medicine, Rome, Italy; ²Sant' Andrea Hospital, Department of Clinical and Molecular Medicine, Rome, Italy

Background: Procalcitonin (PCT) is a protein up-regulated during bacterial infections and it has been demonstrated that in patients with heart failure, plasma PCT concentration are significantly higher than normal controls, and that there is a relation between PCT levels and 90-day mortality.

Purpose: Aim of this work was to evaluate the independent association between PCT and in-hospital mortality in patients admitted from ED with diagnosis of acute heart failure (AHF) with or without evidence of active infection.

Methods: This was a retrospective analysis of patients admitted for dyspnea with a final diagnosis of respiratory infection or AHF with or without infection. We evaluated the serum levels of PCT and BNP at ED arrival in these different groups and in order to determine the prognostic accuracy in terms of in-hospital mortality, we analyzed ROC curves and calculated the area under curves (AUCs).

Results: 351 patients classified in three groups: pulmonary infection (n 154), AHF without infection (n 146) and respiratory infection complicated by AHF (n 51). 18/351 (5.1%) patients died during hospitalization. Compared to the other two groups, in patients with AHF, the mean PCT values were significantly lower (0.24 ± 0.56 ng/ml). We divided patients with AHF without infection in three different classes based on BNP values and we found that the PCT was higher in patients with higher BNP values. PCT showed to be the best predictor of in-hospital mortality in all considered groups: AHF and infection (cut-off >0.90 ng/ml, AUC 0.79, $p < 0.004$); AHF alone (cut-off >0.10 ng/ml, AUC 0.74, $p < 0.0009$) and infection (cut-off >0.17 ng/ml, AUC 0.70, $p < 0.01$) (Fig.1).

Conclusions: Beside its ability to detect the presence of bacterial infection, in patients presenting to ED with dyspnea due to AHF with or without infection PCT is a good predictor of in-hospital mortality. Our results could suggest that the activation of inflammatory response during AHF could interfere with PCT expression and may contribute to increase serum PCT levels.

PCT and in-hospital mortality

P1053

Disturbances of collagen type 1 metabolism are independent predictors of long-term mortality in systolic heart failure.

H Persson¹; J Lofsjogard¹; J Diez²; B Lopez²; A Gonzalez²; S Ravassa²; M Mejert³; M Edner⁴; T Kahan¹

¹Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Stockholm, Sweden; ²University of Navarra, Center for Applied Medical Research, Program of Cardiovascular Diseases, Pamplona, Spain; ³Ersta Hospital, Stockholm, Sweden; ⁴Karolinska Institute, Department of Medicine Solna, Stockholm, Sweden

Purpose: Disturbances of collagen metabolism may alter the myocardial collagen network and contribute to cardiac remodelling and prognosis in heart failure (HF). Myocardial collagen I synthesis and degradation can be assessed indirectly by the circulating biomarkers carboxy-terminal propeptide (PICP) and carboxy-terminal

telopeptide (CITP), respectively. We examined the associations between PICP and CITP and long-term mortality in HF patients.

Methods: The Optimizing congestive heart failure outpatient clinic project (OPTIMAL) studied patients aged ≥ 60 years with NYHA class II–IV and HF with reduced left ventricular ejection fraction (HFrEF) hospitalised with acute HF during 1996–99. On entry, mean age was 75 years, blood pressure 134/80 mm Hg, ejection fraction 34 %, BNP 312 pg/ml; 55 % were in atrial fibrillation. Dates and causes of mortality were collected up until 2008.

Results: Follow-up was 9–13 years in all 132 patients, mean survival was 5.5 ± 4.0 years. Multivariable Cox regression analyses were performed for all-cause ($n = 101$) and cardiovascular mortality ($n = 61$) by two models (Table). First, variables previously shown to predict mortality in OPTIMAL were included. Second, we used the variables in the heart failure risk calculator from Meta-analysis global group in chronic heart failure (MAGGIC).

Conclusions: Disturbances of collagen type I metabolism have independent prognostic implications for long-term all-cause and cardiovascular mortality in patients with HFrEF. We interpret that the results indicate degradation to be the predominant type associated with untoward prognosis.

Prognostic value of CA-125 in combination with N-terminal pro-brain natriuretic peptide in patients with acute decompensated heart failure

SY Jang¹; DH Yang¹; CY Kim¹; NG Kim¹; MH Bae¹; JH Lee¹; HS Park¹; Y Cho¹; SC Chae¹

¹Kyungpook National University Hospital, Daegu, Korea Republic of

Background: Carbohydrate antigen-125 (CA-125) is an emerging prognostic biomarker in heart failure. We aimed to test the long term prognostic value of CA-125 in combination with N-terminal pro-brain natriuretic peptide (NT-proBNP) in patients with acute decompensated heart failure.

Methods: A total of 457 patients (64.4 ± 16.1 years-old, 236 men) suffered acute decompensated heart failure between 2005. Jan and 2013. July were retrospectively enrolled. All-cause mortality was investigated for the prognosis of the patients.

Results: During follow-up (35.9 ± 28.7 months), 152 (33.2%) deaths were recorded. In multivariable analysis model, CA-125 was an independent prognostic marker (log CA-125 hazard ratio 1.241 [1.051–1.465], $p = 0.010$) together with age, sex, NYHA class, systolic blood pressure, β -blocker use, inotropics use and NT-proBNP level. Kaplan-Meier analysis showed that patients with both elevated CA-125 and NT-proBNP level exhibited worse prognosis compared to those with any single marker solely-elevated (Figure 1). Likelihood ratio test showed that addition of NT-proBNP level to established risk factors increase the predictive power for mortality (global chi-square from 156.2 to 167.2, $p < 0.001$). Addition of CA-125 on the top of the combination of NT-proBNP and established risk factors still more increased the predictive power for mortality (global chi-square from 167.2 to 173.7, $p = 0.011$) in patients with acute decompensated heart failure.

Conclusion: CA-125 was an independent prognostic marker in patients with acute decompensated heart failure. Combined use of CA-125 and NT-proBNP provided a significant improvement in prognostic power for mortality in patients with acute decompensated heart failure.

Multi-biomarker profiling and recurrent hospitalizations in heart failure

A Bayes-Genis¹; J Nunez²; M Domingo¹; E Nunez²; J Barallat¹; M De Antonio¹; E Zamora¹; C Pastor¹; J Sanchis²; J Lupon¹

¹Germans Trias i Pujol University Hospital, Badalona, Spain; ²University Hospital Clinic of Valencia, Valencia, Spain

Background: Despite current treatment with evidence-based drugs and devices, patients with heart failure (HF) are frequently admitted to the hospital because of symptom exacerbation, and once admitted, they are often readmitted. Risk prediction of recurrent hospitalizations has often been downplayed, with study endpoints focused on time-to-first event analysis and disregarding the impact of recurrent readmissions that frequently occur in HF. Objective: We sought to explore whether a multi-biomarker panel (including NT-proBNP, hs-TnT, and ST2) is superior to clinical assessment for long-term prediction of recurrent hospitalizations in HF.

Methods: NT-proBNP, high-sensitivity troponin T (hs-TnT), and ST2 levels were measured in 891 consecutive ambulatory HF patients. The state-of-the-art statistics were used. The independent association between the multi-biomarker panel and recurrent hospitalizations was assessed through a multivariable negative binomial regression and expressed as incidence rates ratio. McFadden pseudoR2 and goodness-of-fit measures were also used. The total number of unplanned hospitalizations (all-cause, cardiovascular [CV]-, and HF-related) were selected as the primary endpoints.

Results: At a mean follow-up of 4.2 ± 2.1 years, 1623 all-cause hospitalizations in 498 patients (55.9%), 710 CV-related hospitalizations in 331 patients (37.2%), and 444 HF-related hospitalizations in 214 patients (24.1%) were registered. The crude incidence of all-cause, CV-, and HF-related recurrent hospitalizations was significantly higher for patients with the multi-biomarker panel above the cut-point (hs-TnT > 14 ng/L, NT-proBNP > 1000 ng/L, and ST2 > 35 ng/mL) (all $P < 0.001$) (figure). For all-cause, CV-, and HF-related recurrent hospitalizations, the McFadden R2, Akaike information criterion, and Bayesian information criterion supported the superiority of incorporating the multi-biomarker panel into a clinical predictive model.

Conclusions: A multi-biomarker approach that incorporates NT-proBNP, hs-TnT, and ST2 better identifies HF patients at risk for recurrent hospitalizations. Elucidation of new biophysiological targets for recurrent hospitalizations may identify patient profiles for focused intervention.

P1056

Testing for soluble ST2 in heart failure patients: reliability of a point of care method

D Damien Gruson¹; B Ferracin¹; S Ahn¹; M Rousseau¹

¹Saint-Luc University Clinics, Brussels, Belgium

Background: Soluble ST2 (sST2) is a soluble decoy receptor able to quench the biological activity of IL-33, a cytokine preventing the apoptosis of cardiomyocytes and improving cardiac function. The increase of circulating sST2 levels is related to cardiac remodeling, fibrosis and to the severity of Heart Failure (HF).

Purpose: Our objectives were to determine the clinical validity of a recently developed point of care (POCT) assay for measurement of sST2.

Methods: Samples of forty-nine HF patients (NYHA II-IV; mean age: 67 years; median LVEF: 23%) were measured with the sST2 POCT assay and with a reference ELISA method. Circulating levels of BNP, NT-proBNP, Galectin-3 and PTH(1-84) were determined with automated immunoassays.

Results: The median sST2 levels measured with the POCT and ELISA assays were 37.7 ng/mL (range: 12.5–250) and 39.1 ng/mL (18.4–200), respectively. Both methods were significantly correlated ($r = 0.93$, $p < 0.0001$). Passing-Bablok regression analysis showed a slope of 1.5 and an intercept of 22.5. Bland-Altman plot

evidenced a bias between the methods with a mean bias of 5.2 ng/mL. However, the POCT method was faster by allowing a turnaround time of analysis lower than 30 minutes. Levels of sST2 determined with the POCT were significantly related to the left ventricular ejection fraction. Concentrations of sST2 measured by the POCT assay were also significantly and positively correlated to BNP ($r = 0.75$, $p < 0.001$), NT-proBNP ($r = 0.57$, $p < 0.001$), Galectin-3 ($r = 0.40$, $p < 0.01$) and PTH(1-84) ($r = 0.39$, $p < 0.01$).

Conclusions: Our results confirm the reliability of the sST2 POCT assay and its compatibility with clinical practices. Moreover, the POCT method allows a faster delivery of results to physicians.

P1057

A new marker for poor NYHA functional class in heart failure with reduced ejection fraction: C-reactive protein / lymphocyte ratio

O Osman Beton¹

¹Cumhuriyet University, Cardiology, Sivas, Turkey

Background and objectives: Exercise intolerance and higher New York Heart Association (NYHA) classes predict poor prognosis in patients with heart failure with reduced ejection fraction (HFrEF). Heart failure (HF) is characterized by ongoing inflammation mediated by proinflammatory cytokines and inflammatory mediators. The studies demonstrated that increased C-reactive protein (CRP) level or decreased lymphocytes level is associated with poor functional capacity in patients HFrEF. However no data exists about the association between CRP/lymphocyte ratio and functional capacity in patients with stable HF. In this study, we aimed to investigate the relationship between functional status and CRP/lymphocyte ratio in outpatients with HFrEF.

Methods: A total of 246 consecutive patients with HFrEF diagnosis for at least 6 months duration who were admitted to outpatient cardiology clinic, were included in this prospective study. Patients were divided into 2 groups according to NYHA class: NYHA class I-II (group 1) and NYHA class III-IV (group 2).

Results: The mean age of patients was 43 ± 11 years. CRP value was statistically higher, and lymphocyte level was statistically lower in NYHA III-IV group. Furthermore, the median CRP/lymphocyte ratio (0.8 vs 0.2, $p < 0.001$) was significantly higher in NYHA III-IV group as compared to NYHA I-II group. In multivariate logistic regression model, CRP/lymphocyte ratio (OR: 1.393, 95% CI: 1.080-1.798, $p = 0.011$), hemoglobin level (OR: 0.809, 95% CI: 0.659-0.992, $p = 0.042$), LVEF (OR: 0.872, 95% CI: 0.805-0.945, $p = 0.001$), and digoxin usage (OR: 2.488, 95% CI: 1.132-5.647, $p = 0.023$) were remained associated with poor NYHA functional class in HFrEF outpatients (Table 1).

Conclusion: We demonstrated that CRP/lymphocyte ratio was strongly associated with poor NYHA functional capacity, independently from coronary heart disease risk factors in stable HFrEF outpatients.

Predictors of poor NYHA functional class

P1058

Magnitude of brain natriuretic peptide elevation in the emergency department is associated with all-cause cardiac diagnosis, but not necessarily acute decompensated heart failure

C Cunningham¹; LF Cheng¹; C Cassidy¹; A Seed¹¹Blackpool Teaching Hospitals NHS Trust, Blackpool, United Kingdom

Background: Brain natriuretic peptide (BNP) testing is effective in excluding acute decompensated heart failure (ADHF) in the Emergency Department (ED) due to high negative predictive value. However, BNP is elevated in other cardiac and non-cardiac conditions. The clinical utility of an elevated BNP in ED patients is less well defined.

Purpose: In patients presenting to an ED with no predefined protocol for BNP testing, we aimed to determine (i) the diagnoses associated with elevated BNP according to magnitude of BNP elevation, and (ii) the proportion of these patients with ADHF and left ventricular systolic dysfunction (LVSD).

Method: BNP results were identified from laboratory records over a 3-month period. For patients with elevated BNP, case records were reviewed for clinical features and echocardiographic findings. Primary and subsidiary diagnoses and mortality rates were determined from hospital coding statistics.

Results: 192 patients were included, of whom 62 had normal BNP levels (<100 pg/ml) and 130 elevated: 60 with mildly elevated BNP (100-399 pg/ml; Group A) and 70 with significantly elevated BNP (≥ 400 pg/ml; Group B). As shown in the table, Group B patients were more likely to receive a primary ADHF diagnosis, and to have LVSD. A cardiac primary diagnosis (ADHF, acute coronary syndrome, arrhythmia and valve disease) was twice as likely in this group. A non-cardiac or respiratory diagnosis was more likely in Group A. 6-month mortality was similar between groups. **Conclusion:** ADHF accounted for a minority of primary diagnoses in ED patients with elevated BNP, however ADHF and other primary cardiac diagnoses are more likely in patients with BNP ≥ 400 pg/ml compared to those with BNP 100-399 pg/ml. ED physicians should have high index of suspicion for cardiac disease in patients with BNP ≥ 400 pg/ml, however ADHF should not be diagnosed from elevated BNP alone.

Patient characteristics

	Group A (BNP 100-399, n=60)	Group B (BNP ≥ 400 , n=70)
Mean age, years	75	77
Deaths at 6-months, n (%)	15 (25.0)	17 (24.3)

Diagnosis not determined, n (%)	9 (15.0)	7 (10.0)

P1059

Relation between left ventricular global longitudinal strain and B-type natriuretic peptide in patients with chronic heart failure

R De Vecchis¹; C Baldi²; C Cioppa³; A Giasi¹; G Di Biase³; S Cantatrone¹¹Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy;²Heart Department, Interventional Cardiology, A.O.U. "San Giovanni di Dio e Ruggi D'Aragona", Salerno, Italy;³Neurorehabilitation Unit, Clinica "S.Maria del Pozzo", Somma Vesuviana, Italy

Introduction: In the setting of chronic heart failure (CHF) patients, the finding of elevated levels of B-type natriuretic peptide or of the N-terminal fragment of the pro B-type natriuretic peptide (NT-proBNP) is a reliable marker of pathological increase in myocardial ventricular wall stress and detrimental rise in ventricular filling pressures. However, the ensemble of data concerning the relationship between longitudinal deformation indices and NT-proBNP is still rather vague and approximate.

Methods: We carried out a retrospective study that involved 118 CHF patients admitted to our clinic for CHF outpatients. For inclusion in the study, the CHF patients were required to have undergone at least a determination of global longitudinal strain (GLS) by means of two-dimensional speckle tracking echocardiography and to have practiced at least a determination of NT-proBNP. Furthermore, the two determinations should have been carried out in a condition of substantial simultaneity, that is, the former should have been done not more than 24 hours before or after the latter.

Results: Correlation between log (NT-proBNP) and GLS was highly significant ($r=0.8247$; $p<0.0001$). The observed correlation between log (NT-proBNP) and left ventricular ejection fraction (LVEF) was also significant, but explained a smaller magnitude of the variance ($r=-0.335$; $p=0.0019$). In CHF patients with reduced

ejection fraction (HFREF) and in those with preserved ejection fraction (HFpEF) analyzed separately, log (NT-proBNP) exhibited a stronger overall correlation with GLS (HFREF, $r=0.8426$, $p<0.0001$; HFpEF, $r=0.8472$, $p<0.0001$) compared with LVEF (HFREF, $r=-0.3592$, $p=0.1568$; HFpEF, $r=-0.3437$, $p=0.0502$). The median value of NT-proBNP (namely, 495 pg/mL) was used as a discriminating value for identifying relatively low (i.e., below the median) and relatively high (i.e., above the median) levels of natriuretic peptide. In this manner, higher (namely less negative) values of GLS were associated with significantly increased probability of higher levels of NT-proBNP (i.e., >495 pg/mL). On the contrary, higher values of LVEF were associated with significantly increased probability of reduced levels of NT-proBNP (i.e., ≤ 495 pg/mL). However, the C-statistics for GLS were significantly higher than for LVEF [area under the curve (AUC): 0.949 (GLS) vs. 0.730 (LVEF); $p=0.0038$].

Conclusions: In CHF patients with apparently preserved systolic function as well in those with reduced ejection fraction, GLS is more accurate compared with LVEF in predicting increased levels of NT-proBNP.

P1060

Role of NT proBNP in preventing left ventricular dysfunction in hypertensive patients

I Irina Dimitriu¹; D Voiculescu¹; M Raileanu¹; C Sinescu¹¹Carol Davila University of Medicine and Pharmacy, Cardiology, Bucharest, Romania

Purpose: To study the importance of NTproBNP in guiding treatment to prevent left ventricular dysfunction in hypertensive patients.

Methods: We included 168 patients with hypertension who were present at hospital for cardiology consultation for one and a half year. We excluded patients who are already diagnosed with heart failure, left ventricular systolic dysfunction. We randomized patients into 2 equal groups: a control group (84 patients) and an intervention group (84 patients). NTproBNP value was determined in all patients. In the intervention group patients were treated according to the NTproBNP value. Patients who had NTproBNP value <125 pg / dl (36 patients) received standard treatment for their symptoms. Patients who had NTproBNP value >125 pg / dl (52 patients) were the ones on which we intervened to prevent left ventricular dysfunction. They were investigated by cardiac ultrasound and other specific tests of each case (blood test, stress test, ECG monitoring / 24h). After completing medical balance, each patient received specific treatment. Patients in the control group received standard treatment of for their symptoms regardless of the NTproBNP value.

Results: The end points were: systolic or diastolic left ventricular dysfunction, and the rate of hospitalizations for cardiovascular pathology. After two year, in the control group 29 (34.5%) patients were diagnosed with left ventricular systolic dysfunction, compared to 21 (25%) in the intervention group. In control group were 56 (66.6%) patients diagnosed with left ventricular diastolic dysfunction, compared to 43 (51.1%) in the intervention group. Also, and rate of admissions for heart disease was higher in the control group 33 (39.2%) versus 16 (19%) patients in the intervention group.

Conclusions: Patients in the intervention group, in which the value of NTproBNP was used in choosing therapeutic management have lower rate of incidence diastolic and systolic left ventricular dysfunction or cardiovascular events than patients in the control group. In conclusion medical intervention guided by NT proBNP can prevent or delay left ventricular dysfunction in hypertension patients.

*result as mean(standard deviation); ** result as median (interquartile range)

2015). Sociodemographic, clinical and quality of life variables were recorded. Descriptive statistics were performed: mean (or median) and standard deviations (or interquartile range) were calculated. Otherwise, frequencies and percentages were computed. These statistical analyses were developed using SAS System v9.4.

Results: A sample of 59 patients were recruited, 14(23,7) being female. The mean age was 61,1 years, the Minnesota Living with HF Questionnaire (MLWHFQ) 51,9(24) and 51(87,9%) patients had LVEF \leq 25% (Table)

Conclusions: Relatively young patients(older patients tend to be assigned to internal medicine), male(greater presence of women in preserved LVEF;possible selection bias), low educational level, quality of life greatly affected, most of them having severely depressed LVEF, CVRF and comorbidities(despite probable under-registration). Specialized multidisciplinary holistic approach is crucial.

Is individual patient education a reliable tool to prevent heart failure in diabetes?

A Adriana Coppola¹; AM Bagnasco²; M Fodaro³; P Gallotti³; C Falcone⁴; L Sasso²; C Gazzaruso³

¹Clinical Institute Beato Matteo, Vigevano and University of Genoa, Diabetes and Endocrinology Unit, Vigevano, Italy; ²University of Genoa, Department of Health Sciences, Genoa, Italy; ³Clinical Institute Beato Matteo, Diabetes and Endocrinology Unit, Vigevano, Italy; ⁴University of Pavia, Istituti Clinici Pavia e Vigevano, Pavia, Italy

Background: Diabetes is a strong predictor of Heart Failure (HF). Glycemic control, obesity and blood pressure (BP) can have a major role in the development of HF among diabetic patients. Therapeutic Patient Education (TPE) has a major role in diabetes management and in the improvement of all outcomes. PURPOSE. to evaluate whether individual TPE can reduce some risk factors for HF in diabetes.

Methods: All people followed for at least 24 months in the randomized controlled INTEND (Individual Therapeutic Education in Newly Diagnosed type 2 diabetes) study were recruited. Twenty-seven newly diagnosed type 2 diabetic patients who received an individual TPE (GROUP A) were compared to 27 age- and sex-matched newly diagnosed type 2 diabetic patients in usual care (GROUP B). The two study groups were comparable in age (62.9 \pm 9.2 vs 61.0 \pm 8.6 years), sex (males 40.7 vs 48.1%), HbA1c, BMI, systolic BP and diastolic BP at baseline. No patient had HF at baseline on the basis of clinical, ECG and echo criteria.

Results: After a 24-month follow-up period both GROUP A and GROUP B showed significantly (p<0.01) lower HbA1c (GROUP A: 9.0 \pm 2.4 vs 6.5 \pm 0.9%; GROUP B: 8.7 \pm 1.5 vs 7.6 \pm 0.9%), systolic BP (GROUP A: 168.0 \pm 12.1 vs 144.1 \pm 15.1 mmHg; GROUP B: 168.7 \pm 14.8 vs 149.4 \pm 15.9 mmHg) and diastolic BP (GROUP A: 83.4 \pm 10.6 vs 70.7 \pm 9.9; GROUP B: 84.3 \pm 9.4 vs 75.1 \pm 6.9 mmHg) than at baseline. BMI was significantly decreased at the end of the follow-up in the GROUP A (30.9 \pm 4.9 vs 26.8 \pm 10.1; p<0.01) but not in the GROUP B (29.9 \pm 4.0 vs 30.9 \pm 4.5). At the end of the follow-up HbA1c, BMI, systolic BP and diastolic BP were significantly lower in the GROUP A than in the GROUP B. In addition in 6 patients of the GROUP A and 14 patients of the GROUP B an intensification of therapy for diabetes and/or hypertension was needed. No patient developed HF during the follow-up.

Conclusions: Individual TPE may be a reliable tool to control risk factors for HF in type 2 diabetes

P1063

Role telenursing on quality of life and readmission patient with heart failure

N Elahi¹; SH Baraz¹

¹Chronic diseases Care center of Ahvaz jundishapur medical sciences -Ahvaz- Iran, Nursing, Ahvaz, Iran (Islamic Republic of)

Background: The Nature of heart failure causes reducing the quality of life and higher readmission in patients.

Purpose: To measure the impact of tele nursing on patients discharged with heart failure.DESIGN: Experimental study (RCT).SAMPLE: 42 patients with heart failure were divided into two groups by using the purposive sampling method based on random allocation. Medical centers with traditional care (21patient) and traditional care plus telenursing (21patient).

Methods: This trial compared 2 post-hospitalization nursing care models for reducing congestive heart failure (CHF) readmission charges during 90 days of follow-up. Subjects received in-person visits at baseline and 60 days plus 1 of 2 care modalities in the interim: telenursing(telephone calls and message) and usual care. Minnesota's questionnaire of quality of life was completedFINDINGS: Telenursing patients indicated higher satisfaction. Overall costs for both types of visits were about equal. The control group have increased cost of 1.30 \$ per patient (P \leq 0.002). The results showed telenursing was difference statistically significant) P <0/000).

Conclusions: Combining traditional care and and telenursing is feasible for supporting discharged patients with new heart failur and enhances traditional care, resulting in increased satisfaction overall.

P1064

Perception about heart failure telemonitoring of physicians and nurses from Japan and Sweden

N Kato¹; P Johansson¹; I Okada²; K Kinugawa³; A Stromberg⁴; T Jaarsma¹

¹Linköping University, Department of Social and Welfare Studies, Linköping, Sweden; ²The University of Tokyo, Department of Therapeutic Strategy for Heart Failure, Tokyo, Japan; ³University of Toyama, The 2nd department of Internal Medicine, Toyama, Japan; ⁴Linköping University, Department of Medical and Health Sciences, Linköping, Sweden

Background: Non-invasive telemonitoring of heart failure (HF) patients is increasingly addressed in research. However, little is known about perception of telemonitoring among healthcare professionals who are working with HF patients in daily clinical practice.

Aim: The aim of this study was (1) to describe perception of non-invasive HF telemonitoring among Japanese and Swedish physicians and nurses and (2) to compare the perception between physicians and nurses.

Methods: A cross-sectional questionnaire survey of non-invasive HF telemonitoring was performed in Japan and Sweden between November 2013 and May 2014. A total of 378 Japanese (120 cardiologists, 258 nurses) and 120 Swedish (39 cardiologists, 81 nurses) healthcare professionals from 165 Japanese and 61 Swedish hospitals/clinics nationwide (210 in Japan, 98 in Sweden approached) participated in the study. Participants were asked if they were familiar with HF telemonitoring (yes/no). They were also asked about good ways to follow up stable HF patients (multiple choice). In addition, participants were asked about main purpose for telemonitoring, reasons for introducing telemonitoring in HF patients as well as criteria

to select HF patients for telemonitoring with a questionnaire that was adapted from a previous Dutch study.

Results: There was a significant difference in familiarity of non-invasive HF telemonitoring between physicians (40%, $n=63$) and nurses (16%, $n=55$) ($p<0.01$). In total 24% of physicians ($n=38$) and 27% of nurses ($n=92$) thought that "Telemonitoring" was a good way to follow up stable HF patients. Regardless of profession, the most frequent purpose for choosing HF telemonitoring was "monitoring physical condition and noticing a decline" (physicians 93%, $n=144$; nurses 93%, $n=309$). Among nurses (64%, $n=215$) "patient education" was more frequently seen as a purpose ($p=0.02$) compared with physicians (53%, $n=82$). There were no differences in reasons for introducing telemonitoring rated on a scale from 0-10 (low-high): to reduce hospitalizations (8.4 in physicians and 8.0 in nurses), and to increase patients' self-care (7.6 and 7.8). Regarding criteria to select HF patients for telemonitoring, most of physicians (91%, $n=141$) and nurses (79%, $n=263$) chose "admission/readmission," meanwhile "patient education" and "support and advice" were more frequent criteria among nurses (57%, $n=191$, 47%, $n=157$, respectively; both $p<0.01$).

Conclusions: Nurses are less familiar with non-invasive HF telemonitoring than physicians. Regardless of profession, healthcare providers have expectations of telemonitoring to reduce patients' hospitalizations and increase patient self-care. More nurses have perception that telemonitoring could be a tool for helping patient education and support.

P1065

The greek version of teamSTEPPS teamwork perceptions questionnaire and minnesota satisfaction questionnaire "short form"

Heart Failure Association - nurse training fellowship

I Lakatamitou¹;

E Lambrinou²; L Paikousis²; N Middleton²

¹American Heart Institute/American Medical Center, Nicosia, Cyprus; ²Cyprus University of Technology, Limassol, Cyprus

Background: Teamwork and job satisfaction is important among the multidisciplinary team who care HF patients. TeamSTEPPS and Minnesota Satisfaction Questionnaire "short form" are both self-report questionnaires which examine multiple dimensions of perceptions of teamwork and job satisfaction, respectively within healthcare settings. Our aim is to examine the psychometric properties of the Greek versions of the TeamSTEPPS Teamwork perceptions questionnaire (GrT-TPQ) and Minnesota Satisfaction Questionnaire "short form" (GrMSQ-short). Method: A methodological study was conducted in order to assess the construct validity and reliability of the GrT-TPQ and GrMSQ-short. For that reason, 292 questionnaires were administered by Greek-Cypriot health care professionals (HCPs). Confirmatory factor analysis (CFA) and Exploratory factor analysis were conducted to examine the relationship between the five T-TPQ dimensions. Cronbach's α was calculated as well.

Results: CFA of GrT-TPQ confirmed the initial scale structure with excellent fit indices (χ^2 (df) 1124.75 (550), $p<0.0001$, AGFI=0.986, TLI=0.994, CFI=0.994, RMSEA=0.06, 90%, C.I.[0.055-0.065]). Furthermore, all dimensions were found to be correlated ($r=0.65$ to $r=0.88$) and internal consistency was found adequate (Cronbach's $\alpha=0.96$). Subscales also, demonstrated high internal consistency ($\alpha=0.87-0.95$). CFA for GrMSQ-short, did not confirm the initial scale's dimensions. In EFA items 1, 5, 6, 12 and 18 were eliminated from the analysis due to low communalities and multiple components loading. Two components were found representing the intrinsic and extrinsic aspects of job satisfaction.

Conclusions: GrT-TPQ and GrMSQ-short are construct-valid instruments for measuring perceptions of teamwork and job satisfaction. This has increased implications on future use and research on HCPs who care for patients with HF.

P1066

Self-care behavior and its associated factors among heart failure patients in Pakistan.

AMBREE Gowani¹; RAISA Gul¹; SAJID Dhakam¹

¹Aga Khan University, Medicine, Karachi, Pakistan

Abstract Heart Failure is a progressively worsening clinical syndrome associated with poor quality of life and higher hospital readmissions. Self-care in heart failure is considered equally important to its pharmacological management. Literature indicates that the level of self-care varies among different culture. However, little is known about the self-care behaviors and its predictors among HF patients in the developing countries. Therefore, this study aimed to determine the level of SCB and its associated factors among HF patients in Pakistan. The study was conducted using a sequential mixed method approach. The SCB of 230 heart failure patients were assessed using European Heart Failure Self-Care Behavior Scale_9 (EHFScBS_9) via a cross sectional survey. Moreover, eight patients were interviewed to explore the factors affecting their SCB. The mean score of the EHFScBS was 29.30 ± 7.06 . In multivariate Analysis, education, income and chronicity of the HF diagnosis were associated with better SCB ($P<0.005$). Moreover, analyses of the

qualitative data showed patients' financial status, family support, health education and support of the health care system as important factors affecting the SCB of HF patients. The overall level of the self-care was found to be sub-optimal. The convergence of the quantitative and qualitative findings revealed that patients' financial status, education and experience of the illness are the key determinants of SCB among HF patients in Pakistan. Hence, this study has implications for the health care providers, policy makers and donors to establish HF management programs for the patients in our culture.

P1067

Nursing care in patients undergoing left ventricular assist devices (LVAD) implantation as bridge to transplantation therapy

FABRICIO Fabricio Canova Calil¹; BRUNA Carneiro Oliveira¹; DANILO Ribeiro Galantini¹; BRUNO Biselli¹; MONICA Samuel Avila¹; RENATA Lopes Hames¹; SILVIA Moreira Ayub Ferreira¹; ELAINE Marques Hojaij¹; LUANA Llagostera Sillano¹; MARIA Auxiliadora Ferraz¹

¹Hospital Sirio-Libanês, New Heart Project, Sao Paulo, Brazil

Introduction: the advent of implantable ventricular assist device (VAD) to treat advanced heart failure has changed dramatically this high mortality syndrome. The action of nursing in this context takes on a prominent role, especially in reducing driveline infection and major bleeding related to long term mechanical circulatory support. Purpose: to describe the nursing care practices related to implantable VAD patients and correlate them to the incidence of driveline infection and major bleeding observed in a given period.

Method: qualitative and descriptive (observational) study correlating the standardization of nursing practices to patients treated with implantable VADs from October 10, 2013 to January 18, 2016 and the incidence of major bleeding and driveline infection as INTERMACS registry settings. The standardization followed the practices regarding: (i) patient and caregiver's education (self-care: bathing, exercise and oral hydration); (ii) dressing driveline changes (technical, frequency, materials, exit site wound classification and photographic record); (iii) the stability of driveline; (iv) alarm interpretation (batteries and self-test); (v) home visit (adaptation of day-by-day routines); (vi) oral anticoagulation control (outpatient protocol).

Results: since the beginning of the VAD implant program, a rate of 178 patients-day free of bleeding and/or infection of the driveline exit site according to INTERMACS setting was observed.

Discussion(s): the role of the specialized nursing team in mechanical circulatory support is crucial to major bleeding and driveline infection free survival for patients receiving durable VAD. The systematization and organization of nursing actions in specific protocols is the key. Educational guidance of nurses to patients after VAD implantation covers the surgical recovery process, the care of driveline's exit site and the device handling; contribute to self-post hospital care and possible improvement of symptoms while waiting for a heart transplant.

Usefulness of a simple educational tool with 4-colour leaflets to increase adherence to medication and assessment of patients satisfaction with it

C Costa Grana¹; E Barge Caballero¹; C Naya Leira¹; P Farinas Garrido¹; G Barge Caballero¹; P Blanco Canosa¹; Z Grille Cancela¹; MJ Paniagua Martín¹; D Couto Mallon¹; MG Crespo Leiro¹

¹University Hospital Complex A Coruña, Heart Failure Unit, A Coruña, Spain

Background: Patients with heart failure (HF) require complex pharmacological treatment to increase survival and quality of life. Health education is mandatory to promote patient's self-care and has demonstrated to improve outcomes. The use of simple educational tools may be key to achieve this goal.

Purpose: Primary objective: To assess the usefulness of a simple informational tool (4-colour leaflets, based on the 2012 HF Guidelines ESC) for increase the adherence to medication in HF with reduced ejection fraction (HFrEF) patients. Secondary objective: To assess the patient's acceptance and satisfaction on these informational tools.

Methods: Consecutive patients with HFrEF (defined as LVEF <40%) seen at our HF Unit and receiving any of the disease-modifying therapies for HFrEF drugs (RAAS inhibitors, beta-blockers, mineral receptor antagonists, and ivabradine) were invited to participate. The only exclusion criterion was refusal to participate and/or unavailability to understand the information. Changes in adherence to pharmacological treatment was assessed using the Morisky Medication Adherence Scale (MMAS-4) basal and after 6 months. MMAS (from 0% to 100% according correct response to 1 to 4 questions); 3-4 was considered "full adherence" and 0-2 "poor adherence". Patient's satisfaction was assessed with a survey of 5-point multiple Likert response questions (from 1 minimum to 5 maximum).

Results: Among 234 patients enrolled between March and June 2015, this preliminary analysis on adherence has been done on 174 patients (mean age 67.7 years SD 10.3; 80.5% male) who had completed baseline and 6-month MMAS by the time of data analysis. NYHA class status were as follows: I (37 patients, 21.3%), II (105 patients, 60.3%), III (31 patients, 17.8%) and IV (1 patient, 0.6%). The distribution of etiology was as follows: 77 (44.3%) ischemic, 68 (39.1%) dilated and 29 (16.7%)

other. Most patients (156/174, 89.7%) reported full-adherence by means of MMAS-4 already at entry, proportion that did not significantly changed at six months (152/174, 87.4%; $p = n.s.$). Nevertheless, among patients with poor adherence at entry, 55.6% of them (10 out of 18) became full adherent after tool implementation ($p < 0.001$). In addition, 64.2% of participants who completed the satisfaction survey showed high levels of satisfaction (4 or 5 in the Likert scale).

Conclusions: Even among patients with high adherence to recommended treatments as ours, identification of "low adherents" by means of MMAS and implementation of this well accepted educational tool may be of clinical utility.

P1069

Hospitalised heart failure patients: what is behind their satisfaction with nursing care?

R Rosario Caruso¹; F Dellafore¹; F Pittella²; MP Caruso²; B Fiorini³; R Tramarin³
¹IRCCS, Policlinico San Donato, Health Professions Research and Development Unit, San Donato Milanese, Italy; ²IRCCS, Policlinico San Donato, Nursing Degree Course, San Donato Milanese, Italy; ³IRCCS, Policlinico San Donato, Department of Perioperative Cardiology and Cardiac Rehabilitation, San Donato Milanese, Italy

Introduction: There is an increasing interest on patient satisfaction in healthcare. Moreover, the satisfaction with nursing care is a relevant indicator for hospitals quality of care. Its measurement is also strategic to define and meet patients' needs in terms of care, particularly in patients with a chronic and multifaceted conditions, such as the chronic heart failure (HF). However, the relations between specific domains of clinical practice (i.e. carelessness, emotional support, relationship and caring times) and patient satisfaction with nursing care are not clear. Purpose The aim of this study is to assess which areas of clinical practice influence the patient satisfaction and to describe its relationship with socio-demographic characteristics in patients with HF.

Methods: An observational, cross-sectional and correlational study design was used, with a convenience sample of 201 hospitalized HF patients (NYHA class II-III) (mean age 66.8 years, SD 8.6; 63% men). After a written informed consent and the socio-demographic variables collection, patient satisfaction was assessed using the Newcastle Satisfaction with Nursing Scales (Italian version), measuring 6 domains (overall satisfaction, satisfaction with nursing care, carelessness, emotional support, relationship and caring times).

Results: Overall satisfaction and satisfaction with nursing care had high rating scores and there were no statistically differences considering gender, age and literacy ($P > 0.05$). Considering different multiple regression models results, the domains of relationship ($\beta 1$) and emotional support ($\beta 2$) were the unique predictors of overall satisfaction ($\beta 1 = 0.43$; $P < 0.001$) ($\beta 2 = 0.24$; $P < 0.05$) and for the satisfaction related to nursing care ($\beta 1 = 0.52$; $P < 0.001$) ($\beta 2 = 0.22$; $P < 0.05$).

Conclusion: This study provides a preliminary description of the satisfaction of Italian patients hospitalized for HF: some peculiarities are conflicting with the majority of literature about satisfaction (e.g. no differences in scoring comparison between gender, age and literacy). The results highlight the important role played by relationships and emotional support in nursing clinical practice, being the unique predictors of satisfaction. Indeed, the results showed that the carelessness domain was not a negative predictor of satisfaction. Further multicenter investigations with wider samplings are needed for better understanding of satisfaction in hospitalized HF patients.

P1070

Thirst in patients with heart failure in daily life

MHL Van Der Wal¹; N Waldeus¹; T Jaarsma¹

¹Faculty of Medical and Health Sciences, Department of Social and Welfare Studies, Linköping, Sweden

Introduction: Thirst is one of the distressing consequences of heart failure (HF) and can cause a decrease in quality of life, especially in patients with worsening HF. There is some knowledge on thirst in HF patients seeking health care for medical treatment in a controlled study setting with in- and exclusion criteria. However, it is unknown how often and to what extent thirst occurs in a regular HF population visiting a HF clinic.

Purpose: To assess thirst and thirst intensity in a regular patient population visiting a HF clinic in the Netherlands and to assess which variables are related to thirst intensity.

Methods: Data were collected in 2 HF clinics. In total 197 HF patients (mean age 66 ± 14 ; 40% female) were asked whether they were thirsty at the moment of the visit and if they were thirsty in the week preceding the visit. An additional sample of 66 HF patients (mean age 72 ± 10 ; 54% female; 75% NYHA-II) also assessed their thirst intensity using the visual analogue scale. This is a validated scale ranging from no thirst (0) to worst possible thirst (100). Patients were also asked what they perceived as a cause for their thirst and which interventions they undertook to relieve thirst (open question). HF nurses collected data on age, gender, NYHA-class, prescribed diuretics and fluid restriction.

Results: Of the total 197 patients, 17% reported thirst at the visit to the HF clinic and 28% of all patients experienced thirst the week before they visited the HF clinic.

No differences in age and gender between patients with and without thirst were found. Of the sample with additional data collection the mean thirst intensity was 23 ± 23 (range 0-90). Most of the patients (65%) were prescribed a fluid restriction of 1750 ml; 30% had a restriction of 2000 ml. No significant differences were found in thirst intensity between patients with different amounts of fluid restriction (1750 of 2000 ml), men and women and patients in NYHA-II compared to patients in NYHA-III. Patients with a higher dose of loop diuretics (> 40 mg Furosemide) reported significantly more thirst than patients without or with a lower dose of Furosemide (28 vs. 21; $p = .01$). Most reported reasons for thirst were salty or spicy foods (15%), dry air, heat or exertion (12%) or a low fluid intake (11%). Interventions patients undertook themselves were drinking water, tea or other fluids (62%). Almost 30% of these patients reported to drink just a little bit, probably due to their fluid restriction.

Conclusion: Almost every 5th patient visiting the HF clinic reported to have thirst. Higher dose of loop diuretics was associated with higher thirst. Although most patients were in NYHA class-II, a considerable amount restricted their daily intake of fluids. Clinicians at HF clinics should ask their patients about thirst and help them to find individual management strategies in order to relieve increased thirst in patients with HF.

P1071

Understanding patient experience during emergency admissions for acute heart failure

Funded by Royal College of Nursing as a Mary Seacole Development Award Scholar

S Selina Jarvis¹; T Sandford²; L Wu³; V Srivastava¹

¹King's College Hospital, London, United Kingdom; ²King's College Hospital, Royal College of Nursing, London, United Kingdom; ³University of Manchester, Manchester, United Kingdom

Background: Acute Heart failure (AHF) is associated with frequent hospital admissions and unplanned admissions can be distressing to patients. Patient experiences have the potential to impact on treatment adherence and readmission rates. Initiatives to evaluate patient experience in the UK, such as the National Patient Survey Programme (NPS), have some limitations since it is not disease tailored and the generic questions posed may not be relevant to patients presenting in an acute setting.

Purpose: Since patient experience can be related to outcomes, we aimed to (1) understand the aspects of care patients with AHF thought were important to them during their emergency admission and acute inpatient care experience and (2) to ascertain patients' perceived importance of a 24-item structured 'AHF patient specific questionnaire' to assess their acute care experience.

Methods: A mixed methods approach was used. Individual semi-structured interviews elicited spontaneous and prompted descriptions of patient experience during emergency admissions with AHF. Interviews were transcribed, manually coded with thematic extraction using inductive and deductive approaches. Patients also completed a 24-item structured AHF patient specific questionnaire (adapted from a previous study), and completed a Likert-type ranking scale for each question pertaining to their perceived importance

Results: 31 patients were interviewed with a mean (SD) age of 72.7 (12.3) yrs. Six main themes came from interviews which included; patient perceived physical and emotional burden of heart failure, the need for good communication from clinical staff, co-operative working between health care professionals and co-management of their disease by patients, timely management, and a desire to be given a specific attention for their HF status. The 24-item structured questionnaires revealed that patients felt that they did not receive enough information about medications (56.6%) or their current condition (56.6%). From the structured questionnaire, 22/24 questions were ranked as 'very' or 'extremely' important with the exception of 'friends and family recommendation questions', which were seen to be less important.

Conclusion: Qualitative approaches reveal important insight about the patient experiences of their emergency admission with AHF. We also confirm that most questions posed in our AHF specific structured questionnaire were deemed at least 'very' important. Use of a disease-focused assessment questionnaire may be a more appropriate approach to assess experience and is the subject of ongoing work.

POPULATION STUDIES / EPIDEMIOLOGY

P1072

Heart rate variability and systolic blood pressure: implication for heart failure, attainment by stages

EV Elena Pello¹; TV Kouznetsova²; YP Nikitin¹; JA Staessen²

¹Institute of Internal Medicine, Siberian Branch of the Russian Academy of Medical Sciences, Novosibirsk, Russian Federation; ²University of Leuven, Division of Hypertension and Cardiovascular Rehabilitation, Department of Cardiovascular Sciences, Leuven, Belgium

Purpose: Heart failure is one of the most prevalent and horrific conditions in prognostic utility for cardiovascular disease (CVD). Autonomic dysfunction may antedate development of symptomatic HF, is incorporated into pathogenesis of HF, and is a pawn in concept of adverse events (MESA).

Methods: We executed EPOGH, used power spectral analysis of resting heart rate (RHR), its variability (HRV, 15-min) and clock-time-dependent method narrow approach of diurnal systolic blood pressure (SBP) profile.

Results: If we should actually see in the evidence, theory pretty well off affirmed that elevated RHR and reduced HRV - both express the abruptly turned aside sympathetic/parasympathetic activities. From quite exalted achievement, increased RHR in patients with acute myocardial infarction (MI) is considered as independent of HF predictor of subsequent death, hypotension, shock, and etc. In an embarrassing admission, there is one point (PROSPER) which suggested that baseline RHR/HRV are integrated with worse functional ailments in older adults, unprejudiced toward CVD, - although it is and that is the foretelling items - and exists other point (ASCOT, VALUE) which mentioned that RHR mean levels are better provident factors for CVD events than baseline RHR. Hence, in Pearson pattern we defined ties of TP with day ($r=-0.187$), night ($r=-0.197$), crest ($r=-0.229$), trough ($r=-0.200$), high ($r=-0.205$) and low ($r=-0.220$) waves; VLFn with night ($r=0.168$), trough ($r=0.174$), low ($r=0.189$) wave, high-low waves difference ($r=-0.183$), night:day ratio ($r=0.164$), night fall ($r=-0.150$); LFn with day ($r=0.225$), night ($r=0.216$), crest ($r=0.242$), trough ($r=0.242$), high ($r=0.232$) and low ($r=0.245$) waves; HFn with day ($r=-0.216$), night ($r=-0.258$), crest ($r=-0.238$), trough ($r=-0.276$), high ($r=-0.229$) and low ($r=-0.277$) waves; LFn:HFn with day ($r=0.222$), night ($r=0.237$), crest ($r=0.239$), trough ($r=0.259$), high ($r=0.231$) and low ($r=0.261$) waves of SBP, $P<0.05$ for all. It is looked shrewdly and out of its depth, cardiac control services regulation of circulation and respiration. Moreover, HF - and, what are widely appointed, following MI - provide dysfunction of nervous system constituents. The scientific attention is not slipping concerning systolic hypertension as apprehensive factor for all-cause, CVD/non-CVD mortality (Syst-Eur). To be sure, in younger subjects link between SBP and HF risk is matched up with prehypertension.

Conclusion: Hopefully, yet archaic, we chased up delightful order of priorities for enlargement of patchy knowledge profitability to preserve human being welfare beleaguered by sickness.

P1073

Adverse prognosis with acute myocardial infarction involving proximal left anterior descending artery occlusion

I Deidda¹; P Pitt Lim¹

¹St Georges Hospital, Cardiology Clinical Academic Group, London, United Kingdom

Background: Mortality following myocardial infarction (MI) has markedly reduced with the introduction of primary percutaneous coronary intervention (PPCI) from well above 10% in the thrombolysis era to as low as 1-3% for those who reach the hospital. This is however dependent on the size of the infarct. Post PPCI survival is dependent on the extent of myocardium at risk. The left anterior descending (LAD) artery subtends at least 60% of the left ventricle. As such proximal LAD occlusion is a common cause of moderate left ventricular systolic dysfunction associated with adverse outcome. This report looked at the prognosis of proximal LAD MI in a large tertiary cardiac unit.

Methods: This review extracted data submitted by a Hospital to the British Cardiovascular Intervention Society (BCIS) PCI registry which is linked to the Office of National Statistics (ONS) that tracks country wide mortality in the United Kingdom Findings Between September 2005 and December 2014, 13200 PCI were performed, out of these, 3548 were PPCI and the proximal LAD was involved in 360 patients. The mean age was 61 (SD 14) years with 303 (84%) male patients. The median call to balloon time was 108 mins. Cardiogenic shock was present in 21.8%. Co-morbidities were; prior MI or CABG 14%, PCI 9.4%, smoking 52%, diabetes 14%, renal dialysis 1.4% and hypertension 62%. TIMI III was achieved in 92.5%. In-hospital mortality was 11.61%, 30 days 14.58%, 90 days 15.18% and 1 year 19.67%.

Conclusions: Despite PPCI, proximal LAD MI carries adverse prognosis with the rules of ten; 10% of MI, 10% in-hospital mortality and 10% post-discharge mortality at 1 year. The challenge is to develop strategies that limit infarct size and reduce sudden cardiac death in the community in this at risk patient group with post MI ischaemic cardiomyopathy.

P1074

Readmission and death without readmission after acute heart failure hospitalization: an approach using competing risk analysis

Novartis Farma provided a grant for statistical analysis

RL Ramos¹; I Marques¹; MV Bertao¹; F Ferreira²; S Abreu¹; J Lopes¹; S Nunes³; D Mendonca⁴; L Teixeira⁴

¹Hospital Center of Porto, Internal Medicine Department, Porto, Portugal; ²Hospital da Luz da Arrábida, Internal Medicine Department, Vila Nova de Gaia, Portugal;

³Hospital Center of Entre Douro and Vouga, Polyvalent Intensive Medicine Department, Santa Maria da Feira, Portugal; ⁴University of Porto, Population Studies Department, Institute of Biomedical Sciences Abel Salazar, Porto, Portugal

Introduction: The year after hospital discharge for acute heart failure (AHF) is an adverse event golden period. Death and readmission compete for patient path and one-year outcome, but they are often considered together as a composite endpoint in heart failure studies.

Purpose: This study aims to identify characteristics of patients discharged from an AHF hospitalization that independently influence the risk of readmission for acute heart failure (RAHF), considering death without RAHF as a competing risk.

Methods: Retrospective observational study that enrolled all patients hospitalized for AHF and discharged alive from an internal medicine department in 2012. Clinical records and telephone interviews were used for data collection from the 394 enrolled patients. Survival analysis taking competing risks into account was performed. RAHF was taken as the event of interest and death without RAHF as the competing event.

Results: In the year after discharge, 113 patients (28.7%) died; 131 patients (33.3%) experienced a hospital admission after discharge and 67 (17.0%) died without RAHF. The remaining 196 patients (49.7%) were still alive without RAHF one year after discharge. Multivariable models, adjusting for age, gender and ejection fraction, showed that risk of RAHF was increased for patients with atrial fibrillation (SHR=1.58, $p=0.02$), and for those with higher creatinine (SHR=2.00, $p<0.001$) or taking a betablocker at discharge (SHR=1.61, $p=0.01$). Risk of death without RAHF was increased in males (SHR=1.72, $p=0.04$), those aged 80 years or older (SHR=1.87, $p=0.03$), patients with dementia (SHR=2.68, $p<0.001$) or RDW in the fourth quartile at admission (compared to the first, SHR=2.54, $p=0.03$). Taking a betablocker at discharge and higher Platelet Distribution Width at admission reduced the risk of death without RAHF (SHR = 0.552, $p=0.04$ and SHR = 0.886, $p=0.009$, respectively).

Conclusions: In this one year follow-up study, we identified patients more prone to RAHF, namely those with atrial fibrillation and renal dysfunction. Death without readmission is clearly an event competing with readmission. A simple laboratory value such as RDW at admission can alert clinicians to the risk of dying before RAHF. Betablockers seem to be special drugs to the patients able to tolerate them, leading to readmission and reducing the risk of death before RAHF. If confirmed by larger studies, these results may aid clinicians to select better intervention strategies in the most efficient way for these patients.

Epidemiology of atrial fibrillation and flutter in Northern Italy: a cohort of hospitalized subjects

Unconditional grant by Medtronic Italia SpA

C Tondo¹; C Fornari²; G Botto³;

G Inama⁴; V Chiodini²; LG Mantovani²; F Madotto²; S Conti²; G Cesana²

¹Monzino Cardiology Hospital, Arrhythmology Department, Milano, Italy;

²University of Milano-Bicocca, Research Centre on Public Health (CESP), Monza, Italy;

³Sant'Anna Hospital, Cardiology Department, Como, Italy; ⁴F.S. Camillo

Clinical Institute, Cardiology Department, Cremona, Italy

Introduction: The prevalence of atrial fibrillation (AF) is rapidly rising in the developed world, while only few studies have investigated atrial flutter. Both conditions have been associated with an increased risk of more serious cardiovascular and cerebrovascular disorder and death.

Purpose: We conducted a large retrospective observational study, using healthcare administrative databases (HAD), with the aim of describing the characteristics of the population hospitalized for AF and flutter, and the adverse outcomes associated with both conditions, within a cohort of the general population of Lombardy, a region in Northern Italy.

Methods: From DENALI, a data warehouse that organizes HAD of the Lombardy Healthcare System, we extracted all hospitalizations for AF and flutter occurred between 2000 and 2010. We then identified the cohort of residents who underwent a first hospitalization with a diagnosis of AF or flutter between 2003 and 2009, after a wash-out period of 3 years. We followed each subject until 2010, death or emigration, extracting from DENALI all hospitalizations for outcomes of interest. Based on the diagnoses reported on the claims, we classified the cohort into three groups: people who during follow-up received only AF diagnosis ("AF" group), only flutter diagnosis ("Flutter" group), or both diagnoses ("AF and Flutter" group). We estimated mean annual mortality rates, as well as rates of hospitalization (x 100 person-years) for AF, flutter and ischemic stroke (IS), adjusting by age and gender.

Results: In the time period 2000 - 2010, the yearly average hospitalization rates (x10,000 person-years) for AF and flutter were respectively 46.15 (95% CI: 46.01; 46.28) and 4.33 (95% CI: 4.29; 4.37). We identified a cohort of 162,956 subjects (51% males), with a mean age of 75 years (± 12 SD). The "AF" group absorbed 87.8% of the cohort, while "Flutter" and "AF and Flutter" groups accounted for respectively 5.6% and 6.6%. During a mean follow-up time of 3.2 years (± 2.3 SD), the mean annual mortality rate was 12.43 (95% CI: 12.33 - 12.53), while mean annual hospitalization rates were: 16.89 (95% CI: 16.78 - 17.01) for AF diagnosis, 1.70 (95%

CI: 1.67 – 1.74) for flutter diagnosis and 3.26 (95% CI: 3.21 – 3.31) for IS. Hospitalization rates were highest within the "AF and Flutter" group, they decreased in the "AF" group and they were lowest within the "Flutter" group.

Conclusions: Our results confirm AF as a high healthcare impact disease, and they contribute to enhance the limited evidence regarding flutter, that emerges as a condition that should be carefully addressed.

P1076

Profile of the high coronary risk population

B Borislav Georgiev¹; N Gotcheva¹

¹ National Heart Hospital, Sofia, Bulgaria

Introduction: High blood pressure, lipid disorders, smoking, obesity are the group of major risk factors for heart disease. The risk of heart failure increases if they are not under control.

Purpose: The aim of this study is to analyse the prevalence of major risk factors and their control in Bulgarian high risk patients.

Methods: We analyse the data from Bulgarian cohort of high risk patients involved in EUROASPIRE IV survey (European Action on Secondary and Primary Prevention by Intervention to Reduce Events) held in 2014. The protocols of EUROASPIRE IV comprise standard questionnaires used by all participating countries to determine the patient health status.

Results: Only 36% of high risk patients in EUROASPIRE IV have blood pressure under target levels (SBP/DBP < 140/90 mmHg in patients using blood pressure lowering drugs and < 140/80 mmHg in diabetics). Among the patients in EUROASPIRE IV total cholesterol ≥ 4.5 mmol/L is recorded in 70% of them. LDL cholesterol ≥ 2.5 mmol/L is recorded in 83% of all patients. Therapeutic control of LDL-cholesterol < 2.5 mmol/L is achieved in 27% of the patients on lipid-lowering therapy. The total prevalence of diagnosed and undiagnosed diabetes (self-reported diabetes or fasting glucose ≥ 7 mmol/L) in EUROASPIRE IV is 60%. Undiagnosed diabetes rate (fasting glucose > 7 mmol/L and/or HbA1c $> 6.5\%$) among non-diabetic patients is 40%. 65% of the patients with self-reported diabetes have HbA1c < 7.0% and 45% of them have HbA1c < 6.5%. The prevalence of obesity in EUROASPIRE IV is 50.0% and this of central obesity is 86.0%. The prevalence of smoking among high risk patients in EUROASPIRE IV is 21.8% (an increase of 17.2% compared to EUROASPIRE III) and 40% of the current smokers have no intention to quit smoking (equal as in EUROASPIRE III).

Conclusions: We find a poor global control of blood pressure in high risk patients in Bulgaria. The lipid control in high risk patients is still insufficient - less than 2/3 of the patients do not reach target levels according ESC guidelines. We also find very high prevalence of obesity. Despite the physicians' activities, smoking rate increases in the group of high risk patients.

P1077

Improving the validity of general practice heart failure registers in Scotland through collaborative clinical audit

NHS Greater Glasgow & Clyde

P Forsyth¹; T Clackson²; J O'neil²; A Foster³;

L Moir¹; I Speirits¹; M Petrie⁴; S Jenkins⁵; J Taylor⁵; R Burns³

¹ NHS Greater Glasgow and Clyde, Pharmacy & Prescribing Support Unit, Glasgow, United Kingdom; ² NHS Greater Glasgow and Clyde, Glasgow, United Kingdom;

³ NHS Greater Glasgow and Clyde, Heart Managed Clinical Network, Glasgow, United Kingdom; ⁴ Golden Jubilee National Hospital, Scottish National Advanced Heart Failure Service, Glasgow, United Kingdom; ⁵ Glasgow Royal Infirmary, Glasgow, United Kingdom

Background: Heart failure (HF) appears under-represented in Scottish general practice disease registers compared with accepted prevalence figures. Scottish general practices are required to enter two codes to add patients to a register and also distinguish between HF with reduced ejection fraction (HF-REF) and HF with preserved ejection fraction (HF-PEF).

Purpose: To improve the validity of general practice HF registers in a Scottish regional health authority, including the distinction between HF-REF and HF-PEF.

Methods: General practices undertook an audit from 01.10.14 to 31.03.15 to improve register accuracy. Practices conducted an individual review of the medical records of each patient on existing HF registers to confirm or refute diagnosis. Practices also undertook a case-finding exercise to identify patients with confirmed HF who were missing from registers. Case-finding was achieved by reviewing the medical records of patients taking possible HF medications (e.g. loop diuretics) and/or those with codes for left ventricular systolic dysfunction (LVSD) without HF codes. Validity for inclusion on a register was judged by reviewing the results of previous diagnostic imagery (e.g. echocardiograph) and clinical history in primary and secondary care medical records. Specialist advice was sought where needed.

Results: 143 / 241 general practices (59% of regional health authority) took part in the audit and submitted data (763,112 patients, ~14% Scotland). 5843 patients were on HF registers pre-audit (0.77% prevalence). 516 patients (8.8%) were miscoded as HF (false positives) and were removed from HF registers. 561 patients (9.6%)

were deemed to have a historic diagnosis that was no longer clinically relevant (e.g. acute events, LV recovered, reversible causes) and were re-coded to highlight this. 214 patients (3.7%) on HF register had been incorrectly coded as HF-REF despite having normal ejection fraction. 2066 patients (35.4%) on HF registers had a missing HF-REF code. 1659 additional HF patients were identified that were not on the HF register (false negatives); 1105 patients were identified with sole LVSD codes but were judged to also have clinical HF, and 554 patients were identified from medication case-finding. Post-audit HF registers increased to 7022 patients (0.92% prevalence). This figure also accounts for new diagnoses and deaths during audit period.

Conclusion(s): Clinical audit significantly improved the accuracy and validity of general practice HF registers, with coding problems identified in over half (57.5%) of the patients on baseline registers. Case-finding added 1659 patients that were inappropriately missing from registers. More research is needed to understand the reasons why baseline HF registers in general practice are significantly inaccurate. Work is under way nationally in Scotland to improve the communication of new HF diagnosis information between secondary care and general practice.

P1078

Acute heart failure in colombia

C I Clara Ines Saldarriaga¹; G Gonzalez²; S Navarrete³; LE Echeverria⁴;

M Novoa⁵; N Murillo⁶; A Rivera⁷; MJ Rodriguez⁴; B Rolong⁸; G Trout⁹

¹ Cardiovascular Clinic Santa Maria, University of Antioquia cardiology department, Medellin, Colombia; ² Fundacion Santa Fe de Bogota, heart failure, Bogota, Colombia; ³ Hospital Military Central, cardiology, Bogota, Colombia; ⁴ fundacion cardiovascular, cardiology, bucaramanga, Colombia; ⁵ clinica el Rosario, cardiology, medellin, Colombia; ⁶ Angiografía de occidente, cardiology, Cali, Colombia; ⁷ clinica los Rosales, Cardiology, pereira, Colombia; ⁸ fundacion cardioracica, cardiology, barranquilla, Colombia; ⁹ Universidad del Magdalena, Cardiology, Santa Marta, Colombia

Acute heart failure syndromes poses unique diagnostic and management challenges for clinicians, although much has been accomplished in the management of chronic HF, the absence of evidence-based clinical practice guidelines for acute heart failure is striking. There is a few information about the clinical characteristics of heart failure patients discharged from Colombian hospitals. ROCI project is a pilot registry designed to characterize this population in our country.

Objective: To describe the clinical characteristics of a population of patients discharged from 9 Colombian hospitals in a period of 4 months with diagnosis of acute heart failure and to compare this with the information available from ADHERE and ESC HF AHF arm registry.

Methodology: A prospective cohort study was designed

Results: 250 patients were included in 9 Colombian hospitals in four months. 37% were male, 66% of the population had more than 60 years, 67% had heart failure with reduced ejection fraction. Ischemic cardiomyopathy was the cause of heart failure in 38% of the patients, and 29% had diabetes. There was a high use of medical therapy recommended by the guidelines: beta blockers in 95%, ACE/ARB in 84%, aldosterone antagonist in 73% and ivabradine in 14.7% of the population the comparison of this clinical variables with those reported in international registries is shown in table 1

Conclusion: The ROCI registry showed that the population of acute heart failure patients from Colombia is younger than the reported in ADHERE and ESC HF AHF pilot arm, with a high proportion of women, a low prevalence of ischemic cardiomyopathy and most of our patients had heart failure with reduced ejection fraction. Diabetes was less prevalent in our population. This information is very important to face the challenge of giving a better care to our patients.

Table 1 roci vs adhere vs esc

CLINICAL CHARACTERISTIC	ROCI	ADHERE	ESC HF AHF pilot arm
Age	60	72 ± 14	70 ± 13
Male	37%	48%	63%
CORONARY HEART DISEASE	38%	57.4%	50.7%
HFREF	67%	54%	66%
DIABETES	29%	44%	35.1%

HFREF: heart failure with reduced ejection fraction

P1079

Risk of first myocardial infarction in a population-based cohort of incident heart failure patients.

A Alexander Michel¹; M Martin-Perez²; A Ruigomez²; LA Garcia Rodriguez²

¹ Bayer AG, Global Epidemiology, Berlin, Germany; ² Spanish Center for Pharmacoepidemiologic Research (CEIFE), Madrid, Spain

Background: There is considerable data available on the risk of developing heart failure (HF) following a myocardial infarction (MI), but only very few studies evaluated the reverse constellation in a systematic way, which means following-up a cohort of incident heart failure patients without past MI history until occurrence of first MI. While clinical trials usually represent selected patient populations with limited follow-up time, a longitudinal, large and population-based healthcare database may allow long-term follow-up of a large heart failure inception cohort.

Purpose: To estimate the incidence and case fatality of first MI in a population-based cohort of incident heart failure patients without previous MI.

Methods: A retrospective cohort study was conducted in the UK general practice setting. Patients with a first diagnosis of HF during 2000-2005 and without prior MI or cancer (n = 14,373) were identified from The Health Improvement Network database (a longitudinal primary care database of electronic medical records, representative of the UK population) and followed-up until end of 2011 to ascertain first occurrences of MI. Validation of the HF cohort and the MI cases took place via review of the patient's electronic medical record, including free text comments review. Incidence rates (IR) and corresponding 95% confidence intervals (CI) were calculated.

Results: 858 patients (6% of the initial cohort) developed a first myocardial infarction during a mean follow-up of 2.26 years (incidence 1.49 cases per 100 person-years, CI 95%: 1.39-1.59). Incidence rates stratified by age and sex are displayed in figure 1. The risk was highest in the first year of follow-up after HF diagnosis (incidence rate 3.11 cases per 100 person-years (CI 95%: 2.81-3.44), where nearly half of the MI cases occurred (n=375). Incidence was generally higher in men than in women. Among the 858 patients with MI during follow up, 282 patients (33 %) died within 30 days after MI diagnosis.

Conclusions: Occurrence of a first MI in patients with incident heart failure is not uncommon and this combination is associated with high case fatality. Further analysis of the risk factors and possible preventive factors of MI in this population is warranted.

Figure 1. Incidence rate of myocardial infarction among newly diagnosed HF patients by age and sex

P1080

Beta-thalassemia minor is associated with decreased arterial stiffness and favourable LV diastolic profile

A Chamaid¹; G Karayannis²; A Christidi¹; G Giamouzis¹; C Parisi¹; K Koutrakis¹; E Adreanides³; A Xanthopoulos¹; J Skoularigis¹; F Triposkiadis¹

¹University General Hospital of Larissa, Department of Cardiology, Larissa, Greece;

²Harefield Hospital, London, United Kingdom; ³401 Army General Hospital of Athens, Cardiology Department, Athens, Greece

Background: β -thalassaemia minor (β - τ m) is associated with rheological and biochemical alterations that can affect cardiovascular function.

Purpose: To evaluate systolic and diastolic cardiac function and the elastic arterial properties in a large population of patients with β - τ m.

Methods and Results: 202 asymptomatic individuals with cardiovascular risk factors, 75 with β - τ m and 127 controls were prospectively enrolled. All participants underwent comprehensive echocardiographic evaluation. Arterial parameters were quantified noninvasively using applanation tonometry of the radial and femoral artery. Pulse wave analysis revealed that augmentation pressure, augmentation index, and heart rate-corrected augmentation index were significantly lower [median (interquartile range) 8.75 (4.625-13) vs. 11 (6.5-14.5), $p=0.017$; 26.5 (17.5-33.375) vs. 30.5 (20.75-37.5), $p=0.014$; and 22.25 (15.125-29.5) vs. 27 (20.5-33), $p=0.008$, respectively) in the β - τ m group compared with controls. Evaluation of myocardial diastolic function revealed that left atrial active emptying volume was significantly lower in β - τ m group in comparison with the control group 10.2 (7.4-14.4) vs. 12.0 (8.6-15.8), $p=0.040$ and isovolumic relaxation time was more prolonged (80 ± 19

vs. 87 ± 24 , $p=0.034$) in the control group compared with β - τ m individuals. Left atrial maximal volume index and kinetic energy were also lower in the β - τ m [20.2 (16.4-24.1) vs. 22.2 (17.8-26.4) and 30.1 (19.4-55) vs. 39.3 (23.1-59.5), respectively], although the differences were not statistically significant ($p=0.062$ for both comparisons).

Conclusion: β - τ m is associated with decreased arterial stiffness and a favourable left ventricular diastolic function profile in asymptomatic individuals with cardiovascular risk factors. These findings provide support to a possible cardiovascular protective effect of the β -thalassaemia heterozygosity that needs further evaluation.

P1081

Alterations of the left ventricular end-diastolic pressure-volume relationship are associated with higher mortality in non-heart failure individuals: data from a large-scale, population-based cohort.

M Schwarzl¹; F Ojeda¹; T Zeller¹; M Seiffert¹; PM Becher¹; T Munzel²; PS Wild²; S Blankenberg¹; D Westermann¹

¹University Heart Center Hamburg, Dept. of General and Interventional Cardiology, Hamburg, Germany; ²Johannes Gutenberg University Mainz (JGU), Medical Department, Mainz, Germany

Background: Left ventricular (LV) remodeling impacts on the LV end-diastolic pressure-volume relationship (EDPVR), which is different in heart failure (HF) with reduced ejection fraction (HFrEF) and HF with preserved ejection fraction (HFpEF). In a large-scale, population-based cohort (Gutenberg Health Study) we aimed to investigate alterations of the EDPVR in HF patients and their association to risk factors and all-cause mortality in non-HF individuals.

Methods: Based on clinical and echocardiographic data, participants were divided into "No HF" (n = 14511), HFrEF (n = 215) and HFpEF (n = 79). We estimated LV capacitance (i. e., the position of the EDPVR) and the EDPVR's stiffness-coefficient β from echocardiographic data using a single-beat method. LV capacitance was defined as the LV end-diastolic volume at an LV end-diastolic pressure of 20 mmHg indexed to body surface area. Values are given as median and interquartile range.

Results: The EDPVR was shifted rightward in HFrEF indicating higher LV capacitance compared to "No HF" (69.7 [53.3 - 85.3] vs 53.5 [45.2 - 63.0] ml/m², $p < 0.001$) and leftward in HFpEF indicating lower capacitance compared to "No HF" (51.0 [42.7 - 62.3] vs 53.5 [45.2 - 63.0] ml/m², $p = 0.027$), while the stiffness-coefficient β was increased in both HFrEF and HFpEF (HFrEF: 5.99 [5.94 - 6.11], HFpEF: 6.16 [6.11 - 6.29], No HF: 5.94 [5.92 - 5.98], both $p < 0.001$ vs No HF). In "No HF", a higher stiffness-coefficient β was associated with age, female gender, hypertension, diabetes and obesity, while age and female gender were associated with a leftward shift of the EDPVR, whereas dyslipidemia, obesity, smoking and impaired renal function were associated with a rightward shift of the EDPVR. Both changes of the EDPVR were associated with increased all-cause mortality in "No HF" (both $p < 0.001$, see figure).

Conclusion: In a large-scale, population-based cohort, we show distinct alterations of the EDPVR in HFrEF and HFpEF. Already in non-HF individuals, alterations of the EDPVR are associated with increased mortality.

PSYCHOSOCIAL / ETHICAL CONCEPTS / EDUCATION

P1082

Patients' perspectives of communication about heart failure, prognosis and end-of-life care

A-L Anna-Lisa Hjelmfors¹; AS Sandgren²; AS Stromberg²; JM Hjelmfors³; TJ Jaarsma⁴; MF Friedrichsen⁴

¹Linköping University, Department of Medical and Health Sciences, Linköping, Sweden; ²Linnaeus University, Department of Health and Caring Sciences, Kalmar, Sweden; ³Jonköping University, School of Health Sciences, Jonköping, Sweden; ⁴Linköping University, Department of Social and Welfare Studies, Linköping, Sweden

Background: Improving heart failure (HF) patients' understanding about their condition, including discussing the progression of HF and establish goals for end-of-life care, is an important outcome in patient-professional communication.

Purpose: To explore HF patient's perspectives regarding communication with health care professionals about HF, prognosis and end-of-life care.

Methods: A qualitative study with four focus-group interviews including 15 patients with HF was performed. The patients were in NYHA I-IV, and were not diagnosed with any other major life threatening disease. The participants consisted of 12 men and 3 women with an age range between 63 and 84 years of age. Data was analysed using thematic analysis to identify and interpret patterns in the data.

Preliminary

Results: One essential theme identified was: "Patients" approach to information about the illness and the prognosis" with the sub-themes: "Ignorance is bliss", "Truth gives freedom" and "Unawareness gives insecurity".

Patients used different approaches to discussions about their illness, prognosis and end-of-life care in. The sub-theme "Ignorance is bliss" expresses how some patients prefer to ignore the fact that they might die from their HF. They do not want to talk about the future and might get worried or offended by the topic. They want to decide themselves whether they want to talk about the future with professionals or not. If they choose to talk, they will ask about it themselves.

The second sub-theme "Truth gives freedom" illustrates that some patients believe that knowing "the truth" about their illness and its trajectory is crucial to live as good as possible. The truth for these patients are that they are probably going to die from HF. Patients ask from professionals to be honest with them about the future and help the patient to be able to plan ahead and be prepared for a time when the HF is deteriorating.

The third sub-theme "Unawareness gives insecurity" does not describe an active approach, rather it describes patients who claim that they do not know that they are suffering from a life-limiting illness. They meet professionals who provide little or no information about the illness progression, leaving the patients with an often lacking understanding of what HF is and how it might affect their lives. Patients believe that the professionals are responsible to initiate a communication about the future. But before doing so, they need to be sensitive and read the patients' body language, emotions and feelings to understand if they are ready to talk.

Conclusions: The different approaches patients use when discussing prognosis and end-of-life care might be ways for the patients to cope living with a serious illness. Having knowledge about patients' different approaches to communication is important for professionals in clinical practice who wants to initiate a conversation about prognosis and end-of-life care.

P1083

Predictors of therapeutic adherence in cardio-respiratory failure patients

G Leija-Alva¹; V Pelaez²; R Pablo-Santiago²; E Perez-Cabanas²; A Orea-Tejeda²; B Dominguez-Trejo³; JA Pineda-Juarez²; DG Gonzalez-Islas²; R Herrera-Saucedo²; B Santellano-Juarez²

¹Instituto Politécnico Nacional, Centro Interdisciplinario de Ciencias de la Salud Santo Tomás, México City, Mexico; ²Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart and Respiratory Failure Clinic, Mexico City, Mexico; ³Universidad Nacional Autónoma de México, Faculty of Psychology, México City, Mexico

Background: The acquisition of harmful habits are the main causes of cardiovascular and respiratory diseases. Currently no cure for this condition is available and, although there is growing therapeutic strategies to achieve good control and improve the quality of life of patients, the reality is different. Lack of adherence fluctuates between 40 to 75%. Adherence is a multidimensional phenomenon which must also consider the thoughts, feelings and social interactions of patients. From this need to understand and explain this process the socio-cognitive models emerge. This work takes three models: a) Health Belief Model; b) Theory of Planned Behavior, c) Wallston's model.

Objective: To identify factors that predict the therapeutic adherence of patients with cardio-respiratory failure. **Material:** A clinical transversal and not experimental study was conducted. 134 patients from the cardiology outpatient service and heart failure and respiratory clinic were assessed with the following instruments: a) MBG Questionnaire to evaluate therapy adherence, b) Health Belief Model and Therapeutic Adherence Questionnaire, c) Theory of Planned Behavior Questionnaire, and d) Wallston's Model for Therapeutic Adherence Scale.

Results: Using a stepwise multiple linear regression, a predictor of adherence model, which includes factors of two of the proposed cognitive models, was obtained ($r^2 = 0.217$, $F = 8.931$, $p < 0.01$): perceived benefits ($t = 2.361$, $\beta = -0.199$, $p < 0.01$) of Health Belief Model; attitudes ($t = 1.464$, $\beta = 0.140$, $p < 0.01$), self-efficacy ($t = 2.386$, $\beta = 0.214$, $p < 0.01$) and social norms ($t = 2.386$, $\beta = 0.214$, $p < 0.01$) of Theory of Planned Behavior.

Conclusion: It is important to have patient information about how to think, feel and relate to his disease, treatment and social context. These aspects can intervene to improve the prognosis and health status of the patient. These results hint some factors such as perceived benefits and social norms that are usually not taken into account during treatment and may affect adherence to it. It is necessary to continue

in this line of research to have a holistic model that explains the adherence behavior of the patient and modify them promptly if necessary.

P1084

Measures of health-related quality of life for adults with chronic heart failure: usefulness of the MacNew questionnaire

C Ariano¹; R De Vecchis¹; A Giasi¹; C Cioppa¹

¹Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy

Background: Health-related quality of life (HRQL) is an increasingly well-recognized measure of health outcome in cardiology. The administration of the MacNew questionnaire has been proposed as a routine investigation for patients suffering from chronic heart failure (CHF), with the goal of reducing unnecessary hospitalizations, which really can be avoided with the optimization of therapy and lifestyles, in case of detection of worrying low scores on occasion of the assessment of the questionnaire. The purpose of this study was to assess whether relatively high scores found with the MacNew questionnaire can be associated with a significantly decreased risk of unplanned hospitalizations due to relapses of cardiac decompensation during follow-up.

Methods: The study consisted in a retrospective analysis that involved 210 patients with CHF due to various etiology (ischemic, idiopathic, valvular, etc) followed up for one year after the first episode of acute decompensated heart failure (ADHF). According to customary practice that applies in our Institute, all of the patients underwent an evaluation by means of the MacNew questionnaire, in the context of the practices of psychological and psychosomatic assessment that are routinely implemented in CHF outpatients who are followed-up after a previous hospitalization for ADHF.

Results: At univariate analysis, a high value (namely, located above the median of the ensemble of the calculated values of MacNew score in the entire patient population) of the global score was shown to be associated with a significantly decreased risk of rehospitalization [HR (hazard ratio): 0.0903; 95% CI: 0.0324 to 0.2518; $p < 0.0001$]. After adjustment for age, gender, myocardial infarction as initiating event, reduced left ventricular ejection fraction, baseline renal function and diabetes, that is, by incorporating the above-mentioned covariates within a multivariate Cox proportional hazards' regression model, the protection exerted by a high MacNew score against the risk of hospitalizations remained significant (HR: 0.0885; 95% CI: 0.0317 to 0.2472; $p < 0.0001$).

Conclusions: High HRQL assessed by means of the MacNew questionnaire in outpatients with CHF appears to be associated with a reduced risk of rehospitalization over a one-year follow-up.

P1085

The relationship between acceptance of illness and quality of life in chronic heart failure patients

Financial support was based on NCN grant, number: 2011/03/N/NZ5/00243

M Obieglo¹; A Siennicka²; D Daneš³

¹4th Military Hospital, Centre for Heart Disease, Department of Cardiac Surgery, Wrocław, Poland; ²Wrocław Medical University, Department of Heart Diseases, Wrocław, Poland; ³Polish Academy of Sciences, Anthropology Unit in Wrocław, Wrocław, Poland

Background: This study provided an in-depth insight into relationships between illness acceptance and quality of life (QoL) of chronic heart failure (CHF) patients. While QoL is well-established endpoint in CHF, little is known on illness acceptance in this group.

Aims: To analyse a relationship between QoL and illness acceptance in CHF patients.

Methods: The study included 204 patients (160 men and 44 women, mean age 63 ± 11 years) with at least 6-month clinical evidence of CHF corresponding to NYHA classes I-IV. All the patients were examined with Minnesota Living with Heart Failure Questionnaire (MLHFQ) and Acceptance of Illness Scale (AIS).

Results: Univariate analysis showed that the level of illness acceptance correlated inversely with patient age, and the level of QoL decreased with the severity of CHF (NYHA class). A relationship between illness acceptance and QoL was analysed by structural equation modelling. Model 1 was based on the assumption that QoL is modulated by AIS, Model 2 tested the opposite relationship. Both models included patient age and NYHA class as extrinsic determinants of AIS and MLHFQ scores, respectively. Model 2 proved to be well fitted ($\chi^2(df:2) = 3.22$, $p = 0.20$, RMSEA = 0.055). AIS correlated inversely with age (age \rightarrow AIS = -0.15, SE = 0.05, $p = 0.002$) and QoL (bQoL \rightarrow AIS = -0.15, SE = 0.02, $p < 0.001$), and an increase in NYHA class was reflected by an increase in QoL scores (bNYHA \rightarrow QoL = 5.75, SE = 1.97, $p = 0.004$).

Conclusion: CHF patients may not accept their disease due to deteriorated QoL. As a result, they might be not involved in the therapeutic process, which leads to exacerbation of CHF, further deterioration of QoL and inability to accept the illness.

P1086

Validation of health belief model and therapeutic adherence questionnaire in cardio-respiratory failure patients

G Leija-Alva¹; V Pelaez²; R Pablo-Santiago²; E Perez-Cabanas²; A Orea-Tejeda²; JA Pineda-Juarez²; EW Contreras-Ramirez²; DG Gonzalez-Islas²; RN Sanchez-Santillan²; C Cintora-Martinez²

¹Instituto Politécnico Nacional, Centro Interdisciplinario de Ciencias de la Salud Santo Tomás, México City, Mexico; ²Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart and Respiratory Failure Clinic, Mexico City, Mexico

Background: Cardiovascular risk factors cause 16.7 million deaths per year worldwide. Efforts to improve the diagnostic and therapeutic processes of these diseases have been carried out. Non-adherence remains an obstacle to achieve this goal. In this sense, the cognitions of the patients about their disease and treatment play an important role. The Health Belief Model explains the influence of these cognitions on adherence, so it is important to evaluate them.

Objective: Evaluate the factorial structure and reliability of the Health Belief Model and Therapeutic Adherence Questionnaire in patients with cardio-respiratory failure. Method. 134 patients (74% women, mean age 47 years) from the cardiology outpatient service and heart failure and respiratory clinic were assessed with the Health Belief Model and Therapeutic Adherence Questionnaire (Likert scale 1 to 5). Reliability analysis was performed using Cronbach's alpha and a factor analysis was made using the principal axis factor analysis with varimax rotation.

Results: The final inventory was composed of 15 items with a Cronbach's alpha of 0.803. Four factors were obtained: perception severity, perceived susceptibility, perceived benefits and perceived barriers personal. These explain the 57% of the variance of the construct.

Conclusion: The scale is valid to assess the Health Belief Model factors. The results support the use of the instrument in cardio-respiratory failure patients. Have tools like this help to design intervention strategies to increase therapeutic adherence and effectiveness of medical treatment in these patients, improving their health and quality of life.

P1087

Validation of Self-efficacy of Caregivers of Chronic Patients Scale in caregivers of heart failure patients

V Pelaez¹; R Pablo-Santiago¹; A Orea-Tejeda¹; G Leija-Alva²; JA Pineda-Juarez¹; DG Gonzalez-Islas¹; R Herrera-Saucedo¹; C Cintora-Martinez¹; B Santellano-Juarez¹

¹Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", México City, Mexico; ²Instituto Politécnico Nacional, Centro Interdisciplinario de Ciencias de la Salud Santo Tomás, México City, Mexico

Background: As construct self-efficacy mediates the relationship between knowledge and behavior. Therefore the belief that the caregiver has about his ability and self-regulation to give care to the patient without abandon his own life are decisive for the tasks of their role. The caregiver is the responsible for the patient and, in most cases, he supervise the pharmacological and nonpharmacological treatment of patient. However, despite its importance, self-efficacy is a variable that has not been studied in this population.

Purpose: Evaluate the psychometric properties of Self-efficacy of Caregivers of Chronic Patient Scale in a sample of caregivers of patients with heart failure.

Methods: A sample of 125 caregivers (75.2% female, age 54.8 ± 13.8) of heart failure patients attending the Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas" was evaluated. Reliability analysis and factor was performed using Cronbach's alpha, the variability was calculated using t-student and a factor analysis was made using the method of principal components analysis with varimax rotation.

Results: The final inventory was composed of 19 items with a Cronbach's alpha of 0.895. The variability was statistically significant ($p < 0.05$). Three factors were obtained: personal self-efficacy ($\alpha = 0.828$), socio-affective self-efficacy ($\alpha = 0.857$) and self-efficacy to the patient ($\alpha = 0.809$). These explain the 56.81% of the variance of the construct.

Conclusion: The scale is valid to measure perceived self-efficacy in this population, so the results support the use of the instrument in caregivers of heart failure patients. Design strategies aimed to assess all variables around the caregivers to design intervention strategies to train and take care of them is needed.

P1088

Anxiety and coping based on emotions may contribute to reduced quality of life in patients with mild systolic heart failure

National Science Centre (Cracow, Poland), grant no.: UMO-2011/03/N/NZ5/00243 A E Agnieszka Siennicka¹; J Krzysztofik¹; EA Jankowska¹

¹Wrocław Medical University, Wrocław, Poland

The perception of quality of life (QoL) may result from individual psychological characteristics of the patient. We investigated selected, potentially modifiable psychological features among patients with heart failure (HF) in relation to physical and emotional dimensions of QoL. 169 patients with stable HF (88% men, age: 63 ± 10 years, NYHA (I/II/III): 7/63/30%, ejection fraction: 31 ± 7%), completed:

- (1) Coping Inventory for Stressful Situations;
- (2) Generalised Self Efficacy Scale;
- (3) Acceptance of Illness scale;
- (4) Revised-Life Orientation Test;
- (5) State-Trait Anxiety Inventory and
- (6) Minnesota Living with Heart Failure Questionnaire.

Emotion-oriented coping was related to overall QoL ($r = 0.37$) & somatic and emotional QoL ($r = 0.24$ and $r = 0.62$, respectively, all $p < 0.05$). More reduced QoL (overall in both dimensions) was significantly ($p < 0.05$) but weakly ($r = -0.21$, $r = -0.20$ and $r = -0.26$, respectively) related to lower acceptance of the illness. Higher anxiety was related to more reduced QoL (overall & both dimensions): for anxiety-state: $r = 0.28$, $r = 0.22$ and $r = 0.54$, respectively; for anxiety-trait: $r = 0.29$, $r = 0.25$ and $r = 0.46$, respectively, all $p < 0.05$. Emotional QoL was related to avoidance-oriented coping ($r = 0.26$, including a subtype based on distraction, $r = 0.34$) & lower self-efficacy ($r = -0.20$) and lower optimism ($r = -0.20$, all $p < 0.05$).

We showed that particular, measurable and modifiable psychological features are related to the way how the patients perceive their QoL. Further studies are needed to confirm if psychological support aimed at promoting adequate styles of coping, increasing illness acceptance, self-efficacy and optimism and/or reducing anxiety would result in an improvement of the QoL.

EXERCISE TESTING & TRAINING

P1089

Self-efficacy mediates the relationship between motivation and physical activity in patients with heart failure

L Leonie Klompstra¹; T Jaarsma¹; A Stromberg²

¹Linköping University, Faculty of Health Sciences, Department of Social & Welfare Studies, Norrköping, Sweden; ²Linköping University, Department of Medical and Health Science, Faculty of Health Science, Division of Nursing Science, Linköping, Sweden

Background/Introduction: Motivation to be physically active is needed, but may not sufficient to initiate physical activity in patients with heart failure (HF). Self-efficacy might explain the relationship between motivation and physical activity.

Purpose: This study aims to examine the role of exercise self-efficacy in the relationship between exercise motivation and physical activity in patients with HF.

Methods: Data of 101 stable HF patients (and 88% in NYHA II/III, mean age 67 ± 13, 62% men) were analyzed. Exercise self-efficacy was measured with the exercise self-efficacy scale; exercise motivation with the exercise motivation index and physical activity with a self-report questionnaire. Moderation and mediation are used for refining and understanding causal relationships. Logistic regression analyses were made to examine the moderation and mediation effect of exercise self-efficacy on the relation between exercise motivation and physical activity.

Results: In total 42% of the patient reported to be physically active less than 60 minutes per week. No moderation of exercise self-efficacy was found on the relation between exercise motivation and physical activity. Self-efficacy mediated the relation between exercise motivation and physical activity. Motivation predicted physical activity ($b = .58$, $p < .05$). After controlling for self-efficacy, the relation between motivation and physical activity was no longer significant ($b = .76$, $p = .06$), indicating full mediation. Sex, age and NYHA class did not have a significant association with the level of physical activity ($b = .55$, $p = .36$; $b = -.03$, $p = .22$; $b = -.41$, $p = .46$), but increased the R-square of the model and therefore contributing to explaining physical activity in patients with HF.

Conclusion: In addition to a high motivation to be physically active, it is important that patients with HF to have a high exercise self-efficacy. Motivation leads patients with HF to have higher self-efficacy and therefore are more confident in overcoming barriers to exercise, which in turn leads them to have higher physical activity.

P1090

Observation point in chronic heart failure after training program

NA Koriagina¹; AV Petrischeva¹; DK Sadykova¹

¹Medical Academy, Perm, Russian Federation

Objective: To explore the possibility of the effect of an educational program in a municipal medical institution on the survival of patients, the functional state of the cardiovascular system (CVS), and psychological status.

Material and methods: in the municipal hospital for 4 years as a school health (SHZ) for patients with CVD. A total of 46 cycles of 5 sessions each. Patients aged 40-70 years, and visited more than 3 classes amounted monitoring group - 222 (1 oz.). 39 patients of the same age who are not engaged in the SZ included in the control group (2g.). At the beginning of the study groups were comparable in age: 58.8 ± 7.0 (1g.) Vs 59.1 ± 6.9 years (2g.) ($P = 0.774$). The patients before discharge from the hospital completed the survey of hospital assessment scales of anxiety and depression (HADS); the functional state of the CAS was assessed using the six-minute walk test (TSHH) and index ehokardiografayai - ejection fraction (EF). Patients in Group 1 were observed periodically. Re-examination was carried out in 2 years.

Results: during the 1st examination: the level of anxiety in both groups was at a subclinical level (7.33 ± 3.56 and 7.62 ± 5.09 points, $p = 0.694$); symptoms of depression were not in both groups. The average distance traveled in TSHH, did not differ between groups ($1g. 439.09 \pm 95.88$ m in 2 m. 430.77 ± 86.13 m, $p = 0.630$), I corresponded functional class NYHA, value EF has been satisfactory in the 1st and 2nd groups ($58.13 \pm 8.51\%$ and $56.71 \pm 9.38\%$, $p = 0.376$). After 2 years in group 1 remained 211 patients: a 3 person there is no information, 8 - died (1 - from cancer pathology, by CVD -7 (overall mortality rate - 3.69% of the pathology CCC - 3.21%). In the control group left 35 people, and 4 died from CVD (mortality rate - 10.26%). In 2 years studied parameters were evaluated separately in each group. In group 1 significantly reduced the level of anxiety and depression ($p = 0.000$). Distance TSHH increased from 437.02 ± 104.08 m to 466.34 ± 86.96 ($p = 0.000$), ejection fraction increased slightly to $59.35 \pm 7.68\%$ ($p = 0.623$). A different pattern was observed in the control group: indicators of anxiety and depression has not improved ($p = 0.465$ and $p = 0.583$, respectively). At the insignificant decrease of PV up to $53.27 \pm 12.07\%$ ($p = 0.859$) in the distance TSHH declined from 405.00 ± 65.65 m to 300.17 ± 50.91 m ($p = 0.028$).

Conclusions: The active participation of patients with CVD in the educational programs in order to maintain communication with your doctor allows you to have a positive effect on a surrogate point (improvement in functional status and psychological status), and the final result (reduction in mortality).

P1091

Linear correlation between cardiac output and oxygen uptake at peak exercise in patients with heart failure with reduced ejection fraction

N Nicoletta Corrieri¹; F Nicolini¹; A Del Torto¹; S Farina²; C Vignati²; A Apostolo²; E Salvioni²; M Morosini³; P Agostoni¹

¹University of Milan, Milan, Italy; ²Cardiology Center Monzino IRCCS, Milan, Italy;

³Postgraduate School in Cardiovascular Sciences, Trieste, Italy

Background: Oxygen uptake (VO₂) during exercise is among the most reliable parameters to assess heart failure (HF) severity and prognosis. According to Fick law, $VO_2 = \text{cardiac output (CO)} \times \text{arteriovenous O}_2 \text{ differences } [\Delta(\text{Ca-Cv})O_2]$. Therefore, an increase of peak exercise CO is associated with an increase of peak VO₂, provided that $\Delta(\text{Ca-Cv})O_2$ does not decrease. During progressive exercise (ramp protocol), VO₂ is independent from CO up to the anaerobic threshold and becomes CO-dependent above it. Several factors can indeed influence the $\Delta(\text{Ca-Cv})O_2$ value at peak exercise in HF, either increasing or decreasing it, including exercise-induced haemoconcentration, muscle metabolic efficiency and peripheral blood flow distribution. Consequently, in HF, a constant peak exercise $\Delta(\text{Ca-Cv})O_2$ is not a definite event and non-invasive measure of CO is still a challenge.

Purpose: We tested the hypothesis of effective correlation between CO and VO₂ at peak of exercise in heart failure patients.

Methods: We analysed clinical data from 170 consecutive heart failure patients with reduced ejection fraction (HFrEF) who underwent full clinical evaluation at our HF unit. Patients' age was 65 ± 11 years, 86% were males. Average LVEF was $31 \pm 8\%$. All patients were in stable clinical condition, in New York Heart Association (NYHA) functional class I-III. They underwent Cardiopulmonary Exercise test with non-invasive measurement of CO (CPET-CO) by inert gas rebreathing (IGR) at rest and peak exercise. The IGR technique uses an oxygen-enriched mixture of an inert soluble gas (0.5% nitrous oxide) and an inert insoluble gas (0.1% sulphur hexafluoride) inflated into a bag by the machine.

Results: CO increased from 3.23 ± 0.97 L/min at rest to 6.57 ± 2.52 L/min at peak exercise, and VO₂ at peak exercise was 1178.32 ± 410.42 mL/min, which corresponds to $61.20 \pm 18.09\%$ of predicted. We found a linear correlation between CO and VO₂ peak, described by the equation: $CO = 5.1246 \times VO_2 + 0.5566$ ($R^2 = 0.6671$). [image 1]

Conclusions: The concomitant measurement of CO and VO₂ at peak exercise in a large population of HF patients allowed us to obtain a predictive equation, which can be simply used to derive CO from VO₂ peak values measured at CPET. This equation has only been validated in HFrEF patients.

Amount or intensity? Potential targets of exercise interventions in patients with heart failure with preserved ejection fraction.

A Bobenko¹; T Trippel¹; R Lindhorst¹; K Nolte²; G Hasenfuss²; HD Duengen¹; G Gelbrich³; R Wachter²; B Pieske¹; F Edelmann¹

¹Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany; ²University Medical Center Göttingen (UMG), Department of Cardiology and Pneumology, Göttingen, Germany; ³University Julius Maximilian of Würzburg, Institute for Clinical Epidemiology and Biometry, Würzburg, Germany

Background: Heart failure (HF) with preserved ejection fraction (EF) is a common condition where no pharmacological therapy has yet been identified. Physical activity prevents the development of HF with reduced EF and improves symptoms and quality of life (QoL) in prevalent HF irrespective of EF. The aim of this study was to determine the association of physical activity (amount and intensity) on phenotype including exercise performance in patients with HF with preserved EF.

Methods: 422 patients (Aldo-DHF trial) with stable HF with preserved EF were investigated (52% women, age 67 ± 8 years). All patients underwent detailed cardiopulmonary exercise testing (CPET) and echocardiography. Daily physical activity and physical function in QoL were assessed by self-reporting questionnaires (KöBet, SF-36). Exercise performance was measured by 6-minute walk test and CPET (peak oxygen uptake, peak VO₂). Patients were classified according to the amount and intensity of physical activity and the association of physical activity and submaximal/maximal exercise capacity, diastolic function and QoL was analysed.

Results: Total physical activity (MET hours per week) was positively correlated with 6-minute walking distance ($p < 0.002$) and QoL ($p < 0.05$), but not with peak VO₂. 6-minute-walking distance and peak VO₂ values were significantly higher in patients who performed high intensity exercise >8 hours per week ($p < 0.001$ and $p = 0.02$, respectively). Time of high physical exercise was also positively correlated with 6-minute walking distance ($r = 0.21$, $p < 0.001$), with peak VO₂ and QoL (both $r = 0.13$, $p = 0.01$), whereas low physical exercise did not show significant associations. Interestingly, type or amount of exercise was not significantly related to any measure of diastolic function.

Conclusion: The total amount of daily physical activity is related to submaximal exercise capacity and QoL, whereas only daily high intensity exercise is associated with maximal exercise capacity in patients with HF with preserved EF.

P1093

Outcome of advanced heart failure patients with restrictive diastolic echocardiographic filling pattern (RDEFP) undergoing exercise based residential cardiac rehabilitation (EBCR)

F Tarro Genta¹; M Tidu¹; F Bertolin¹; Z Bouslenko¹; E Picardi¹

¹Salvatore Maugeri Foundation, IRCCS, Division of Cardiac Rehabilitation, Turin, Italy

Background: EBCR is recommended and useful in chronic stable heart failure patients.

Purpose: We aimed to evaluate safety and outcome of EBCR in patients with RDEFP (early mitral deceleration time [DT] ≤ 140 ms) and severe left ventricular dysfunction after recent episode of acute heart failure.

Methods: from June 2010 to May 2013, 20 consecutive patients (90% male, age 63 ± 15 years) with RDEFP and severe left ventricular dysfunction were admitted to a 3-weeks EBCR program (twice cycling or treadmill daily sessions with progressive increase as tolerated up to 14 Borg Rating of Perceived Exertion Scale, respiratory training) after a recent (1-3 weeks) episode of acute heart failure. Echocardiography on admission, Six minute walking test distance (6MWT), NT-proBNP on admission

and at discharge were assessed. Patients able to attend two daily sessions (30 minute each) at a workload of more than 30W Cycling or more than 2.5 Km/h at Treadmill by the end of rehabilitation program were categorized as Fit. Primary outcome was the occurrence at 1 year follow up of death (D), heart transplantations (HTx) or left ventricle assist device implantation (LVAD).

Results: All patients completed the rehabilitation program without complications related to exercise. At follow up primary outcome occurred in 9 patients; compared to alive at follow up (11 patients), these patients tolerated lower training workload and had lower 6MWT performance at admission and discharge; moreover they had higher NT-proBNP value at admission and discharge (Table)

Conclusions: In patients with RDEFP and severe left ventricular dysfunction after a recent acute heart failure EBCR is feasible and safe; exercise workload tolerance and submaximal exercise capacity by the end of EBCR program can help to predict outcome as well as NT-proBNP value.

Table

	PATIENTS	ALIVE	D/LVAD/HTx	p

CHF who filled WHO5 (World Health Organization) questionnaire before and after receiving EECP therapy.

Results: There was no significant different between two groups regarding the baseline characteristic of CHF patients. There was no significant difference from the questionnaire results in sham group before and after EECP therapy, but in EECP group it showed statistically significant different ($p < 0.05$). The WHO5 questionnaire attributes result were found significantly improvement of felt cheerful and good spirit ($p = 0.003$) and woke up feeling fresh ($p = 0.030$) in EECP group compare with sham group.

Conclusion: EECP therapy is effective to reduce depression so that improve QoL in patients with CHF

Older patients and cardiac rehabilitation: indication or limitation

M Marta Braga¹; A Rocha¹; H Nascimento¹; G Pestana¹; M Tavares Silva¹; R Pinto¹; J Rodrigues¹; J Araujo¹; F Parada-Pereira¹; M J Maciel¹

¹Sao Joao Hospital, Porto, Portugal

Introduction: Coronary artery disease (CAD) is an important cause of morbidity and death. Cardiac rehabilitation programs (CRP) have proven benefits over cardiovascular (CV) risk factors and exercise capacity. Among individuals with CAD, older patients (pts) are less likely to be referred to CRP.

Purpose: We aimed to compare pts aged ≥ 65 years with those < 65 years regarding baseline clinical profile and exercise performance and their response to a CRP.

Methods: This study was based on a prospective analysis of 433 consecutive pts who underwent CRP after acute coronary syndrome (ACS) in a tertiary centre from January 2009 to October 2015. Pts were divided into two groups, G1: age ≥ 65 years and G2: age < 65 years. Exercise performance was assessed using both duration and metabolic equivalents (METs) achieved in standard exercise test (ET) using Bruce protocol.

Results: Only 68 pts (15.7%) were aged ≥ 65 years. Mean age was 69.3 ± 4.1 in G1 and 51.8 ± 7.8 in G2. Older pts were less educated ($p = 0.005$). Hypertension (60.3% vs. 43.0%, $p = 0.009$) and diabetes (38.2% vs 15.7%, $p < 0.001$) were more frequent in older pts, whereas active smoking and family history of CAD were more often in younger pts. CAD was different between both groups. Lesion of 3 coronary arteries (CA) was more common in G1 (22% vs 9.0%, $p = 0.002$) with also higher prevalence of significant residual stenosis in those pts (42.2% vs. 23.2%, $p = 0.001$). Echocardiography showed normal or near-normal left ventricular (LV) systolic function with

Backgrounds: Depression is associated with a 5 fold increased risk of all cause mortality in patients with Chronic Heart Failure (CHF). The Enhanced external counter-pulsation (EECP) treatment can improve exercise tolerance in CHF patients. Regular exercise relieve depression and improve quality of life (QoL).

Purpose: to evaluate the risk of depression level before and after EECP therapy to improve quality of life in CHF patients.

Methods: A double blind randomized clinical trial was performed in 99 patients with CHF who had received EECP therapy in a clinic in Indonesia between January 2014 and June 2015. Subjects were categorized into 2 groups, i.e. 49 subjects had sham EECP therapy and 50 subjects had EECP therapy. All subjects were patients with

1094. Table 1

Post EECP WHO-5	Subjects' Responses	p value

Filled with interesting	13	3	21	17	12	17	4	10	3	2 0.052

The comparison of WHO-5 questionnaire after EECP between groups

similar fractional ejection in both groups (G1: $51 \pm 12\%$ vs G2: $52 \pm 11\%$). Absolute functional capacity was significantly different between groups (G1: 7.5 ± 1.6 METs vs. G2: 8.8 ± 2.3 METs, $p < 0.001$; G1: 6.9 ± 1.6 min vs. G2: 8.3 ± 2.4 min of ET duration, $p < 0.001$). At the end of CRP both groups similarly improved their performance (G1: 9.2 ± 1.8 METs vs. G2: 10.8 ± 2.1 METs; G1: 8.8 ± 1.7 min vs. 10.3 ± 2.2 min of ET duration). After comparing the results of CRP, we found no statistically significant difference between two groups (more 25.8% METs in G1 vs. 27.6% METs in G2, $p = 0.641$).

Conclusion: Older pts remain largely underrepresented in CRP cohorts. Although older pts had worse functional capacity, the relative improvement in exercise performance is similar in both younger and older pts. Age should not be considered, per se, criteria for referral/non-referral to CRP.

P1096

After acute coronary syndromes - who are we rehabilitating

G Goncalo Neves Pestana¹; A Rocha²; R Pinto¹; M Tavares-Silva¹; M Braga¹; H Nascimento¹; JD Rodrigues¹; V Araujo¹; F Parada²; MJ Maciel¹

¹Sao Joao Hospital, Cardiology, Porto, Portugal; ²Sao Joao Hospital, Physical Medicine and Rehabilitation, Porto, Portugal

Purpose: Cardiac rehabilitation (CR) has been shown to improve quality of life and reduce recurrent events and mortality. Still, rates of participation in CR programs are low, a problem which seems to particularly affect specific groups. We aimed to evaluate the rate of referral for CR after acute coronary syndromes (ACS) and significant determinants in daily practice.

Methods: We reviewed the clinical files of all patients (pts) admitted to our Cardiology Department with an ACS in 2014 and excluded those transferred to or with follow up in other departments or hospitals. Logistic regression was used to compare those referred for CR with those who weren't, regarding several sociodemographic and clinical characteristics; results are presented as odds ratio (OR) and p-value.

Results: We identified 639 pts hospitalized for ACS during 2014, 278 with follow up in our outpatient clinic. Mean age in the latter group was 63 years, with 206 (74%) male pts; 106 (38%) were referred for CR while the remaining 172 (62%) had follow up in the Ambulatory General Cardiology Clinic.

On univariate analysis, women (OR 0.49, $p = 0.018$), older pts (OR 0.92 for a one year increase, $p < 0.001$), those with a previous ACS (OR 0.35, $p = 0.002$) or other important morbidities, namely cerebrovascular disease, peripheral artery disease or chronic kidney disease (OR 0.20, $p = 0.001$), and those not in Killip I class (OR 0.18, $p = 0.001$) were less likely to be referred to CR. In contrast, a diagnosis of myocardial infarction (MI) compared to unstable angina (OR 2.66, $p = 0.014$), the presence of one vessel disease on coronary angiography (OR 2.93, $p < 0.001$) and performance of percutaneous angioplasty (OR 3.50, $p < 0.001$) were associated with bigger rates of CR referral. The number of cardiovascular risk factors, left ventricular systolic dysfunction and other ACS complications didn't have a statistically significant association with the outcome.

In a stepwise multivariate model, excluding previous ACS and one vessel disease for concerns of collinearity, older age (OR 0.93, $p < 0.001$), Killip class (OR 0.19, $p = 0.003$), comorbidities (OR 0.36, $p = 0.041$), diagnosis of MI (OR 2.57, $p = 0.031$) and coronary angioplasty (3.55, $p < 0.001$), kept their statistically significant association with CR referral.

Conclusions: Our study shows more "linear" subjects have a higher rate of CR referral, while older patients, with more comorbidities and complicated clinical course tend to be left out. This referral bias is not totally unexpected, still we believe it should move us towards a more inclusive CR paradigm; most of all, those who could benefit the most should not be left out. Further research into this topic is warranted, comparing these results with variables influencing CR outcomes and testing strategies to overcome such barriers.

P1097

The long term effects of high intensity exercise; a 5 years follow-up of a randomized controlled trial in heart transplant recipients

M Yardley¹; L Gullestad²; K Nytroen³

¹The Norwegian Health Association, Oslo, Norway; ²University of Oslo, Faculty of Medicine, Oslo, Norway; ³Oslo University Hospital, Department of Cardiology, Rikshospitalet, Oslo, Norway

Background: High-intensity interval training (HIT) has repeatedly proven to be superior to moderate continuous exercise regarding improvement of aerobic capacity in normal subjects and patients with established heart disease. Heart transplanted (HTx) patients has traditionally not been exposed to HIT because of chronotropic incompetence, but we have recently shown that HIT is safe and efficient also in this group. We now report 5 yr long-term effects of this intervention.

Purpose: To evaluate the long-term effects of HIT.

Method: 48 HTx patients completed a randomized control trial at our hospital in 2009-2011, comparing a 12-month HIT intervention with usual care. Four years after completed intervention, 41 patients were eligible for follow-up testing, to evaluate long-term effects of HIT. The patients underwent cardiopulmonary exercise

testing, blood sampling, echocardiography, intravascular ultrasound (IVUS) in coronary arteries, health-related quality of life questionnaires (QoL), measurement of body composition and isokinetic testing of muscle strength.

Results: Mean age (SD) of the patients at baseline was 49 (16) yr, 68 % men and mean years after HTx was 4 (2) yr. During 12 months of HIT, VO₂peak increased significantly from 27.7 (5.7) to 31.2 (5.3) and thereafter decreased to 26.0 (6.2) ml/kg/min at 5 yr follow-up, while it remained slightly decreased during the whole period in the control group: 28.9(6.7), 28.7 (6.3) and 26.1 (7.1) mL/kg/min at baseline, 12 mo and 5 yr respectively. The HIT-group also had significantly higher muscular capacity and less coronary artery vasculopathy (CAV) at 12 mo. Analysis of variance (baseline, 12 mo, 5 yr) showed no changes between groups in VO₂peak, muscular capacity, body composition, weight, chronotropic responses during exercise, glucose tolerance or lipid profile. The indifference in aerobic performance between groups, was in line with the similar everyday activity frequency and intensity measured by senseWear armband at 5 yr follow-up.

Conclusion: Patients who had completed a 12 month HIT-intervention were not able to maintain their high post-exercise VO₂peak levels and muscle capacity during long-term follow up. There were no significant differences in VO₂peak levels between the two groups at 5 yr follow-up and they reported similar activity frequency and intensity. Despite the reduced VO₂peak other positive effects may have sustained: for example the reduced CAV progression, which currently is being analyzed. However, our findings so far suggest that moderate levels of exercise and intensity are insufficient in order to maintain the achieved VO₂peak levels. Intermittent periods of HIT are probably necessary to maintain high VO₂peak levels.

P1098

Exercise-induced changes of pulse wave in chronic heart failure patients with reduced ejection fraction

V Dornberger¹; B Hoerth¹; S Gross¹; M Bahls¹; WJ Pietruschka¹; MR Markus²; SB Felix¹; M Doerr¹

¹German Centre for Cardiovascular Research (DZHK), Greifswald, Germany;

²University Medicine of Greifswald, Institute of Community Medicine, Greifswald, Germany

Purpose: Arterio-ventricular coupling plays an important role in the pathophysiology of heart failure with reduced ejection fraction (HFrEF). A decreased augmentation index (AIx) is found in HFrEF patients. The changes in central hemodynamic parameters of these patients during exercise are still not well known. We investigated the changes in parameters of pulse wave analysis during cardiopulmonary exercise testing (CPET) in HFrEF patients.

Methods: We compared 26 patients with chronic HFrEF characterized by ejection fraction (EF) $\leq 40\%$, NYHA class ≥ 2 and absence of atrial fibrillation (CHF) to 26 control subjects without a history of heart failure (CON) matched according to sex, age and renal function. Pulse wave analysis was assessed before and immediately after CPET and for ten minutes during the recovery period with an oscillometric device. The regression models were adjusted for history of hypertension and coronary artery disease, smoking status, body mass index, use of ACE inhibitors and calcium antagonists and heart rate.

Results: In supine position at rest the AIx was significantly lower in CHF compared to CON (19.85 ± 2.82 vs. 28.43 ± 3.39 , $p = 0.05$). After CPET, the AIx increased in CHF significantly compared to baseline ($19.73 \pm 2.37\%$ vs. $30.36 \pm 2.59\%$, $p < 0.001$) and to CON four minutes after exercise cessation ($28.90 \pm 2.21\%$ vs. $22.81 \pm 2.52\%$, $p = 0.05$). Furthermore, the amplitude of the reflected wave was reduced after exercise in CON but not in the CHF (13.3 ± 6.04 mmHg vs. 16.4 ± 7.2 mmHg,

$p < 0.001$). In addition, the pulse wave velocity after exercise was significantly lower in CHF compared to CON (8.45 ± 0.29 m/s vs. 9.09 ± 0.25 m/s, $p < 0.05$).

Conclusion: This study provides new insights into the complex hemodynamic changes and the importance of arterio-ventricular coupling in patients with HFREF under exercise conditions. We observed an increased augmentation index in heart failure patients which might be one of the reasons for exercise intolerance observed in these subjects. The clinical utility of these findings, e.g. for individualized treatment adjustment, has to be evaluated by future studies.

P1099

Left atrial function dynamics during exercise in heart failure of both reduced and preserved ejection fraction: pathophysiological implications on the right heart

T Sugimoto¹; F Bandera¹; G Generati¹; M Pellegrino¹; E Alfonzetti¹; M Guazzi¹
¹IRCCS Policlinico San Donato, Heart Failure Unit, Milan, Italy

Background: Left atrial (LA) function plays a key role in the hemodynamics of heart failure (HF) of reduced (rEF) and preserved (pEF) ejection fraction. Extensive investigation of LA dynamics, however, has been performed exclusively at rest.

Purpose: We hypothesized that LA dynamic impairment during exercise may trigger right ventricular (RV) to pulmonary circulation (PC) uncoupling and ventilation inefficiency.

Methods: 49 patients with HFREF, 20 with HFpEF and 32 healthy subjects with normal LA size and reservoir function (LA volume index < 34 ml/m², and peak LA strain during LA relaxation $> 23\%$) underwent cardiopulmonary exercise testing and contemporary Echo-Doppler assessment of LA-Strain and strain rate (SRa) and of RV to PC coupling (pulmonary arterial systolic pressure (PASP)/tricuspid annular peak systolic excursion (TAPSE) ratio), measured at rest, at 40% of predicted peak oxygen consumption, and during recovery.

Results: In controls, LA-Strain increased during exercise and recovery. HFpEF patients showed some LA-Strain increase during exercise and recovery whereas no changes occurred in HFREF. Baseline LA-SRa was greater in controls and only in this group a significant enhancement during recovery was observed (figure). LA-Strain at rest, exercise, and recovery significantly correlated with PASP/TAPSE and ventilation vs carbon dioxide slope in a continuous fashion across groups ($r = -0.63$ and $r = -0.59$; $r = -0.65$ and $r = -0.50$; $r = -0.70$ and $r = -0.53$ for controls, HFpEF, and HFREF, respectively, $P < 0.05$).

Conclusions: In HF, an impaired LA-Strain response is a key hemodynamic trigger for RV to PC uncoupling and exercise ventilation inefficiency with some overlap between HFpEF and HFREF phenotypes. Reversibility of LA dynamic appears an unmet target of specific therapeutic interventions.

Changes in LA-strain and LA-SRa

P1100

Peak VO2 is still a valuable prognostic marker in the current era. A subanalysis of the Meckl score group

A Verde¹; S Binno¹; P Agostoni²; U Corra³; GQ Villani¹; U Corvi¹; MC Murru¹; M F Massimo Francesco Piepoli¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy;

²Cardiology Center Monzino IRCCS, Cardiology, Milan, Italy; ³Salvatore Maugeri Foundation IRCCS, Pavia, Italy

Background: Cardiopulmonary exercise testing (CPET) is used to define prognosis of HF and for heart transplant (HT) listing, but its role has witnessed changes as well the prognostic profiles of HF

Objectives: To evaluate the changes in prognosis between different decades and the changing role of the CPET in advanced heart failure (AHF) patients enrolled in the MECKI score database

Methods: We selected, from a multicenter Italian HF database, 715 ambulatory patients with AHF, as defined by peakVO2 criteria for HT, to evaluate long-term follow-up using death+urgent HT as end-point. Clinical, laboratory, echocardiographic and cardiopulmonary-exercise-test data were analyzed for the entire

population and for patients grouped according to the time of CPET performed, before 2005, (n=354) or after 2005 (n=361)

Results: The average peakVO2 and follow-up were 10.2 ± 1.7 ml/kg/min and 941 ± 600 days. Overall survival rates were 91%-62% at 1-5 years. Survival rates at 1-5 years were significantly lower in patients before 2005 (85.5%- 62.3 %) with respect to the population studied after (94.3 %-79.1 %) ($p = 0.002$), when adjusted for age and gender. The difference was maintained even when the analysis was unadjusted. With respect to the old decades (before 2005) the AHF population after 2005 is older (65.4 ± 10.5 vs 63.1 ± 10.4 yr, $P < 0.001$), presents higher left ventricular ejection fraction (30.9 ± 9.0 vs 26.8 ± 9.3 %, $P < 0.0005$), lower ventilatory response to exercise (VE/VCO2 slope, 36.2 ± 8.5 vs 38.2 ± 8.8 %, $P < 0.01$), higher percentage of not ischaemic aetiology (41.0 vs 32.7 %, $P < 0.001$), CRT (14.6 vs $5.0 \pm$ %, $P < 0.0001$), ICD (24.6 vs 11.8 %, $P < 0.0001$). The following variables were significantly related to prognosis in both old and actual decades (Peak VO2, LVEF) while Beta-blockade therapy was protective only in the older group and the renal function only in the actual group.

Conclusions: PeakVO2 maintains its prognostic value in patients also in current era, of older, but better treated patients.

PROGNOSIS

P1101

Impact of the number of leukocytes on admission in patients with takotsubo syndrome

M Michiko Yoshizawa¹; T Itoh¹; S Nakajima¹; Y Ishikawa¹; M Ishida¹; T Fusazaki¹; M Nakamura²; Y Morino¹

¹Iwate Medical University, Division of Cardiology, Morioka, Japan; ²Iwate Medical University, Division of Cardiovascular Medicine, Nephrology and Endocrinology, Morioka, Japan

Background: Several studies have reported that Takotsubo syndrome have a good outcome in hospital. However, it is proposed that male gender and underlying disease are independent prognostic factors Takotsubo syndrome. The aim of our study was to evaluate prognostic factors in patients Takotsubo syndrome.

Method: Patients were consisted with consecutive 97 cases in our institute. We retrospectively corrected clinical characteristics from medical record. We defined major adverse cardiac event (MACE) as in-hospital cardiovascular death, cardiac shock, severe heart failure and fatal arrhythmia. Patients were divided into the MACE group and non-MACE groups. We compared clinical characteristics between the two groups.

Results: Patients were consisted with 47 MACE and 50 non-MACE. Although there was no significant difference in age between the two groups, male was significantly higher in the MACE group than the non-MACE group (27.7 vs. 12.0 : $p = 0.052$). The number of leukocytes on admission ($8,918 \pm 3,417$ vs. $10,216 \pm 4,051$; $p = 0.059$), underlying disease (70.5 vs. 39.6 %; $p = 0.003$) and physical stress (44.2 vs. 28.9 %; $p = 0.01$) are significantly higher in the MACE group than in the non-MACE group. Multivariate logistic regression analysis revealed that the high leukocytes on admission (odds ratio=1.00; 95%CI=1.00-1.00; $p = 0.046$), underlying disease (7.67 ; 95%CI=2.38-24.7; $p = 0.001$) and physical stress (1.00; 95%CI=1.000-1.003; $p = 0.007$) were independent predictors of MACE.

Conclusion: High leukocytes on admission, underlying disease and physical stress were independent predictors for major adverse cardiac event. Not only underlying disease and physical stress but also the number of leukocytes on admission is important prognostic factors in patients with Takotsubo syndrome.

P1102

Serum lipoprotein levels and survival in patients with advanced cancer

MS Anker¹; B Hildebrandt²; N Ebner³; J Springer³; H Riess²; W Haverkamp⁴; SD Anker³; U Landmesser¹; S Von Haehling³

¹Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany;

²Charite - Campus Virchow-Klinikum (CVK), Department of Hematology and

Oncology, Berlin, Germany; ³University Medical Center Gottingen (UMG),

Department of Cardiology and Pneumology, Gottingen, Germany; ⁴Charite -

Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany

Background: We set out to evaluate a cohort of patients with advanced cancer and to assess the prognostic impact of lipoproteins, which are known as markers of cardiovascular disease.

Methods: From 2005 through 2010, we enrolled 137 patients with histologically confirmed cancer (age 59 ± 10 yrs, 54% men, body mass index [BMI] 24.5 ± 5 kg/m², tumour stage I/II/III/IV 9/9/31/50%) and 56 healthy controls (age 61 ± 11 yrs, 55% men, BMI 26 ± 4 kg/m²). Patients were followed until censoring in February 2014 or until death. The cancer group consisted of 35 patients with colorectal, 65 patients with pancreatic, and 37 patients with non-small cell lung cancer. At baseline, a thorough cardiology assessment was performed including a full blood chemistry in the morning hours, before which patients were allowed a small breakfast.

Results: With respect to the metabolism we compared cancer patients with control subjects. In cancer patients, triglycerides (TG) levels were 146 ± 73 mg/dL, low-density lipoprotein (LDL) 108 ± 43 mg/dL, high-density lipoprotein (HDL) 55 ± 17 mg/dL, LDL/HDL ratio 2.2 ± 1.4 , and total cholesterol (TC) 193 ± 50 mg/dL. Controls showed TG levels of 149 ± 75 mg/dL, LDL 124 ± 36 mg/dL, HDL 58 ± 16 mg/dL, LDL/HDL ratio 2.3 ± 0.9 , and TC 211 ± 41 mg/dL. The difference between cancer patients and controls was significant for LDL ($p = 0.017$) and TC ($p = 0.018$). During a mean follow-up of 27 months, 82 patients (57%) died from any cause. In general, we found that tumour stage, metastases, BMI, surgery, anticoagulation and haemoglobin all predicted survival (all $p < 0.05$). With respect to the lipid metabolism TG, HDL and LDL/HDL ratio predicted survival in continuous analysis (TG – hazard ratio (HR) 0.996 [0.993-0.999] $p = 0.018$; HDL – HR 1.014 [1.000-1.028] $p = 0.045$; LDL/HDL ratio – HR 0.79 [0.63-0.99] $p = 0.040$). C-reactive protein did not predict survival. TG lower than 160 mg/dL (8.9 mmol/L) increased mortality significantly (HR 2.0 [1.2-3.3] $p = 0.0097$). The effect for TG lower than 160 mg/dL stayed significant in a multivariable model (HR 2.3 [1.4-3.8] $p = 0.0009$), which was adjusted for all before mentioned univariate predictors. In a second model we additionally included sex and age and the effect remained significant (HR 2.3 [1.4-3.7] $p = 0.0012$).

Conclusion: Once colorectal, pancreatic or lung cancer have developed the prognostic factors shift into a state where low TG and LDL/HDL ratio and high HDL predict poor survival independently. This phenomenon has been described for heart failure and termed cholesterol paradox.

P1103

Prognostic assessment in heart failure: what is the role of risk scores?

S Sara Guerreiro¹; H. Soares¹; J. Ferreira¹; C. Aguiar¹; A. Ventosa¹; M. Trabulo¹; M. Mendes¹

¹Hospital de Santa Cruz, Lisbon, Portugal

Background: The prognostic stratification of risk in heart failure (HF) is crucial for therapeutic guidelines with devices and heart transplant. Therefore, the use of risk scores that incorporate several variables with prognostic impact can be an advantage. We evaluated the performance of 3 risk scores in a specialized HF consultation.

Methods and Results: Retrospective and observational study that included 147 patients with HF: mean age 57 ± 15 years; 68% men and mean left ventricular ejection fraction $36\% \pm 15\%$. We calculated the scores: Seattle Heart Failure (SHF), MAGGIC Heart Failure Risk Calculator (MHFRC) and EMPHASIS-HF risk score (EHFRC) with patients basal values. The predictive value of mortality by risk scores and NT-proBNP was evaluated by c-statistics (AUC – Area Under the Curve). The mortality on follow-up period (median of 5 years) was 21.8%. The predictive value of mortality by risk scores and NT-proBNP are presented on table 1.

Conclusions: In a specialized HF consultation representative of real world, the predictive value of mortality by risk scores was weak. The performance demonstrated by the NT-proBNP in our population suggests a lightly superior potential benefit in comparison with the scores – which are composed by several variables and difficult to apply in clinical practice.

Table 1

	Median (interquartile interval)	AUC e CI 95%
SHF	18 [13; 29]	0,63 (0,41-0,86)
MHFRC	17 [13; 24]	0,55 (0,43-0,68)
EHFRC	4 [3; 6]	0,54 (0,43-0,65)
NT-proBNP (pg/ml)	782 [283; 3464]	0,67 (0,55-0,79)

P1104

Predictors of LV dyssynchrony worsening in the presence of normal EF

D. Dmitry Duplyakov¹; Z. Vozhdaeva²; E. Sysuenkova²; V. Glukhova²; S. Khokhlov¹

¹Samara Regional Cardiology Dispensary, Samara, Russian Federation; ²VAZ Medical Center, Togliatti, Russian Federation

Aim: To reveal the predictors of electrical and mechanical dyssynchrony worsening in patients with LBBB and normal EF during a prospective study.

Methods: 68 consecutive patients (mean age $55,8 \pm 9,0$ years; M47%) with LBBB revealed during annual check-up were enrolled into the study. History of CAD had 35 (51,5%) patients, hypertension – 64 (94,1%), 4 patients had no overt heart diseases after thorough examination. There were no patients with EF below 45%, and NYHA class > II. Fifty two (76,5%) of 68 patients had taken the recommended medication, mainly ACE-inhibitors and beta-blockers; however, 16 patients refused the recommendations. Follow-up period duration was 32 ± 13 months (6-58 mths). Logistic regression (SPSS 11.5) was used to identify characteristics that might have the greatest impact on the dynamics of dyssynchrony. Twenty six parameters were analyzed altogether.

Results: QRS duration during the FU period has increased in 33,9% of patients, mostly in women: 41.9% vs. 25.8% among men; but overall QRS duration has not changed during FU (149 ± 13 ms vs. 152 ± 14 ms, $p = 0.66$). An independent predictor of its progression was end-diastolic volume index (EDVI; OR = 1,24; 95% CI: 1,00-1,52).

In the beginning of the study only 19 (21,1%) patients had signs of atrio-ventricular (AV) dyssynchrony. During the FU period 10 (14,7%) new cases of AV-dyssynchrony have occurred. Multivariate analysis showed the influence of chronic heart failure (CHF; OR 6,91; 95% CI: 1,95-24,50; $p = 0.003$), and heart rate (HR; OR = 1,84; 95% CI: 1,18-2,87; $p = 0.026$).

According to the univariate analysis interventricular (IV) dyssynchrony deterioration was related to the signs of previous myocarditis on cardiac MRI with gadolinium (OR = 3,5; 95% CI: 1,8-10,6; $p = 0.013$), medical treatment by ACE-inhibitors and beta-blockers (OR = 1,9; 95% CI: 1,3-3,8; $p = 0.02$), age (OR = 0,93; 95% CI: 0,87-0,99; $p = 0.041$), BNP level (OR = 0,53; 95% CI: 0,28-0,99; $p = 0.046$), IVS thickness (OR = 0,03; 95% CI: 0,01-0,82; $p = 0.04$). Multivariate analysis revealed the influence of previous myocarditis (OR = 5,0; 95% CI: 1,5-16,68; $p = 0.009$) and medical treatment (combination of ACE-inhibitors and beta-blockers) (OR = 2,6; 95% CI: 1,4-5,8; $p = 0.008$). Interestingly, during FU period IV-dyssynchrony has decreased among those patients who followed the recommendations on medical treatment ($68,29 \pm 15,63$ ms vs. $61,95 \pm 15,85$ ms; $p = 0.005$). However, it worsened in patients who refused them ($55,62 \pm 18,96$ ms vs. $64,38 \pm 15,04$ ms; $p = 0,032$).

Conclusions: In patients with LBBB and normal EF EDVI was responsible for the increase of QRS complex duration during FU period of 32 ± 13 months. Presence of CHF and HR was associated with AV dyssynchrony worsening. Predictors of IV-dyssynchrony were the signs of previous myocarditis on cardiac MRI with gadolinium and poor adherence to medical treatment.

Influence of music therapy on patients with heart failure and early post-infarction angina; a substudy of the MUSIC-HF study

P. Predrag Mitrovic¹; B. Stefanovic¹; A. Paladin²; M. Radovanovic¹; N. Radovanovic¹; D. Rajic³; G. Matic³; I. Subotic³; V. Bulatovic⁴; Z. Vasiljevic¹

¹University Institute for Cardiovascular Diseases, CCS, School of Medicine, University of Belgrade, Belgrade, Serbia; ²Serbian National Broadcasting Agency, Belgrade, Serbia; ³Clinical Center of Serbia, Institute for Cardiovascular Diseases, Belgrade, Serbia; ⁴First Health Medical Center, Chicago, United States of America

Most studies have shown that early post-infarction angina (EPA) implies an unfavorable long-term prognosis among patients with acute myocardial infarction (AMI). Unrelieved anxiety can produce an increase in sympathetic nervous system activity leading to an increase in cardiac workload. The purpose of this study was to evaluate the effectiveness of music therapy for reduction of anxiety and pain in patients with heart failure (HF) and EPA.

Material and methods: The effectiveness of music in reducing anxiety and pain during EPA attacks was tested using a two-group pretest–posttest experimental design with 230 patients with HF and EPA. Patients were randomly assigned to receive 30 min of sedative music ($n = 115$) or treatment as usual ($n = 115$). Anxiety, pain sensation, and pain distress were measured with visual analogue scales at start of chest pain episodes and 30 min later.

Results: Repeated measures MANOVA indicated significant group differences in anxiety, pain sensation, and pain distress from pretest to posttest ($p = 0.0124$). Post hoc dependent t-tests and univariate repeated measures ANOVA ($p = 0.0162$) indicated that in the sedative music, anxiety, pain sensation, and pain distress all decreased significantly ($p = 0.0101$), while in the treatment as usual group, no significant differences occurred. Independent t-tests indicated significantly less posttest anxiety, pain sensation, and pain distress in the sedative music group than in treatment as usual groups ($p = 0.0284$).

Conclusion: Sedative music was more effective than treatment as usual in decreasing anxiety and pain in patients with HF and EPA. Patients with HF should have beneficial of using sedative music as an adjuvant to medication during EPA episodes.

P1106

The readmission in de novo heart failure patients within 30 days, either cardiovascular or non-cardiovascular causes, affecting the prognosis

Chang Gung Memorial Hospital

P-H. Chu¹; Y-C. Tung¹

¹Linkou Chang Gung Memorial Hospital, Cardiology, Tao-Yuan, Taiwan ROC

Background/Introduction: Heart failure (HF) readmission results in heavy expenditure on HF management. In a Medicare database study, HF is the most frequent reason of readmission within 30 days of discharge in both medical and surgery populations.

Purpose: This study aimed to evaluate the readmission rate, outcome, and predictors of HF readmission.

Methods: Patients with de novo reduced left ventricular ejection fraction (LVEF <40%) who were admitted for acute decompensation of de novo HF were enrolled for analysis of readmission rate, mortality and predictors of readmission.

Results: A total of 688 de novo HF patients with LVEF <40% were enrolled. The in-hospital and 6-month mortality rates were 3.7% and 13.2%, respectively. In the patients surviving the index HF hospitalization, the 30-day and 6-month readmission rates were 11.9% and 28%, respectively. At the end of 6-month follow-up, the readmission group had higher mortality than the non-readmission group (27.4% vs. 10.2%; $p = 0.001$). The survivors of the 30-day readmission had similar mortality rates at 6 months, regardless the causes of the readmission (cardiovascular vs. non-cardiovascular: 23% vs. 30.2%, $p = 0.634$).

Conclusion(s): The HF patients suffered from 30-day readmission had worse prognosis at 6-month follow-up. Regardless of the readmission causes, the patients surviving the 30-day readmission had similar mortality rates at 6-month follow-up. These results underscored the importance of reducing readmission as a means to improve HF outcome.

Validation of a new very simple score for outcome prediction in patients with chronic left ventricular systolic heart failureheart failure with reduced ejection fraction

G Fragasso¹; F Loiacono¹; G Calori¹; G Marinocchi²; A Salerno¹; R Belardinelli³; P Di Napoli⁴; R Roberto Spoladore¹; G Rosano⁵; A Margonato¹

¹San Raffaele Hospital (IRCCS), Milan, Italy; ²University of Insubria, Varese, Italy;

³University Hospital Riuniti of Ancona, Ancona, Italy; ⁴University of Chieti-Pescara, Chieti, Italy; ⁵St George's University of London, London, United Kingdom

Aim of this study was to develop and validate a prognostic score for patients with chronic heart failure (CHF), simple to calculate using only easily obtainable parameters exclusively through collection of past and present medical history. 376 consecutive outpatients with left ventricular systolic CHF (ejection fraction $\leq 45\%$) were recruited through the Outpatient Heart Failure Clinic of San Raffaele Hospital (OSR). Twelve variables, collected at baseline, were individually correlated with 5-year mortality risk by univariate Cox regression analysis. They were: gender; age; presence of coronary artery disease, previous acute myocardial infarction (AMI), previous acute decompensated heart failure (ADHF), left ventricular ejection fraction (EF) $<30\%$, NYHA class IV, diabetes mellitus, atrial fibrillation (AF), chronic renal failure (CRF), not taking beta-blockers (BB); not taking ACE-inhibitor (ACE-I). The variables that resulted significantly associated with increased mortality were then used to build a model of cardiac and overall risk of death through multivariate Cox regression analysis. The score thus obtained was subsequently validated on a different sample of 325 patients previously enrolled in other clinical studies. Previous ADHF, AF, EF $<30\%$, not taking BB, CRF resulted significant predictors of cardiac and overall mortality. The model provides a maximum score of 14 points, subdivided as 3 points each for previous ADHF, AF, EF $<30\%$, not taking BB and 2 points for CRF. The OSR risk score was validated on a different validation sample for cardiovascular (CVD) death by tertiles of score (1st tertile: 0-2; 2nd tertile: 3-5; 3rd tertile: >5). Log Rank test showed a significant difference in 5-year CVD mortality risk ($p = 0.004$). A significant difference in survival time by tertiles of OSR risk score was also observed for all-cause mortality (log-rank test: $p = 0.003$). Compared to the first tertile of OSR score, the second tertile had an increasing risk for CVD admission (HR: 2.7; 95% CI: 1.5-4.9) and for admission due to HF worsening (HR: 4.3; 95% CI: 1.3-14.5). In the third tertile the risk for CVD admission and for admission due to HF worsening was also increased (HR: 3.2; 95% CI: 1.7-6.1 and HR: 3.8; 95% CI: 1.03-14.1). In conclusion, the OSR Heart Failure Risk Score, derived and validated in chronic HF outpatients with left ventricular systolic dysfunction, is a simple, quick, inexpensive and readily-available tool for predicting patient outcome in 5-year time, in terms of cardiac and global mortality and morbidity. This prognostic model is exclusively based on patient's past and present medical history.

P1108

High levels of galectin-3 is associated incremental risk of all-cause death in chinese patients with heart failure

QY Chen¹; H Wang²; YY Li²; JF Yang²

¹West China Hospital Sichuan University, Cardiology, Chengdu, China People's Republic of; ²Beijing Hospital, Cardiology, Beijing, China People's Republic of

Background: Galectin-3, a novel biomarker associated with fibrosis and inflammation, has been used to stratify and prognosticate heart failure (HF). However, the usefulness of value in prognosis is controversial and data in Chinese HF population are sparse.

Purpose: To evaluate the prognosis value of galectin-3 in chinese HF patients.

Methods: Galectin-3, N-terminal pro B-type natriuretic peptide (NT-proBNP) levels and other clinical related variables were measured on admission in consecutive patients with HF in cardiology department of our hospital. Specifically, galectin-3 was detected by an enzyme-linked immunosorbent assay method. The primary end point was all-cause mortality and/or readmission at end of follow-up. The adjusted hazard ratio (HR) was determined by Cox regression model.

Results: We studied 272 patients with median age of 77 years and 55.9% were male. During a median follow-up period of 558 days, 53 patients (19.5%) died and 103 patients (37.9%) died and/or required re-hospitalization. Plasma galectin-3 levels by tertiles were associated with increased risk for main adverse cardiac events ($p = 0.00$). Kaplan-Meier survival curves show the third tertile of galectin-3 were associated with incremental rate of primary end point (compared to second and first tertiles, the log rank $p = 0.001$ and 0.000 , respectively). Multivariable Cox regression model show the highest tertile of galectin-3 was associated with increased risk of all-cause death or readmission for HF (HR=2.13, 95% confidence interval [CI]: 1.24-3.68, $P = 0.006$) compared with the lowest tertile after adjustment of age, NT-proBNP, creatinine, uric acid, albumin, hemoglobin and estimated glomerular filtration rate (eGFR).

Conclusion: Plasma galectin-3 is a novel independent predictor of all-cause mortality and/or readmission in Chinese patients with HF. High levels of galectin-3 is associated incremental risk of death in chinese HF patients.

kaplan-meier survival curve for death

P1109

Predictors of outcome in outpatients with chronic heart failure during a long term follow-up

M Triggiani¹; I Papa¹; E Rocco¹; L Lupi¹; G Sacca¹; C Villa¹; G Milesi¹; A Manerba¹; N Berlinghieri¹; S Nodari¹

¹University of Brescia, Department of Clinical and Surgical Specialties, Cardiology section, Brescia, Italy

Background: despite progress in the treatment and management of Heart Failure (HF), the prognosis of HF patients (pts) remains poor. Therefore an accurate prognostic stratification remains crucial to identify pts at high risk of mortality and hospitalizations who need a tailored treatment and closer follow-up.

Purpose: we aimed to assess the different predictive value of clinical, laboratoristic and instrumental parameters in outpatients with stable chronic HF.

Methods: we analyzed pts with reduced left ventricular ejection fraction (LVEF $\leq 45\%$) with optimized medical therapy according to current guidelines, clinically stable for at least 3 months, followed in our 'HF clinic'. All pts underwent clinical evaluation, laboratory exams, electrocardiogram and echocardiography. Median follow-up was 43 months. The composite end-point was: mortality and hospitalization for HF and for cardiovascular causes. Univariable analysis was performed using the t test for continuous variables and chi-square for categorical variables; multivariable analysis using Cox regression method.

Results: from 1st January 2011 to 31st December 2012 we evaluated 570 consecutive pts (mean age 67 ± 12 years, 83% male); 486 pts (85.3%) were in NYHA class I-II, ischemic etiology was in 53% and idiopathic 44.7% of pts, 34.7% were diabetics and 26.3% were in atrial fibrillation. The average values of the main variables considered were: LVEF $35 \pm 7\%$; eGFR 64.1 ± 36 ml/min/1.73 m², creatinine 1.35 ± 0.9 mg/dl, hemoglobin 13.3 ± 1.6 g/dl, HR 67.9 ± 12.34 bpm. During the follow-up events occurred in 294 (52%) pts (121 death). Table 1 show the main prognostic parameters at univariable and multivariable analyses.

Conclusion: in our study population of outpatients with chronic HF and left ventricular systolic dysfunction, age, LVEF, diuretic dose and clinical congestion status remain the most powerful predictors of adverse outcomes during a long term follow-up.

¹University Medical Center of Göttingen, Georg-August University, Department of Cardiology and Pneumology, Göttingen, Germany; ²University of Alabama Birmingham, Birmingham, United States of America; ³Stony Brook University Medical Center, Stony Brook, United States of America; ⁴Veterans Affairs Medical Center, Washington, United States of America; ⁵University of California Los Angeles, Los Angeles, United States of America; ⁶University of California San Francisco, San Francisco, United States of America; ⁷New York Medical College, Valhalla, United States of America; ⁸Geriatrics and Extended Care Services, Department of Veterans Affairs, Washington, United States of America

Background: Low serum potassium is associated with higher risk of long-term mortality in ambulatory patients with heart failure (HF). The objective of the current study is to examine this association in patients hospitalized for worsening HF using propensity score matching design.

Methods: Of the 8049 patients hospitalized with a principle discharge diagnosis of HF, 1052 patients had hypokalemia (serum potassium <4.0 mmol/L) and 3142 had normokalemia (4.0 to 5.5 mmol/L), both on admission and at discharge. Propensity scores for hypokalemia were estimated for each of the 4194 patients and used to assemble a matched cohort of 995 pairs of patients with hypokalemia and normokalemia.

Results: Matched patients (n=1990) had a mean age of 75 years, 60% were women, and 28% African American. During 8 years of follow-up, all-cause mortality occurred in 66% and 62% of matched patients with hypokalemia and normokalemia, respectively (hazard ratio [HR], 0.94; 95% confidence interval [CI] 0.84-1.05; P=0.3). Similarly, no significant association between hypokalemia and all-cause mortality was found among different subgroups of patients. Hypokalemia had no association with all-cause hospitalization (HR, 0.99; 95% CI, 0.87-0.1.13; P=0.9) or HF hospitalization (HR, 0.95; 95% CI, 0.81-1.10; P=0.5).

Conclusion: Unlike in younger ambulatory patients with HF, hypokalemia was not associated with long-term mortality among real-world hospitalized HF patients.

P1111

Growth differentiation factor-15 is associated with poor prognosis in chinese patients with heart failure

National Key Technology Support Program of china. Research subject number: BJ-2012-143

H Wang¹; QY Chen²; YY Li¹; XC Jing²; JF Yang¹

¹Beijing Hospital, Cardiology, Beijing, China People's Republic of; ²West China Hospital Sichuan University, Cardiology, Chengdu, China People's Republic of

Background: Growth differentiation factor-15 (GDF-15), a novel biomarker associated with remodeling, oxidative stress and inflammation, has been used to stratify and prognosticate heart failure (HF). However, the prognostic value of GDF-15 in Chinese HF population is still unknown and related data are sparse.

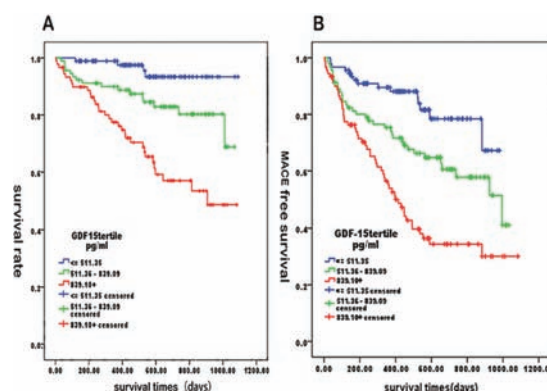

Purpose: To evaluate the prognostic value in chinese HF patients.

Methods: GDF-15 and other clinical related variables were examined on admission in 272 consecutive patients with HF in cardiology department of our hospital. GDF-15 was detected by a commercial enzyme-linked immunosorbent assay method. The primary end point was all-cause mortality; the secondary end point was main adverse cardiac events(MACE) including all-cause mortality and/or readmission for heart failure. The adjusted hazard ratio (HR) was determined by multivariate Cox regression model.

Results: A total of 272 patients with median age of 77 years and 55.9% were male. 53 patients (19.5%) died and 103 patients (37.9%) had MACE during a median follow-up time of 558 days. The third tertile of GDF-15 was associated with incremental rate of primary endpoint (compared to middle and low tertiles of GDF-15, the log rank p=0.001 and 0.001, respectively) and secondary endpoint (compared to middle and low tertiles of GDF-15, the log rank p=0.002 and 0.000, respectively). The incidence of primary endpoint and secondary endpoint also increased significantly when comparing the middle tertile to the low tertile of GDF-15 (the log rank p=0.02 and 0.01 respectively). Multivariate Cox regression model shew the highest tertile of GDF-15 was associated with increased risk of all-cause death for HF [hazard ratio(HR)=5.95, 95% confidence interval(CI):1.88-18.78, P=0.002]

compared with the lowest tertile after adjustment of interference of related coexisted clinical factors including age, renal function or NT-proBNP.

Conclusion: Plasma GDF-15 is a novel independent predictor of all-cause mortality and/or readmission in Chinese patients with HF. It may potentially be used to stratify, prognosticate HF patients.

Survival analysis for mortality or MACE

Recovered heart failure: a different class of heart failure according to outcome?

C Díez-López¹; J Lupon¹; M De Antonio¹; M Domingo¹; E Zamora¹; J Santesmas¹; MI Troya¹; C Díez-Quevedo¹; M Boldo¹; A Bayes-Genis¹

¹Germans Trias i Pujol University Hospital, Badalona, Spain

Background: Advances in drug therapy, devices, coronary revascularization and valvular repair are responsible for systolic function improvement (even sometimes to normal or almost-normal values) in a non-negligible number of patients with heart failure (HF) and reduced left ventricular ejection fraction (LVEF). The existence of a third class of HF beyond HF with reduced LVEF (HFrEF) and with preserved LVEF (HFpEF) has been proposed. Objective: Outcomes analysis of patients with recovered HF (baseline LVEF <45% that improve after one year of follow-up to a LVEF ≥45) compared to HFrEF and HFpEF. All-cause, cardiovascular, HF-related and sudden death were the specific end-points.

Patients and Method: LVEF at first visit and at one-year follow-up were assessed by echocardiography in 1063 patients (72.7% men; mean age 65.6 ± 11.9 years, range 30-96 years). Aetiology of HF was mainly ischemic heart disease (52.2%), followed by dilated cardiomyopathy (14%), valvular disease (8.7%) and hypertensive cardiomyopathy (8.6%). Mean LVEF was 32% ± 12. Most patients were in NYHA functional class II (68.3%) and III (25%). Patients were classified into three groups: 1) Recovered HF (LVEF <45% at baseline and ≥45% at one year; n=237); 2) HFpEF (LVEF ≥45% at baseline; n=145); and 3) HFrEF (LVEF <45% both, at first and at one-year visits; n=681). Mean follow-up was 4.7 ± 3.1 years after the second echocardiography (up to 10 years).

Results: Four hundred thirty-four patients (40.8%) died during follow-up. In Cox regression analysis (taking as reference recovered HF) outcomes for HFpEF and HFrEF patients were: all-cause mortality (HR 1.68 [95%CI 1.19-2.38], p=0.003; and HR 1.65 [95%CI 1.26-2.16], p<0.001, respectively); cardiovascular mortality (HR 2.30 [95%CI 1.40-3.60], p=0.001 and HR 2.41 [95%CI 1.61-3.60]; and HF-related mortality (HR 4.11 [95%CI 1.96-8.59], p<0.001 and HR 3.17 [95%CI 1.73-6.36], p<0.001, respectively). Sudden death was only significantly higher in HFrEF (HR 3.62 [95%CI 1.45-9.07], p<0.001) and not in HFpEF (HR 1.40 [95%CI 0.38-5.22], p<0.66).

Conclusion: Recovered HF patients showed a better prognosis than HFpEF and HFrEF patients, mainly due to lower hazard of HF-related and sudden death.

P1113

Prognostic value of prothrombin activity percentage measurement in patients with acute decompensated cardiac failure

G Daquarti¹; L Battioni¹; M L Talavera²; AC Iribarren¹; I Chillik¹; R Campos¹; A Acosta²; MS Trivi¹; M Diez²

¹Cardiovascular Institute of Buenos Aires (ICBA), Cardiology, Buenos Aires, Argentina; ²Cardiovascular Institute of Buenos Aires (ICBA), Heart Failure, Buenos Aires, Argentina

Background: Abnormal liver function tests (LFTs) is a common feature in heart failure. It has been previously shown that abnormal LFTs predicts poor outcome in follow up. Prothrombin Activity Percentage (PA%) correlates with prognosis in patients with acute liver failure in settings such as acetaminophen intoxication, however prognostic implications of PA% in acute decompensated heart failure (ADHF) has not been evaluated previously. The present study was conducted to investigate the impact of PA% on cardiovascular outcomes in patients with ADHF in our institution.

Objective: To evaluate the relation between PA% and death/heart transplantation and hospital readmission due ADHF at 180 days in patients (pts) hospitalized with ADHF.

Methods: 223 consecutive pts admitted with ADHF between January-2013 and August-2014 were selected; patients on vitamin K antagonists were excluded (n=94). Heparin was not administered to any patient before blood collection. Blood samples were obtained at hospital admission; PA% was measured with an automatic coagulation analyzer (CA-500, Sysmex). Patients' basic characteristic data including sex, age, past medical history, medications, as well as blood exam results, were analyzed. The primary endpoint was a composite of all-cause death or readmission for heart failure at 180 days of follow up.

Results: There were 117 pts analyzed, mean age was 78 years old (+/- 11) and 68 pts (58%) were male, 49 pts (42%) had preserved ejection fraction (>50%); median PA% was 62.5% (IQR 25-75: 25-81), and median creatinine was 1,22 mg/dl (IQR 25-75: 0,95-1,66). There were 40 (34%) death/heart transplantation and hospital readmission due ADHF and 22% (26) death at 180 days; PA% was significantly lower in the event group: 71 % versus 80% (p < 0.013), cox proportional hazards regression analysis showed that decreased prothrombin activity (<70%) is an independent predictor of event (OR=3.82 CI95: 1,47-9,8, p=0.006) among variables including serum creatinine, hs- troponin and glucose at 180 days of follow up. (Figure)

Conclusion: decreased PA% at admission is a novel powerful predictor of death/heart transplantation in non-anticoagulated pts hospitalized due to ADHF suggesting the impact of liver dysfunction on disease process of heart failure. This variable could be included in a future as a part of risk stratification in acute heart failure setting.

Figure. Primary endpoint

Systolic blood pressure target: a new challenge in cardiovascular prevention in community-based population?

C Concetta Di Nora¹; A Iorio²; L Rivetti¹; B Ortis¹; C Mazzone³; A Cherubini³; G Faganello³; L Tarantini⁴; G Sinagra¹; A Di Lenarda³

¹University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ²Ospedale Papa Giovanni XXIII, Bergamo, Italy; ³Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy; ⁴San Martino Hospital, Belluno, Italy

Background: Arterial hypertension (AH) is one of the most known risk factor for cardiovascular disease (CVD). Until now, systolic blood pressure (SBP) level ≤ 140 mmHg has been considered the optimal SBP to reduce blood pressure-related adverse outcomes. Nevertheless, in SPRINT trial, SBP goal < 120 mmHg resulted in lower CVD risk.

Objectives: To determine prevalence, characteristics and outcome in a group of hypertensive patients without known CVD compared to an increased cardiovascular risk (ICR) subgroup taking into account SBP goal < 120 mmHg.

Methods: We enrolled patients with AH and one other cardiovascular risk factor from 11/2009 to 10/2014. Patients with diabetes, known ejection fraction (EF) < 35%, New York Heart Association (NYHA) class III-IV and age < 50 years were excluded. Of these, we also identified an ICR subgroup defined by clinical or subclinical cardiovascular disease, chronic kidney disease (eGFR of 20 to < 60 ml/min per 1.73 m²), or an age ≥ 75 years. All patients were in optimized medical therapy. Clinical variables of study population were derived from the E-data chart for Outpatient Clinic collected in a Cardiovascular Observatory.

Results: Of all 3003 cases, after exclusion of diabetes and known EF < 35% (1239 pts, 41%), we identified a cohort of 1764 patients ≥ 50 years old (71 \pm 9 years old, 51% males). Current smoking status was in 250 patients (14%), dyslipidemia in 1072 (61%) and obesity in 452 patients (26%). Median value of SBP was 138 \pm 19 mmHg and of diastolic blood pressure (DBP) was 81 \pm 9 mmHg. Medical therapy was consistent in renin-angiotensin receptor blocker (ARB) for 1028 patients (58%), calcium antagonist (CA) therapy for 321 (18%), beta blockers (BB) for 777 (45%) and diuretics for 457 (25%). Atrial fibrillation (AF) was in 575 patients (32%), of whom, 353 (20%) was persistent or permanent AF. Anticoagulant therapy was present in 376 patients (21%). We also identified a subset of 1156 ICR patients (65%, 80 \pm 4 years old, 52% males). In this latter group SBP was 140 \pm 20 mmHg (< 120 mmHg in 234 patients, 20%) and medical treatment was ARB for 670 patients (58%), CA for 196 (17%), BB for 497 (43%) and diuretics for 266 (23%). In a median follow up of 22 months, 236 patients (13%) of the first group died or were admitted for HF, conversely 17% showed an event in the ICR subgroup. Taking into account SBP different goals, we had 3% (in SBP < 120 mmHg) vs 3.8% (in SBP ≥ 120 mmHg) of total events in the first group (p=NS), and 13.2% (SBP < 120 mmHg) vs 14.4% (SBP ≥ 120 mmHg) of total events in the ICR group (p=NS).

Conclusions: In the subset of hypertensive patients, obtaining an effective blood pressure control is crucial. Nevertheless recent studies have proposed a more aggressive control, our results showed that SBP target < 120 mmHg didn't influence outcome, also in a high risk subgroup (ICR). Clinical characteristics of our population (as the older age) could explain these results, discouraging the SBP target < 120 mmHg as driver to medical therapy.

P1115

Prognostic impact of left atrial function by 2D speckle-tracking echocardiographic analysis in patients with chronic systolic heart failure.

A Malagoli¹; L Rossi¹; C Sticozzi¹; A Zanni¹; M Piepoli¹; G Villani¹
¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Introduction: The size of the left atrium (LA) have been proposed as a powerful predictor of major adverse cardiac events (MACEs) in patients with heart disease. The prognostic impact of the LA function is still widely debated. Speckle-tracking two-dimensional strain echocardiography (2DSE) analysis is considered a feasible and reproducible approach to quantify LA dynamics.

Purpose: Accordingly, the purpose of this study was to assess the prognostic impact of the LA intrinsic myocardial function using 2DSE analysis in patients with chronic systolic heart failure (HF).

Methods: From October 2011 to December 2014, 427 consecutive outpatients were referred to our HF-center. Eligible patients were 18 to 85 years of age, with left ventricular ejection fraction (LVEF) < 40% and sinus rhythm. Exclusion criteria were refractory atrial arrhythmias to medical therapy, pregnancy, primary valvular disease, mechanical valve prosthesis, recent myocardial infarction or coronary intervention, severe obstructive pulmonary disease or severe renal failure (creatinine clearance < 30 ml/min). The final study population included 209 outpatients (80% male, mean age 68.2 \pm 11.0 years) with either idiopathic or ischemic etiology. Peak atrial longitudinal strain (PALS) were measured in all enrolled subjects. PALS values were obtained by averaging all segments (global PALS), and by separately averaging segments measured in the 4-chamber and 2-chamber views. Primary endpoint was MACEs.

Results: After 39.8 \pm 9.0 months of follow-up (range, 22-51 months), 84 patients (40.2%) met the primary endpoint (Figure 1). Global PALS, LA volume, LV end-systolic volume and LVEF differentiated patients with MACEs at the univariate regression analysis. According to the multivariate Cox regression analysis, reduced global PALS results the only predictor of MACEs [hazard ratio (HR) 0.946, 95% CI 0.917-0.976, P=0.001].

Conclusions: In patients with chronic systolic HF, global PALS is an independent predictor of prognosis useful to stratify patients at high risk.

P1116

Prognostic value of ultrasound lung artefacts (comet tail sign) in acute heart failure.

Health Research Project (FIS) P112/00694

C Josa¹; C Butcher²; JGF Cleland²; I Torres¹; J Rubio¹; M Martinez-Marín¹; I Gimenez-Lopez³; P Samperiz¹; A Sola⁴; JI Perez-Calvo¹

¹Clinical University Hospital Lozano Blesa, Zaragoza, Spain; ²Imperial College London, National Heart & Lung Institute, Royal Brompton & Harefield Hospitals, London, United Kingdom; ³University of Zaragoza, Zaragoza, Spain; ⁴Bellvitge Institute of Biomedical Research (IDIBELL), Barcelona, Spain

Introduction: Assessment of interstitial oedema at the bedside with lung ultrasound (LUS) produces a pattern known as comet-tail artefact (CTA), as the sonographic equivalent of Kerley-B lines.

Purpose: We investigated the prevalence of CTA in patients admitted to hospital with a diagnosis of acute heart failure (AHF) and evaluated their relationship with HF biomarkers and prognosis.

Methods: From 2013 to 2014, consecutive patients with AHF were prospectively enrolled. During the first 24 hours, a bedside thoracic ultrasound was performed (V-SCAN; GE) to identify CTA. Cumulative mortality over 12 months according to the presence or absence of CTA was recorded. Patients were classified according to LUS and plasma NT-proBNP (defined by median) into four groups. Multivariable adjusted risk for mortality was generated.

Results: Of 204 patients, median age was 81 ± 9 years, 51% were men and median hospital stay was 8 ± 7 days. The prevalence of CTA on admission was 51% and persisted for a mean of 3 ± 2.5 days. Patients with positive CTA had higher median NT-proBNP ($p=0.006$) and lower haemoglobin ($p=0.08$). Forty-six patients (23%) died by 12 months. Patients who died were older ($p=0.001$), had had a longer hospital stay ($p=0.027$) and higher plasma urea ($p=0.000$), creatinine ($p=0.034$), NT-proBNP ($p=0.000$) and Cystatin C ($p=0.014$). CTA was associated with higher mortality (OR=2.19; $p=0.011$; KM Log Rank 0.01). Compared to patients without CTA, those with CTA had a higher 12-month mortality if NT-proBNP was greater than median ($> 3,300$ pg/mL) (38% vs 23%) and for patients with NT-proBNP below median, 12-month mortality was 19% and 10% for those with and without CTA ($p=0.004$ amongst the four groups, figure 1). The strongest univariate predictors of 12-month mortality were Cystatin C [Exp(B)=3.3, $p=0.009$], NT-proBNP [Exp(B)=2.1, $p=0.000$] and CTA [Exp(B)=2.2, $p=0.013$]. Multivariable analysis demonstrated that age, length of hospital stay, Cystatin C, NT-proBNP and plasma urea and creatinine were independent predictors of prognosis at one year. When NT-proBNP was taken out of the model, CTA also predicted outcome.

Conclusion: CTA identified with LUS may be used to stratify mortality risk in daily clinical practice for patients with AHF, either alone or combined with NT-proBNP.

KM defined by CTA and NT-proBNP

PULMONARY HYPERTENSION

Prognostic value of MMP/TIMP imbalance at follow up assessment in idiopathic pulmonary arterial hypertension

V Veronika Wetzl¹; SL Tiede²; L Faerber³; N Weissmann²; RT Schermuly²; HA Ghofrani²; H Gall²

¹University of Regensburg, Department of Pharmacology and Toxicology, Regensburg, Germany; ²University of Giessen and Marburg Lung Center (UGMLC), member of the German Center for Lung Research (DZL), Giessen, Germany; ³Novartis Pharmaceuticals, Nuremberg, Germany

Introduction: Pulmonary arterial hypertension (PAH) is a progressive pulmonary disease which is caused by remodeling and vasoconstriction of the small pulmonary arteries resulting in right heart failure. Despite treatment mortality remains high in PAH patients and 1- and 3-year survival is estimated at 88% and 68%. Many biomarkers have been tested for clinical assessment of PAH, but up to now, only brain natriuretic peptide (BNP) and NT-proBNP are widely used in routine practice to estimate disease prognosis. Extracellular matrix accumulation and remodeling processes in lung and heart are of particular interest for the progression of PAH. Matrix metalloproteinases (MMPs) and their endogenous inhibitors TIMPs are involved in this pathological condition.

Purpose: The aim of this study was to investigate MMP/TIMP ratios of selected biomarkers (MMP2, MMP9, TIMP1, TIMP4) at follow up examination (V2) and their prognostic value in patients with idiopathic PAH (IPAH).

Methods: Blood samples were taken from patients with IPAH during right heart catheterization at diagnosis and follow-up examination (V2). Coincident with sample collection hemodynamic, laboratory and clinical parameters were acquired. In this sub-study MMP2, MMP9, TIMP1, and TIMP4 plasma levels at V2 were measured as duplicates by ELISA as instructed by the manufacturer. Data analysis was performed with SPSS.

Results: Ratios of MMP2/TIMP1 and MMP9/TIMP1 did not correlate with the hemodynamic data, whereas MMP2/TIMP4 and MMP9/TIMP4 ratios showed good correlations with mPAP and MMP2/TIMP4 ratio additionally with PVR. No correlations were found for BNP. Furthermore, MMP2/TIMP4 plasma ratio shows good correlation with tricuspid annular plane systolic excursion (TAPSE). Additionally, biomarker ratios correlate with markers of renal dysfunction. For clinical worsening and survival analysis, patients were divided into two groups, according to their MMP2/TIMP4 plasma level ratios. Log rank test showed significantly reduced mortality rates and clinical worsening events, respectively, for patients below the cut off value.

Conclusion: A strong correlation of MMP2/TIMP4 ratio was found with hemodynamic parameters for disease progression as well as with TAPSE, a marker of right ventricular function and prognostic marker in PAH. Moreover, MMP2/TIMP4 ratio is a good predictor for survival and clinical worsening in our patient cohort.

P1118

Pulmonary endarterectomy across borders - an ongoing effort for chronic thromboembolic pulmonary hypertension management

S Sofia Alegria¹; MJ Loureiro¹; F Ferreira¹; AR Almeida¹; O Simoes¹; D Repolho¹; L Lopes¹; H Pereira¹

¹Hospital Garcia de Orta, Cardiology, Almada, Portugal

Introduction: Pulmonary endarterectomy (PE) remains the gold standard treatment for chronic thromboembolic pulmonary hypertension (CTEPH). Most patients (pts)

present substantial clinical and haemodynamic improvement after surgery, while pts who are not submitted to PE have an unfavourable prognosis.

Purpose: Characterization of a population of pts with CTEPH submitted to PE across borders and assessment of the postoperative course.

Methods: Retrospective analysis of 16 pts with CTEPH followed in a referral center for the treatment of pulmonary hypertension (PH) and submitted to PE in a specialized surgical center abroad.

Results: Sixteen pts with mean age 54 ± 10 years and female predominance (75%) were included. In the preprocedure evaluation 63% presented with WHO functional class III, the mean distance in the 6-minute walk test (6MWT) was 376 ± 130 meters and the median NT-proBNP was 510 pg/ml (interquartile range 122-2456 pg/ml). TTE revealed preserved RV function in 36% (average TAPSE 18 ± 5 mm), dilated RV in 64% and RA in 70%, mean PASP of 90 ± 17 mmHg and mild pericardial effusion in 20%. Right heart catheterization showed a cardiac index (CI) of 2.52 ± 0.97 l/min/m², mean pulmonary artery pressure (PAPm) of 44 ± 14 mmHg and pulmonary vascular resistance (PVR) of 11.1 ± 5.9 WU. Before surgery 63% were treated with phosphodiesterase type 5 (PDE5) inhibitors, 25% with endothelin receptor antagonists and 6% with prostacyclin analogues. In the postoperative evaluation, performed 285 ± 247 days after surgery, there was a substantial improvement in the WHO functional class (79% in class I), mean distance in the 6MWT (mean increase of 104 ± 58 meters) and NT-proBNP (mean reduction of 339 pg/ml). TTE showed normalization of RV dimensions in 63% of pts and of the RA dimensions in 33%, as well as marked reduction in PASP (mean reduction 50 ± 22 mmHg) and absence of pericardial effusion in all pts. Haemodynamic evaluation demonstrated reduction in PAPm to 28 ± 11 mmHg and in PVR to 5.3 ± 1.7 WU. Nevertheless, 79% maintained residual PH (defined as PAPm ≥ 25 mmHg and/or PVR > 3 WU). Regarding postoperative therapy, 89% of pts suspended PDE5 inhibitors and all suspended endothelin receptor antagonists and prostacyclin analogues, while 29% started riociguat. There was also a significant reduction in the number of hospital admissions and duration of hospitalizations due to cardiovascular causes in the 12 months following PE, comparing with the 12 months before surgery (0.14 ± 0.36 vs. 0.44 ± 0.51 admissions per patient, $p = 0.025$; 2 ± 8 vs. 12 ± 17 days, $p = 0.027$).

Conclusion: Although a significant proportion of pts submitted to PE maintains residual PH, we documented a substantial improvement in clinical, laboratory echocardiographic and haemodynamic parameters, as well as improvement in quality of life and long term prognosis. This study highlights the role of international cooperation in the management of pts with CTEPH.

P1119

Pulmonary hypertension as an independent predictor of cardiovascular mortality in patients with renal replacement therapy

M Cafka¹; M Rroji²; J Seiti¹; S Seferi¹; J Djamandi³; A Goda¹

¹University Hospital Center Mother Theresa, Department of Cardiology & Cardiac Surgery, Tirana, Albania; ²University Hospital Center, Nephrology-Dialysis-Transplant Department, Tirana, Albania; ³Hygeia Hospital, cardiology department, Tirana, Albania

Introduction: Hemodialysis patients are at increased risk of cardiovascular (CV) mortality. Pulmonary hypertension (PH), has been recently reported as unrecognized threat in dialysis patients. The aim of the present study was to determine the incidence and the value of PH in predicting CV mortality in dialysis patients.

Methods: We studied 80 stable hemodialysis patients (females 37.5%, mean age 50.36 ± 12.34 years) and 45 peritoneal dialysis patients (females 40%, mean age 55.07 ± 13 years) on renal replacement therapy (RRT) for more than 3 months. All patients had been followed up for 2 years and the endpoint was CV mortality. PH was defined as systolic pulmonary artery pressure (SPAP) ≥ 35 mmHg as determined by Doppler echocardiographic evaluation. To rule out secondary PH, patients with pulmonary disease, collagen vascular disease, and volume overload at the time of echocardiography were excluded.

Results: According to the echocardiographic findings, PAH was found in 35 (28%) in overall patients. Cardiovascular mortality during follow up was 15.5% (19 events). The main causes of CV death were sudden deaths (31.5%), deaths from ischemic heart disease and stroke with 26.4% respectively. Significant higher value of SPAP was found in patient with CV mortality in comparison with patients alive in therapy: 40.27 ± 9.145 vs 33.29 ± 6.37 ($p = 0.011$). Binary regression logistik analysis showed an increase of 14% of cardiovascular mortality for each unit increase of PAH [OR = 1.14 (1.00-1.30) $p = 0.05$].

In conclusion: Our study showed that PH is frequent in patients treated with RRT. It is an independent predictor of CV mortality.

P1120

A new index for risk stratification in patients with pulmonary hypertension.

M Michele Correale¹; D Lacedonia¹; A Ferraretti¹; G Galgano²; P Schino²;

R Petrucci¹; GE Carpagnano¹; M Di Biase¹; MP Foschino¹; ND Brunetti¹

¹University of Foggia, Foggia, Italy; ²Hospital "Mullini", Acquaviva delle Fonti, Italy

Introduction: In patients with systemic sclerosis a ratio between Forced-Vital-Capacity (FVC) and diffusing capacity of carbon-monoxide (DLCO, FCV%/DLCO%) > 1.5 could be a predictor of pulmonary hypertension (PH). The aim of this study was therefore to evaluate whether this index could be used in patients with PH, regardless of etiology.

Methods: 83 consecutive outpatients with suspected PH at non-invasive work-up underwent spirometry and DLCO test before right heart catheterization (RHC); FVC%/DLCO% ratio was then calculated and compared with mean pulmonary-artery-pressure (mPAP) and mortality at 5-year follow up.

Results: Significant correlations between FVC%/DLCO% and PASP and mPAP levels were found ($p < 0.05$). After ROC curve analysis and definition of best cut-off values for PASP and FVC%/DLCO%, increased mPAP values at RHC were observed comparing subjects with both PASP and FVC%/DLCO% values below cut off values ($-/-$), either PASP or FVC%/DLCO% above cut off values ($+/-$), or both above ($+/+$) ($p < 0.05$). Poorer survival rates were observed at follow up with higher FVC%/DLCO% values (0% for < 1 , 17.4% for 1-3, 33.3% for > 3 , $p < 0.05$), and comparing subjects with either increased PASP and FVC%/DLCO% values or both with those with lower (Log-Rank $p < 0.05$).

Conclusions: FVC%/DLCO% values are related to mPAP in subjects with suspected PH and may further stratify the risk of mortality in addition to PAP.

Society of Pediatrics, Buenos Aires, Argentina; ⁷Model Institute of Cardiology,

Cordoba, Argentina; ⁸Section of pulmonary circulation of the Argentinean

Association of Respiratory Medicine, Buenos Aires, Argentina; ⁹Hospital "San Juan

de Dios", La Plata, Argentina

Purpose: Epidemiology of pulmonary hypertension (PH) might have regional differences based on several modifiers, including socioeconomic, geographic and ethnic factors as well as prevalent diseases. The aims of RECOPILAR Registry were to evaluate epidemiology, clinical profile, management and therapeutic strategies, of a broad population with PH under collaborative effort of five medical scientific societies.

Method: Between Jul-14/Jul-15, 305 incident and prevalent patients with PH were prospectively included by 60 investigators from 20 provinces from Argentina. The inclusion criteria were: 1-patients over three months of age; 2 -mean pulmonary arterial pressure (mPAP) at rest ≥ 25 mmHg by right heart catheterization (RHC) and 3 - clinical stability in the absence of hospitalization in last month.

Results: Mean age was 49 ± 18 years and 73% were women. A half of patients were referred from other centers, 34% were incident cases and 19% did not have social security. Classification of PH in groups 1 to 5 (Nice) was the following: 68%; 14%; 7%; 8% and 3%. The clinical manifestations were dyspnea 93%, fatigue 64%, syncope 12%, chest pain 19%, palpitations 24% and heart failure in 21% with previous hospitalization in 33%. The diagnostic work-up included ECG (95%), chest X-ray (91%), echocardiogram (95%), general lab (93%), serological test for connective tissue disease (59%), natriuretic peptides measurement (53%), V/Q scan (76%), pulmonary function test (71%), 6-minute walking test (83%), cardiopulmonary exercise test (5), angio CT (31%) and vasoreactivity test (77%). Treatment included diuretics (59%), mineralocorticoid receptor antagonist (57%), digoxin (26%), anticoagulants (49%), ACE-I/ARB (20%), betablockers (21%) and calcium antagonist (14%). Oxygen supplementation was used in 20% and cardiopulmonary rehabilitation in 12%. In patients with pulmonary arterial hypertension (PAH) vs other groups, the use of specific therapy was 79 vs 87% ($p = NS$), without differences in the prescription of sildenafil in 73 vs 75% ($p = NS$), iloprost 9.6 vs 5.3% ($p = NS$), bosentan in 32 vs 35% ($p = NS$), ambrisentan in 14.2 vs 19% ($p = NS$), treprostinil in 7.4 vs 8% ($p = NS$), macitentan (4 vs 6.7%). The follow-up was available in 197 patients (65%), with an overall mortality of 11.2% in PAH vs 11.1% in other groups ($p = NS$).

Conclusion: In this Argentinean registry, two thirds of patients had pulmonary arterial hypertension. The diagnostic work-up was consistent with current recommendations according to guidelines. Therapeutic interventions included a high proportion of specific therapy, in PAH as well as in other groups. These findings remark the need of multidisciplinary approach and expert centers in the management of PH.

P1122

Vasoreactivity testing with intravenous sildenafil in patients with pre-capillary pulmonary hypertension associated with connective tissue disease

A Andreas Rieth¹; A Berkowitsch¹; I Tärner²; M Frerix²; V Mitrovic¹; CW Hamm³

¹Kerckhoff Heart Center, Bad Nauheim, Germany; ²Kerckhoff Clinic, Rheumatology,

Bad Nauheim, Germany; ³Justus-Liebig University of Giessen, Giessen, Germany

Aims: The aim of the study was to investigate whether vasoreactivity testing (VRT) with intravenous sildenafil (SIL) is effective and predictive of the response to oral therapy in patients with pre-capillary pulmonary hypertension associated with connective tissue disease (CTD-PAH). **Methods and**

Results: Ten patients with CTD-PAH (9 female, mean age 62 y) without specific pretreatment were diagnosed by right heart catheterization, and VRT was performed by infusion of SIL 10 mg. Comprehensive evaluation of hemodynamic parameters before and after SIL included measurements at rest and during exercise. In terms of mean changes in the entire cohort, the mean pulmonary artery pressure (mPAP) decreased by 4.8 mmHg, the cardiac index (CI) increased by 0.28 l/min/m², and pulmonary vascular resistance (PVR) decreased by 71 dyn·s·cm⁻⁵, with the largest effect being observed after 30 min. The largest individual decrease in mPAP was 8 mmHg. Exercise hemodynamics showed similar changes with reduction of the total pulmonary resistance (TPR = mPAP/CO) during exercise. The parameters of the systemic circulation were changed to a similar extent as the pulmonary circulation. After a treatment period (3 x 20 mg SIL p.o.) of 90 days, a multitude of parameters (NTproBNP measurement, cardiopulmonary exercise testing, repeated hemodynamic measurements) did not change significantly in the entire cohort. Only echocardiographic RV peak free wall strain showed a trend to improvement after therapy (median -4.37, p=0.059). Four individual responders were identified due to strict criteria derived from the pulmonary hypertension guidelines. The individual reaction of the responders upon VRT was not distinct from the others, but the parameter PAC (pulmonary artery compliance = stroke volume / PA pulse pressure, a measure of pulmonary artery stiffness) during exercise was markedly lower (i.e. worse) in nonresponders than in responders (p=0.01). This difference showed to be more pronounced after intravenous administration of SIL (median 1.9 vs. 1.57).

Conclusions: In our small pilot study, VRT using i.v. SIL reduced mPAP and PVR and increased CI but failed to fulfill the Sitbon criteria for a positive test result. Intravenous administration of SIL was safe, and the effects were not selective for the pulmonary circulation. Responsiveness in VRT did not correlate with the clinical outcome, but PAC during exercise correlated with the success of an oral therapy.

P1123

The role of electrical cardiometry in non-invasive assessment of hemodynamic parameters in patients with pulmonary arterial hypertension

R Remigiusz Kazimierzczuk¹; M Marcinkiewicz-Siemion¹; B Sobkowicz¹; WJ Musiał¹; KA Kaminski¹

¹Medical University of Białystok, Department of Cardiology, Białystok, Poland

Background: The electrical cardiometry (EC) technique could estimate cardiac output (CO), cardiac index (CI) and other parameters related to cardiac contractility and fluid status by measuring the thoracic electrical bioimpedance. It has been validated and is utilized in patients with left ventricular dysfunction, however its diagnostic performance in patients with pulmonary arterial hypertension (PAH) is unclear. In PAH patients, right-sided heart failure is very common cause of deterioration of patients' state and often leads to death. EC could be an opportunity to assess hemodynamic state of patient in non-invasive way.

Purpose: To investigate the usefulness of electrical cardiometry in assessment of hemodynamic status in PAH patients in comparison results obtained during RHC and echocardiography.

Methods: EC parameters were assessed by hemodynamic monitor in 21 patients diagnosed with PAH shortly after RHC and echocardiography. Statistical analysis was done to indicate the correlation between parameters obtained using both invasive and non-invasive techniques.

Results: All subjects with PAH (54.1 ± 17.2 years old, 11 females (52%)) were in II-IV functional class according to WHO. The etiology was idiopathic (71.4%, n = 15) and PAH associated with connective tissue diseases (28.6, n = 6). Patients with congenital heart diseases were excluded from the study. Mean weight of patients was 72.83 ± 17.35 kg and mean body surface area 1.81 ± 0.21 m².

We observed a significant correlation (r = 0.64; p = 0.002) between thermodilution cardiac output measurement results (4.19 ± 1.13 l/min) and CO results obtained by ICON (4.72 ± 1.04 l/min). The mean difference between the two methods was 0.89 l/min.

Furthermore, EC monitor provides information about left ventricle afterload represented by systemic vascular resistance (SVR). There was a significant correlation between SVR calculated by EC monitor and SVR obtained during RHC (r = 0.66; p = 0.001). On the other side this technique could also indirectly predict right-sided cardiac function e.g. index of contractility (ICON) significantly correlated with parameters assessed by echocardiography like tricuspid annular plane systolic excursion (r = 0.57; p = 0.01). ICON also correlated with inferior vena cava diameter (r = 0.54; p = 0.014).

Conclusions: Electrical cardiometry method provides non-invasive insight into hemodynamic function of the heart. When compared to the thermodilution method during RHC, EC provides satisfactory CO measurements. RHC cannot be replaced but electrical cardiometry may provide fast assessment of patient's state at bedside or in outpatient care.

Pediatric heart transplantation recipients: echocardiographic evaluation of left ventricular mechanics

R Rita Gravino¹; G Limongelli¹; A Petraio²; A Rea¹; R Vastarella¹; M Verrengia¹; C Amarelli²; C Maiello²; MG Russo³; G Pacileo¹

¹Heart Failure Unit, AO dei Colli-Monaldi Hospital, Department of Cardiology, Second University of Naples, Naples, Italy; ²Cardiac Transplantation Unit, AO dei Colli-Monaldi Hospital, Naples, Italy; ³Pediatric Cardiology Unit, AO dei Colli-Monaldi Hospital, Department of Cardiology, Second University of Naples, Naples, Italy

Introduction: Recently some studies dealing with assessment of cardiac function by Speckle Tracking Imaging (STI) in heart transplant (HTX) recipients have been published, an integrated assessment of all myocardial properties of deformation is lacking.

Purpose: The aim of this study is to perform, by using Speckle Tracking Imaging, an integrated study of LV mechanics (longitudinal, radial, circumferential regional deformation, twist, untwist onset and diastolic function) in HTX recipients with preserved ejection fraction and good clinical conditions (NYHA I).

Methods: We enrolled 20 HTX subjects without symptoms (NYHA I) and with preserved ejection fraction (HTX group), and 40 normal subjects as control group (CTRL group).

Results: HTX patients were characterized by an early diastolic dysfunction, detectable by an increased value of E/E' ratio (HTX 10.58 ± 2.94; CTRL 5.3 ± 1.5; p < 0.0001). Compared to control group our HTX recipients showed: a) impaired longitudinal and radial strain values with normal circumferential strain values b) LV rotation was preserved at apex and impaired at basal level (bas rot CTRL -7.35 ± 1.6; HTX = -5.05 ± 2.89 p < 0.001; ap rot CTRL 6.92° ± 2.56°; HTX = 9.73 ± 4.38 p < 0.0001) with normal LV twist (CTRL 14.22 ± 3.4; HTX = 14.78 ± 5.58; p value not significant); c) delayed untwisting due to prolonged twist (time to peak twist/systolic time: CTRL 80.48 ± 13.69, HTX 103.45 ± 18.42 p < 0.0001).

Conclusions: Of interest "healthy" HTX patients, even in presence of widespread impairment of regional myocardial deformation, normal apical rotation, which account for normal amplitude of twist and in turn global ejection fraction. In addition delayed untwisting (after aortic valve closure) due to prolonged twist could be responsible of an early impaired LV diastolic filling.

P1125

Changes of ventricular-arterial coupling may reflect early cardiac remodeling in patients with myocardial infarction treated with percutaneous coronary intervention

E Elena Zharikova¹; S Villevalde¹; ZH Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Ventricular remodeling may occur following myocardial infarction (MI) of the left ventricle (LV) and such remodeling has been shown to be correlated with increased patient morbidity and mortality. It is important to estimate the likelihood of remodeling from the state of the infarcted LV. The aim of the study was to assess the ventricular-arterial coupling (VAC) in patients with ST segment elevation (STEMI) and non ST segment elevation MI (NSTEMI) treated with percutaneous coronary intervention (PCI).

Methods: In 93 patients with acute coronary syndrome and PCI (70% male, age 61.5 ± 10.1 years (M ± SD), 57 (61.3%) with STEMI, smokers 25%, arterial hypertension 20.4%, blood pressure (BP) 129 ± 6/82 ± 7 mmHg, LVEF 47.4 ± 4.3%) 2-dimensional echocardiography was performed to assess arterial elastance (Ea) and end-systolic LV elastance (Ees) on admission and in 4 weeks. VAC was assessed as the ratio Ea/Ees.

Results: Baseline LVEF was 47.4 ± 4.3, E/A 0.95 ± 0.18, Ea 1.9 ± 0.3 mmHg/ml/m², Ees 2.1 ± 0.4 mmHg/ml/m², VAC 0.89 ± 0.1. At baseline all patients had LVEF > 40% and VAC in optimal range. In 4 weeks after PCI VAC > 1.2 (upper optimal level) was revealed in 19% of patients with STEMI and 44% with NSTEMI. In patients with achieved VAC > 1.2 Ees (2.1 ± 0.4 vs 1.6 ± 0.2 mmHg/ml/m², p < 0.001), stroke work (SW) (6254 ± 1516 vs 6112 ± 1059 mmHg*ml/m², p > 0.05), potential energy (PE) (62.8 ± 4.3 vs 56.3 ± 5.4 mmHg*ml/m², p < 0.001), pressure-volume area (PVA) (6317 ± 2136 vs 6179 ± 1060 mmHg*ml/m², p < 0.001), LV work efficiency (SW/PVA) significantly decreased (p < 0.001) while Ea (1.9 ± 0.3 to 2.1 ± 0.4 mmHg/ml/m², p > 0.05) did not change. In patients with VAC in optimal range in 4 weeks Ees decreased from 2.3 ± 0.3 to 2.1 ± 0.4 mmHg/ml/m² (p < 0.001), Ea (p < 0.001) and VAC (p < 0.001) did not change.

Conclusions: Impairment of functioning of cardio-vascular system assessed by increased value of VAC > 1.2 was revealed in 27% of patients with acute coronary syndrome. Increase of VAC is associated predominantly with decrease of Ees and LV work efficiency (SW/PVA). Increased in the VAC index > 1.2 indicating LV-arterial

uncoupling may be an early marker of cardiovascular remodeling in MI or systolic dysfunction.

P1126

Heterogeneous response of ventricular-arterial coupling and left ventricular efficiency to afterload increase in untreated hypertensive subjects

A Anna Bogomaz¹; Y Kotovskaya¹; ZH Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Aim: to evaluate cardiovascular adaptation to increased afterload during handgrip isometric exercise (HIE) in untreated hypertensive patients.

Methods: 75 untreated hypertensive patients (age 54 ± 7 years, 44 males, BP 153/93 mmHg) underwent simultaneous EchoCG and blood pressure (BP) acquisition at rest and during HIE. End-systolic pressure was determined as $0.9 \times$ brachial systolic BP (SBP). Arterial elastance (Ea) and LV elastance (Ees) were calculated as end-systolic pressure (ESP) /stroke volume (SV) and ESP/end-systolic volume (ESV). Ventricular-arterial coupling index was assessed as Ea/Ees. Efficiency of left ventricle (ELV) was evaluated by stroke work (SW)/pressure-volume area (PVA) ratio. $SW=ESP \times SV$, $PVA=SW+PE$ ($ESP \times ESV/2$ -end diastolic pressure \times ESP/4). $p < 0.05$ was considered significant.

Results: Ea/Ees < 0.5 was found in 76% ($n=57$, 18 female) before HIE. In 38% ($n=22$, 4 (23%) female) Ea, Ees, Ea/Ees and SW/PVA did not change significantly. In 11% there was further decrease of Ea/Ees associated with significant increase of ELV. In 51% ($n=29$, 14 (49%) female) Ea/Ees increased due to increase of Ea from 1.98 ± 0.32 to 2.35 ± 0.41 ($p < 0.05$) while Ees increased from 5.95 ± 2.2 to 4.58 ± 1.0 ($p < 0.05$). Ea/Ees increase was associated with decrease of ELV from 0.89 ± 0.02 to 0.84 ± 0.02 ($p < 0.05$) indicating cardiovascular misadaptation to HIE.

In subjects ($n=18$, 3 female) with normal Ea/Ees $0.5-1.2$ before HIE Ea/Ees and ELV did not change in 8 (49%, all males). In 10 subjects (3 female) Ea/Ees decreased due to significant increase of Ees (from 3.15 ± 0.68 to 5.02 ± 1.34 ($p < 0.05$), and ELV increased from 0.81 ± 0.03 to 0.88 ± 0.01 ($p < 0.05$).

Conclusion: Cardiovascular misadaptation to afterload is the most prevalent type of reaction to HIE in subjects with decreased baseline Ea/Ees and may be also observed in subjects with normal baseline ventricular-arterial coupling. This misadaptation in subjects with baseline ventricular arterial uncoupling is associated with female gender.

P1127

Ventricular-arterial uncoupling may be an early sign of cardiovascular remodeling in hypertensive men

A Anna Bogomaz¹; Y Kotovskaya¹; ZH Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: To evaluate ventricular-arterial coupling (VAC), left ventricular hypertrophy (LVH), diastolic function and arterial stiffness in young and middle-aged men with uncomplicated arterial hypertension

Methods: 97 young men aged 18-27 years (21.2 ± 1.9 years, BP $156.5 \pm 14.0/98.5 \pm 9.1$ mmHg) and 68 middle-aged men aged 40-60 years ($n=68$, age 53.9 ± 7.2 years, BP $152.7 \pm 9.6/94.8 \pm 7.8$ mmHg) (M) underwent simultaneous EchoCG, blood pressure (BP) and pulse wave velocity measurement. VAC index was calculated as arterial elastance (Ea) and left ventricular elastance (Ees) ratio. $Ea=\text{end-systolic pressure}/\text{stroke volume}$, $Ees=\text{end-systolic pressure}/\text{end-systolic volume}$. LVH was diagnosed if LV mass index was > 115 g/m². Increased arterial stiffness -if PWV > 10 m/s, diastolic dysfunction - if E/A < 1.0 and E/E' < 7 m/s.

Results: In young men Eea 1.86 ± 0.32 and index VAC (0.52 ± 0.10) was similar to that in middle-aged (1.9 ± 0.47 and 0.48 ± 0.19 , respectively), despite that Ees in young men was significantly lower (3.67 ± 0.85) than in middle-aged men (4.6 ± 2.1 , $p < 0.01$). VAC index < 0.5 was found in 34% young men and in 57% middle-aged men ($p < 0.05$), LVH in 7.4% and 67% ($p < 0.05$), diastolic dysfunction 4.1% and 62%, respectively. VAC index was similar in those with and without LVH or diastolic dysfunction in the both age groups. In young men with LVH VAC index was 0.63 ± 0.26 , without LVH 0.54 ± 0.12 , in middle-aged patients with LVH - 0.45 ± 0.16 , without LVH - 0.49 ± 0.21 . In young men with diastolic dysfunction VAC index was 0.61 ± 0.13 , without diastolic dysfunction - 0.58 ± 0.16 . In middle-aged men 0.45 ± 0.14 and 0.48 ± 0.16 , respectively. $PWV > 10$ m/s was found in 22.7% of young men and in 80.1% of middle-aged ($p < 0.05$). No significant correlation between VAC index and BP, LVMI, PWV, E/A, E/E' was found.

Conclusion: Decrease in the VAC index < 0.5 indicating LV-arterial uncoupling may be an early marker of cardiovascular remodeling in hypertensive men that may be observed before development of LVH, diastolic dysfunction or increased arterial stiffness.

P1128

Patients with acute coronary syndromes without left ventricular function evaluation represent a special high risk population: a single centre observation.

F Fernando Montenegro Sa¹; C Ruivo¹; A Antunes¹; F Saraiva¹; J Correia¹; J Guardado¹; P Gomes¹; S Pernencar¹; N Carvalho¹; J Morais¹

¹Hospital Santo Andre, Cardiology, Leiria, Portugal

Introduction: According to the guidelines left ventricular (LV) function should be routinely assessed in patients with acute coronary syndromes (ACS). Nevertheless and for multiple reasons this recommendation is not always followed.

Objective: In a single centre, authors (AA) sought to characterize the group of patients with ACS in that LV function was not evaluated, regardless of the reason. Methods and

Results: A series of 963 patients with ACS (unstable angina - 165; non ST elevation acute myocardial infarction - AMI - 404; ST elevation AMI - 394) were split in four groups according to LV function: Gr.A - LV function not evaluated ($n=87$); Gr.B - normal LV function ($n=661$); Gr.C - moderate impairment (ejection fraction $> 30\% < 50\%$) ($n=161$); Gr.D - severe impairment (ejection fraction $< 30\%$) ($n=54$). Groups were compared regarding clinical and laboratorial characteristics at admission and also in-hospital management. Main differences are showed in the Table.

Conclusions: According to the current data the group of patients not investigated for LV function showed a specially high risk profile and, paradoxically, an invasive strategy and revascularization were less used when compared with the group of patients with normal LV function.

Left ventricle diastolic function impairment in patients with arterial hypertension and no LV hypertrophy

O Olena Torbas¹; S Kushnir¹; YU Sirenko¹; O Rekovets¹

¹NSC Institute of Cardiology M.D. Strazhesko, Symptomatic hypertension, Kiev, Ukraine

Objective: The mechanisms of formation of left ventricular diastolic dysfunction (LV DD) remains unclear. One of the main reasons for LV DD is arterial hypertension (AH). Blood vessels are the first target organ that is affected by AH. However, whether the arterial stiffness may impair left ventricle diastolic function (DF LV) has been insufficiently studied. We tried to correlate the arterial stiffness, ventriculararterial coupling (VAC) and indicators of DF LV.

Design and methods: We examined 67 patients with essential AH stage 2 (mean SBP 157.57 ± 5.46 mmHg, mean DBP 92.13 ± 2.87 mmHg; BMI 28.99 ± 0.99 ; age 52.77 ± 3.59), 33 men and 34 women with no symptoms of heart failure. The following diagnostic procedures were performed: office BP measurement, measurement of central BP (cSBP) and adjusted augmentation index (Alx75%), carotid-femoral (cfPWV) pulse wave velocity, Doppler echocardiography according to local full protocol, LV DD was determined by measuring velocity of the peak E and peak A of transmitral flow with determination of E/A, velocity of peak E' by tissue Doppler with determination of E/E', deceleration time (Dt) and isovolumic relaxation time (IVRT) measurement. LV myocardium mass index (LVMMI) was evaluated using ASE formula. To assess the relationship between these values we used Spearman correlation analysis.

Results: As we can see according to the office measurement peripheral BP of patients was high, respectively central SBP level was also elevated (142.78 ± 5.85 mmHg). Systolic function (EF $64.07 \pm 1.45\%$) was preserved, indicators of DF LV were also within normal limits, but there was a slight tendency to their impairment (E/A 1.07 ± 0.1 ; E/E' 9.07 ± 2.59 ; Dt 236.58 ± 14.74 ; IVRT 87.78 ± 6.03), maybe,

due to mild LV hypertrophy (LVMMI 97.50 ± 5.42). However we have found a worsening of arterial stiffness (cfPWV 12.02 ± 0.78) and ventriculararterial coupling (VAC 1.59 ± 0.05). E/A correlated with Alx75% ($r=0.433$; $p<0.001$) and cfPWV ($r=0.32$; $p=0.1$). E/E' correlated with VAC ($r=0.292$; $p=0.026$), LVMMI ($r=0.55$; $p<0.001$), Alx75% ($r=0.469$; $p<0.001$), cfPWV ($r=0.303$; $p=0.02$). Dt correlated with LVMMI ($r=0.268$; $p=0.035$), Alx75% ($r=0.317$; $p=0.011$). IVRT correlated with LVMMI ($r=0.290$; $p=0.025$), Alx75% ($r=0.430$; $p=0.001$) and cfPWV ($r=0.270$; $p=0.035$). But we have found no significant correlation between VAC and cfPWV, however VAC was correlated with LVMMI ($r=0.342$; $p=0.006$).

Conclusions: We found significant correlation between arterial stiffness and all the indicators of DF LV, but there was no correlation between cfPWV and VAC. The strongest correlation was between Alx75% and all of indicators of DF LV.

Predictors of preclinical left ventricular diastolic dysfunction in type 2 diabetes mellitus

A Albana Doko Banushi¹; V Paparisto¹; N Kuka²; I Refatllari¹; J Dragoti¹; A Goda¹

¹University Hospital Center Mother Theresa, Tirana, Albania; ²Polytechnic University, Tirana, Albania

Some studies have shown that diabetes may be an independent risk factor for left ventricular (LV) diastolic dysfunction (DD).

Purpose: To determine the prevalence of preclinical diastolic dysfunction (DD), and risk factors associated with this entity in type 2 diabetes mellitus (T2DM) patients with normal ejection fraction (EF), with or without hypertension (HT), no overt coronary artery disease, asymptomatic for heart failure.

Methods: Case-control study of 380 patients (256 DM, 124 DM+HT, mean age 58.9 ± 7.3 years) and 100 age-matched control subjects, recruited from Mars 2008 through December 2012. LV diastolic function was evaluated by Doppler echocardiography (combined transmitral flow, TDI and propagation velocity).

Results: The prevalence of DD was 58.7% in DM vs 80% in DM+HT ($p<0.001$). The multivariate analysis showed that the best predictors of DD were LV remodeling (OR=19.72, 95%CI 6.97-55.2), glycemic control (HbA1c) (OR=1.49, 95% CI 1.3-1.69) and diabetes duration (OR=1.14, 95% CI 1.06-1.22).

Conclusions: The prevalence of preclinical DD was high in type 2 diabetic patients. LV remodeling, glycemic control, and diabetes duration were the best predictors of preclinical DD.

¹Medical University of Vienna, Internal Medicine III/ Cardiology, Vienna, Austria

Background: Patients with heart failure (HF) and preserved ejection fraction (HFpEF) suffer from functional impairment resulting in reduced quality of life. Specific pathomechanisms underlying symptoms have not yet been defined.

Methods and Results: Between January 2011 and December 2014, 193 HFpEF patients were enrolled. Those in more advanced New York Heart Association (NYHA) functional classes (III/IV, $n=136$) were older ($p=0.008$), had higher body mass indices (BMI, $p=0.004$) and higher levels of NT-pro-brain natriuretic peptide (NT-pro-BNP, $p=0.001$) as compared with less symptomatic patients (NYHA II, $n=57$). Furthermore, parameters reflecting left ventricular (LV) diastolic dysfunction were more pronounced in advanced NYHA classes (early mitral inflow velocity/early diastolic mitral annular velocity: $p=0.023$) as well as parameters reflecting right ventricular (RV) afterload (diastolic pulmonary artery pressure (dPAP), $p=0.001$). By multivariable regression analysis, age ($p=0.007$), BMI ($p=0.002$), NT-pro-BNP ($p<0.001$) as well as early mitral inflow velocity/ mitral peak velocity of late filling ($p=0.031$) and dPAP ($p<0.001$) were independently associated with advanced NYHA classes. After 21.9 \pm 13.1 months of follow-up, 64 patients (33.2%) reached the combined endpoint defined as hospitalization due to HF and/ or cardiac death. By multivariate Cox analysis NYHA functional class was independently associated with outcome (HR 2.133, $p=0.040$) as well as NT-pro-BNP (HR 1.655, $p<0.001$) and a visually impaired RV function (HR 2.360, $p=0.001$).

Conclusion: Symptoms of breathlessness in HFpEF are multi-factorial and largely related to BMI, LV diastolic function and the pulmonary vasculature. Clinically meaningful therapeutic interventions should target body weight, LV stiffness as well as concomitant pulmonary vascular disease.

P1132

The prognostic value of EAS index and E/DT in heart failure patients with preserved ejection fraction

F Vakilian¹; DR FE Ghaderi¹; MRS F Haghighparast¹

¹Mashad University of Medical Sciences, Cardiology Department, Mashad, Iran (Islamic Republic of)

Objective: Doppler-derived parameters assessed by trans thoracic echocardiography (TTE) have been proposed for predicting prognosis in Heart Failure patients with reduced Ejection Fraction (HFrEF). This prospective study investigates the prognostic value of two novel Doppler parameters EAS index and E/DT among other parameters in Heart Failure patients with preserved Ejection Fraction (HFpEF).

Methods: In this prospective cross sectional study, conducted in 2015, 100 consecutive HFpEF patients (left ventricular Ejection Fraction $\geq 45\%$) were enrolled. The mean age was 63 ± 18.3 years. Doppler-derived diastolic variables including two new parameters E/DT and EAS index were measured by TTE. The primary endpoint for six months follow up were cardiac death, heart failure hospitalization, need for inotropic agent infusion, and cardio renal syndrome. Cox regression test determine the predictors for poor prognosis.

Results: During the six months follow up, no death was reported. The E/DT was prolonged in patients who were hospitalized, had cardiorenal syndrome, or needed inotropic agent infusion. There was also correlation between higher EAS index and poor prognosis. In the univariable analysis, E/Em, E/DT, EAS index, and LAVI were significantly correlated with short term outcome (P value < 0.001). In the multivariable analysis, E/DT and EAS index were independently predictor of short term prognosis (hazard ratio = 1.02, $P = 0.001$).

Conclusions: E/DT and EAS index, easily measured by echocardiography, may have a useful incremental prognostic value in patients with HFpEF.

Predictors of long-term prognosis of ambulatory patients with heart failure and preserved ejection fraction

E Eduard Sole Gonzalez¹; J Alvarez-Garcia¹; A Ferrero-Gregori²; J Carreras Mora¹; S Mirabet Perez¹; A Mendez Fernandez¹; N Mesado Batalla¹; MJ Pirla Buxo¹; E Roig Minguell¹

¹Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain; ²Hospital de la Santa Creu i Sant Pau, Epidemiology Department, Barcelona, Spain

Background: Patients (pts) with heart failure and preserved ejection fraction (HFpEF) have been historically considered with better prognosis than those with reduced systolic function (HFrEF). However, actual prognosis of these patients is uncertain.

Purpose: To assess the prognosis of pts with HFpEF.

Methods: A cohort of 536 outpatients with HF was prospectively followed in a tertiary HF clinic during the 2010-2015 period. Clinical, ECG, echocardiographic and biochemical data were registered. Cox regression analysis was used to identify the predictors on mortality of patients with HFpEF.

Results: Mean age was 68 ± 13 years and 67% were men. The etiology of HF was ischemic (35%), cardiomyopathy (25%), valvular (16%), hypertension (14%) and others (10%). Pts were in NYHA functional class I-II (61%) and III-IV (39%). HFrEF was found in 348 pts (65%) and the remaining 188 (35%) had HFpEF. Mean follow up was 24 ± 20 months. Comparing HFrEF with HFpEF, the latest group had older age (74 ± 12 vs. 65 ± 13 years; $p<0.001$), more frequently were females (51 vs. 33%; $p<0.001$), had higher hypertension rates (80 vs. 71%; $p=0.02$), higher incidence of atrial fibrillation (56 vs. 33%; $p<0.001$) and lower median of NT-ProBNP values (1369 [642-2499] vs. 2000 [857-4416]; $p=0.002$). Pts with HFpEF had higher mortality (32 vs. 16%; $p=0.001$). Kaplan-Meier curves comparing 3-years survival of the two groups, showed that pts with HFpEF had a significant worse survival (60 vs 78%; $p=0.003$) (figure 1). Multivariate analyses identify as independent predictors of worse prognosis in HFpEF: older age (1.068 [95% CI 1.031-1.106]; $p<0.001$), NT-proBNP > 1500 ng/L (2.837 [95% CI 1.614-4.984]; $p<0.001$), Na+

<135 mmol/L [2.316 [95% CI 1.05-5.109]; $p=0.03$] and lower systolic pressure (0.767 [95% CI 0.655-0.899]; $p=0.001$). The discrimination ability of this model was 0.77 (c-statistics index), with a good internal validation after the boots trapping (0.75).

Conclusions: 1) In this cohort, patients with HFpEF had worse prognosis than HFrEF. 2) NT-proBNP >1500 ng/L may help to identify patients at higher risk of death. 3) Based on the worse prognosis of patients with HFpEF, more studies are needed to improve their survival.

Figure 1. Kaplan-Meier curves.

P1134

Predictive value of diastolic left ventricular function on exercise capacity in heart failure patients with preserved ejection fraction

Z Zarko Hristovski¹; LJ Georgievska-Ismail²

¹Acibadem Sistina Clinical Hospital, Cardiology, Skopje, Macedonia The Former Yugoslav Republic of; ²University Clinic of Cardiology, Skopje, Macedonia The Former Yugoslav Republic of

Background: Limitation in exercise capacity (EC) is a one of the typical manifestation of heart failure with preserved ejection fraction (HFpEF) that is closely related to poor quality of life. Single pathophysiological mechanism governing exercise intolerance in HFpEF is unlikely to exist. The purpose of this study was to identify the role of diastolic left ventricular (LV) function echocardiographic variables, especially LV filling pressure in prediction of reduced EC in patients with HFpEF.

Methods: We assessed LV systolic and diastolic function in 171 patients (62.1 ± 9.9 y; 39.8% men and 60.2% women) who fulfill clinical and/or echocardiographic criteria of HFpEF presence using 2D echocardiography and tissue Doppler imaging. EC measured in units of metabolic equivalents (METs) was assessed using Bruce protocol treadmill stress testing. We defined reduced EC as <7 METs. Pulmonary function tests and complete blood cell count were also performed to exclude non-cardiac causes of exercise intolerance.

Results: HFpEF patients had preserved LVEF (66.1 ± 6.8%) and LV diastolic indexes in favor of diastolic dysfunction. Patients with reduced EC of <7 METs vs. those with capacity of ≥7 METs were older ($p=0.007$), more frequently women ($p=0.012$) with diabetes mellitus ($p=0.018$), showed significantly higher body mass index ($p=0.007$) and wider waist circumference ($p=0.002$). As for diastolic echocardiographic parameters there was lack of significant difference between those with and without reduced EC. However, there was a significant positive correlation between reduced EC of <7 METs and reduced ratio of early and late transmitral filling velocities (E/A, $r=0.237$, $p=0.002$), along with significant negative correlation with elevated LV filling pressure measured as a ratio of peak early diastolic filling velocity to early diastolic mitral annular velocity (E/e') at septal point as well as an average ratio ($r=-0.209$; $p=0.006$; $r=-0.171$, $p=0.025$; respectively). On multivariate regression analysis of diastolic variables, reduced EC <7 METs was independently negatively related to E/e' septal ratio ($\beta=-0.121$; 95%CI: -0.164 to -0.004; $p=0.001$) and positively related to E/A ratio ($\beta=1.05$, 95%CI 0.186 to 1.917, $p=0.018$).

Conclusion: LV diastolic dysfunction was strongly associated with exercise capacity in patients with HFpEF. Reduced E/A ratio and elevated LV filling pressure, as its markers, were identified as independent predictors of poor exercise capacity.

P1135

Potential value of stress NT-proBNP assessment for the prediction of subclinical HFpEF in hypertensive patients

A Kisko¹; M Babcak¹; N Kishko²

¹University in Presov, Faculty of Health Care, Presov, Slovak Republic; ²Sekcov Polyclinic, Presov, Slovak Republic

Our aim was to determine if, in asymptomatic hypertensive patients (HTs), NT-proBNP assessment obtained during physical stress could have diagnostic utility for detection of subclinical diastolic dysfunction.

112 ambulatory adequately-controlled asymptomatic HTs (62 females, 55.4%, aged 48-66 years, mean age 56.4 ± 6.8 years) with normal coronary angiography or myocardial perfusion scintigraphy results were enrolled into the study. Heart failure with preserved ejection fraction (HFPEF) was defined as LVEF $\geq 50\%$ and E/Vp ≥ 2.5 (ratio of early peak diastolic transmitral E wave velocity to intraventricular flow propagation velocity Vp; E/Vp ≥ 2.5 significantly correlates with impaired myocardial relaxation). The levels of NT-proBNP were assessed at rest and within 3 minutes in the recovery during maximal stress testing (cycle ergometer, James protocol). Two clinical groups were formed according to the results of E/Vp ratio evaluation (E/Vp < 2.5; $n=58$ and E/Vp ≥ 2.5 ; $n=54$).

There was no significant difference in rest levels of NT-proBNP in both groups (182 ± 80 ng/l vs 198 ± 60 ng/l, $p < 0.5$). HTs with E/Vp < 2.5 had mean stress NT-proBNP concentrations of 226 ± 80 ng/l; those with E/Vp ≥ 2.5 had a significantly higher mean stress NT-proBNP levels of 889 ± 92 ng/l ($p < 0.05$).

The assessment of NT-proBNP in asymptomatic HTs during physical stress, but not in rest might be of potential value for identification of those with subclinical HFPEF. These patients should be considered for closer monitoring and appropriate treatment adjustment to avoid subsequent progression of this very common in hypertensive population type of heart failure.

P1136

Relation between serum Parathyroid hormone and diastolic function in heart failure preserved ejection fraction

DR FE Ghaderi¹; F Vakilian¹; NA Chogan¹

¹Mashad University of Medical Sciences, Cardiology Department, Mashad, Iran (Islamic Republic of)

Background: The pathophysiology of heart failure with preserved ejection fraction is complex. Previous studies have suggested hyperparathyroidism in the pathogenesis of systolic heart failure, associated with cardiac hypertrophy, fibrosis and heart failure severity. In this prospective cross-sectional study, we evaluated the relation between serum PTH level and diastolic dysfunction severity in HFPEF.

Methods: 60 stable chronic heart failure patients with Left Ventricular Ejection Fraction > 40% were enrolled. Patients with atrial fibrillation rhythm, significant valvular pathology and systemic diseases were excluded. Mean age was 67.15 ± 7.25 (71.7% women). Serum PTH, calcium and phosphate were measured in fasting state. Diastolic dysfunction grade were determined by transthoracic echocardiography based on E/A ratio, E deceleration time, E/Em ratio and LA volume index in the same day. Patients were divided to 3 subgroups grade 1, 2 and 3 diastolic dysfunction. The association of serum PTH, calcium and phosphate with the severity of diastolic dysfunction was assessed.

Results: Mean PTH level were 59.1 ± 34.21 , 87.77 ± 30.3 , and 119.75 ± 30.3 pg/mL in grade 1, 2 and 3 of diastolic dysfunction respectively (P value: 0.0001). There was significant correlation between E/Em ratio and serum PTH level ($r=0.737$, P value < 0.05). This study didn't show significant association of E/Em ratio (or diastolic grade) with serum Ca and P level.

Conclusion: Elevated PTH can be directly related to the severity of diastolic dysfunction in patients with heart failure preserved ejection fraction

Table 1

P value	SD	Mean PTH level(mg/dl)	Diastolic grade	
0.002	15.5	48.9	I	<60 years
23.2	86.3	II		
20.4	109.3	III		
0.001	26.8	66.6	I	> 60 years
39.3	88.9	II		
36.4	130.2	III

Quantifying the risk of repeated hospitalizations following an admission for acute heart failure: preserved versus reduced ejection fraction

E Santas¹; E Valero¹; A Mollar¹; P Palau²; L Bondanza¹; S Garcia-Blas¹;

D Escribano¹; G Minana¹; FJ Chorro¹; J Nunez¹

¹Hospital Clinico Universitario. INCLIVA. Universitat de Valencia, Valencia, Spain;

²Hospital de La Plana, Villarreal, Spain

Background: Heart failure with preserved ejection fraction (HFpEF) and reduced ejection fraction (HFrEF) share a comparable high mortality risk. However,

differences in rehospitalization burden over time between these two entities remains unclear.

Methods: We prospectively included 2013 consecutive patients discharged for acute heart failure (AHF). Left ventricular ejection fraction was assessed by echocardiography in all patients during index hospitalization. 1082 (53.7%) patients had HFpEF and 931 (46.2%) had HFrEF. Cox and negative binomial regression methods were used to evaluate the risk of death and repeated hospitalizations, respectively.

Results: At a median follow up of 2.36 years (IQR: 0.96-4.65), 1018 (50.6%) patients died and 3849 readmissions were registered in 1406 (69.8%) patients. Of them, 2233, 1571, and 1589 were cardiovascular (CV), non-CV, and HF-related, respectively. Overall, there were no differences between HFpEF and HFrEF in the rates of mortality (16.7 vs. 16.1 per 100 person-years, respectively; $p=0.794$), and all-cause repeated hospitalizations (70.8 vs. 70.2 per 100 person-years, respectively, $p=0.791$). After multivariable adjustment, and compared to patients with HFrEF, those with HFpEF exhibited a similar risk of all-cause readmissions (IRR: 1.04 CI 95%:0.93-1.17; $p=0.461$). With regard to specific causes, HFpEF showed similar risks of CV and HF-related rehospitalizations (IRR: 0.93, CI 95%:0.82-1.06; $p=0.304$, and IRR: 0.96, CI 95%:0.83-1.13; $p=0.677$, respectively), but higher risk of non-CV readmissions (IRR: 1.24; CI 95%:1.04-1.47; $p=0.012$).

Conclusions: Following an admission for AHF, HFpEF patients have a similar total rehospitalization burden compared to those with HFrEF. However, HFpEF patients are more likely to be readmitted for non-CV causes.

P1138

Predictive value of left ventricular global longitudinal strain on exercise capacity in heart failure patients with preserved ejection fraction

L. Ljubica Georgievska-Ismail¹; Z. Hristovski²; P. Zafirovska³

¹University clinic of cardiology, Skopje, Macedonia The Former Yugoslav Republic of; ²Acibadem Sistina Clinical Hospital, Skopje, Macedonia The Former Yugoslav Republic of; ³Special Hospital for Surgical Diseases Filip II, Skopje, Macedonia The Former Yugoslav Republic of

Background: Echocardiographic left ventricular (LV) global longitudinal strain (GLS) analysis using two-dimensional speckle-tracking (2D-STE) is an accurate contemporary method in detecting subclinical systolic dysfunction. It has been reported that diastolic function correlates better to exercise capacity than systolic function. We hypothesized that exercise capacity (EC) is more closely related to GLS than to ejection fraction (EF), especially in heart failure patients with preserved ejection fraction (HFpEF).

Method: In order to justify the hypothesis, we assessed LV systolic function in 180 pts (62.0 ± 9.8 y; 54.0% men and 46.0% women) who fulfill clinical and/or echocardiographic criteria of HFpEF presence using 2D echocardiography and speckle tracking software for myocardial deformation assessment. EC measured in units of metabolic equivalents (METs) was assessed using Bruce protocol treadmill stress testing. We defined reduced EC as <7 METs.

Results: Out of 180 patients with HFpEF 56 pts (31.1%) had EC of <7 METs. Patients with reduced EC of <7 METs vs. those with capacity of >7 METs were older ($p=0.013$), of female gender ($p=0.006$) with diabetes mellitus ($p=0.030$), showed significantly higher body mass index ($p=0.001$) and wider waist circumference ($p=0.001$). Unlike other systolic parameters which were insignificantly lower in pts with reduced EC of <7 METs, GLS was significantly lower ($p=0.019$) vs. those with capacity of >7 METs ($-16.46 \pm 5.12\%$ vs. $-17.95 \pm 3.25\%$, respectively) as it was the number of segments with LV strain $<-12\%$ (4.41 ± 3.87 vs. $2.85 \pm 2.72\%$, respectively) ($p=0.002$). On multivariate regression analysis of systolic parameters, the number of segments with GLS of $<-12\%$ ($\beta=-0.204$; 95%CI: -0.317 - -0.094); $p=0.0001$) and GLS of $<-12\%$ ($\beta=1.349$; 95%CI: 0.080 - 2.617 ; $p=0.037$) appeared as significant independent predictors of reduced EC of <7 METs.

Conclusion: The assessment of GLS with speckle-tracking echocardiography identified individuals with subclinical LV systolic dysfunction despite preserved LVEF. Greater impairment of GLS in patients with HFpEF appeared as significant independent predictor of reduced EC measured in METs.

Combination of platelet activation and membrane fragility signs for estimation of HF progression

Grant of Belarusian Republican Foundation for Fundamental Research, 2011

N. Maroz-Vadlazzhskaya¹; L. Kukharenska²; E. Drozd³; I. Russkikh⁴; I. Ostrovskii⁴

¹Republican Scientific-Practical Centre of Sport, Minsk, Belarus; ²Belarusian State Medical University, Minsk, Belarus; ³National Academy of Science, Heat and Mass Transfer Institute, Minsk, Belarus; ⁴Scientific and Practical Center of Cardiology, Minsk, Belarus

The activation of platelets at sites of vascular injury plays a key role in hemostasis. Although, the elevated levels of platelet activation markers have been demonstrated also in patients with severe-to-end stage heart failure (S-ESHF), which could followed by heart failure progression, thromboembolic complications (TEC) and adverse cardiac and non-cardiac events in follow up.

Aim: Local elastic properties (LEP) of platelets were investigated by atomic force microscopy (AFM) in patients with ischemic S-ESHF, whom were admitted for open heart surgery. Cohort of study included 6 male with HF NYHA class III (mean age 56,7 years, preoperative LVEF $29,7 \pm 6,4\%$) – group A and 4 male with HF NYHA class IV (mean age 52,4 years, preoperative LVEF $16,1 \pm 3,1\%$) – group B. All patients were operated in hyperpotassium blood cardioplegia condition: group A – coronary bypass grafting and mitral valve and/or left ventricular plasty, group B – implantation of left ventricular assist device (VAD). Blood sample volumes were taken before surgery, after bypass starting and after surgery in operation room. AFM images were captured in air using contact mode with commercially available silicon cantilevers CSC38 ("MikroMasch" Co., Estonia, spring constant of 0.03 N/m). Platelet (from 10 to 15 specimens) LEP were quantitatively determined on the basis of force spectroscopy (Young's modulus, kPa). Additionally, at least 10 singly located platelets of one patient were visualized for presence of activity (platelet lamellipodia, aggregates). The data were compared to healthy male volunteers, matched in age.

Results: Patients of group A had lower Young's modulus ($p<0.02$) in spite of the presence of platelet lamellipodia, but not of the platelets aggregates. The visual analysis and multiple data measurement by AFM in both groups showed significant correlation ($r=0.7$ $p=0.001$) between NYHA class, end point (stroke, death, heart transplantation) and AFM data (Young's modulus and lamellipodia presence). Moreover, patient of group B with TEC had significantly higher Young's modulus (319.7 ± 37.2 kPa), if compare to group A (125.2 ± 24.5 kPa, $p=0.001$) and patients without TEC of group B (284.17 ± 44.9 kPa, $p=0.06$).

Conclusions: Platelet fragility has been increased in patients with HF progression. In patients with severe-to end stage HF signs of platelet activity (presence of lamellipodia) and high Young's modulus could be a composite predictor of end point. Platelet cytoskeleton dysfunction pattern of a combination of platelet fragility and its activation should be further investigated properly to effect HF progression pathways.

P1141

The influence of the gut microbiota on heart failure so far

C. Lewinter¹

¹Lillebaelt Hospital, Cardiology, Vejle, Denmark

Background/Introduction: The gut microbiota may play an influential role in the pathophysiology of Heart Failure (HF) through the generation of disease modifying metabolites. This could have an important part in developing new strategies inside HF treatments.

Purpose: The aim was to assess the association between the human gut microbiota and the underlying disease mechanisms in HF through the existing literature.

Methods: A search incorporating "gut microbiota & cardiovascular disease" was undertaken in PubMed.

Results: A total of 277 studies were found. Of these, 162 included humans, and 113 were reviews. Atherosclerosis is a keen predictor of HF and has been linked in human experiments to phosphatidylcholine (PC), choline and carnitine through trimethylamine-N-oxide (TMAO). PC and its intermediates are substantial parts of red meat, fish, egg yolk, and some vegetables. Overall, disease mechanisms leading to HF through the gut microbiota are separated into two theories. First, insufficient perfusion of the human gut may lead to dysfunction of the barrier of the intestines allowing inflammatory and bacterial metabolites to translocate into the systemic circulation. For instance, increased systemic bacterial DNA in patients with cardiovascular may be associated to higher inflammatory markers such as CRP. However, translation into the HF pathophysiology remains unsolved. Second, metabolites generated in the human gut microbiota may impact the HF pathophysiology through cardiorenal conversions. Patients with chronic kidney disease retain uremic toxins, which are produced by the microbiota. An example is indoxyl sulfate, which may induce hypertrophy and fibrosis in the heart. Diabetes type 2 has been associated to alterations of the gut microbiota through inflammatory proteins such as TNF, IL-1 β and IL-6. This leads to hyperglycemia causing β -cell autoinflammation, which predicts a lower insulin production. However a connection between diabetes and HF through the microbiota remains unestablished.

Conclusions: So far, the role of the gut microbiota remains elusive in the HF pathophysiology, but further investigations will determine its importance. However, underlying diseases of HF such as atherosclerosis and hyperglycemia are associated with the human gut microbiota.

Endothelial dysfunction, level of leptin and body mass index in patient with coronary heart disease with preserved systolic function in combination with hepatic steatosis.M Mariya Grechanyk¹; NM Grechanyk²; AJ Filippova²; AV Kuryata¹¹Dnepropetrovsk Medical Academy, Dnepropetrovsk, Ukraine; ²Dnepropetrovsk Regional Hospital Mechnikov, Dnepropetrovsk, Ukraine**Objective:** To compare the relationship blood lipid spectrum, endothelial dysfunction, level of leptin and body mass index (BMI) in patient with coronary heart disease with preserved systolic function in combination with hepatic steatosis.**Methods:** Examined 28 men (mean age 57.2 ± 1.21 years) with coronary heart disease with preserved systolic function and hepatic steatosis. Allocated 3 groups according to BMI: group 1 consisted of 8 (32%) people who are overweight (BMI 25 to 29.9 kg/m²), group 2 - 13 (44%) with first degree of obesity (BMI 30 to 34.9 kg/m²), group 3 - 7 (24%) with second degree of obesity (BMI 35 to 39.9 kg/m²). Studied biochemical parameters: the levels of leptin, total cholesterol (TC), low density lipoprotein cholesterol (LDL-C), triglycerides (TG), high density lipoprotein cholesterol (HDL-C), level of C-reactive protein. The reactive hyperemia test for assessment of endothelial dysfunction was consecutively performed in all patients. Brachial artery enlargement by less than 10% was considered as a sign of endothelial dysfunction.**Results:** Found that in the initial state increasing BMI in the range of 25 – 34.9 kg/m² was not associated with a significant difference in the lipid spectrum. According to the reactive hyperemia test data, endothelial dysfunction was found in 7 patients (77%) in a group 1, and in all patients in a group 2 and in a group 3. Vasospastic response observed in 2 patients (22%) in a group A. Reactive hyperemia index (RHI) was lower ($4.0 \pm 5.3\%$) in the group B and in group C ($4.4 \pm 1.7\%$) than in group A ($7.8 \pm 5.2\%$) ($p < 0.05$). The mean level of leptin were 16.0 ± 9.7 ng/ml in a group 1, 24.2 ± 14.6 ng/ml in a group 2 then in a group 3 - 43.5 ± 20.2 ng/ml ($p < 0.05$). There was correlation between the endothelial dysfunction and level of TC ($r=0.94$, $p=0.01$), level of LDL-C ($r=0.92$, $p=0.01$) in a group 1 and level of leptin ($r=0.76$, $p=0.01$) in a group 2 however in a group and 3 such connection was not observed.**Conclusion:** Thus, in patients with coronary heart disease with preserved systolic function in combination with in combination with hepatic steatosis and overweight (BMI 35 to 39.9 kg/m²) level of leptin were more expressed in those who had first degree of obesity (BMI 25 to 34.9). RHI was lower in the group 2 and 3 than in group A. There was an association the endothelial dysfunction and level of TC, level of LDL-C and level of C-reactive protein in a group 1 and level of leptin in a group 2 however in a group and 3 such connection was not observed.

Vagal deficiency in cardiac failure: role of deep breathing testN Mouine¹; N Loudiyi¹; M El Bakkali¹; L Coghan¹; M El Minaoui¹; S Aboudrar¹; H Benjelloun¹¹Ibn Sina University Hospital, department of cardiology, Rabat, Morocco**Introduction:** Vagal stimulation, a new very promising management of cardiac failure is under investigation. Measuring vagal response as a daily practice in cardiac failure patients would be of interest. The objective of this study is to report vagal response, obtained by the deep breathing test, in cardiac failure patients.**Materials and methods:** This prospective study is including a group of symptomatic cardiac failure subjects with ejection fraction EF <40% [group 1] with sinus rhythm, able to perform the deep breathing test, compared to a group of healthy subjects [group 2]. All of them had clinical examination, ECG, echocardiography and deep breathing test. Statistical study will use Student's test, P will be significant when <0.05.**Results:** We included 34 patients, 10 patients [group 1] compared to 24 patients [group 2]. Preliminary results showed vagal response of $7.8 \pm 1.7\%$ in group 1 versus $27 \pm 7.4\%$ in group 2 [$p < 0.05$].**Conclusion:** This preliminary result showed a significant vagal deficiency response in cardiac failure patients when compared to normal subjects. This study is still going on and we intend to include more patients to validate this result

P1144

MIR30-GALNT1/2 axis-mediated glycosylation at threonine 48 and 71 plays an essential role in the increased secretion of unprocessed pro-brain natriuretic peptide by failing heartsK Koichiro Kuwahara¹; Y Nakagawa¹; T Nishikimi¹; K Kangawa²; N Minamino³; K Nakao⁴; T Kimura¹¹Kyoto University Graduate School of Medicine, Cardiovascular Medicine, Kyoto, Japan; ²National Cerebral and Cardiovascular Center, Department of Biochemistry, Osaka, Japan; ³National Cerebral and Cardiovascular Center, Department of Molecular Pharmacology, Osaka, Japan; ⁴Kyoto University Graduate School of Medicine, Medical Innovation Center, Kyoto, Japan**Background:** Plasma levels of biologically less active prohormone of brain natriuretic peptide (proBNP) is increased in patients with heart failure, as well as mature BNP-32. The underlying mechanisms of increased plasma proBNP levels in heart failure remain unclear, however.**Purpose:** We investigated mechanisms underlying the increased plasma levels of proBNP in heart failure.**Methods:** We assessed cardiac production and peripheral metabolism of proBNP in patients with heart failure by measuring plasma proBNP levels using human proBNP-specific assay system, which we have developed, and the conventional BNP assay system, which detects both proBNP and BNP-32. To elucidate the molecular mechanisms underlying the processing and secretion of proBNP, we generated lentivirus vectors carrying several mutations in glycosylation sites of proBNP. [Results] In samples from coronary sinus, plasma proBNP/BNP ratios were significantly elevated in heart failure patients in accordance with the disease severity. In conditioned medium of cultured ventricular myocytes expressing wild type human proBNP, proBNP/BNP ratio was 37%, while in those of myocytes expressing glycosylation-resistant mutant of proBNP, proBNP/BNP ratio was only 3%, demonstrating the essential contribution of glycosylation to the secretion of proBNP. Among 7 glycosylation sites, we found that glycosylation of Thr48 and Thr71 in proBNP is critical for the secretion of proBNP from ventricular myocytes by attenuating proBNP processing. We identified GalNAc-transferase (GALNT) 1 and 2 mediates the glycosylation-regulated increase in cardiac proBNP secretion by screening with siRNAs. Indeed, GALNT1 and 2 expression was increased in FCS-treated ventricular myocytes and failing hearts. We further found that GALNT1 and 2 expression is suppressed by miR-30 family, which is abundantly expressed in the myocardium, and that miR-30s expression is decreased in FCS-treated ventricular myocytes and failing hearts.**Conclusions:** We have elucidated a novel miR-30-GALNT1/2 axis that mediates glycosylation at threonine 48 and 71 in proBNP, thereby increasing the proportion of proBNP secreted and impairing the compensatory actions of BNP during the progression of heart failure.

Role of sarcoplasmic reticulum calcium leak in heart failureBA Mohamed¹; C Richter²; S Neef¹; D Lbik¹; S Khadjeh¹; S Sossalla¹; SE Lehnart¹; S Luther²; G Hasenfuss¹; K Toischer¹¹Clinic of Cardiology and Pneumology, Georg-August-University, Göttingen, Germany; ²Research Group Biomedical Physics, Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany**Background:** Increased diastolic sarcoplasmic reticulum (SR) Ca²⁺ leak via the cardiac ryanodine receptor (RyR2) occurs in heart failure (HF) and has been suggested to have a mechanistic role in the development of HF.**Objective:** We tested the hypothesis that inhibiting or inducing SR Ca²⁺ leak modulates HF progression.**Methods:** Wild-type C57BL/6J mice were subjected to transaortic constriction (TAC)-induced pressure overload (PO), treated with or without a selective, small chemical RyR2 stabilizing Rycal compound (S36). Moreover, knock-in mice with the patient mutation RyR2-R2474S (Ryr2RS/WT) were subjected to shunt-induced volume overload (VO).**Results:** In TAC model, SR Ca²⁺ leak was significantly reduced in S36- versus placebo-treated mice at 3 weeks post-TAC. However, both treatment groups developed comparable contractile dysfunction. Interestingly, S36-treated mice exhibited an improved survival after TAC (72.01 % vs. 49.12 %, $P < 0.05$). Implanted ECGs showed a markedly decreased arrhythmia score by 42% after TAC (2.05 ± 0.42 vs. 3.54 ± 0.39 , $P < 0.05$). Using optical imaging we observed significantly reduced arrhythmia susceptibility by 72% post-TAC (11.33 ± 4.36 vs. 40.94 ± 8.47 , $P < 0.05$). In VO model, thought SR Ca²⁺ leak dramatically increased in Ryr2RS/WT mice,

both WT and Ryr2RS/WT mice had a similar depressed pump function after shunt. **Conclusion:** These results suggest that SR Ca²⁺ leak may not primarily influence contractile remodeling in two different HF models, whereas ventricular arrhythmias were significantly reduced and survival was improved by S36 treatment. We conclude that selective SR Ca²⁺ leak inhibition via the new drug compound S36 might be a promising option for selective treatment of cardiac arrhythmias in HF due to increased PO.

P1146

Perfusion-metabolic scintigraphy for prognosis of recurrent left ventricular remodeling after the comprehensive surgical treatment of patients with ischemic cardiomyopathy

The study was supported by a grant from the Russian Science Foundation (No.15-15-10016)

Y Lishmanov¹; K Zavadovsky¹; M Gulya²; S Andreev¹; E Alexandrova¹; V Shipulin¹

¹State Research Institute of Cardiology of Tomsk, Tomsk, Russian Federation;

²Tomsk Polytechnic University, Tomsk, Russian Federation

Purpose of the study was to study perfusion and metabolism of the left ventricular (LV) myocardium in patients with ischemic cardiomyopathy (ICMP) and to identify the scintigraphic predictors of the efficacy of comprehensive surgical treatment of the left ventricular dysfunction.

Methods: The study comprised 32 patients with ICMP who underwent comprehensive surgical correction of the LV dysfunction (myocardial revascularization, LV cavity reconstruction, and restoration of the obturator function of the mitral valve if necessary). Inclusion criteria: > 75% stenosis of coronary arteries; one and more myocardial infarctions in the past medical history; heart failure (HF) III-IV NYHA functional class; LV ejection fraction (EF)<45%; end systolic volume index (ESVI)> 60 mL/m²; and the presence of akinetic and dyskinetic areas of the LV according to data of echocardiography. Before surgical treatment, all patients received scintigraphy with 99mTc-MIBI and with 123I-BMIPP for evaluation of myocardial perfusion and metabolism, respectively. In early period (four weeks) and 12 months after the surgery, all patients underwent echocardiography study to estimate intracardiac hemodynamics.

Results: Twelve months after surgical treatment, patients were assigned to two groups: group 1 comprised patients (n=18) with beneficial outcome of the operation that stopped the process of LV remodeling (LVESVI ≤ 15% one year after surgery compared with the early postoperative period). Group 2 comprised patients (n=14) in whom LV remodeling was progressing despite successful performance of the surgery (LVESVI > 15% compared with the early postoperative period). Prior to surgery and in the early postoperative period LV pumping function (LVEF, LVESV, LVEDV) didn't significantly differ between groups. Also groups didn't significantly differ in the following scintigraphic parameters: myocardial perfusion defect size and metabolic defect size. Groups differed significantly in size of perfusion-metabolic mismatch (13.23 ± 11.7% and 4.1 ± 11.5%, p<0.01). The best cut of value 12% for perfusion-metabolic mismatch size can predicted the efficacy of comprehensive surgical treatment for the left ventricular dysfunction with the sensitivity and specificity of 100% and 56%, respectively.

Conclusions: The results of myocardial perfusion-metabolic scintigraphy can be used as a method for prediction of the progressing cardiac remodeling in the post-operative period of comprehensive surgical correction of LV dysfunction in patients with ICMP.

P1147

Development of recommendations for the improvement of palliative care of patients with chronic heart failure

Deutsche Herzstiftung (German Heart Foundation)

J Ziehm¹; E Farin-Glattacker¹; G Becker²; S Koeberich¹

¹Medical Center - University of Freiburg, Institute for Quality Management and Social Medicine, Freiburg, Germany; ²Medical Center - University of Freiburg, Department of Palliative Care, Freiburg, Germany

Background and Purpose: Despite similar symptom burden patients with chronic heart failure (CHF) receive less palliative care (PC) than patients suffering from malignant diseases. Reasons are seen e.g., in the cyclic course of disease, lack of knowledge about possibilities and structures of PC, and insufficient interprofessional communication. However, research suggests that CHF patients benefit from PC as shown in fewer drug use and hospitalization rates as well as higher quality of life. Within a 3-round Delphi method this study purposes on the development of recommendations for the German healthcare system in order to improve availability of PC for CHF patients.

Method: Altogether 18 experts/practitioners agreed to participate within the Delphi method. In the 1st round 16 of them submitted suggestions for the improvement of access to PC of CHF patients by answering questions regarding overcoming barriers, improvement of treatment, and appropriate time for beginning of PC verbatim within an online platform. Questions were derived from results of an initial

questionnaire which was developed based on interviews with healthcare professionals regarding attitudes and experiences with PC for CHF patients. Participants were M=49.00 years old (SD=15.75) and had M=21.29 years of work experience (SD=7.51), 56.3% worked as physicians and 25% as nurses (18.7% other/not specified), 56.3% were male.

Results: Suggestions for improvement concentrated on better education regarding PC as well as CHF of patients, professionals, and public; need for more research regarding PC of CHF patients; and better visibility of PC for CHF. Sets of criteria (e.g., medical variables), definition of red flags, use of tools (e.g., surprise question, algorithms for electronically identifying and forwarding PC candidates) were recommended in order to better determine accurate time for initiation of PC. Further, closer cooperation between the different medical disciplines and professional groups involved in care of CHF as well as more intense involvement of nursing staff were suggested. In the next 2 rounds participants will judge the suggestions which will be complemented with research findings regarding their relevance and practicability. Delphi method will be finished at the end of February 2016.

Conclusion: Overall, a need for the improvement of CHF patients' access to PC was perceived by healthcare professionals. Barriers to PC might be able to overcome by better education, improvement of cooperation between the different groups involved, and definition of markers for better identification of PC need in CHF patients.

P1148

The evolution of functional parameters at patients with diastolic heart failure after cardiovascular rehabilitation

S Silvia Filimon¹; E Vataman¹; D Lisii¹; A Grivenco¹; O Priscu¹; S Aprodu¹; C Jucovschi¹

¹Institute of Cardiology, Heart failure, Chisinau, Moldova Republic of

Purpose: To determine the effect of the comprehensive rehabilitation program on functional parameters at patients with coronary heart disease (CHD) and diastolic heart failure after coronary revascularization.

Methods: The study included 45 patients, mean age 60.8 ± 0.7 years, 25 men and 20 women, with the CHD and diastolic heart failure (EF ≥ 45%, NYHA class III, stage C), which have undergone to coronary revascularization. Patients were divided into 2 groups: Gr. I- with cardiovascular rehabilitation (CVR); Gr. II- without CVR. All patients received secondary prevention treatment. Echocardiographic examination and exercise stress test (EST) was done initially, after 1, 3, 6 months.

Results: After 6 months of supervision at patients from Gr. I the left ventricle end-systolic volume (ESV) decreased by 14.87% (p<0.05), the left ventricle end-diastolic volume (EDV) decreased by 15.92% (p<0.05). At the patients from Gr. II ESV and EDV had a tendency to increased (10.90 % and 5.07%). The left ventricular ejection fraction (LV EF) increased by 10.89% in Gr.I and decreased by 4.34% in Gr.II, but insignificant statistically. The duration of the test increased in both groups (68.83 % vs 25.93 %). The total working volume (kgm/min) increased more in Gr. I than Gr. II (47.89 % vs 1.39 %). Double product at peak of EST (systolic blood pressure x heart rate/ 100) had a tendency to increased in both groups (12.39 % vs 5.84 %). The significant positive correlations have revealed between ESV and myocardial aerobic deficiency- r = 0.65 (p<0.001), LV EF and duration of the test- r = 0.64 (p<0.001), LV EF and double product- r = 0.68 (p<0.001). The opposite correlation have revealed between ESV and the duration of the test- r = -0.63 (p<0.01), ESV and double product- r = -0.69 (p<0.001), EDV and double product- r = -0.60 (p<0.01), LV EF and myocardial aerobic deficiency- r = -0.64 (p<0.001).

Conclusions: 1.The cardiovascular rehabilitation program after coronary revascularization improved the functional parameters and diastolic heart failure profile of patients with ischemic heart disease; 2.A significant correlation was observed between volumetric parameters, LV ejection fraction and exercise test indices.

P1149

Short-to-mid term effects of Levosimendan on biochemical and clinical parameters in patients with congestive heart failure

G Peperas¹; G Garyfallia Pepera²; D Tousoulis³

¹General Hospital of Lamia, Lamia, Greece; ²University of Essex, Colchester, United Kingdom; ³National & Kapodistrian University of Athens, Athens, Greece

Introduction: The Levosimendan is a new calcium sensitizer with vasodilatory, antiapoptotic and inotropic actions in myocardial cells.

Purpose: The aim of this study was to evaluate the short-to-mid term effects of Levosimendan on biochemical and clinical parameters in patients with congestive heart failure chronic heart failure (HF), admitted to the Cardiac Intensive Care Unit.

Materials and Methods: Forty-eight patients with deregulation HF (aged 65 ± 12 years), an ejection fraction of 30% or less, and New York Heart Association (NYHA) functional class III or IV symptoms, participated in this study. All the patients received a 24-h infusion of Levosimendan and changes of hematological parameters (hematocrit, white blood cells, platelets), biochemical parameters (urea, creatinine, uric acid, creatine phosphokinase, Creatine phosphokinase-MB, lactate dehydrogenase), plasma NT-proBNP levels and clinical profile were assessed.

Results: There were a statistically significant reduction in NT-proBNP, white blood cells, urea, creatinine and lactate dehydrogenase and hematocrit levels. However, most of the other clinical parameters showed non-significant improvement. The clinical profile of patients improved significant.

Conclusions: Levosimendan is a new positive inotropic agent for safe and effective treatment of advanced heart failure. Short-to-mid term intravenous treatment with levosimendan might improve the survival of HF patients. However, the predictive value of these cardioprotective effects requires further investigation in the form of larger, multicenter, randomized studies.

Longitudinal study of long-term effects of doxycycline on cardiac structure and functions using high-frequency, high-resolution ultrasound imaging in a mouse model of Marfan syndrome

JZ Cui¹; LL Lee²; X Sheng²; GG Sandor¹; C Van Breemen¹; GF Tibbits²; M Mitra Esfandiari³

¹University of British Columbia, Vancouver, Canada; ²Simon Fraser University, Burnaby, Canada; ³Midwestern University, Biomedical Sciences, Glendale, United States of America

Background: Our previous study showed that treatment with doxycycline, a general inhibitor of matrix metalloproteinases (MMPs), is more effective than atenolol in preventing thoracic aortic aneurysm in Marfan mice by preserving elastic fiber integrity and normalizing aortic function. Our data also suggests that doxycycline reduces aortic dilation and stiffness in the aorta of Marfan mice.

Purpose: In this study we have investigated the effects of doxycycline on the cardiac structure and functions by performing longitudinal study on Marfan mice (3, 6, 9, & 12 months) using high resolution ultrasound imaging.

Methods: Marfan (n = 12) and control (n = 13) mice were given sub-antibiotic dose of doxycycline in their drinking water (0.24 g/L/day) starting at 6 weeks of age, when non-treated groups received plain drinking water. Various parameters including aortic diameter, pulse wave velocity, cardiac ejection fraction & stroke volume, left ventricular (LV) wall thickness, LV mass and mitral valve early and atrial velocities (E/A) ratio were measured in doxycycline and sham treated control and Marfan mice.

Results: Measurements of the normalized thickness of the interventricular end diastolic septum (IVSd) showed significant increase in Marfan compared to control mice starting at 6-month of age ($p < 0.05$), however, with doxycycline treatment, Marfan mice no longer showed significant difference in IVSd thickness vs. controls. Likewise, Marfan mice showed significant increase in normalized LV mass compared to control mice, starting at 3-month of age ($p < 0.01$), but no difference between treated Marfan and control mice from 6 months on. With respect to the cardiac function, a significant decrease in early filling velocity and E/A ratio was found in Marfan mice at all age groups compared to controls ($p < 0.05$), regardless of doxycycline treatment. Both stroke volume and cardiac output did not show significant difference in Marfan vs. control mice, regardless of age and treatment. Of note, low dose of doxycycline was very effective in decreasing aortic dilatation and normalizing pulse wave velocity in treated Marfan groups. This is in agreement with our previous data showing improvements in elastin organization and structural integrity within the aortic wall in doxycycline-treated Marfan mice.

Conclusions: Our findings suggest that long-term doxycycline treatment may have protective effects in preventing both cardiac hypertrophy and aortic dilatation in Marfan mice, with no apparent beneficial effects on left ventricular diastolic dysfunction.

P1151

Alterations of plasma macrophage migration inhibitory factor (MIF) concentration in patients with chronic heart failure treated with cardiac resynchronization therapy

E Sawicka¹; K Ptaszynska-Kopczynska¹; M Marcinkiewicz-Siemion¹; A Lisowska¹; M Witkowski¹; K Charkiewicz²; P Laudanski²; WJ Musial¹; KA Kaminski³

¹Medical University of Bialystok, Department of Cardiology, Bialystok, Poland;

²Medical University of Bialystok, Department of Perinatology and Obstetrics, Bialystok, Poland; ³Medical University of Bialystok, Department of Cardiology,

Department of Community Medicine and Civilization Disease Prevention, Bialystok, Poland

Introduction: Inflammatory activation plays a pivotal role in a chronic heart failure with reduced ejection fraction (HF-REF). Cardiac resynchronization therapy (CRT) is a unique treatment method, that may reverse the course of HF-REF. Macrophage migration inhibitory factor (MIF) is a proinflammatory cytokine that has been shown to mediate both disease-exacerbating and beneficial effects.

Purpose: We aimed to evaluate the MIF concentration in HF-REF patients and its relationship with disease severity and CRT.

Methods: The study included 37 patients (64.1 ± 11.04 years, 6 females) with chronic stable HF-REF, EF < 35%, controlled at baseline and after 6 months of CRT. The control population without history of HF-REF included 27 healthy volunteers

(63.9 ± 8.1 years, 8 females). MIF serum concentrations was determined using multiplex method (Quantibody Array Human Chemokine, Ray-Biotech Inc.).

Results: HF-REF patients were characterized by higher MIF concentration comparing to healthy volunteers both at baseline (39.95 IQR: 23.6–89.8 vs 32.34 IQR: 16.27–43.15 pg/mL, $p = 0.022$, respectively) and after 6 months of CRT (42.94 IQR: 23.6–89.8 vs 32.34 IQR: 16.27–43.15 pg/mL, $p = 0.045$, respectively). In HF-REF population at baseline concentration of MIF correlated with serum level of chemokines: CCL28 ($R = 0.67$, $p = 0.001$), I-TAC ($R = 0.65$, $p = 0.002$) and IL-28A ($R = 0.61$, $p = 0.021$). Furthermore, MIF correlated directly with EF ($R = 0.57$, $p = 0.02$) and with the lung gas exchange parameters measured in cardiopulmonary exercise testing (CPET): maximal end-tidal CO₂ pressure (PETCO₂) ($R = 0.57$, $p = 0.02$) and inversely with ventilatory equivalent for CO₂ (VE/VCO₂ slope) ($R = -0.55$, $p = 0.02$). There were no differences in MIF concentration between patients who benefited from CRT (responders) and those who did not benefit (nonresponders) at baseline (34.98 IQR: 20.3–114.92 vs 42.32 IQR: 38.37–59.52 pg/mL, $p = 0.6$) and 6 month follow-up (46.92 IQR: 24.15–124.6 vs 39.26 IQR: 23.18–75.17 pg/mL, $p = 0.47$).

Conclusions: HF-REF patients present increased MIF concentration compared to healthy subjects, however its levels correlate with markers of better prognosis. The CRT-related improvement in patient's functional status is not associated with changes in MIF. The precise role of MIF in pathogenesis of HF-REF and its prognostic value remains to be established.

P1152

The role of clinical particularities and co-morbidities in the development of different types of left ventricular dysfunction after 12 months from coronary revascularization- retrospective analysis

AA Grivenco¹; EB Vataman¹

¹Institute of Cardiology, Department of Heart failure, Chisinau, Moldova Republic of

Background: The clinical manifestations and co-morbidities were crucial in the development of chronic heart failure and the prognosis life of patients. Purpose: comparative analysis of clinical parameters, comorbidities in different types of left ventricular disfunction after coronary revascularization over 12 months.

Methods: 186 patients who have revascularization by coronary artery bypass grafting or percutaneous coronary angioplasty, mean age 59, 8 ± 0.7 years, the final stage (after 12 months from coronary revascularization) were divided into 3 groups (Gr.) depending on the value ejection fraction (EF), determined ultrasound Simpson's method: Gr.1 - EF ≤ 35% (n = 30), Gr.2- EF between 35% and 45% (n = 36), Gr.3- EF ≥ 45% (n = 121)

Results: Congestive heart failure (New York Heart Association classes III-IV) was recorded in Gr.1 = 75 %, Gr.2 = 70 %, Gr.3 = 10.74%. NT proBNP levels (pg/ml) it was higher in Gr.1 = 462.09 ± 60.3 compared to Gr.2 = 248 ± 52.5 and Gr.3 = 90.48 ± 21.36 ($p < 0.01$). Charlson Comorbidity Index was comparable between Gr.1 and Gr. 2 (5.15 ± 0.43 vs 4.86 ± 0.43) and statistically significantly lower Gr.3 = 3.35 ± 0.35, $p < 0.0001$. There were significant differences in the presence of chronic pulmonary disease (Gr.1 = 58.33%, Gr.2 = 40%, Gr.3 = 33.06%, $p < 0.05$), of moderate renal disease (respectively 62.5% ; 53.34%; 31.4%, $p < 0.05$;), Q-Wave old myocardial infarction (91.67% , 83.33%, 39.67%, $p < 0.05$), which were compared between Gr.1 and Gr.2 and significantly lower in Gr. 3

Conclusions: 1. The presence of Q-Wave old myocardial infarction, chronic obstructive pulmonary disease, moderate renal disease have negativ impact on the development of left ventricular disfunction after 12 months from coronary revascularization

2. The patients with mild systolic dysfunction are similar to patients with severe systolic dysfunction by the studied parameters

P1153

Relationship between renal function and age in patients with chronic heart failure and preserved ejection fraction

Y Yulia Kushnir¹; A Kuryata¹

¹Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Background: As known, heart failure with preserved ejection fraction is associated with age and renal dysfunction. functional disorders of the kidneys. Also? decreased glomerular filtration rate (GFR) is a bad prognostic factor among these patiens.

Objectives: we aimed to evaluate relationship between renal function and age in patients with chronic heart failure and preserved ejection fraction (HFpEF).

Methods: 46 pts (31 M, 15 F, mean age – 68,10 ± 1,10 years) with CHF NYHA II-III class and preserved ejection fraction were enrolled. Pts were divided into three groups: 74 pts aged 59 years (1 group), 73 pts from 60 to 75 years old (2 group), and 51 pts aged older 76 years old (3 group). GFR was calculated by MDRD formula.

Results: The average GFR in the first group was 82.2 ± 12.7, the second – 65.5 ± 17.7 in the third and 64.0 ± 11.6 ($p < 0.05$). Normal GFR was found in 6.8% (5 pts) of the first group, 17.8% (13 pts) of the second group and in 5.9% (3 pts) in the third group, mild reduction of 52.7% (39 pts) of the first group, 45.2% (33 pts) of the second group and in 37.3% (19 pts) of the third group, chronic renal failure in

20.2% (15 pts) of the first group of patients, 37% (27 pts) of the second group and in 56.9% (29 pts) of the third group ($p < 0.05$).

Conclusion: Renal dysfunction was found in patients with chronic heart failure with preserved LVEF in all age groups. But it showed a reduction of GFR in patients with increasing age and increasing number of patients with moderate renal functional impairment and chronic renal failure depending on age. The development of renal dysfunction associated with age in patients with heart failure with preserved ejection fraction.

P1154

Anemia in chronic heart failure

B Bakhodir Narziev¹

¹Tashkent Medical Academy, Cardiology, Tashkent, Uzbekistan

Background: In recent decades, life expectancy has increased significantly in patients with chronic heart failure (CHF). In this regard, before the cardiologists and physicians got a number of new questions about the management of patients with a large number of related diseases and conditions, such as anemia and decreased renal function.

Methods and Results: The prevalence of anemia among patients with cardiovascular disease is relatively well studied. Anemia is a frequent co-morbidity in chronic heart failure [2-10], its prevalence varies in a wide range of 4 to 61% (average 18%) depending on the severity of the main disease (functional class by NYHA) and used criteria of anemia. The fact of increasing the overall and cardiovascular mortality in the presence of anemia in patients with chronic heart failure is confirmed in numerous studies. Thus, in a retrospective study SOLVD shown, reduction the hematocrit rate by 1%, increases the total mortality in patients with CHF by 2.7% [13]. OPTIME study showed, at the level of hemoglobin less than 12 g / dl, risk of death or rehospitalization increased by 12% [14].

Conclusion: Nowadays, there are reliable data on the need for active detection and correction of anemia in patients with CHF. Accumulated documentary base in these patients for the treatment of anemia with erythropoietin as a single agent or in combination with intravenous iron preparations does not allow unambiguously to determine the expedience and safety of this approach. These studies on the use of intravenous iron preparations as monotherapy in patients with CHF and iron deficiency, regardless of the presence of anemia could significantly expand the indications for their use in this pathology.

P1155

Impact of diabetes on epidemiology and treatment of patients with chronic heart failure

S Oualim¹; A Abardazzou¹; CE Ait El Harda¹; M El Hattatoui¹

¹Marrakech University Hospital, cardiology, Marrakech, Morocco

Introduction: The prevalence of patients with concomitant heart failure (HF) and diabetes mellitus (DM) continues to increase with the general aging of the population. Patients with concomitant HF and DM have diverse abnormalities that potentially contribute to worse outcomes than those without comorbid DM. The purpose of our study is to re-evaluate the epidemiology and therapy of HF patients with concomitant DM.

Methods: We conducted a prospective study at the day hospital of HF in a university hospital where 430 patients were admitted for HF between January 2014 and April 2015. Only 145 had DM. We randomly selected a subset of 145 patients diagnosed as non-diabetic to ensure a significant statistical comparison between the diabetics and non diabetics HF patients.

Results: Patients with DM had a higher prevalence of ischemic cardiomyopathy

(74% vs 44.9%, $p < 0.001$). The left ventricular ejection fraction was significantly lower in the group with DM (27, 1% vs 17, 5%, $p < 0.001$). Age, cardiovascular risk factors, clinical symptoms and repolarization disorders did not significantly differ. 25% of the patients with DM were on insulin and 60.5% were controlled on oral antidiabetics only. Inhibitor of angiotensin converting enzyme (ACE inhibitor) and angiotensin II receptor blockers (ARBs) were more prescribed for patients with DM (78% vs 63,1% for ACE inhibitors and 18,3% vs 13,4% for ARBs).

Conclusion: Our paper discusses the impact of DM in HF patients and underscores the potential need for the development of targeted therapies.

P1156

The cost-effectiveness of sacubitril/valsartan in chronic heart failure with reduced ejection fraction

JJV McMurray¹; MR Cowie²; A Briggs³; M Taylor⁴; E Hancock⁵; D David Trueman⁵; R Haroun⁶; C Deschaseaux⁶

¹University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; ²Imperial College London, Faculty of Medicine, National Heart & Lung Institute, London, United Kingdom; ³University of Glasgow, Health Economics and Health Technology Assessment, Glasgow, United Kingdom; ⁴York Health Economics Consortium Ltd., York, United Kingdom; ⁵DRG Abacus, Bicester, United Kingdom; ⁶Novartis Pharma AG, Basel, Switzerland

Background: Chronic heart failure with reduced ejection fraction (HFrEF) represents a major public health issue and is associated with significant morbidity and mortality.

Purpose: We evaluate the cost-effectiveness of sacubitril/valsartan (formerly LCZ696) compared with an angiotensin-converting-enzyme (ACE) inhibitor in the treatment of HFrEF from a UK National Health Service perspective.

Methods: A cost-utility analysis was performed based on PARADIGM-HF, a large Phase III multicentre randomised controlled trial comparing sacubitril/valsartan with enalapril in HFrEF patients with New York Heart Association Functional Classification II-IV symptoms. We created a series of regression models which extrapolated health-related quality of life (EQ5D), hospitalisation rates and survival over a life-time horizon. A parametric survival model was used in the base-case to predict all-cause mortality from PARADIGM-HF. In an alternative analysis, cardiovascular (CV) mortality was modelled from PARADIGM-HF, and non-CV mortality taken from national life tables. Negative binomial and multilevel models were used to predict all-cause hospitalisation and EQ-5D over time, respectively. Adverse event rates were assumed to be constant. Costs and outcomes were discounted at 3.5%. The primary outcome was the incremental cost-effectiveness ratio (ICER). Deterministic (DSA) and probabilistic sensitivity analyses (PSA) were performed.

Results: Sacubitril/valsartan was associated with ICERs of approximately £17,900 (all-cause mortality) and £16,600 (CV mortality) vs enalapril. In the base-case scenario, compared with enalapril, treatment with sacubitril/valsartan was predicted to improve patient survival by 0.48 years and lead to 0.42 additional quality-adjusted life years and 15% fewer hospitalisations (0.06/year absolute reduction; 8% reduction in discounted lifetime hospitalisation costs). DSA showed that results were most sensitive to the extrapolation of mortality. Results were also sensitive to assumptions around duration of treatment-effect and time horizon, but were robust to other structural changes, with most scenarios associated with ICERs below £20,000. PSA suggested that the probability sacubitril/valsartan was cost-effective at thresholds of £20,000 and £30,000 was 66% and 95%, respectively.

Conclusions: Our analysis suggests sacubitril/valsartan is likely to be cost-effective vs an ACE inhibitor (the current standard of care) at conventional willingness-to-pay thresholds, in patients with HFrEF and NYHA class II-IV symptoms. This conclusion is consistent with the results of an independent analysis performed in the US setting.

P1157

Predictors of 12- and 36-month mortality in chronic heart failure

N Nataliya Tkach¹

¹NSC Institute of Cardiology M.D. Strazhesko, Heart Failure department, Kiev, Ukraine

Background: Despite good knowledge about predictors of long-term mortality in chronic heart failure (CHF) the comparable value of them in dependence of patient's follow-up duration is still non-well investigated. Aim: The purpose of study was to identify the predictors of 12- and 36-month mortality in CHF.

Methods: 95 clinical, echocardiographic and laboratory variables in 267 CHF patients with left ventricular ejection fraction LVEF < 40 % were analyzed. Predictors of 12- and 36-month mortality were determined in stepwise multiple logistic regression model.

Results: Table 1. Most important predictors of 12- and 36-month mortality in CHF patients.

Conclusion: HOMA index is a strongest predictor of CHF patients mortality irrespective of follow-up duration. Predictors related to left ventricular function (low LVEF, high LVEDVI) are valuable only in relation to 36-month mortality prognosis. The predictive value of elevated plasma UA and level SAP < 100 mmHg is the high in regard to both 12- and 36-months mortality. According to follow-up duration increases the predictive value of low BMI, size LA > 49 mm and HR > 75 beats p.m.

Table 1

12 month	OR	36 month	OR
HOMA > 2,65	8.48	HOMA > 2,65	6.67
HR > 75 beats p.m.	7.9	BMI < 22kg/m ²	5.99
SAP < 100mmHg	5.4	SAP < 100mmHg	3.95
BMI < 22kg/m ²	3.59	LA > 49mm	3.01
UA > 500μmol/l	3.125	UA > 500μmol/l	2.78
Blood lymphocyte < 21%	2.69	LVEDVI > 133 ml/m ²	2.68
6 min walk distance < 360m	2.43	Blood lymphocyte < 21%	2.65
LA > 49mm	2.18	LVEF < 30%	2.45

* All predictors are significant (p < 0.05). HOMA – HOMA index; UA - uric acid; BMI - body mass index; LVEDVI - left ventricular end diastolic volume index; HR - heart rate; SAP - systolic arterial pressure; LA - left atria size; LVEF - left ventricular ejection fraction.

Levels of adiponectin, leptin, inflammatory and anti-inflammatory cytokines in patients with systolic chronic heart failure in relation to insulin resistance state

A Alina Lyashenko¹

¹NSC Institute of Cardiology M.D. Strazhesko, department of heart failure, Kiev, Ukraine

Background: Insulin resistance (IR) is observed in 30-49% cases of systolic chronic heart failure (CHF). Nevertheless, the levels of adiponectin, leptin, inflammatory and anti-inflammatory cytokines in IR associated with CHF were studied insufficiently. Objective. To evaluate the levels of adiponectin, leptin, inflammatory and anti-inflammatory cytokines in relation to IR state.

Methods: The study involved 107 CHF patients (NYHA II – IV) with left ventricular ejection fraction ≤ 40% without diabetes. IR was defined as HOMA index ≥ 2,77. The levels of adiponectin, leptin, inflammatory and anti-inflammatory cytokines were determined by IFA method. The index of systemic inflammatory (ISI) was calculated as ratio of inflammatory to anti-inflammatory cytokine levels.

Results: The patients were divided in 2 groups in accordance to presence of IR. IR patients had a significantly higher level of insulin than the non-IR patients (< 0,05). CHF patients demonstrated significantly higher (< 0,05) adiponectin and leptin levels in comparison with the control age-matched persons. In CHF patients the levels of inflammatory and anti-inflammatory cytokines were significantly lower (< 0,05) than controls. There was no significant difference in cytokine levels between IR and non-IR groups. IR group demonstrated a significantly higher ISI in comparison with non-IR group.

Conclusion: HF patients are characterized by higher levels of adiponectin, leptin, inflammatory and anti-inflammatory cytokines. Simultaneously, CHF patients with IR demonstrated a higher inflammatory response than non-IR patients.

Table 1. The levels of adiponectin, lep

Index	Control group (= 15)	HOMA	
Group 1 Group 2			
Insulin, mU/ml	9,3 ± 1,1	7,6 ± 0,4	24,8 ± 3,5**
Glucose, mmol/l	4,7 ± 0,2	5,0 ± 0,1	5,4 ± 0,1*

The relationship between the heart rate variability and poor outcome in patients with Q-myocardial infarction

RD Kurbanov¹; GU Mullabaeva¹; AA Anvar Kilichev¹

¹Cardiology Center of Uzbekistan, arrhythmology, Tashkent, Uzbekistan

Objective: To estimate the initial level of the heart rate variability (HRV) in patients with AMI complicated further by the sudden cardiac death (SCD).

Materials and Methods: We analyzed data 205 male patients Q- MI. All patients were hospitalized with Republican Specialized Center of Cardiology for the period 2006-2010, with a diagnosis of acute Q- wave myocardial infarction. Mean age was 51.7 ± 9 years. All patients on the 10-14 day of the disease Holter ECG monitoring was performed with an analysis of HRV. The observational period was 36 months. Depending of the outcome, the patients were divided into 2 groups: I group (n = 191) of survivors, II group (n = 14) who died suddenly.

Results: Comparative analysis of clinical and anamnesis data showed that the mean age of the groups were not statistically different. Analysis of the level of HRV showed that the average SDNN on II group of patients was 92.07 ± 12.9 ms. At the same time, the qualitative analysis showed that 9 (70 %) patients of the II group was below 100 ms. The SDNN less than 50 ms identified in 2 (22%), the mean value SDNN (50-100 ms) in 78 % of patients. The activity index of the parasympathetic system RMSSD was also significantly lower in patients who died suddenly. Thus, the average rate was 21.8 ± 3.8 ms. At the same time, the vast majority of patients (84.6 %) had on pre-discharged stage RMSSD below 36 ms. The pNN50% averaged 476 ± 20 while indices below 5.5 % have eight (81.5%) patients. Study of spectral parameters revealed that on patients with SCD the baseline total power spectrum at 72% consisted of ultra performance, low and very low frequencies. But the ratio LF/HF, which characterizes the relation of low and high frequencies averaged 3.0 ± 0.4. The analysis of the calculated HRV index computed by combining SDNN and HRVti showed that in comparison groups on the initial stage, it was only moderately reduced on 2 patients (15%) and on 17 (10.7 %) patients, respectively, while 15% of patients with SCD at baseline HRV was reduced significantly, that significantly above the group with a favorable outcome. In addition, on 23% of patients with a poor outcome group revealed an independent predictor of fatal arrhythmias in the next 3 years, while in the group of survivors, it was detected in 8.3 % of cases.

Conclusion: patients with AMI complicated by SCD already in subacute stage of the disease characterized by a greatly reduced total HRV and spectral indices presented ultra-low and very low frequencies.

P1160

The systolic function and heart rhythm variability at patients with myocardial infarction

RD Kurbanov¹; AA Anvar Kilichev¹; GU Mullabaeva¹

¹Cardiology Center of Uzbekistan, arrhythmology, Tashkent, Uzbekistan

The purpose: studying of interrelation between the left ventricular (LV) systolic function with vegetative regulation of heart rhythm at patients with Q-wave myocardial infarction (MI).

Materials and methods: 112 males (middle age 51,8 ± 13,6 years) with Q-wave (IT) are surveyed. To all patients for 10-14 day of disease were performed echocardiogram and Holter monitoring with the analysis of heart rhythm variability (HRV). LV systolic function was estimated on a parameter of ejection fraction (EF). According to EF patients have been divided into 3 groups: I – with normal of EF (55 % and more) – 36 person; II – moderate decrease of EF (55-35 %) – 45 person; III – with significant decrease of EF (less than 35 %) – 31 person.

Results: the dispersive analysis revealed the statistically significant shortening interval RR in process of deterioration LV systolic function. SDNN decreased in parallel with decreasing of EF. Besides attracted attention of distinction in values dRR and %HF with the maximal difference between groups I and III (=0,04). Results of the correlation analysis have shown, that HRV has been correlated with myocardium contractile functions: correlations LV EF with RR (r=0,7 p < 0,05) and SD (r=0,6 p < 0,01) are revealed. The correlation analysis has revealed interrelation between low EF and frequency of heart rate (r=0,7 p < 0,05).

The conclusion: on 10-14 day of Q-wave MI the worsening of LV contractile abilities is associated with disturbance in heart rhythm regulation clinically determined as increasing of sympathetic activity and suppression of parasympathetic influences.

Assessment of RV function following percutaneous transvenous mitral commissurotomy (PTMC) for rheumatic mitral stenosis

H S Natraj Setty¹; H Veeresh Patil¹; T Joseph¹; K S Ravindranath¹; T Kumar Swamy¹; C N Manjunath¹

¹Sri Jayadeva Institute of Cardiovascular Sciences and Research, Cardiology, Bangalore, India

Objective: Abnormal right ventricular function plays an important role in development of clinical symptoms and overall prognosis of patients with mitral stenosis. Hemodynamic and radionuclide studies have demonstrated long-term improvement in RV function after PTMC. However, exact quantification by conventional echocardiographic technique is difficult owing to complex 2D anatomy. This study evaluates the immediate and short term follow up impact of successful percutaneous transluminal mitral valve commissurotomy on RV function in patients with mitral stenosis using 2D Echo and Doppler tissue imaging echo.

Methods: 219 patients (mean age 26 ± 6yrs) with rheumatic MS, all in sinus rhythm were studied before and 24-48hrs after PTMC. Parameters of global and longitudinal RV function were assessed by conventional and tissue Doppler imaging echo.

Results: Immediately following PTMC mitral valve area increased from baseline of $0.71 \pm 0.15 \text{ cm}^2$ to $1.84 \pm 0.17 \text{ cm}^2$ ($P < 0.0001$), RV outflow tract fractional shortening (RVOT - FS) increased from $33.94 \pm 7.55\%$ to $37.33 \pm 7.67\%$ ($P < 0.001$). There was a significant decrease in systolic pulmonary artery pressure from $48.93 \pm 13.08 \text{ mmHg}$ to 29.56 ± 7.71 ($P < 0.0001$). RV Tei-index decreased from 0.47 ± 0.12 to 0.32 ± 0.11 ($P < 0.001$).

Conclusion: Long term evaluation of RV function and benefits using invasive and radionuclide methods post PTMC has shown incongruous results in improvement of right ventricular (RV) function immediately after PTMC. In this study, immediately after successful PTMC significant improvement in parameters of infundibular and global RV function as assessed by RVOT fractional shortening, Tei index and tissue Doppler velocities was observed

The role of biomarkers in risk stratification of kidney injury in patients with acute coronary syndrome

IR Vyshnevskaya¹; MP Kopytsya¹; OV Petyunina¹; NV Tytarenko¹; NV Bila¹

¹ Government institution 'L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

The development of renal dysfunction in patient with acute myocardial infarction, especially in those who underwent angiography, is an actual problem, because it worsens the prognosis for those patients. In order to diagnose this condition in time the search for biomarkers is going. One of them is the Growth differentiation factor 15 (GDF 15).

Purpose: estimate the role of various markers in the development of cardiorenal syndrome in patients with acute coronary syndrome (ACS).

Methods: 73 patients were screened with different forms of ACS (55 male and 18 female), mean age was 61, 8 ± 1 , 3 years. In anamnesis patients had: 23% - previous myocardial infarction, 51% - stable angina, 84% - hypertension, 16% - diabetes mellitus, 6% - chronic kidney disease. Based on the results of the examination glomerular filtration rate (GFR) was calculated by Modified diet renal disease method (MDRD). A group of patients has been selected ($n = 54$), their creatinine level was determined during the first 24 hours and after 48 hours. All patients were divided into two groups according to acute kidney injury network classification (AKIN): 21 patient

in the first group with negative dynamic (1st stage AKIN and higher), 33 patient in the second group without creatinine dynamic. In addition, the levels of GDF 15, N terminal-pro B-type natriuretic peptide (NT-pro BNP) were determined during the first day of hospitalization (normal range of GDF 15 <1200 pg / ml, NT pro-BNP <200 ng/ml). The follow-up period was 6 months.

Results: By comparing selected groups significant difference was found in creatinine level and GFR in both groups (< 0.001 ; < 0.01 , respectively). The analyses of biomarkers interconnection (NT pro-BNP, GDF 15) and GFR showed significant difference of estimated parameters in both groups as well (≤ 0.04 ; ≤ 0.02 , respectively). Also, correlation of high and medium strength was found between biomarkers (GDF 15, NT pro-BNP) and GFR (≤ 0.0001 , $p \leq 0.01$).

Conclusions: The biomarker GDF 15 can be used for risk stratification in development of acute kidney injury in patients with ACS, its as sensitive as the known marker NT-pro BNP. For high prognostic possibility we can use combination of biomarkers.

P1163

Daily activity per minute slept drops with renal impairment in patients with chronic stable heart failure.

EE Egom¹; R B Pharithi²; A Jago³; S Fay³; A Maher²; S Fall²; C Murphy²; V Maher²

¹ Trinity College Dublin, Department of Clinical medicine, Dublin, Ireland; ² The Adelaide and Meath Hospital, Tallaght, Heart Efficiency Unit, Cardiology Department, Dublin, Ireland; ³ Institute of Technology, Tallaght, Department of Science, Dublin, Ireland

Background: Optimal sleep may replenish energy levels and improve functional capacity. Daily activity levels per minute slept may reflect the efficiency of nocturnal energy storage. It is not known what factors may influence this relationship and whether it affects functional capacity.

Objective: We evaluated what factors were related to nocturnal energy storage in patients with chronic stable heart failure.

Methods: 105 consecutive patients with chronic Heart failure participated. We evaluated patients' activity and sleep levels using FitBit Activity trackers. From this it was possible to calculate the average number of steps taken daily per minute slept at night. We also assessed NYHA and 6 minute walk distances, body composition, diet and cardiac parameters.

Results: 76 men and 29 women, avg 67 years were enrolled. Steps per minute slept correlated significantly with age ($r = -0.43^{***}$), eGFR ($r = 0.36^{**}$), BNP ($r = -0.36^{**}$), 6 min walk distance ($r = 0.46^{***}$), NYHA ($r = -0.23^{*}$), protein intake ($r = 0.29^{**}$), Fat free Mass ($r = 0.25^{*}$), Total body water ($r = 0.25^{*}$), LV ejection fraction (ns) and LV diameter (ns). However estimated GFR (**) was the only significant parameter in a multivariate analysis to correlate with nocturnal energy storage in these patients. N.B {ns = not significant) $p < 0.05$ * $p < 0.01$ **, $p < 0.001^{***}$ }

Conclusion: Our results highlight that in patients with chronic stable heart failure, renal function may determine nocturnal muscle energy storage and subsequent functional capacity in patients with heart failure.

Phenotype of a mouse model of type 3 cardio-renal syndrome

Inserm and Paris Diderot University

M Prud'homme¹; M Coutrot¹; S Kinugasa²; S Placier²; E Polidano¹; M Genest¹; R Merval¹; N Vodovar¹; CE Chadjichristos²; M Legrand¹

¹Inserm UMR-S 942, Paris, France; ²Inserm UMR-S 1155, Paris, France

Introduction: Acute Kidney Injury (AKI) has been strongly associated with both short and long-term mortality in hospitalized patients. Reasons for such an association remain uncertain but damage on remote organs has been proposed as a cause of long-term morbidity and mortality. The Cardio-renal Syndrome type 3 (CRS-3) is characterized by an initial AKI that leads to an acute cardiac injury and/or dysfunction. Our first objective was to develop a mouse model of CRS-3 in order to better understand the mechanisms involved.

Methods and Results: In C57Bl6 mice we performed nephrectomy of the right kidney and 25 minutes ischemia of the left kidney followed by reperfusion. To get insights into the kinetics of the kidney-heart cross-talk after renal I/R, mice were sacrificed at different time points after reperfusion (3, 6, 12, 24, 48, 72h and 28 days, $n = 7$ per time point). Renal tissue damage was detected within the tubulo-interstitial compartment as early as 3h post-I/R, leading to renal dysfunction at 24h (increased $\times 10$ serum creatinine and Blood Urea Nitrogen levels, $p < 0.001$). All functional renal parameters returned to baseline levels at 2-3 days post-I/R. From a cardiac standpoint, renal I/R induced heart damage illustrated by the increase in different cardiac markers of injury (BNP, ANP and QSOX1-mRNAs, $p < 0.01$), oxidative stress (DHE $\times 3$, $p < 0.001$) and cardiac inflammation (CD68, MCP1, TGF β and Galectin-3-mRNA $\times 2$) but cardiac function was normal. Similarly to the kidney, all stress markers returned to basal levels within 3 days post-I/R but markers of cardiac inflammation (CD68 and TGF β $\times 2$: $p < 0.01$) remained elevated at day 28 post-I/R. This sustained inflammation was accompanied by a cardiac dysfunction ($\sim 10\%$ in fraction shortening, $p < 0.001$) and fibrosis ($\times 3$, $p < 0.001$) 28 days after renal I/R.

Conclusion: Altogether the data indicated that an acute renal I/R provokes an early cardiac injury and long-term cardiac dysfunction, therefore providing an innovative mouse model of CRS-3.

P1165

IFN-gamma plays protective roles in the pathogenesis of cardio-renal syndrome type 1 through the induction of intracardiac ANP expression.

A Akihiko Kimura¹; Y Ishida¹; M Nosaka¹; N Mukaida²; T Kondo¹

¹Wakayama Medical University, Department of Forensic Medicine, Wakayama, Japan; ²Kanazawa University, Cancer Research Institute, Division of Molecular Bioregulation, Kanazawa, Japan

Introduction: The dysfunction of heart and kidney is frequently accompanied in patients, leading to increased morbidity and mortality. Dysfunction of heart often leads to that of the kidney - the so called cardio-renal syndrome (CRS) type 1. Although the growing evidences indicate that inflammation plays important roles in the pathogenesis of CRS, the pathogenic roles of cytokines in CRS is still not fully understood. In our study on cardiac hypertrophy induced by transverse aortic constriction (TAC) in IFN-gamma deficient (IFN-g-KO) mice, we found that IFN-g-KO mice were prone to CRS type 1. Thus, we investigated the involvement of IFN-gamma in the pathogenesis of CRS type 1 by using mice subjected to severe TAC.

Methods: Male BALB/c (WT) and IFN-g-KO mice (8-12 week-old) were subjected to TAC. TAC was achieved by tying around the transverse thoracic aorta against a 28-gauge needle using a 7-0 silk suture, and then removing the needle. Three days after TAC, cardiac function was examined by echocardiography. The intracardiac and intrarenal gene expression induced by pressure overload was evaluated by real-time RT-PCR. Acute renal injury was evaluated with blood urea nitrogen (BUN), serum creatinine (CRE), histological, immunohistochemical examination and TUNEL staining.

Results: Upon the evaluation of cardiac function by echocardiography at 3 days after TAC, there was no significant difference between WT and IFN-g-KO mice. However, 60% of IFN-g-KO mice died within 10 days after TAC, whereas 90% of WT mice survived. The gene expression for ANP significantly increased in the left ventricle of WT mice 3 days after TAC, which was not observed in IFN-g-KO mice. In WT mice, neither significant elevation of serum BUN and CRE levels and histopathological alterations of the kidneys was observed. On the other hand, TAC induced significant increase of BUN and CRE in IFN-g-KO mice. Consistently, IFN-g-KO mice exhibited significant histopathological alterations such as tubular dilatation as well as disappearance of brush borders in damaged tubules with massive infiltration of neutrophils. Moreover, extensive tubular cell apoptosis was found in IFN-g-KO but not WT mice. Furthermore, intrarenal gene expression of inflammatory cytokines was more up-regulated in IFN-g-KO mice compared with WT ones. Prior administration of neutralizing anti-IFN-gamma antibody to WT mice significantly suppressed TAC-induced ANP gene expression in the heart and increased serum BUN and CRE levels. On the contrary, ANP infusion into IFN-g-KO mice significantly reduced TAC-induced elevation of serum BUN and CRE levels.

Conclusion: IFN-gamma plays protective roles in the pathogenesis of CRS type 1 through the induction of intracardiac ANP expression.

P1166

The role of adiponectin receptor 1 and tnfr-a in the process of skeletal muscle adiponectin resistance, mitochondrial dysfunction and impaired myogenesis in chronic heart failure.

T Sente¹; AM Van Berendoncks²; E Franssen³; VY Hoymans²; CJ Vrints²

¹University of Antwerp, Translational Pathophysiological Research - Cardiology, Antwerp, Belgium; ²University of Antwerp Hospital (Edegem), Department of Cardiology, Antwerp, Belgium; ³University of Antwerp, StatUa Center for Statistics, Antwerp, Belgium

Background: Skeletal muscle metabolic alterations including adiponectin resistance and mitochondrial dysfunction are common features in chronic heart failure (CHF). We previously demonstrated that CHF patients are characterized by a functional adiponectin resistance at the level of the skeletal muscle.

Purpose: The aim of the present study was to examine the role of adiponectin receptor 1 (AdipoR1) and TNF- α on adiponectin signalling and mitochondrial function in skeletal muscle.

Methods: Myoblasts and myotubes cultures were initiated from muscle biopsies (m. vastus lateralis) of 10 CHF patients (LVEF; $31.30 \pm 2.89\%$) and 10 age- and gender matched healthy controls. Cultures from healthy donors were transfected with siAdipoR1 and/or treated with TNF- α (10ng/ml; 72h).

Results: Primary CHF myotubes preserve the features of adiponectin resistance in vitro as evidenced by a tendency toward increased adiponectin expression ($p=0.058$) and a downregulation of AdipoR1 ($p=0.051$) and its underlying signalling pathway ($p<0.05$). Upon siRNA-mediated silencing of AdipoR1, phosphorylated AMPK and AMPK activation were reduced (pAMPK, pAMPK/AMPK, $p<0.01$). High-resolution assessments of myoblast proliferation were evaluated using the

xCELLigence RTCA and a delayed growth rate was observed ($p<0.0001$). Moreover, the expression of AdipoR1 was negatively correlated with the time needed to reach the maximal cell index ($r=-0.7319$, $p=0.003$). Incubation with TNF- α decreased the mRNA expression levels of genes involved in lipid (PPAR α , ACADM), glucose (AMPK, HK2) and mitochondrial (FOXO3) metabolism ($p<0.0001$), and led to impaired myogenesis (MyoD1, Myogenin; $p=0.047$ and $p=0.031$; respectively). In addition, an increased cellular senescence, as evidenced by SA- β -gal activity and p53 acetylation ($p<0.05$) was apparent and accompanied by increased secretions of IL-1 β , IL-6, IL-10 and IFN- γ (Meso Scale Discovery; $p<0.05$). TNF- α treatment partially restored the siAdipoR1-induced delay in myoblast proliferation ($p<0.001$).

Conclusion: Primary CHF muscle cells exhibited characteristics typical to in vivo skeletal muscles of CHF patients including a conserved adiponectin resistance. Silencing of AdipoR1 attenuated the proliferation of muscle cells and the activation of AMPK. In contrast, inflammation induced impairment of adiponectin signalling, myogenesis and mitochondrial biogenesis, suggesting that an increased inflammatory constitution contributes to adiponectin resistance and skeletal muscle dysfunction in CHF patients.

P1167

Metabolic reprogramming as therapeutic strategy to ameliorate skeletal muscle tissue engineering procedures

E Ferraro¹; C Gargioli²; A Musaro³; G Rosano¹

¹IRCCS San Raffaele Pisana, Rome, Italy; ²University of Rome Tor Vergata, Rome, Italy; ³Sapienza University of Rome, Rome, Italy

Background: Stem cells and regenerative medicine raise great expectations because of the promise to reconstitute aged, injured and diseased tissues. While success has been achieved for hematological and epithelial diseases, several hurdles remain for diseases affecting skeletal and cardiac muscle. Maximizing the survival and the myogenic activity of the engrafted cells used for tissue engineering by preconditioning with suitable bioactive molecules would allow better therapeutic outcomes. Notably, energy management and metabolic reprogramming seem to play a key role in stem cell differentiation. We, therefore, propose that myogenic precursors preconditioning by metabolic shift induction might potentiate and ameliorate the efficacy of reconstructive muscular tissue strategies.

Methodology: We will evaluate the effect of metabolic reprogramming on stem cell myogenic capabilities and survival and on 3D artificial muscle generation in vitro and in vivo.

Results: Our data show that TMZ exert a profound effect on stem cells, altering their gene expression profile. It stimulates differentiation of both C2C12 and satellite cells as shown by enhanced expression of muscle-specific genes and proteins and by higher myotube size and fusion index. Moreover we developed a biotechnology demonstrating the possibility to build in vitro and in vivo a complete and functional artificial muscle in mice.

Conclusions: We expect to select metabolic remodeling agents able to improve the generation and implantation of artificial muscles. We will also clarify the key metabolic changes occurring during muscle differentiation, and this will allow further specific therapeutic approaches for muscle replacement.

P1168

Megestrol acetate improves cardiac function in a model of cancer-cachexia induced cardiomyopathy by autophagic modulation

V Vincenzo Musolino¹; M Gliozzi¹; C Carresi¹; C Drescher²; C Muscoli¹; W Doehner³; S Von Haehling²; SD Anker²; J Springer²; V Mollace¹

¹Institute of Research for Food Safety & Health (IRC-FSH), University of Catanzaro "Magna Graecia", C. Catanzaro, Italy; ²Division of Innovative Clinical Trials, Department of Cardiology, University Medical Center Göttinge, Berlin, Germany; ³Center for Stroke Research, Charité Medical School, Campus Virchow- Klinikum, Berlin, Germany, berlin, Germany

Background: Cachexia is a complex metabolic syndrome associated with cancer. One of the features of cachexia is the loss of muscle mass, characterized by disbalance of protein synthesis and protein degradation. Muscle atrophy is due to hyperactivation of the main cellular catabolic pathways, including autophagy. Cachexia also affects cardiac muscle and the atrophy of the heart impairs cardiac function and is likely to contribute to mortality. Anti-cachectic therapy in patients with cancer cachexia is so far limited to nutritional support and anabolic steroids. The use of the appetite stimulant megestrol acetate (MA) has been discussed as a treatment for cachexia.

Methods: In this study the effects of MA were tested in cachectic tumour-bearing rats (Yoshida AH-130 ascites hepatoma). Rats were treated with 100mg/kg/d MA or placebo starting one day after tumor-inoculation for 16 days. Body weight and body composition were assessed at baseline and at the end of the study. Cardiac function was analyzed by echocardiography at baseline and day 11. Locomotor activity and food intake were assessed before tumor inoculation and at day 11. Autophagic markers were assessed in gastrocnemius muscle and heart by western blot analysis.

Results: Treatment with 100mg/kg/d MA significantly attenuated the loss of body weight ($-9 \pm 12\%$, $p < 0.05$) and the wasting of lean and fat mass ($-7.0 \pm 6\%$ and $-22.4 \pm 3\%$, $p < 0.001$ and $p < 0.05$ respectively). Administration of 100mg/kg/d MA significantly protected heart from general atrophy (633.8 ± 30 mg vs placebo 776 ± 10 mg, $p < 0.001$). Tumor-bearing rats displayed cardiac dysfunction, e.g. left ventricular ejection fraction (LVEF), left ventricular fractional shortening (LVFS), the stroke volume (LVSV), the end diastolic volume (LVEDV) and the end systolic volume (LVESV) were significantly impaired in tumour-bearing rats. MA significantly improved LVEF, LVFS and LVESV. Western blotting analysis showed an upregulation of the autophagic pathway in gastrocnemius and hearts of tumor-bearing rats. MA was able to modulate the autophagic markers (e.g. Beclin-1, p62, TRAF-6 and LC3) in the gastrocnemius and in the hearts of tumor-bearing rats. Most importantly, 100mg/kg/d MA reduced mortality (HR: 0.44; 95%CI: 0.20-1.00; $p = 0.0486$).

Conclusions: MA improved survival and reduced wasting through a marked down-regulation of autophagy, occurring in both skeletal and heart muscle, the latter effect leading to a significant improvement of cardiac function. Our data suggest that MA might represent a valuable strategy to counteract the development of cancer cachexia-induced cardiomyopathy.

Mineralocorticoid receptor activation affects skeletal muscle development and metabolism.

A Feraco¹; A Armani²; V Marzolla²; E Ferraro¹; M Caprio²; GM Rosano¹

¹San Raffaele Pisana Hospital IRCCS, Laboratory of Pathophysiology of Cachexia and Metabolism of Skeletal Muscle, Rome, Italy; ²San Raffaele Pisana Hospital IRCCS, Laboratory of Cardiovascular Endocrinology, Rome, Italy

Background: It's known that Mineralocorticoid Receptor (MR) activation affects adipocytes differentiation and function and we showed that MR antagonism is able to improve insulin-stimulated glucose uptake in a mouse model of diet-induced obesity and insulin resistance. Adipose tissue secretome shows a paracrine effect on vascular system and cardiac function, as well as on skeletal muscle metabolism. Interestingly, MR blockade is able to affect skeletal muscle metabolism, improving insulin signaling. In addition, renin-angiotensin-aldosterone system (RAAS) activation, through MR-dependent mechanisms, leads to skeletal muscle atrophy in mice.

Purpose: Our aim is to evaluate a possible involvement of MR activation in regulating skeletal muscle differentiation and function in vitro and in vivo.

Methods: We investigated the involvement of MR in regulating murine skeletal muscle cells (C2C12) differentiation and we started to characterize the impact of adipose MR activation on skeletal muscle metabolic profile and development in a novel adipose-specific MR knockout (MRKO) mouse model.

Results: We first characterized the ontogenesis of MR in a murine myoblast cell line (C2C12) by RT-PCR and western blot analyses in order to evaluate the expression of MR during myotubes differentiation in vitro. We observed an increase in MR protein expression in skeletal myotubes during differentiation (96h). To evaluate the effects of MR activity on C2C12 cells, we treated C2C12 myoblasts, after differentiation stimulus, with aldosterone (Aldo, 10^{-8} mol/L) for 6h and 24h and we observed that Aldo significantly reduced Heavy Chain Myosin (MHC) mRNA levels, suggesting that MR activity represses muscle cell differentiation. Such effect was also MR dependent, given that Spiro was able to revert such effect.

We also analyzed skeletal muscle insulin sensitivity in vivo in MRKO mice evaluating soleus muscle insulin receptor substrate-1, tyrosinephosphorylated IRS-1, GLUT4 levels mRNA expression and Akt phosphorylation. Interestingly, we observed improved soleus muscle insulin signaling parameters and systemic insulin sensitivity in MRKO mice compared to controls. Further studies are necessary to explore the effect of MR activation on skeletal muscle development in vivo.

Conclusions: These data reveal a potential role of MR in modulating skeletal muscle differentiation and insulin sensitivity, which suggest a potential application of MR antagonists to improve skeletal muscle function.

Z Drahota³; H Nuskova³; J Kovalcikova³; T Pluhacek⁴; J Benes¹; J Kautzner¹; J Houstek³

¹Institute for clinical and experimental medicine, Prague, Czech Republic; ²Charles University of Prague, Dept. of Pathophysiol., 1st Faculty of Medicine, Prague, Czech Republic; ³Academy of Sciences of the Czech Republic, Institute of Physiology, Prague, Czech Republic; ⁴Palacky University, Faculty of Natural Sciences, Olomouc, Czech Republic

Background: Iron replacement improves clinical status in iron-deficient patients with heart failure (HF), but the pathophysiology is poorly understood. Iron is essential not only for erythropoiesis, but also for cellular bioenergetics. The impact of

myocardial iron depletion (MID) on mitochondrial function, measured directly in the failing human heart, is unknown. We hypothesized that myocardial iron content is decreased in HF patients and that HF with MID is associated with mitochondrial dysfunction.

Methods: LV samples were obtained from 91 consecutive HF patients undergoing transplantation and 38 HF-free organ donors (controls). Total myocardial iron was measured by inductively-coupled mass spectrometry in lyophilized samples. High-resolution respirometry, citric acid cycle and respiratory chain enzyme activities, respiratory chain components (complex I-V) and ROS-protective enzymes protein expression were measured in tissue homogenates to quantify mitochondrial function.

Results: Myocardial iron content was 22% lower in HF compared to controls (156 ± 41 vs 200 ± 38 $\mu\text{g/g}$ dry weight, $p < 0.001$). MID was present in 22% of HF patients and was associated with more extensive coronary disease, less beta-blocker usage and longer HF duration compared to non-MID HF patients. Compared to controls, HF patients displayed reduced myocardial O₂ respiration and reduced activity of all examined mitochondrial enzymes (all $p < 0.001$). Myocardial iron correlated with aconitase and citrate synthase activity in HF patients. MID in HF was associated with reduced aconitase and citrate synthase (by -27% and -16%, $p < 0.05$), preserved activity of respiratory chain oxidoreductases, but reduced expression of respiratory chain complexes III and V, catalase and glutathione peroxidase.

Conclusions: Myocardial iron content is systematically decreased in advanced HF. Myocardial iron deficiency is associated with mitochondrial dysfunction. These relations may lead to reduced substrate flexibility, impaired energy production and diminished ROS-defense in iron-deficient failing myocardium.

New oral anticoagulants in heart failure

O A Otilia Cristea¹; O Tica²; MI Popescu¹

¹University of Medicine of Oradea, Cardiology, Oradea, Romania; ²University of Medicine of Oradea, Pathology, Oradea, Romania

Background/Introduction: Anemia and iron deficiency is associated with a high risk of poor outcomes in patients with heart failure, especially those using oral anticoagulants. Anemia is common in heart failure but nevertheless is associated with poor outcomes.

Purpose: This study is aimed to evaluate whether the new oral anticoagulants (NOAC) – apixaban, rivaroxaban and dabigatran-, are less or more related to iron deficiency and anemia compared to classical oral anticoagulants: vitamin K antagonists (VKAs) and thus if they contribute to the patients outcomes?

Methods: A total 108 patients admitted consecutively in our clinic were evaluated during hospitalization and after discharge periodically. Patients included had the discharge diagnosis from our clinic: heart failure and anemia. The patients were divided into 3 groups, depending on whether they used NOAC or VKAs or none: 45 patients (41.66%) were using VKAs, 37 patients (34.26%) were on NOAC, while 26 patients (24.04%) used neither one. Among the first group, 8 patients (21.62%) used rivaroxaban, 12 patients (32.43%) used apixaban and 17 patients (45.94%) used dabigatran. A follow up time of 2 years proved that patients using NOAC versus VKAs had poor outcomes. The endpoint assessed in our study were: NYHA decompensation, iron deficiency, stroke, myocardial infarction, peripheral arterial disease, thromboembolism, renal failure and mortality.

Results: The use of NOAC (27.21%) are less related to iron deficiency and anemia compared to group using VKAs (43.64%). Two year mortality rate was significantly reduced in patients with NOAC versus VKAs (12.73% versus 31.42%, $p < 0.001$). The other composite endpoints showed no significant differences between the compared groups. Anemia is an independent risk factor for heart failure. The role of anemia is controversial but it is linked to other risk factors /comorbidities.

Conclusion(s): NOAC are more safer and proven their efficacy better than VKAs which are more related with anemia and have poor outcomes. Patient using oral anticoagulants should be monitored often, every 2 months for iron deficiency and anemia.

P1172

Anemia in heart failure

O A Cristea¹; O Tica²; MI Popescu¹

¹University of Medicine of Oradea, Cardiology, Oradea, Romania; ²University of Medicine of Oradea, Pathology, Oradea, Romania

Background/Introduction: Anemia is an independent risk factor for heart failure patients. It is proven to be linked to other risk factors or to other comorbidities. Anemia is common in heart failure but nevertheless is associated with poor outcomes.

Purpose: Quality of life in heart failure patients is reduced compared with that of patients who suffer from other comorbidities like: hypertension, diabetes mellitus, stroke patients, parkinson disease, renal failure.

Methods: A total of 517 patients admitted consecutively in our clinic were evaluated during hospitalization and after discharge periodically. The patients included

had heart failure and anemia or iron deficiency. The follow-up periode of 4.2 years performed included surveillance and a quality of life questionnaire completed by the patient. Blood test were performed for a more accurate stratification (hemoglobin, hematocrit, iron level, red blood cells size and color, ferritin and transferrin saturation).

Results: Patients expressed their physical symptoms and functional limitations associated with chronic heart failure through symptoms like: shortness of breath (21.64%), fatigue (22.61%), pulmonary rales (16.38%), leg oedema (19.23%) decrease in effort capacity (20.14%). The scores assessed (from the quality of life questionnaire) outline a depreciated life quality compared to patients with other comorbidities.

Conclusion(s): Anemia turned out to be an ominous sign in patients with chronic heart failure. Chronic heart failure patients strongly express their desire in improving: life, effort intolerance, physical and psychological capacity (score) and functional status.

P1173

The reduction of central sleep apnea severity in the left lateral position is not due to an improvement in cardiac hemodynamics in patients with chronic heart failure

G D Gian Domenico Pinna¹; D Rossi¹; R Maestri¹; F Olmetti¹; MT La Rovere¹; E Traversi¹

¹Salvatore Maugeri Foundation, IRCCS - Scientific Institute of Montescano, Montescano, Italy

Background: Moderate-to-severe central sleep apnea (CSA) affects about one-third of patients with chronic heart failure (CHF) and systolic dysfunction. CSA severity markedly decreases moving from the supine to the lateral position, with no difference between the left and the right position, but the mechanisms have not been fully defined.

Purpose: We tested the hypothesis that CSA attenuation in the left lateral position is due, at least in part, to an improvement in cardiac hemodynamics.

Methods: 16 clinically stable CHF patients (male, age: 60 ± 7, NYHA class: 2.6 ± 0.5, EF: 30 ± 5 %) with CSA and an apnea-hypopnea index ≥ 15 events/h were studied. Each subject underwent two consecutive echo-Doppler examinations in random order, one in the left lateral (90°) and the other in the supine (0°) position. The following parameters were investigated: left ventricular end-diastolic volume (LVEDV), left atrial volume (LAV), ejection fraction (EF), mitral regurgitation (0-4) (Mitr_Reg), cardiac output (CO), deceleration time (DT), E/e' ratio, right atrial volume (RAV), tricuspid annular plane systolic excursion (TAPSE) and right ventricular-atrial gradient (Right_VA_grad). Results. As shown in the table below, we found a general trend, albeit of modest clinical relevance, towards worse hemodynamics in the left lateral position.

Conclusions: This study shows that the reduction of CSA severity from the supine to the left lateral position in patients with CHF is not due to an improvement in cardiac hemodynamics as assessed by echo-Doppler. Other factors, particularly position-induced changes in lung volumes, might be the main cause.

Table 1

	Supine position	Left lateral position	P
LVEDV (ml)	196 ± 66	202 ± 75	0.41
LAV (ml)	108 ± 39	117 ± 43	0.037
EF (%)	32.3 ± 5.9	29.6 ± 5.2	0.031

Acute exercise-induced response of monocyte subtypes and relation to endothelial function in heart failure with preserved ejection fraction

AB Gevaert¹; K Van Ackeren¹; SC Latet¹; G Frederix²; AH Van Craenenbroeck²; PJ Beckers³; K Lemmens¹; VY Hoymans¹; CJ Vrints¹; EM Van Craenenbroeck¹

¹University of Antwerp, Cardiovascular Diseases, Translational Pathophysiological Research, Antwerp, Belgium; ²University of Antwerp Hospital (Edegem),

Department of Cardiology, Laboratory of Cellular and Molecular Cardiology, Antwerp, Belgium; ³University of Antwerp Hospital (Edegem), Department of Cardiology, Cardiac Rehabilitation Unit, Antwerp, Belgium

Background: Exercise intolerance is the main symptom of heart failure (HF) with preserved ejection fraction (HFpEF). Training improves symptoms, but underlying mechanisms are obscure. Recently, endothelial dysfunction was advocated as *primum movens* in HFpEF pathophysiology. Monocytes play a crucial role in low-grade vascular inflammation causing endothelial dysfunction, associated with prognosis in HF.

Purpose: In untrained HFpEF patients, we aimed to evaluate the effect of an acute exercise bout on (1) endothelial function and (2) levels of circulating monocyte subtypes.

Methods: Nine HFpEF patients were included. Before and after a maximal cardiopulmonary exercise test (CPET), microvascular endothelial function was measured using Framingham reactive hyperaemia index (FRHI). Also, monocyte subtypes were quantified by flow cytometry: CD14++CD16-CCR2+ (phagocytic Mon1), CD14++CD16+CCR2+ (intermediate Mon2), and CD14+CD16++CCR2- (patrolling Mon3). Data are reported as median (interquartile range).

Results: Patients were predominantly female (66.7%), elderly, obese and hypertensive. Peak oxygen uptake was 13.9 (12.1-16.8) ml/kg/min and maximum workload was 60 (60-75) watts, indicating severely impaired exercise capacity. FRHI, monocyte count and subtypes at baseline and after CPET are reported in Table 1. Endothelial function was impaired (FRHI ≤ 0.51) in 77.8% at baseline, and improved significantly after CPET. Baseline absolute monocyte count was normal (reference 200-1000 cells/μL) and showed a trend towards increase after CPET. Proportionally, Mon2 increased at the expense of Mon1, while Mon3 remained unchanged.

Conclusion: Endothelial dysfunction is a characteristic of HFpEF. After an acute exercise bout, endothelial function improves. This improvement is associated with a change to a less inflammatory profile in monocytes. These findings point towards a role for monocyte subtypes in vascular inflammation and endothelial dysfunction in HFpEF.

	Results			
	Before exercise	After exercise	% Change	P value before-after comparison
Monocyte count (cells/μL)	380 (320 - 540)	490 (365 - 580)	+19.2 (-6.6 - 31.2)	0,078
Mon1 (% of monocytes)	83.9 (77.3 - 90.1)	82.1 (73.0 - 84.5)	-3.7 (-6.5 -1.2)	0,012
Mon2 (% of monocytes)	6.2 (4.7 - 6.6)	8.4 (4.7 - 13.2)	+32.1 (4.5 - 79.2)	0,020
Mon3 (% of monocytes)	10.8 (5.5 - 16.2)	12.2 (6.8 - 13.9)	+13.1 (1.0 - 36.6)	0,164
FRHI	0,30 (0,07 - 0,53)	0,67 (0,36 - 1,00)	+134 (-3 - 214)	0,020
Mon1: CD14++CD16-CCR2+, Mon2: CD14++CD16+CCR2+, Mon3: CD14+CD16++CCR2-, FRHI: Framingham reactive hyperemia index.

Proinflammatory cytokines and heart rate variability in women with coronary heart disease

NA Koriagina¹; AV Petrisheva¹; LM Vasilts¹; VV Schekotov¹; DK Sadykova¹; AV Tuev¹

¹Medical Academy, Perm, Russian Federation

Examine the level of proinflammatory cytokines and time parameters of heart rate variability in coronary heart disease (CHD) due to minimal thyroid insufficiency, a comparative analysis of structural - functional parameters of heart disease in women with the content of thyroid stimulating hormone (TSH) 0.5-2.0 mU / l and 2.1-4.2 mU/l.

Materials and methods: Formed two groups (gr.) of women with CHD: 1 - 35 gr. with TSH 0.5-2.0 mU/l, 2 gr. -30 with TSH 2.1-4.2 mU/l, 52.4 ± 6.7 years. All surveyed, except for general clinical studies conducted ECG monitoring using complex 'Astro-card' (Moscow) with the same software; rate variability was determined by the daily ECG. And echocardiography with measurement of the basic structural and functional parameters. For the quantitative determination of tumor necrosis factor alpha (TNF-alpha), interleukin1 (IL-1) and interleukin6 (IL-6).

Results: In the group with TSH levels > 2.0mU/l compared with women with TSH 0.5-2.0 mU/l end-diastolic dimension (EDD) is 12% higher (p = 0.001), interventricular septum 14% thicker (p = 0.0034), the rear wall of the left ventricle at 10% thinner (p = 0.046). When comparing transmitral flow in women with high normal TSH levels (gr. 2), the median value of blood flow velocity in the late diastolic filling (peak

A) above by 10% ($p=0.04$), time slowing blood flow early diastolic filling (DTE) is higher by 14% ($p=0.04$), and left ventricular isovolumic relaxation time higher by 12% ($p=0.001$) compared with 1 group of women. Revealed a weak correlation between the level of TSH and KDR ($r=0.17$, $p=0.049$), and between level svT4 and DTE ($r=0.28$, $p=0.038$). Violations of the autonomic regulation of the heart rate group 2 patients showed pronounced declines in SDNN and SDANN. All surveyed CHD patients with TSH > 2.0 mU/l there was a significant increase in levels of circulating pro-inflammatory cytokines IL-1, IL-6 and TNF- α , compared to patients with ischemic heart disease 0.5-2.0 mU/l ($p < 0.01$).

Conclusions: CHD with decreased thyroid activity is accompanied by disorders of the autonomic regulation of the heart rate with a reduction in the absolute values of the time parameters of heart rate variability, as well as overproduction of proinflammatory cytokines IL-1, IL-6, TNF- α . A structural and hemodynamic changes in heart begin with TSH levels > 2.0 mU/l, which gives reason to believe such a minimum level of TSH thyroid insufficiency, affects the course of CHD in women and the development of measures to prevent the early development of heart failure.

Exposure to CXCL12 prolongs naive CD4+ T lymphocytes survival.

L. Vitiello¹; E Elisabetta Ferraro¹; S. De Simone²; G. Rosano¹; L. Racioppi³
¹IRCCS San Raffaele Pisana, Rome, Italy; ²National Research Council, Naples, Italy; ³Duke University Medical Center, Durham, United States of America

Background/Introduction: Naive T lymphocytes recirculate through the body, traveling from secondary lymphoid organs through tissues and via lymphatic vessels and peripheral blood into other secondary lymphoid organs and into the bone marrow. In these tissues, lymphocytes are exposed to the chemokine CXCL-12 (also known as SDF-1) which is abundantly produced in bone marrow and in lymph nodes by stromal cells. CXCL12 is known to drive lymphocytes chemotaxis, and in other cells types such as stem cells an antiapoptotic effect has been described.

Purpose: Here we analyzed the effect of CXCL12 exposure on naive CD4+ T lymphocytes cultured in a nutrient poor medium.

Methods: CD4+ naive T cells were purified from peripheral blood by immunomagnetic negative isolation, and were cultured in 2% FBS for up to 9 days in presence or not of CXCL12.

Results: CXCL12 exposed cells survived longer than untreated lymphocytes, as at day 7 living CXCL12 treated cells were 52% versus 27% in untreated controls ($p < 0.001$). This pro-survival effect was specific for resting naive lymphocytes, as in vitro activated lymphoblasts, both treated or not with CXCL12 died rapidly by day 3. The increased percentage of living cells observed was not due to proliferation, as we did not observe a costimulatory effect of CXCL12. The pro-survival effect seems to be mediated by PKA-dependent CREB activation, and consequent increased expression of the antiapoptotic factor Bcl2, that, together with BclXL, could account for the prolonged lifespan of CXCL-12 exposed naive T lymphocytes.

Conclusion(s): This previously unreported activity of CXCL12 could contribute in vivo to the maintenance of the naive T lymphocytes pool.

Inhibition of long noncoding RNA Chast prevents pressure-overload induced cardiac hypertrophy

J Janika Viereck¹; R Kumarswamy¹; A Foinquinos¹; S Batkai¹; K Xiao¹; F Weidemann²; LJ De Windt³; S Engelhardt⁴; T Dandekar⁵; T Thum¹

¹Hannover Medical School, Institute of Molecular and Translational Therapeutic Strategies, Hannover, Germany; ²Julius-Maximilians University, Department of Cardiology, Wuerzburg, Germany; ³Cardiovascular Research Institute Maastricht (CARIM), Department of Cardiology, Maastricht, Netherlands; ⁴Technical University of Munich, Institute of Pharmacology and Toxicology, Munich, Germany; ⁵University of Wuerzburg, Functional Genomics and Systems Biology Group, Wuerzburg, Germany

Purpose: Long noncoding RNAs (lncRNAs) are a new class of regulators that recently have been implicated to play an important role in the pathophysiology of the heart. However, the underlying mechanisms remain largely unknown. To address this issue, we aimed to identify lncRNAs involved in the development of cardiac hypertrophy and to translate these findings into a therapeutic strategy.

Methods and Results: Global lncRNA expression profiling revealed that several lncRNA transcripts are deregulated during pressure overload induced cardiac hypertrophy. Among these transcripts, we identified the so far unknown lncRNA Chast (cardiac hypertrophy associated transcript) that was strongly upregulated in cardiomyocytes after transverse aortic constriction. Modulation of the pro-hypertrophic calcineurin-NFAT pathway and chromatin immunoprecipitation revealed that NFAT is a direct inducer of Chast expression. Further, overexpression of Chast was sufficient to enhance cardiomyocyte hypertrophy in vitro and in vivo, since this

transcript provokes cardiomyocyte growth and pro-hypertrophic gene expression. lncRNA-pulldown assays identified a number of cardiac hypertrophy relevant interaction partners that are likely to be involved in the pathological remodelling process. Consequently, pharmacological inhibition of Chast ameliorated pressure-overload induced hypertrophy and protected murine hearts from cardiac remodelling and heart failure. Structure-sequence alignments to the human genome indicated a central conserved sequence. Examining the expression in hypertrophic human heart tissue from aortic stenosis patients and healthy controls, this transcript revealed a strong upregulation in diseased hearts, indicating a conserved function of Chast.

Conclusions: Based on a genome-wide lncRNA profiling we identified the novel lncRNA Chast that promotes cardiomyocyte hypertrophy. Targeting this transcript in vivo represents a promising therapeutic approach for the treatment of heart failure.

P1178

Pivotal role of regulator of G-protein signaling 12 in pathological cardiac hypertrophy

J Jia Huang¹

¹Zhongda Hospital, Department of Cardiology, Nanjing, China People's Republic of

Background: Cardiac hypertrophy is a major predictor of heart failure and is regulated by diverse signaling pathways. As a typical multi-domain member of the regulator of G-protein signaling (RGS) family, RGS12 plays a regulatory role in various signaling pathways. However, the precise effect of RGS12 on cardiac hypertrophy remains largely unknown.

Purpose: This study aims to explore the role of RGS12 in the development of cardiac hypertrophy and heart failure.

Methods: We generated genetically engineered mice and neonatal rat cardiomyocytes (NRCMs) to investigate the effects of RGS12 in cardiac hypertrophy. Echocardiography as well as pathological and biochemical analyses were performed to determine the extent of cardiac adverse remodeling triggered by hypertrophic stimuli. Subsequently, western blots and rescue experiments were performed to explore the signaling pathways responsible for RGS12-mediated cardiac hypertrophy. Furthermore, co-immunoprecipitation experiments were performed to confirm the association between RGS12 and MEK1/2 in NRCMs.

Results: Four weeks after aortic banding, RGS12 deficiency prevented cardiac hypertrophy with preserved fractional shortening ($43.0 \pm 3.4\%$ versus $28.4 \pm 2.2\%$ in control mice; $P < 0.05$), whereas RGS12-overexpressing mice exhibited exaggerated cardiac hypertrophy and reduced fractional shortening ($20.8 \pm 4.1\%$ versus $28.6 \pm 3.2\%$ in wild type mice; $P < 0.05$). Similarly, after angiotensin II administration, the cell surface area was decreased in NRCMs infected with AdshRGS12 ($1442.2 \pm 154.1 \mu\text{m}^2$ versus $2389.0 \pm 220.4 \mu\text{m}^2$ in AdshRNA infected NRCMs; $P < 0.05$), but further increased in NRCMs infected with AdRGS12 ($3437.9 \pm 430.2 \mu\text{m}^2$ versus $2524.0 \pm 337.8 \mu\text{m}^2$ in AdGFP infected NRCMs; $P < 0.05$). Mechanistically, our data indicated that the activation of MEK1/2-ERK1/2 signaling may be responsible for the pro-hypertrophic action of RGS12. Furthermore, a physical interaction between RGS12 and MEK1/2 was identified by co-immunoprecipitation experiments.

Conclusion: We provide the first evidence that RGS12 contributes to pathological cardiac hypertrophy by augmenting MEK1/2-ERK1/2 signaling pathways. Therefore, RGS12 may represent a novel diagnostic and therapeutic target for pathological cardiac hypertrophy and heart failure.

EMAP II reduces arterial stiffness and end-diastolic myocardial stiffness in hypertension and diabetes

N A Natali Dorofeyeva¹; GG Vorobyov¹; VF Sagach¹

¹Bogomoletz Institute of Physiology, Kiev, Ukraine

Endothelial monocyte-activating polypeptide-II (EMAP-II) plays an important role in the development of inflammation, apoptosis and angiogenesis and is able to increase blood tissue barrier permeability. It studied as an antitumor agent. On the other hand, EMAP II is able to stimulate the expression of inducible NOS (iNOS) and increase endothelium- and NO-dependent dilatation, that increase the synthesis of NO. Continuous growth of hypertension and diabetes leads to an increased prevalence of coronary artery disease.

The aim of work was to investigate whether EMAP II could improve heart function in spontaneously hypertensive rats (SHR) and streptozotocin-induced diabetic rats. Rats were divided into control, diabetic, and SHR groups. The functional cardio-hemodynamic indicators registered via Pressure-Volume System. The recombinant endothelial monocyte activating polypeptide II -EMAP II (0.85 mg/kg in 10 μl) was administered intravenously.

It was shown that after EMAP II end-diastolic pressure in streptozotocin-induced diabetic rats was decreased by 25.4%. End-systolic and end-diastolic pressure of SHR didn't change. After EMAP II the end-diastolic myocardial stiffness reduced in 4.7 times in SHR, the end-diastolic myocardial stiffness decreased by 25.5% in streptozotocin - induced diabetic rats. In SHR after treatment with EMAP II, arterial

stiffness decreased by 23.2%, in streptozotocin-induced diabetic rats, arterial stiffness was decreased by 26.3% ($P < 0.05$).

Thus, EMAP II improves pathological features of heart function in SHR and streptozotocin - induced diabetic rats. The positive effect of EMAP II in hypertension and streptozotocin-induced diabetes was in the decrease of arterial stiffness and end-diastolic myocardial stiffness.

P1180

Cardiovascular remodelling in L-NAME-induced hypertension: effect of ivabradine

VEGA 1/0071/15, VEGA 2/0195/15, UK/96/2015

F Simko¹; L Paulis¹; M Adamcova²; S Aziriova¹; K Krajcovicova¹; K Repova¹; A Dukat³; T Baka¹

¹Comenius University, Faculty of Medicine, Department of Pathophysiology, Bratislava, Slovak Republic; ²Charles University in Prague, Department of Physiology, Hradec Kralove, Czech Republic; ³Comenius University, 2nd Clinic of Internal Medicine, Bratislava, Slovak Republic

Introduction: Ivabradine reduces heart rate via If channel-inhibition in the sinoatrial node. In the SHIFT study, ivabradine reduced CV morbidity and mortality in heart failure. Beside bradycardic effect, ivabradine may achieve part of its protective cardiovascular benefit by its potential antiremodelling action. The aim of the study was to show the effect of ivabradine on blood pressure, heart rate (HR), left ventricular (LV) remodelling and LV function in L-NAME-hypertension.

Material and methods: 30 male Wistar rats were divided into 4 groups: control (C), ivabradine (10 mg/kg/day, Iv), L-NAME (40 mg/kg/day, L-NAME) and L-NAME+ivabradine (L-NAME+Iv). Systolic BP and HR were measured once a week (tail-cuff method). After 4 weeks of treatment rats underwent echocardiography. Afterwards rats were killed and LV were removed and processed for biochemical investigation.

Results: L-NAME significantly ($p < 0.05$) increased BP, LV weight and slightly increased LV hydroxyproline concentration and content, associated with deterioration of echocardiographic systolic and diastolic LV-function parameters. Ivabradine reduced HR (by 15%), systolic BP (by 8%) and attenuated systolic and diastolic dysfunction of the LV in L-NAME-hypertension. Hemodynamic benefits were associated with partial prevention of LV hypertrophy and fibrosis.

Conclusions: Ivabradine prevented LV dysfunction supposedly by reducing HR, BP and myocardial fibrosis.

Recently, it was proved the impact of arterial hypertension (AH) on the development of cognitive impairment (CI), which lead to a decrease in quality of life, professional and social exclusion. So far unresolved issue of timely detection and correction of cognitive disorders in patients with hypertension. Objective. Improving the program management of patients with hypertension in the practice of the family doctor for early detection and correction of cognitive impairment syndrome. Methods and materials. The study involved 67 outpatients with controlled hypertension 1-2 stages and impaired cognitive function. The average age of the surveyed amounted to 53.1 ± 8.3 years, the average - AH 12.4 ± 6.7 years. All patients underwent a comprehensive examination protocol for cardiac patients, made additional diagnostic procedures, ambulatory blood pressure monitoring, neuropsychological examination, integrated assessment of cognitive functions on a scale MMSE, quality of life - by the method of "36 health status survey". Patients received a personalized mono- or combination antihypertensive therapy of four major classes of antihypertensive drugs first line, in addition to beta-adrenergic receptors, because the risk of bradycardia when combined with ipidakrin. Additionally, all patients were prescribed nootropic drug - phenibut, dose of 250 mg 3 times a day and 30 are added to the treatment of anticholinergic drugs - ipidakrin 10 mg x 2 times a day. Duration of treatment - 6 weeks. Results. In analyzing the course of hypertension steps 1 and 2 found that even in patients with controlled hypertension against a background of effective non-pharmacological therapy and emerging drug CI: In 34.4% - were light level, in 56.1% - moderate and in 9.5% - mild dementia. In analyzing the structure of CI found that their performance at various levels of higher brain functions meet all cognitive areas of human activity, but suffer neural processes of nature (the ability of concentration, psychomotor speed reactions) and verbal memory. In a further appointment ipidakrin and phenibut combination in patients with hypertension and syndrome of CI recorded significantly better performance integrated intelligence, the positive dynamics in the areas of attention, concentration, reaction speed, verbal memory, levels of reactive and personal anxiety, quality of life compared with patients which additionally used only phenibut. Conclusion. The long-term observation of patients with hypertension in the practice of the family doctor must conduct a

dynamic analysis of cognitive and neuropsychological examination, assessment of cognitive functions integrated on a scale MMSE. Combined therapy of hypertension and CI should include more than antihypertensive and effective nootropic (phenibut) and anticholinergic drugs (ipidakrin), which leads to the correction of cognitive disorders and emotional state, improve the quality of life and level of adaptation in society.

P1182

Hypertension patients: the cerebral circulation and impairment of cognitive functions

VU Krotova¹; TA Khomazyuk¹; OV Olena Soya¹

¹Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Background: Recent findings were proved the impact of arterial hypertension (AH) on the development of cognitive impairment. Nevertheless, the cognitive disorders and cerebrovascular circulation are less studied in hypertensive patients. The aim of our study was to investigate cognitive function changes and cerebral circulation in hypertensive patients compared to the control group.

Methods: In study was included 245 patients with AH 1-2 stages (134 women and 111 men aged 34-69 years, median age - 53.8 ± 4.3 years) and 47 age-matched healthy controls were enrolled. The cerebral blood flow velocities were evaluated by transcranial Doppler. Mean velocity of middle cerebral artery (MCA) was monitored at resting in patients and controls. All patients were examined according to the recommendations of European Society of Cardiology (2013); neuropsychological diagnostics included integrated assessment of cognitive functioning by MMSE scale; assessment of cognitive disorders by Frontal Assessment Battery (FAB) scale; memory - by Luria's method of "Remembering 10 words"; attention and speed of sensory-motor reactions were analyzed by Schulte and Rybakov's technique.

Results: We have not found significant differences in mean velocity of MCA in patients with AH compared to controls (75.5 ± 7.2 m/s vs 71.2 ± 6.4 m/s, $P > 0.05$). Cognitive disorders were revealed in 33.9% patients (49 women and 34 men). By MMSE method mild CD (27-26 points) were revealed in 28.9% of patients, and moderate CD (25-24 points) - in 68.7%. Two patients (2.4%) were diagnosed with mild dementia (23 points). Decrease in verbal memory, speed of sensory-motor reactions and impaired ability to concentrate was revealed in 63.8% of patients and in 12.8% of controls.

Conclusion: The patients with arterial hypertension 1-2 stages are characterized by the development of mild to moderate cognitive disorders, significantly affecting the quality of life, worsening of efficiency of certain types of work, reducing quality and volume of work performed. Cognitive impairment was more often in patients with arterial hypertension 1-2 stages even without changes in cerebral circulation.

Rs2274273 from LGALS-3 locus and cardiac ventricular remodeling after first myocardial infarction: preliminary results

A Ana Djordjevic¹; T Djuric¹; M Zivkovic¹; I Zivotic¹; M Dekleva²;

N Markovic-Nikolic²; D Alavantic¹; A Stankovic¹

¹Institute for Nuclear Science "Vinca", Belgrade, Serbia; ²Health Center "Zvezdara", Belgrade, Serbia

Purpose: Post-myocardial infarction remodeling is characterized by acute loss of myocardium, which leads to changes in heart structure and function. A hallmark of this process is fibrosis formation. Galectin-3 (gal-3), a β -galactoside-binding lectin, promotes fibrosis in multiple organs. It has been suggested to play an important role in the pathophysiology of left ventricular (LV) remodeling after first acute myocardial infarction (AMI). The rs2274273 ($C > T$) has been most significantly associated with plasma gal-3 levels in the only GWAS of circulating gal-3. Our study aimed to assess the relationship between this SNP and echocardiographic parameters of cardiac remodeling after first AMI.

Methods: 167 patients (mean age, 55.5 ± 8.4) who have suffered first AMI were prospectively included in the study. Doppler echocardiography was performed 3 to 5 days after AMI and repeated after 6 months. Genotyping was performed by Taqman real-time PCR.

Results: Our results showed that carriers of CC genotype, according to the T allele dominant model (CC vs. CT + TT), had significantly shorter LV diameter in long-axis, at the baseline (81.70 ± 10.24 vs. 85.23 ± 7.66 , Mann-Whitney U test, $p = 0.02$) and 6 months after (83.20 ± 9.37 vs. 85.98 ± 7.74 , Mann-Whitney U test, $p = 0.04$), and shorter LV diameter in short-axis, according to the T allele recessive model (CC + CT vs. TT) 6 months after (49.40 ± 6.98 vs. 53.29 ± 5.67 , Mann-Whitney U test, $p = 0.02$). Carriers of TT genotype, according to the T allele recessive model had larger right ventricle at the baseline (33.45 ± 5.85 vs. 36.68 ± 3.89 , Student's t-test, $p = 0.03$). Carriers of T allele, according to the T allele dominant model had higher end-diastolic volume at the baseline (105.45 ± 31.27 vs. 116.16 ± 33.28 , Mann-Whitney U test, $p = 0.03$).

Conclusions: Our preliminary results suggest that rs2274273, previously associated with plasma gal-3 levels, might be a significant predictive marker of cardiac ventricular remodeling, after first AMI. Further study on larger sample size should be conducted to replicate and estimate the validity of these preliminary results.

The non coding repressor of NFAT (NRON) and its role in heart disease

J Julia Beermann¹; R Kumarswamy¹; T Thum¹

¹Institute for Molecular and Translational Therapeutic Strategies (IMTS), Hannover, Germany

Non-coding regulator of NFAT (NRON) inhibits NFAT activation by preventing nuclear export of transcription factor NFAT. In response to increased intracellular Ca²⁺ levels, calcineurin dephosphorylates and activates NFAT, while NFAT proteins are rephosphorylated and inactivated by multiple NFAT kinases, such as glycogen-synthase kinase 3 (GSK3), CK1, and dual-specificity tyrosine-phosphorylation regulated kinase 1 (DYRK1) and DYRK2. NRON promotes phosphorylated (inactive) state of NFAT by forming a RNA-protein scaffold complex with NFAT, DYRK2, GSK3, CK1 and IQGAP1. Inhibition of NRON and its interacting partners is essential for efficient NFAT activation. Although the function of NFAT in heart diseases is well established, the role of NRON was never investigated in this context. NRON expression is suppressed in pressure over-loaded murine hearts. Conversely, inhibition of NRON in isolated rat primary cardiomyocytes and cultured mouse HL-1 cells has significantly increased cardiomyocyte size. Interestingly, bioinformatic analysis revealed that NRON and NFAT inhibitory kinases DYRK2 and GSK3 can be targeted by pro-hypertrophic microRNAs such as miR-212/132 implying that NRON's action on NFAT can be modulated by miR-212/132 directly by targeting NRON or indirectly by targeting NRON interacting kinases. During myocardial infarction (MI), intracellular Ca²⁺ levels are elevated and NFAT is activated. Consistent with this, NRON expression changes when cytoplasmic Ca²⁺ levels are manipulated by treating cells with reagents such as thapsigargin, ionomycin, CPA (cyclopiazonic acid) or PMA (phorbol myristate acetate). Interestingly, DYRK2 expression also paralleled NRON expression, which was significantly reduced in failing hearts, suggesting that NRON may also function of a decoy target for DYRK2 targeting miRNAs such as miR-212/132. To further validate the important role of NRON in heart disease, we generated a NRON knockout mice model. First experiments show that indeed NRON knockout leads to a deregulated NFAT action. The role of NRON needs to be further assessed in detail, by different models for heart failure induction and more sophisticated proteomic methods like SILAC in vivo.

Diabetes associated DNA variants relation with prevalent left ventricular hypertrophy and diastolic dysfunction

M Magnusson¹; J Molin¹; PM Nilsson¹; M Leosdottir¹; U Lindblad²; B Daka²; L Bennet¹; L Rastam¹; O Melander¹; V Lysenko¹

¹Department of Clinical Sciences, Lund University, Skåne University Hospital, Malmö, Sweden; ²University of Gothenburg, Institute of Medicine, Department of Public Health and Community Medicine, Sahlgrenska Academy, Gothenburg, Sweden

Purpose: Although diabetes, hyperglycemia and insulin resistance increases risk of future cardiovascular disease (CVD), earlier genetic studies have failed to show associations between diabetes related SNPs and CVD-risk. Here we set out to examine if 43 single-nucleotide polymorphisms (SNPs) with earlier established genome wide association with increased risk of type 2 diabetes (T2D), hyperglycemia and insulin resistance were also associated with prevalent early signs of heart disease as measured by echocardiographical examination (UCG).

Methods: We genotyped 43 SNPs in 43 genes that reported genome-wide significant association with T2D, hyperglycemia and insulin resistance traits, in 1792 subjects from the population-based Malmö Preventive Project (MPP) with full UCG data (mean age 68 years; 29% women, 36% prevalent T2D). Logistic regression was used to adjust for covariates (age, sex, systolic and diastolic blood pressure, hypertensive treatment and diabetes status).

Results: In the fully adjusted logistic regression analysis common variants in 4 genes were associated ($p < 0.05$) with increased risk of prevalent diastolic dysfunction (DD) ADAMTS9 (Odds ratio (OR), 1.22, $p = 0.045$), HNF1B (OR, 1.21, $p = 0.028$), JAZF1 (OR, 1.18, $p = 0.044$), TSPAN8 (OR, 1.25, $p = 0.023$) and common variants in 4 genes were associated with decreased risk of prevalent DD HNF1A (OR, 0.77; $p = 0.011$), KLF14 (OR, 0.85, $p = 0.044$), TCF7L2 (OR, 0.81, $p = 0.018$), NOTCH2 (OR, 0.72, $p = 0.021$). The genetic risk scores (GRS) of the 4 SNPs associated with increased risk of DD and the 4 SNPs associated with decreased risk of DD association with prevalent DD were (OR = 1.19, 95% CI 1.08-1.32, $p = 0.001$) and (OR = 0.82, 95% CI 0.74-0.91, $p = 1.4 \times 10^{-4}$), respectively. Furthermore, common variants in 3 genes were associated ($p < 0.05$) with decreased risk of prevalent left ventricular hypertrophy (LVH) HNF1A (OR, 0.67, $p = 0.001$), ADAMTS9 (OR, 0.79, $p = 0.038$), GIPR (OR, 0.74, $p = 0.018$). The GRS of these 3 SNPs was also highly significantly associated with decreased LVH risk (OR = 0.74, 95% CI 0.64-0.85, $p = 3.1 \times 10^{-5}$).

Conclusion: Here we show that identified in GWAS T2D and glycemic traits susceptibility loci are associated with both increased and decreased risk of structural heart abnormalities as measured by UCG. Replication of these findings is presently ongoing in an independent Swedish cohort.

P1187

Impact of KCNJ11 gene polymorphisms of ATP-sensitive potassium channel on left ventricular end-diastolic volume and mass in chronic systolic heart failure

I Irina Mazur¹; L. Voronkov¹; V. Dosenko²; R. Strutynskyi²; N. Gorovenko³

¹National Scientific Centre - Strazhesko Institute of Cardiology, Kyiv, Ukraine;

²Bogomoletz Institute of Physiology, Nationale academi of medical sciences of

Ukraine, Kyiv, Ukraine; ³Institute of genetic and regenerative medicine of National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Background: ATP-sensitive potassium channels play an important role in the normal functioning myocardium, especially under stress. Intense physical activity or systemic hypertension in animals with knockout of the KCNJ11 gene, encoding the Kir6.2 pore-forming subunit of these channels lead to the rapid development of heart failure and death. The same consequences can be for single nucleotide polymorphisms in KCNJ11, which can impair the function of the channel.

Aim: To investigate KCNJ11 gene polymorphisms of ATP-sensitive potassium channel in relation to echocardiographic parameters in chronic heart failure (CHF) patients (pts).

Methods: 98 stable (NYHA II-III) CHF pts of ischemic origin with left ventricular systolic dysfunction (ejection fraction (EF) $\leq 45\%$) on standard treatment were examined. Echocardiographic data (left ventricular (LV) end-diastolic volume (EDV), LV end-systolic volume (ESV), LV mass, LVEF, left atrium and right ventricle sizes, systolic pulmonary artery pressure) were measured by standard method. KCNJ11 polymorphisms (Val337Ile (rs5215) and Lys23Glu (rs5219)) was genotyped by polymerase chain reaction-restriction fragment length polymorphism analysis.

Results: The frequency of Val337Ile genotypes was: Ile/Ile – 40,8% ($n = 40$), Ile/Val – 44,9% ($n = 44$), Val/Val – 14,3% ($n = 14$). The pts with Val/Val genotype had LV mass 362,3 [238,0;392,0] g, which was significantly lower vs Ile/Val pts – 400,2 [288,0;450,0] g, ($p = 0,037$). The frequency of Lys23Glu genotypes was: Glu/Glu – 42,9% ($n = 42$), Lys/Glu – 44,9% ($n = 44$), Lys/Lys – 12,2% ($n = 12$). The pts with Lys/Lys genotype had LV EDV – 170,0 [150,0;210,5] ml and LV mass 335,3 [268,5;365,3] g, these are significantly lower than Lys/Glu group: LV EDV-221,5 [154,5;270,0] ml ($p = 0,052$) and LV mass-428,4 [306,3;460,1] g, ($p = 0,036$).

Conclusion: In stable ischemic systolic CHF greater LV EDV is associated with Lys/Glu genotype of Lys23Glu, while greater LV mass is associated with Ile/Val genotype of Val337Ile and Lys/Glu genotype of Lys23Glu of KCNJ11 gene polymorphisms.

⁴University Hospital Henri Mondor, Department of Pathology, Creteil, France;

⁵University Hospital Henri Mondor, Platform of biological Resources, Creteil,

France; ⁶University Hospital Henri Mondor, Department of Physiology, Creteil,

France; ⁷University Hospital Henri Mondor, Department of clinical Immunology, Creteil, France

Aims: Serial invasive endomyocardial biopsies (EMB) for histological grading remain the gold standard for acute cellular rejection (ACR) diagnosis.

Purpose. We aimed to explore the myocardial Gene Expression Profiling (GEP) value for diagnosing and identifying predictive biomarkers of ACR.

Methods and Results: A case-control study nested within a retrospective heart transplant patients cohort included 126 patients with median (IQR) age 50.3 (41.2-57.2) years and 111 (88%) males. Among 1157 EBM performed, 467 were eligible (i.e. corresponding to either ISHLT grade 0 or $\geq 3A$), among which 36 were selected for GEP according to the grading: 0 (CISHLT, $n = 13$); rejection $\geq 3A$ (RISHLT, $n = 13$); 0 one month before ACR (BRISHLT, $n = 10$). We found 294 genes differentially expressed between CISHLT and RISHLT, mainly involved in immune activation, and inflammation. Hierarchical clustering showed a clear segregation of CISHLT and RISHLT groups and heterogeneity of GEP within RISHLT. All BEM presented immune activation, but some RISHLT BEM were strongly subject to inflammation, whereas others, closer to CISHLT, were characterized by structural modifications with lower inflammation level. We identified 15 probes significantly

different between BRISHLT and CISHLT, including the gene of the muscular protein TTN. This result consolidates the concept of structural alterations preceding inflammation in ACR. Using a Linear Discriminant Analysis based on these 15 probes, we identified the histological status of every 36 EMB.

Conclusion: Myocardial GEP is a helpful method to accurately diagnose ACR, and predict rejection one month before its histological occurrence. These results should be considered in cardiac allograft recipients' care.

The right ventricle molecular changes associated with pulmonary arterial hypertension are attenuated by Urocortin-2 treatment

C Maia-Rocha¹; R Rui Adao¹; P Mendes-Ferreira¹; D Santos-Ribeiro²; M Rademaker³; AF Leite-Moreira¹; C Bras-Silva¹

¹University of Porto, Faculty of Medicine, Department of Physiology and Cardiothoracic Surgery, Porto, Portugal; ²Centre de Recherche de l'Institut Universitaire de Cardiologie et de Pneumologie de Quebec, Quebec, Canada; ³University of Otago Christchurch, Christchurch Heart Institute, Department of Medicine, Christchurch, New Zealand

Pulmonary arterial hypertension (PAH) leads to right ventricular (RV) failure and death. Urocortin (UCN)-2 is a peptide highly expressed in the cardiovascular system. It was previously shown, in an experimental model of MCT-induced PAH, that UCN-2 treatment is able to restore PAH-induced severe abnormalities in cardiac function and structure. This study investigated the underlying molecular mechanisms to the beneficial effects of UCN-2 in myocardial function, in the same experimental model. Male Wistar rats randomly received monocrotaline (MCT, 60mg/Kg) or vehicle. After 14 days, animals were randomly assigned to receive UCN-2 (5µg/Kg/day) or vehicle. The study resulted in 4 groups: CTRL (n=9), CTRL+UCN-2 (n=9), MCT (n=7) and MCT+UCN-2 (n=10). RV sample collection, for RT-PCR and western blot, was performed 24-25 days after MCT administration. Only significant results (mean ± SEM, p < 0.05) are given.

Molecular analysis showed that expression of UCN-2 and its receptor CRHR2 are altered in MCT animals. In the RV, the UCN-2 levels are increased in MCT animals (MCT vs. CTRL: 2.5 ± 0.9 vs 1.0 ± 0.3 AU), while CRHR2 levels are decreased (0.5 ± 0.1 vs 1.0 ± 0.1 AU). These values are reversed with UCN-2 treatment (0.5 ± 0.1 and 0.9 ± 0.1 AU, respectively). Pathology markers are increased in MCT animals, namely BNP (15.3 ± 2.5 vs 1.0 ± 0.1 AU), ET-1 (3.4 ± 0.4 vs 1.0 ± 0.2 AU) and HIF- α (1.6 ± 0.3 vs 1.0 ± 0.2 AU) and are attenuated or reversed with UCN-2 treatment (6.9 ± 2.1 , 1.8 ± 0.6 , 1.0 ± 0.1 AU, respectively). At the metabolic level, the MCT group showed higher expression of GLUT1 (3.8 ± 0.8 vs 1.0 ± 0.1 AU) and lower expression of GLUT4 (0.5 ± 0.1 vs 1.0 ± 0.1 AU) when compared to control animals, while in MCT+UCN-2 group, GLUT1 expression is reversed (1.5 ± 0.4 vs 1.0 ± 0.1 AU) and GLUT4 expression remained lower (0.6 ± 0.1 vs 1.0 ± 0.1 AU). Caspases 3 and 8, two apoptotic markers, are elevated in the MCT animals (3.9 ± 0.6 vs 1.0 ± 0.1 AU and 2.8 ± 0.3 vs 1.0 ± 0.2 AU, respectively) and are attenuated by UCN-2 treatment (2.0 ± 0.4 and 1.3 ± 0.2 AU, respectively). Moreover, we have found decreased expression levels of STAT3, ERK and p38 protein phosphorylation in MCT animals (0.6 ± 0.1 , 0.5 ± 0.1 and 0.5 ± 0.2 AU), values which were also reversed with UCN-2 treatment (1.0 ± 0.1 , 0.9 ± 0.1 , 1.1 ± 0.2 AU).

In conclusion, we show that UCN-2 treatment is able to restore the changes in expression of markers of cardiac overload, hypertrophy and hypoxia induced by PAH. The beneficial effects of UCN-2 treatment appear to be associated with the modulation of different signaling pathways, namely apoptotic, metabolic, and survival/proliferation pathways.

P1190

Clinical and prognostic profile of patients with dilated cardiomyopathy caused by mutations in MYBPC3 gene

A Sousa¹; P Canedo²; B Moura³; L Lopes⁴; O Azevedo⁵; S Amorim⁶; F Rocha Gonçalves¹; JC Machado²; J Silva Cardoso⁶; E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Institute of Molecular Pathology and Immunology at the University of Porto, Porto, Portugal; ³Regional Military Hospital n° 1, Porto, Portugal; ⁴Garcia de Orta Hospital, Lisbon, Portugal; ⁵Alto Ave Hospital Center, Guimaraes, Portugal; ⁶Sao Joao Hospital, Porto, Portugal

Background: MYBPC3 mutations are frequent in patients (pts) with hypertrophic cardiomyopathy (HCM), representing 40–50% of all HCM mutations. Mutations in this gene are also found in pts with dilated cardiomyopathy (DCM), accounting for approximately 2% of the cases, where knowledge of genotype-phenotype correlations remains sparse.

Purpose: We aimed to describe the clinical course of pts with DCM carrying mutations in MYBPC3 gene.

Methods: We evaluated 107 pts with idiopathic DCM (age ≤ 50 years) or familial DCM (irrespective of the age). Detailed clinical data were obtained. Echocardiographic, resting and 24h-ECG and CMR parameters were collected. Molecular analysis included LMNA/C, MYH7, MYBPC3, TNNT2, ACTC1, TPM1, CSRP3, TCAP, SGCD, PLN, MYL3, TNNI3, TAZ and LBD3 genes. Pts with mutations in MYBPC3 gene were comprehensively analyzed.

Results: Ten variants in MYBPC3 gene were found in 9 (8.4%) pts (4 men, mean age 52 ± 12 years, 6 cases of familial DCM). None of the variants had been previously described in association with DCM, but six were associated with HCM (Asp75Asn, Gly278Glu, Gly279Ala, Glu441Lys, Arg495Gln and Glu619Lys). Mean age at diagnosis was 44 ± 10 years and symptoms of heart failure (HF) were the initial manifestation in 7 pts. Five pts had previous hospitalization (2 from HF and 3 from arrhythmic causes), two received an ICD and one a CRT device. In 3 pts there was history of heart transplant in a family member and in 2 there was family history of sudden death. Mean LVEDD was 67 ± 3 mm, LVEF $32 \pm 10\%$ and in 3 pts there was right ventricular function impairment. Three pts had AF, 5 LBBB and episodes of nonsustained VT (NSVT) were documented in 2. LGE was present also in 2 pts. Three pts exhibited a particular dismal clinical course: a woman with c.1226+6T > C mutation, LVEDD 71 mm and LVEF 18%, AF, LBBB and NSVT, presented 3 HF-hospitalizations, had ICD implantation and eventually died of HF; a man with Arg495Gln mutation, had LVEDD 67 mm and LVEF 32%, extensive LGE, a previous hospitalization from arrhythmic cause, presented aborted cardiac arrest and subsequent ICD implantation; a woman with Ala433Gly mutation presented in NYHA class III, LVEF 15%, LVEDV 212 mL/m² and 10 previous HF-hospitalizations. On the other hand, one pts had two MYBPC3 variants (Glu441Lys+Gly279Ala) and another an additional mutation in TNNT2 gene (Ser275Phe) beyond MYBPC3 mutation (Arg44His): both were in NYHA class I and had no congestion; LVEF/LVEDD were 49%/61mm and 45%/51mm and neither had right ventricle impairment; the latter had AF and a previous arrhythmia-related hospitalization.

Conclusions: In our population, mutations in MYBPC3 gene appear to be more common than in previous series. Although most of the variants found were previously associated with HCM, a causative role also in DCM seems plausible. Carriers of mutations in MYBPC3 gene present a variable, but in general dismal, clinical course, with very severe outcome in some instances.

P1191

Grapevine microRNAs in an in vitro model of cell line: new potential insight on their role in the setting of human health.

B Svezia¹; M Cabiati²; E Bertolini¹; C Passino¹; V Lionetti¹; S Del Ry²; ME Pe¹

¹Sant'Anna School of Advanced Studies, Institute of Life Sciences, Scuola Superiore Sant'Anna, Pisa, Italy; ²Institute of Clinical Physiology of CNR, Pisa, Italy

Introduction: microRNAs, the most abundant class of small-non coding RNA involved in post-transcriptional regulations, are emerging as the next generation "smart" biomarkers and could be helpful in further improving the diagnostic and therapeutic processes of cardiovascular diseases, the major causes of morbidity and mortality of industrialized countries. Growing evidence has indicated that diet-derived miRNAs, might be considered as a nutraceutical compound able to have an active role in human health. However, studies on the potential action of plant miRNAs at cardiac level are still lacking. To date, few experimental models have been built to evaluate the role of plant miRNA administered either in vivo or in vitro in mammalian cell lines.

Purpose: aim of this study was to evaluate the effect of miRNA extracted from selected Tuscany Vitis vinifera grapevine on an in vitro model of murine cardiac endothelial cell line (MCEC-1).

Methods: small RNAs were extracted from Vitis vinifera berries, cultivar Sangiovese, at last developmental stage (harvest), by a two steps extraction and evaluated for purity and integrity. MCEC-1 line were maintained in DMEM-low glucose supplemented with 10% FBS and seeded for 24 hours. The cells were then transfected with grapevine small RNAs at different doses (5, 20, 50 ng) in triplicate. After 48 hours

of treatment the MTT system was used to evaluate the effects of different doses of small RNA on MCEC-1 cell line. As control MCEC-1 untreated cell line were used. Bioinformatics analyses were carried out to identify putative mammalian targets to the most abundant miRNAs of grapevine berries.

Results: grapevine small RNAs treatment increased cells viability in comparison with the control untreated cells. The result showed a significantly viability increased in MCEC-1 treated with a dose of 50 ng small RNA. Even though MCEC-1 treated viability was higher than untreated cells, any statistically significant difference at 5 ng and 20 ng doses were observed. The bioinformatics analysis, supported by manual annotation, identified 36 more abundant grapevine miRNAs in mature Sangiovese berries, for which 141 putative target expressed in MCEC-1 cell line were obtained.

Conclusion: in this study we evaluated for the first time the effect of grapevine small RNAs on a model of murine cell line. The experiment allowed observed a positive effect of grapevine small RNAs administration to MCEC-1 viability and to identify the best effective dose. We also reported a preliminary bioinformatics analysis for the identification of putative murine targets to grapevine miRNAs. Our observation reinforce the hypothesis that grapevine miRNAs could represent a novel avenue for nutraceutical approach in the cardiovascular diseases.

P1192

The ageing and high arterial pressure change IGF-1/miRNA-1 regulation in hypertrophied myocardium of SHR and Wistar rats

T Tetiana Lapikova-Bryhinska¹; V Gurianova¹; A Portnychenko¹; S Goncharov¹
¹ Bogomoletz Institute of Physiology, general and molecular pathophysiology, Kiev, Ukraine

Purpose: The miRNA-1 has inhibitory effect on IGF-1, which is known as a potent stimulator of cardiac hypertrophy. The aim of the study was to determine the features of IGF-1/miRNA-1 regulation of the cardiac hypertrophy development under high arterial pressure and in ageing.

Methods: The experiments were performed in male Wistar rats and SHR 6 or 18 months in age. In young rats, left ventricular (LV) hypertrophy was induced by low dose isoprenaline (ISO) injections for 7 days. Control rats treated NaCl saline. In all groups, parameters of heart function were investigated using the ultra-small catheter 2F ("Millar Instruments", USA). The samples of heart LV tissue were collected from narcotized rats in the dynamics of the experiments, and were assayed using morphological methods. The levels of mRNA, miRNA or protein expression were estimated by real time PCR and WestBlot.

Results: After ISO injections, the progressive LV hypertrophy was revealed in both lines of young animals. The parameters of heart function and structural rebuilding in rats were typical for heart remodeling and these changes were strongly pronounced in SHR. The old rats, especially SHR, showed the development of the first stage of a pathological heart remodeling including myocardial hypertrophy, fibrosis and diastolic and pumping dysfunction. Furthermore, it was found that initial IGF-1 protein expression was higher in SHR than in Wistar rats. Maximal induction of IGF-1 protein was found in third day of ISO application. In opposite, IGF-1 mRNA expression was prevailing in Wistar rats, and it was reduced in third day of the treatment. The expression of miRNA-1 was also changed showing the dynamic of its reciprocal regulation with IGF-1. During ISO treatment, SHR demonstrated a lower levels of IGF-1 mRNA and protein than Wistar rats that indicates the presence of inhibitory effect of miRNA-1. In old rats, the decrease of miRNA-1 expression levels was found.

Conclusions: The data obtained indicate that significant changes in miRNA-1 expression occur in heart due to pressure afterloading and senescence. These changes lead to reciprocal modulation of IGF-1 mRNA and protein level followed by cardiac remodeling. Dynamic of these changes during LV hypertrophy development confirms the presence of phase regulation of IGF-1 by miRNA-1 at the translation level. High arterial pressure in SHR leads to intensification of inhibitory translational regulation of IGF-1 in LV. In ageing, reduction of miRNA-1 level and its inhibitory effect on IGF-1 may be a factor of the progression of heart failure, especially in SHR.

Polymorphisms of GSTT1 is associated with higher risk of chronic heart failure among smokers

N Natasa Jankovic¹; DV Simic¹; S Radovanovic²; O Gudelj³; M Marinkovic¹; S Suvakov⁴; V Coric⁴; T Simic⁴

¹ Clinical Center of Serbia, Clinic for Cardiology, Belgrade, Serbia; ² Department of Cardiology, Medical Center Bezanjska Kosa, Belgrade, Serbia; ³ Military Medical Academy of Belgrade, Belgrade, Serbia; ⁴ Institute for Medical Biochemistry, Belgrade, Serbia

Background: Chronic heart failure (CHF) secondary to ischemic heart disease belongs to oxidative disease. Glutathione transferase T1 enzyme (GSTT1) is involved in detoxification of byproducts of tobacco smoke. Around 15-30% of white population doesn't exhibit GSTT1 enzyme activity (GST1 null genotype) because of GSTT1 gene deletion polymorphism. Smoking is a potent source of free radicals and well

known risk factor for coronary disease. Aim: To examine influence of different risk factors and GSTT1 polymorphism on the risk of development CHF.

Material and methods: One hundred and twenty patients suffering from CHF were included in the study. The criterion for admission was left ventricular ejection fraction (LVEF) < 45%. Sixty nine healthy controls matched for sex and age served as control group. Age, sex, smoking history, hypertension, dyslipidemia, diabetes mellitus and obesity were evaluated as risk factors. GST genetic polymorphism was determined by PCR. Both patients and controls were dichotomized into GSTT1 null and GSTT1 active genotype. Independent factors on CHF risk were evaluated by multiple logistic regression model.

Results: Distribution of GSTT1 gene polymorphism did not differ between patients and controls. It corresponded to the results obtained in white population, with 24.2% of participants having GSTT1 null genotype. Among controls, GSTT1 null was found in 23.2%. Hypertension (OR=6.65; CI: 2.75-16.30; p<0.05), diabetes (OR=8.88; CI: 1.76-14.89; p<0.05), old age (more than 50 year) (OR=5.78; CI: 1.35-24.67; p<0.05) and obesity (OR=2.62; CI: 1.13-6.08; p<0.05) were independent risk factors for CHF. Smoking wasn't independent risk factors for CHF (OR=1.63; CI: 0.79-3.39; p>0.05). GSTT1 null genotype alone wasn't independent risk factor for CHF (OR=1.06; CI: 0.52-2.12; p>0.05), but GSTT1 null genotype in smokers was independent risk factor (OR=3.68; CI: 1.05-12.89; p<0.05).

Conclusion: We conclude that presence of GSTT1 null genotype increases the risk of CHF in smokers.

P1194

The prognostic value of different allelic distribution of aldosterone synthase receptor in a congestive heart failure caucasian population.

M Mauro Feola¹; M Monteverde²; D Vivenza³; M Testa³; L Leto¹; F Mussapi²; A Vado⁴; M Merlano²; C Lo Nigro²

¹ Cardiovascular Rehabilitation-Heart Failure Unit, Fossano, Italy; ² Santa Croce E Carle Hospital, Laboratory Cancer Genetics and Translational Oncology and Medical Oncology, Cuneo, Italy; ³ School of Geriatrics University of Turin, Turin, Italy; ⁴ Santa Croce E Carle Hospital, Cardiovascular Disease, Cuneo, Italy

Blockade of the aldosterone receptor has shown to improve congestive heart failure (CHF) outcomes. Aldosterone synthase is on chromosome 8q22 and exists as a common single nucleotide polymorphism C to T transition for position -344. The C allele determines an increased in aldosterone production more efficiently than T allele.

Purpose: to assess the -344T/C polymorphism of the aldosterone synthase promoter in a Caucasian CHF population.

Methods: CHF consecutive patients were enrolled. The DNA from peripheral blood was isolated and genotyping for the -344 T/C SNP in the aldosterone synthase gene was performed.

Results: on 175 CHF patients (114 male; age 69.9 ± 10.2 years) 61 had a TT genotype (34.9%), CT in 80 (45.7%) and finally a CC in 34 (19.4%). CHF patients were divided into C-group (-CT/CC genotype, 114 subjects) and T-group (-TT genotype, 61 subjects). The two groups did not differ in term of age, non-invasive cardiac output at rest (4 ± 1.4 vs 4.1 ± 0.9 l/min, p=0.7), creatinine plasma level (1.34 ± 0.8 vs 1.24 ± 0.5 mg/dl, p=0.8) or end-systolic or diastolic left ventricle diameter (p=0.6 and p=0.29 respectively), left ventricle ejection fraction (LVEF) (p=0.29) and plasma BNP (p=0.3). C-group patients had a higher degree of disability than T-group (Barthel Index, p=0.004), NYHA class (p=0.02) and a lower cardiac index (p=0.01) (Table 1). The two groups showed a similar clinical outcome at

Table 1. Main clinical features.

	CT/CC genotype (n=114)	TT genotype (n=61)
NYHA on admission/discharge	3 ± 0.7 / 2.1 ± 0.5	2.7 ± 0.7* / 1.8 ± 0.4*
Left Ventricle Ejection Fraction [%] LV end systolic/diastolic diameter[mm](n=105)	33.3 ± 12 / 46.2 ± 15.1 / 56.4 ± 12.5	35.4 ± 12.5 / 48.2 ± 10.1 / 59.7 ± 10.6
BNP on admission / discharge [pg/ml] (n=92)	1576.6 ± 1973.8 / 23.6 ± 1171.2	1156.5 ± 1665.4 / 1019.9 ± 795.9
Cardiac Index [l/min/mq] (n=55)	2.1 ± 0.6	2.4 ± 0.6*
6min walk test discharge[meters](n=82)	317.3 ± 126.1	315.2 ± 127.4
Barthel index admission / discharge	82.3 ± 25.4 / 88.5 ± 19.5	93.3 ± 10.9* / 98.3 ± 4.9**

*p < 0.05; ** p < 0.01 Pearson Chi2.

48-months follow-up (Kaplan Meier survival curves $p=0.16$; log-rank 1.99) with 22 dead patients (12.6%), no cardiac transplantation and 15 (8.6%) readmission to hospital for an acute decompensated heart failure.

Conclusions: in Caucasian patients the C allele (CC or CT) at -344T/C SNP in aldosterone synthase gene does not significantly influence clinical prognosis of CHF.

Molecular characterization of portuguese patients with dilated cardiomyopathy

PTDC/BIM-MEC/0650/2012

A Sousa¹; P Canedo²; O Azevedo³; L Lopes⁴;
T Pinho⁵; F Rocha Goncalves¹; L Goncalves⁶; J Silva Cardoso⁵; JC Machado²;
E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Institute of Molecular Pathology and Immunology at the University of Porto, Porto, Portugal; ³Alto Ave Hospital Center, Guimaraes, Portugal; ⁴Garcia de Orta Hospital, Lisbon, Portugal; ⁵Sao Joao Hospital, Porto, Portugal; ⁶Faculty of Medicine University of Coimbra, Coimbra, Portugal

Introduction: Dilated cardiomyopathy (DCM) affects 1:2500 adults. Familial forms account for 30-50% of all the cases and autosomal-dominant inheritance is the dominant pattern of transmission. Mutations were identified in several genes and molecular diagnosis appears to have implications for clinical practice, genetic counseling and risk stratification.

Purpose: We intend to estimate the frequency and molecular basis of familial and idiopathic cases of DCM in Portugal.

Methods: Multicentric study of unrelated familial and idiopathic DCM patients (pts). Detailed clinical data were obtained. Search for mutations in LMNA/C, MYH7, MYBPC3, TNNT2, ACTC1, TPM1, CSRP3, TCAP, SGCD and PLN, MYL2, MYL3, TNNI3, TAZ, LDB3 genes was performed, using PCR technique with direct-sequencing (NGS with at-least a 30-fold coverage combined with Sanger sequencing). Pathogenicity was assessed by comparisons with mutations previously described, functional tests and segregation studies.

Results: 107 pts were included, 59% men, mean age at diagnosis 38 ± 13 years, with 45% of familial cases. Mean LVTD was 64 ± 9 mm and LVEF $31 \pm 11\%$. Most pts were in NYHA class I (48%). Atrial fibrillation, left bundle branch block and non-sustained VT were present in 11%, 26% and 26% pts, respectively. ICD was implanted in 27%, CRT in 11% and conventional pacemaker in 6%. Previous hospitalization from heart failure was documented in 39% and from arrhythmic cause in 20% of pts, and heart transplantation was performed in 10% of pts. Familial history of sudden death was present in 24%. In total, 34 rare variants, in 8 genes, were identified in 28 (26%) pts, most in MYBPC3, TNNT2 and LMNA genes. Four pts had 2 mutations (in same or different genes) and one pts had 3 mutations in LMNA. Diagnosis yield was higher in familial cases (33%vs22%). Only one variant had been previously associated with DCM (LMNA) and 8 with hypertrophic cardiomyopathy (2 in MYH7 gene and 6 in MYBPC3 gene). There were no significant differences in age, gender, previous cardiac-related hospitalizations, use of devices, heart transplantation and major ECG, echocardiographic and CMR parameters, between pts with and without genetic mutations.

Conclusion: Our results reflect the complexity and diversity of DCM genetics and the difficulty in determine a clear phenotypic pattern of pts with rare variants. Studies with larger number of pts/family members and longer follow-up period, will elucidate the causative role of the variants found and allow further insight in genotype-phenotype correlations and risk stratification in DCM pts.

P1196

Does the gene expression differentiate patients with ischaemic heart failure from healthy individuals?

J Dabek¹; M Piechota²; M Majewski¹; J Glogowska-Ligus³; Z Gasior¹

¹Medical University of Silesia in Katowice, School of Health Sciences, Chair and Department of Cardiology, Katowice, Poland; ²City Hospital in Tychy, Department of Cardiology, Tychy, Poland; ³Medical University of Silesia, School of Pharmacy with the Division of Laboratory Medicine, Department of Molecular Biology, Sosnowiec, Poland

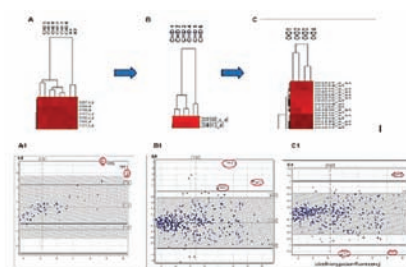

Introduction: Cardiovascular diseases are leading cause of death surpassing even those of malignancies. Heart failure (HF) is not only a major cause of mortality but also frequent reason for hospitalization, disability, sickness absence and as a consequence generates significant economic costs. The main cause of HF is coronary artery disease (CAD).

Purpose: The aim of the study was to compare genetic similarities and differences between groups of healthy and affected (both ischaemic and non-ischaemic HF) subjects as well as to determine distinctive genes.

Methods: Semi-quantitative analysis using oligonucleotide microarray HG-U133A (Affymetrix) technique: from the group of patients with ischaemic HF ($n=52$) 6 and from the group of patients with CAD without coexisting HF ($n=23$) 2 persons were randomly selected for further analysis. The control group were healthy individuals

($n=2$) in who exclusion of CAD was confirmed by coronary angiography and 64-row computed tomography with coronary artery calcium score assessment (CACS=0). Mean age of studied subjects was 69 yrs. Material for the molecular tests was RNA extracted from peripheral blood mononuclear cells. Results Increased transforming growth factor beta-1 (TGF- β 1) and tissue inhibitor of metalloproteinase type 1 (TIMP-1) differentiated patients from healthy individuals. Patients with ischaemic HF were characterized by increased gene expression of TGF- β 1, TIMP-1 and TIMP-2 as compared to patients with CAD without coexisting HF. Reduced TGF- β 1 and TIMP-1 as well as increased TIMP 9 expression was associated with HF progression and lower left ventricular ejection fraction. Results of cluster analysis for gene transcripts directly connected with HF and CAD are presented in figure 1 (A, B and C): A - all studied group, B - patients with ischaemic HF and those with CAD without HF, C - patients with different clinical stage of ischaemic HF (CHD 1-2 - LVEF <20%, CHD 3-4 - LVEF 20-40%, CHD5-CHD6 patients with CAD without HF, K1-K2 - controls). Typing, using Bland-Altman method, differentially expressed genes (A1, B1 and C1). Hatched boxes' area - genes with non-discriminative value: ± 1 minimum double decrease or increase of transcript expression (biological criterion); ± 1.3 time change of fluorescence level providing utility of designated transcript differentiating in quantitative RT-PCR (statistical criterion).

Conclusions: Evaluation of cluster analyzes identified TGF- β 1 gene to be most differentiating patients with advanced ischaemic HF from patients with CAD without coexisting HF. Statistically significant decline of TGF- β 1 transcriptional activity and its receptor III in patients with HF and its further reduction during decompensation of HF suggest important role of these genes in development and decompensation of HF. Transcriptional activity of TGF- β 1 could be useful diagnostic and prognostic marker identifying patients with CAD and high risk of HF developing and decompensation.

Cluster analysis and genes' typing

The eye, a window to the heart - Retinal vessel analysis in heart failure

Funded by the Swiss Heart Foundation.

M Matthias Naegel¹; I Sudano¹;

S Cantatore¹; F Enseleit¹; F Ruschitzka¹; AJ Flammer¹

¹University Heart Center, Cardiology, Zurich, Switzerland

Background: Endothelial dysfunction appears to play an important pathophysiological role in heart failure. Previous studies focused on the relevance of brachial endothelial dysfunction in disease pathogenesis. Less is known about the extent of endothelial dysfunction in other vascular beds, the retinal microcirculation in particular. Retinal vessel analysis (RVA) is a new method allowing study of the retinal microcirculation in a standardized way using high-resolution caliber measurements of retinal vessels.

Purpose: The primary goal of this study was to evaluate the extent of retinal microvascular endothelial dysfunction as assessed by flicker-induced dilatation of retinal vessels in heart failure patients compared to age- and sex matched healthy controls.

Methods: In this prospective, observational, single-center study, patients with a diagnosis of heart failure on stable pharmacological therapy and currently compensated status and healthy controls were recruited for the assessment of vascular function. RVA was conducted using an Imedos retinal vessel analyzer (Jena, Germany) with the assessment of retinal flicker-induced vasodilatation (FID) using an established stimulation protocol and the measurement of retinal arteriovenous ratio (AVR) calculated from retinal vessels using fundus photographs.

Results: 45 heart failure patients (mean age 60.3 ± 10.4 years, 24 % female, mean left ventricular ejection fraction 36.9 ± 14.2 %) and 31 healthy controls (mean age 57.4 ± 15.3 years, 26% female) were included in this analysis. Heart failure patients showed significantly reduced FID of retinal arterioles and venules compared to

healthy controls (mean arteriolar FID $1.2 \pm 1.9\%$ vs. $3.2 \pm 2.0\%$; mean venular FID $2.8 \pm 1.8\%$ vs. $4.8 \pm 2.1\%$, both $p < 0.0001$ respectively). No significant difference in retinal AVR was found between both groups (mean AVR 0.84 ± 0.07 in heart failure patients and 0.85 ± 0.06 in healthy controls, $p = 0.32$).

Conclusions: Heart failure patients are characterized by a profound alteration in retinal microvascular endothelial function as assessed by FID of retinal arterioles and veins. RVA may be a useful tool for the non-invasive assessment of microvascular function in heart failure.

P1198

Stress-induced vascular dysfunction: Evaluation of sympathetic activity and endothelial function in patients with takotsubo syndrome

I Sudano¹; M Naegele¹; AJ Flammer¹; F Enseleit¹; TF Luescher¹; F Ruschitzka¹; G Noll¹

¹University Heart Center, University Hospital and University of Zurich, Zurich, Switzerland

Background: Transient left ventricular apical ballooning syndrome or Takotsubo cardiomyopathy is an acute cardiac syndrome mimicking ST-segment elevation myocardial infarction. This syndrome is typically observed in patients experiencing sudden physical or emotional stress. The precise etiology and pathophysiology of this syndrome as well as its prognosis remains unclear.

Purpose: Aim of this study was to evaluate the vascular function and structure as well as sympathetic nervous activity in patients with Takotsubo syndrome and matched controls.

Methods: 22 patients with Takotsubo syndrome and 21 controls, matched for age, cardiovascular risk factors and medications were included in this prospective observational study. Flow-mediated vasodilatation (FMD) of the brachial artery at baseline and during stress tests was used as a marker for endothelial function. Arterial stiffness was evaluated by tonometric measurement of pulse wave velocity. Carotid atherosclerosis was assessed using ultrasound measurement of intima-media thickness and total plaque area. Sympathetic activation was measured using microneurography and quality of life was assessed using EQ-5 questionnaires.

Results: Compared to controls, patients with Takotsubo syndrome had a significantly reduced endothelial function (FMD $3.0 \pm 1.7\%$ vs. $5.0 \pm 1.7\%$; $p = 0.016$) and an increased sympathetic nervous activity (MSA 49.7 ± 27.5 vs. 28.7 ± 15.1 Burst/100HB, $p = 0.04$). Cardiovascular risk factors (age, weight, glucose, lipid profile and physical activity), pharmacological therapies, pulse wave velocity, intima-media thickness, total plaque area and quality of life were similar between both groups.

Conclusions: Our findings highlight the potentially important role of sympathetic activation and endothelial dysfunction in patients with Takotsubo syndrome.

CD34 positive bone marrow derived cells inhibit intimal hyperplasia in mouse model of vascular injury

S Sharan Ananthasethan¹; E Kurzejamska¹; M Lazarczyk¹; P Religa¹

¹Karolinska University Hospital, Medicine, Solna, Stockholm, Sweden

Introduction: Vascular progenitor cells contribute to repair of injured vasculature. In this study, we aimed to investigate the role of bone marrow derived cells in the intimal formation after arterial injury.

Methods and Results: Balloon injury of wild type mice femoral artery was followed by local delivery of bone marrow-derived cells from GFP transgenic mice. The arteries were collected 1, 4, 7 and 14 days after injury and studied for morphology, localization and phenotypes of delivered cells. Bone marrow-derived cells were present in the intima only at the early stages of arterial injury and expressed endothelial progenitor cell markers (CD31, CD34, VEGFR-2). In the areas where intima was thicker, bone marrow-derived cells differentiated to intimal smooth muscle cells but they did not fuse with intimal cells. Delivery of CD34+ cells contributed to a 1.4 fold inhibition of intimal hyperplasia.

Conclusion: Bone marrow-derived endothelial cells differentiated but not fused with vascular smooth muscle cells at the early stages of intimal formation and inhibited intimal hyperplasia.

RAPID FIRE 3 – CHRONIC HEART FAILURE MANAGEMENT

Monday 23 May 2016 08:30–10:00

Location: Agora

1236

Morbidity, mortality, and cost impact of stage b and stage c heart failure: comparative analysis to underline the clinical and economic need for heart failure prevention strategy.SI James¹; DF Waterhouse¹; C Kenny¹; MD Wilkinson¹; T Murphy¹; E O'connell²; J Gallagher²; C Watson³; M Ledwidge²; K McDonald¹¹St Vincent's University Hospital, Cardiology, Dublin, Ireland; ²Heart Beat Trust, Dublin, Ireland; ³Conway Institute, Dublin, Ireland

Introduction: Heart failure (HF) has hit the epidemic proportion and is incurring significant cost to the health care system. Given the major morbidity, mortality and economic burden of this condition, a prevention strategy needs careful assessment to determine its role in the future health care policy. The STOP-HF Programme has underlined the clinical and cost effectiveness of a biomarker driven risk stratification and intervention strategy in those at risk for HF. Supportive data to establish the widespread application of this prevention strategy would come from a comparative analysis of patients at risk for HF and those of a new community diagnosis of HF followed in a disease management programme. To assess the importance of HF prevention, we report the morbidity, mortality and economic costs of an at-risk cohort compared to established community HF.

Method: 1517 patients attending the HF prevention unit and rapid access clinic for possible new onset HF from 2002 up to end of 2012 were selected for this analysis. The demography, medical diagnoses, biomarkers, echocardiographic parameters and medications were recorded. Defined by Doppler echocardiography, patients were categorised to stage A, stage B, and stage C HF. Follow-up time for events was until the end of 2014. Hospitalisations were collected, confirmed by HIPE records and categorised as HF event, non-HF cardiovascular (non-HF CV) event, non-cardiovascular (non-CV) event and death. In the pre-specified cost analysis, direct costs associated with emergency hospitalisations and total costs were analysed using a case-mix approach from the perspective of the healthcare provider. Result: 1071 patients were in stage A, 146 in stage B, and 300 in stage C (184 C-PEF and 116 C-REF). Mean follow-up years were 3.3 years. BNP increased through the stages at 18.7pg/mL (stage A), 62.2pg/mL (stage B), 232pg/mL (stage C), 183pg/mL (stage C-PEF) and 382pg/mL (stage C-REF). The HF events rate is 8.1% in stage C. The unadjusted annual death rate increased across the spectrum (0.6% in stage A, 2.1% in stage B and 11% in stage C). The non-HF CV events were significantly higher in stage C (7%). The non-CV events were 42% in stage C, a significant 3-fold increase compared to stage B (12.4%). The non-CV events were similar both in stages C-REF and C-PEF (41.9% vs 42%). The HF, non-HF CV and death events were higher in the stage C-REF group. In the costing sub-study, emergency hospitalisation costs per patient per annum were €439 (stage A), €1114 (stage B) and €8803 (stage C). The total costs per patient per annum were €903 (stage A), €1748 (stage B) and €9763 (stage C).

Conclusion: The clinical and costs impact of HF care escalate significantly with the development of the symptomatic phase of HF syndrome. These data along with the positive clinical and cost effectiveness analysis of the STOP-HF Programme data underline the importance for focused HF prevention strategies.

1237

Effects of 5 years treatment with nebivolol, carvedilol and bisoprolol in heart failure patientsG Marazzi¹; G Campolongo¹; F Pelliccia²; L Cacciotti³; M Sbarigia¹; M Capaldi¹; G Rosano¹¹IRCCS San Raffaele Pisana Hospital, Rome, Italy; ²Sapienza University of Rome, Department of Cardiovascular Diseases, Rome, Italy; ³Madre Giuseppina Vannini Hospital, Rome, Italy

Background: Beta blockers improve left ventricular (LV) systolic function and prognosis in patients with chronic heart failure (CHF). Aim. This study compared the effects of long term treatment with nebivolol versus carvedilol or bisoprolol on

LV ejection fraction (EF) in CHF patients. Secondary end points were to assess the effect of the 3 beta blockers on exercise capacity and clinical outcome.

Methods and Result: A total of 150 CHF patients with EF <40% and NYHA class I, II or III were randomly assigned to receive nebivolol or carvedilol either bisoprolol for 5 years. At baseline and at the end of treatment all patients underwent clinical evaluation, echocardiography and 6 minutes walking test. The target doses were 5 mg/d for nebivolol, 50 mg/d for carvedilol and 10 mg/d for bisoprolol. At the baseline there were not significant different between 3 groups for NYHA class, EF and walking test distance. Compared with baseline values, EF increased by a similar extent in the carvedilol (C), nebivolol (N) and bisoprolol (B) groups (C from 33,1% to 37,9%, $p < 0,001$; N from 34,6% to 38,5%, $p < 0,001$; B from 34,3% to 38,2%, $p < 0,001$). NYHA class decreased significantly in all groups and the 6 minutes walking distance increased (C from 415 m to 478 m, $p < 0,001$; N from 431 m to 490 m, $p < 0,001$; B from 422 m to 483 m, $p < 0,001$). During 60 months 16 carvedilol patients (32%), 14 nebivolol patients (28%) and 16 bisoprolol patients had cardiac event including 5,4 and 6 deaths, respectively.

Conclusion: In very long term, nebivolol, carvedilol and bisoprolol appear to be similar effective in the treatment of patients with CHF.

1238

MTP-131, a cardiolipin-targeting peptide, improves mitochondrial activity in the failing human heartB Brian Stauffer¹; G Sparagna¹; S Chau¹; J Rodegheri-Brito¹; A Ambardekar¹; A Korst¹; S Miyamoto²; C Sucharov¹; K Chatfield²¹University of Colorado, Medicine/Cardiology, Aurora, United States of America;²University of Colorado, Pediatrics/Cardiology, Aurora, United States of America

Background: Mitochondrial dysfunction contributes to myocellular abnormalities in the failing human heart. We have previously shown significant abnormalities in cardiolipin content and electron transport chain complexes in failing human heart. MTP-131 (elamipretide) is a mitochondria-targeting peptide currently being investigated in several Phase 2 clinical trials for heart failure. In animal models of heart disease, MTP-131 improved cardiac and mitochondrial function through a mechanism involving stabilization of cardiolipin-dependent respiration.

Purpose: To determine whether MTP-131 treatment of the human failing heart improves mitochondrial function, assessed at different sites along the respiratory chain.

Methods: Ventricular tissue was rapidly harvested at the time of cardiac transplantation for end-stage heart failure secondary to idiopathic dilated cardiomyopathy (F), or from age-matched donor hearts (NF) not implanted for technical reasons. Tissue was either immediately used for respirometry or rapidly frozen at -80°C. In fresh tissue, mitochondrial Complex I- and II-dependent respiration was determined using high-resolution respirometry. Total Complex IV activity was determined using spectrophotometric assays. From frozen samples, Complex IV in-gel activity assays were performed in Blue Native (BN)-PAGE to determine activity attributed to within the supercomplex (SCIV) or from uncomplexed, free Complex IV (FCIV).

Results: State 3 respiration (in pmol/(s*mg)) was lower in F than NF when mitochondria were respiring via Complex I- or II-dependent substrates (glutamate/malate: 40 ± 11 vs 75 ± 6 ; succinate: 64 ± 16 vs 108 ± 11). MTP-131 treatment improved state 3 respiration in F mitochondria at both complexes I and II (glutamate/malate: 74 ± 6 ; succinate: 125 ± 13), but did not alter respiration in NF mitochondria under any substrate conditions. In BN-PAGE studies, SCIV activity was 30% lower ($P < 0.05$) in F compared to NF-samples, but unchanged in the FCIV fraction. MTP-131 treatment increased SCIV activity ($P < 0.05$) but did not change FCIV activity, suggesting that MTP-131-mediated improvements in respiration occur in mitochondrial supercomplexes. MTP-131 treatment of freshly-isolated F mitochondria increased Complex IV activity by 50% ($P < 0.01$).

Conclusion: MTP-131 treatment improves mitochondrial function at the level of the individual complex, supercomplex and intact mitochondria in the failing human

heart. These findings suggest that stabilizing cardioliipin-dependent respiratory complexes represents a novel treatment for improving mitochondrial function in heart failure.

1239

Is the cohort of paradigm-hf representative of the real world population of patients with systolic heart failure?

G M Gustavo Miguel Rocha Rodrigues¹; PF Freitas¹; CA Aguiar¹; CS Strong¹; DM Matos¹; AT Tralhao¹; AV Ventosa¹; MM Mendes¹

¹Hospital Santa Cruz, Cardiology, Lisboa, Portugal

Background: Neuro-hormonal blockade is the main-stem of the management of systolic heart failure (HF). In a recent trial, a combination of valsartan+sacubitril showed a greater benefit than enalapril. The relevance of such findings may be hampered by a strict protocol. Aim: To evaluate the representativeness of this trial in a real world population of patients with systolic HF.

Methods: We reviewed the records of 196 patients of a heart failure outpatient clinic between January 2013 and December 2014. We excluded 44 patients with preserved ejection fraction (EF), and applied the inclusion and exclusion criteria of the PARADIGM-HF study to the remaining population.

Results: From 152 patients with systolic heart failure, 106 patients (69.7%) lacked ≥ 1 inclusion criteria and 37 (24.3%) have ≥ 1 exclusion criteria. In the patients with an EF $\leq 35\%$ (n=88), 43 patients (48.9%) lacked ≥ 1 inclusion criteria and 27 patients (30%) had ≥ 1 exclusion criteria. Combining inclusion and exclusion criteria, 26.9% (n=41) of patients with systolic HF and 39% (n=34) of patients with an EF $\leq 35\%$ were eligible for the PARADIGM-HF trial (Table1). Conclusion: One of every four patients with systolic HF would be considered for treatment with the novel angiotensin receptor-neprilysin inhibitor.

Table1. Inclusion and exclusion criteria

Inclusion criteria, n(%) missing	Systolic HF (n = 152)	EF $\leq 35\%$ (n = 88)
NYHA > 1	30 (19,7%)	10 (11,3%)
EF $\leq 35\%$	64 (42,1 %)	0
NT-proBNP ≥ 600 pg/ml	42 (27,6%)	18 (20,4%)
ACEI/ARB equivalent to enalapril 20mg	47 (30,9%)	25 (28,4%)
β -blocker	4 (2,6%)	1 (1,1%)
Exclusion criteria, n(%)		
Hypotension	15 (8,2%)	9 (10,2%)
Systolic blood pressure < 95 mmHg	6 (3,9%)	6 (6,8%)
eGFR < 30 mL/min/1.73m ²	11 (7,2%)	9 (10,2%)
K ⁺ > 5,4 mmol/L	7 (4,6%)	4 (4,5%)
Severe pulmonary, GI or liver disease	7 (4,6%)	3 (3,4%)
Severe valvular disease	3 (1,3%)	1 (1,1%)
Life expectancy < 5 years	12 (7,9%)	8 (9,1%)

Table1. Values are expressed in percentages (%); HF - heart failure; EF - ejection fraction; NYHA (New York Heart Association); ACEI - Angiotensin converting enzyme inhibitor; ARB - angiotensin receptor blocker; eGFR - estimated glomerular filtration rate;

Evidence-based medications in multi-ethnic Asian patients with heart failure are associated with better outcomes in spite of lower doses

KTH Teng¹; WT Wan Ting Tay¹; SP Chan²; PSD Yeo D Sim³; FR Jaufeerally⁴; GKT Leong H-Y Ong⁵; LH Ling⁶; AM Richards²; RN Doughty⁷; CSP Lam⁸

¹National Heart Centre Singapore, Singapore, Singapore; ²National University of Singapore, Cardiovascular Research Institute; Yong Loo Lin School of Medicine, Singapore, Singapore; ³Tan Tock Seng Hospital, Department of Cardiology, National Heart Centre Singapore, Singapore, Singapore; ⁴Singapore General Hospital, Department of Internal Medicine, Singapore, Singapore; ⁵Changi General Hospital, Department of Cardiology, Khoo Teck Puat Hospital, Department of Cardiology, Singapore, Singapore; ⁶National University Health System, Cardiac Department, Singapore, Singapore; ⁷The University of Auckland, Cardiovascular Research Group, Auckland, New Zealand; ⁸National Heart Centre Singapore, Cardiovascular Research Institute, NUS, Singapore, Singapore

Background: Evidence-based medical therapy (EBT) is the cornerstone of heart failure (HF) management. However data are scarce regarding the effect of EBT and their doses on outcomes in Asian patients with HF and reduced or preserved ejection fraction (HFrEF or HFpEF). Aims: To determine the effect of EBT on outcomes in Asian patients with HF

Methods: A prospective nationwide cohort (n=1087, 62 \pm 12 years old, 75.5% men, 61% Chinese, 27% Malay, 11% Indian) of HF was followed for 1 year for all-cause mortality or HF hospitalizations as a composite outcome.

Results: In 706 HFrEF (EF<40%), baseline EBT included ACEI/ARB (74%), β -blockers (90%) and aldosterone antagonists (56%). Corresponding proportions in 345 HFpEF (EF \geq 40%) were 63%, 83% and 21% (all p<0.05 vs HFrEF). Diuretic use was high in both HFrEF (92%) and HFpEF (84%). Median EBT doses (over 1-year) were lower than guideline recommended target doses e.g. enalapril 10mg mg/day, bisoprolol 2.5 mg/day, carvedilol 12.5 mg/day, spironolactone 25 mg/day. At 1-year follow-up, there were 360 composite events (111 deaths). There was continued use of ACEI/ARBs, β -blockers and aldosterone antagonists at 1 year in 60%, 83% and 44% of surviving HFrEF and 51%, 75% and 12% in surviving HFpEF. Baseline use of β -blockers was related to continued use at 1 year (p<0.001) and associated with reduced adjusted hazards of the composite outcome [HR=0.70 (95% CI 0.52-0.94) overall; HR=0.65 (95% CI 0.45-0.94) in HFrEF]. There was a protective effect (but not statistically significant) in HFpEF. Baseline use of ACEI/ARBs was related to continued use at 1 year (p<0.001) and associated with reduced hazards of the composite outcome in HFrEF [HR=0.73 (0.55-0.96)] but not the overall cohort or HFpEF alone. Aldosterone antagonists and diuretic use were not associated with reduced risk of the composite outcome. Dose of EBT was not related to outcomes. There was no interaction by ethnicity.

Conclusions: In Asian patients with HFrEF, use of ACEI/ARBs and β -blockers at baseline presentation is related to continued use during follow up and better outcomes, even at lower than guideline recommended-targeted doses.

M Kaspar¹; G Gueder¹; S Brenner¹; B Kraus¹; CE Angermann¹; G Ertl¹;

F Puppe²

¹University of Würzburg, Würzburg, Germany; ²Chair Informatics VI, Würzburg, Germany

Background: Heart failure (HF) is the leading cause of hospitalization and a major cause of death in Germany. Cardiac societies, health policy makers and funding agencies strive to design and implement appropriate means to improve the quality of HF care, but quality control of such efforts has rarely been attempted. The University Hospital of Würzburg has a long research track in HF management. E.g., in 2003, a large multicentre intervention trial was started, revealing major positive effects of a dedicated HF management program executed by dedicated HF nurses (Circ Heart Fail. 2012;5:25-35). In Nov 2010, the Comprehensive Heart Failure Center (CHFC), sponsored by the Federal Ministry for Education and Research, was founded as an Integrated Center for Research and Treatment serving the aim to improve "Prevention of Heart Failure and its Complications". Since then, the CHFC has implemented several tools which allow to assess the quality of intra- and extra-hospital HF care and to analyse in detail clinical outcomes over time.

Methods: A dedicated data warehouse system was installed allowing reliable estimation of the true number of HF patients and their characteristics treated at the Center. The data warehouse exploits multiple information sources from standard clinical reports including the International Classification of Diseases (ICD) coded discharge diagnoses. We here analyse subjects with either of the 2 principal HF diagnoses I50 ("heart failure") and I11.0 ("hypertensive heart disease with heart failure") from years 2003 to 2014. Each subject was counted only once per year regardless of rehospitalization frequency.

Results: We observed a pronounced increase in the absolute number of HF in- and out-patients attending the Medical Department of the University Hospital in the reported period for both principal HF diagnoses (Figure); in 2003: n=52 (I11.0), and n=699 (I50); in 2014: n=780 (I11.0), and n=2508 (I50). The proportion of women remained fairly stable over time at about 40% (45-50% for I11.0, and about 40% for I50, respectively). The proportion of patients aged > 65 years continuously dropped from about 82% in 2003 to 74% in 2014, while the proportion of patients aged > 79 years remained fairly constant about 30% over time. In the same period, median hospital-length of stay in HF patients decreased from 10 days to 7 days, and in-house mortality decreased from 15% in 2003 to 6% in 2012 and 5% in 2014 (Figure).

Conclusions: The deliberate implementation of research and care structures was paralleled by major changes in patient populations treated at our tertiary care center. Improved awareness facilitating more adequate diagnostic coding is likely to affect mortality percentages (in particular in years 2013/2014). Improved measures for intra-hospital care and discharge management seem to help diagnosing HF earlier, attract more patients, and are associated with improved quality indicators.

Secular trends in heart failure patients

1242

Statins attenuate but not eliminate the reverse epidemiology of total serum cholesterol in patients with non-ischemic chronic heart failureH Hanna Froehlich¹; T Taeger¹; K Goode²; M Grundtvig³; T Hole⁴; JFG Cleland²; HA Katus⁵; S Agewall⁵; AL Clark²; L Frankenstein¹¹University Hospital of Heidelberg, Heidelberg, Germany; ²Castle Hill Hospital, Hull, United Kingdom; ³Inlandet Hospital, Lillehammer, Norway; ⁴Norwegian University of Science and Technology, Trondheim, Norway; ⁵Oslo University Hospital, Oslo, Norway**Background:** As opposed to general cohorts, in patients with heart failure (HF) increasing levels of total serum cholesterol are associated with improved survival – termed reverse epidemiology. The potentially confounding impact of statin treatment thereon is unclear.**Purpose:** To investigate the impact of statin treatment on the reverse epidemiology of cholesterol in patients with HF.**Methods:** 2,992 consecutive patients with non-ischemic systolic HF were studied from three European HF registries. 1,736 patients were individually double-matched on both cholesterol levels and the individual propensity scores for statin treatment. All-cause mortality was analysed as a function of baseline cholesterol and statin use in both the general and the matched sample.**Results:** 1,209 patients (40.4%) received a statin. During a follow-up of 13,740 patient-years, 360 statin users (29.8%) and 573 (32.1%) statin non-users died. When grouped according to cholesterol levels as low (≤ 3.6 mmol/L), moderate (3.7–4.9 mmol/L), high (5.0–6.2 mmol/L), and very high (≥ 6.3 mmol/L), we found improved survival with very high as compared with low cholesterol levels. This association was present in statin users and non-users in both the general and matched sample ($p < 0.05$ for each group comparison). The negative association of TC and mortality persisted when cholesterol was treated as a continuous variable (HR 0.83, 95%CI 0.77–0.90, $p < 0.001$ for matched patients), but it was less pronounced in statin users than in non-users (HR 0.85, 95% CI 0.77–0.95, $p = 0.004$ and HR 0.81, 95%CI 0.73–0.90, $p < 0.01$ for matched statin users and non-users, respectively).**Conclusion:** Statins attenuate but not eliminate the reverse epidemiology of total serum cholesterol in patients with non-ischemic HF.

Heart failure therapy in patients over 90 years diagnosed with left ventricular systolic dysfunctionJ A Palfy¹; M Cortes Garcia¹; ML Martin Mariscal¹; A Romero Daza¹; M Lopez Castillo¹; A Garcia Ropero¹; JA Franco Pelaez¹; J Farre Muncharaz¹¹Foundation Jimenez Diaz, Cardiology, Madrid, Spain**Introduction:** Heart failure due to left ventricular systolic dysfunction (LVSD) is a very common condition in the elderly. Medical therapy increases survival, but very little data is available regarding its utility and efficacy in nonagenarian patients.**Methods:** Between January 2008 and December 2013 we prospectively enrolled all patients diagnosed with LVSD (ejection fraction $< 35\%$), and aged over 90 years. Clinical characteristics, electrocardiographic and echocardiographic results were collected, and a prospective follow-up was carried out via medical record review or telephone interviews.**Results:** Out of the 60 patients who were enrolled, 51.7 % of them were male, and the mean age was 92.6 (± 6.1) years. 85 % had high blood pressure, 38.3 % chronic kidney disease, 20 % cerebrovascular disease, 6.7 % chronic obstructive pulmonary disease, and 18.3 % were diabetic. 73.3 % were independent for their daily activities and only 5 % had a moderate-to-severe cognitive impairment. The mean left ventricular ejection fraction (LVEF) was 27.2 % (± 6.1) but etiologic study of the LVSD was not carried out in almost the half of the study population (46.7%). Ischemic origin was identified in 36.7 % of the cases, nevertheless 68.1 % of this subgroup did not undergo coronary angiography. NYHA class I or II was present in 63.3% of the patients. Regarding the medical therapy, 46.7% were on betablockers, and the most common reason of not taking it, was bradycardia, but in more than the half of the cases the reason remained unknown. 70 % of the study population took either ACE inhibitor or ARAll blocker and 25 % was on aldosterone antagonist. Until the end of the mean follow-up of 14.3 \pm 11.9 months, 83.3 % of the patients died. The multivariate survival analysis with Cox regression showed that betablocker therapy was the only protective predictor (OR 0.23, IC95% 0.08–0.64) related to mortality.**Conclusions:** According to our results, there is an underuse of the medical treatment in nonagenarian patients with LVSD. This could be related with a relatively high comorbidity rate or a probably less rigorous application of the current clinical guidelines in this study population. The single independent variable related to a higher survival was beta blocker therapy in nonagenarians.

1244

Liberal vs. restrictive oral fluid intake in patients with heart failure. Results of a metaanalysis that addresses the respective associations with rehospitalizations or with all-cause mortalityR De Vecchis¹; C Baldi²; S Cantatrione¹; L Palmisani³¹Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy;²Heart Department, Interventional Cardiology, A.O.U. "San Giovanni di Dio e Ruggi D'Aragona", Salerno, Italy; ³Hospital Directorate, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy**Background:** The guidelines of the Scientific Societies of Cardiology suggest limiting fluid intake in the diet as one of the non-pharmacological measures for the management of chronic heart failure. However, many patients with heart failure may suffer from severe thirst, even irrespective of a possible restricted fluid intake, and this has received relatively little attention in clinical studies. Therefore, we decided to perform a meta-analysis of studies that evaluated the efficacy and safety of the strategy of reducing the intake of water and other beverages in the diet of patients with chronic heart failure.**Methods:** The studies included had to have the characteristics of randomized controlled trials that compared patients with heart failure undergoing limitation in fluid consumption with patients who had free access to water or other beverages. Primary outcomes of interest were heart failure hospitalizations and all-cause mortality. The effect size was expressed as pooled odds ratio (OR) in the case of binary variables, and as weighted mean difference (WMD) in the case of continuous variables.**Results:** Six studies were incorporated into the meta-analysis. Significant heterogeneity was detected for the majority of investigated outcomes. Patients subjected to restricted fluid intake compared with patients admitted to free intake of beverages showed a similar rehospitalization rate (5 studies, pooled OR = 1.52; 95%CI: 0.67 to 3.43; $p = 0.32$) and a similar mortality rate (5 studies, pooled OR = 1.55; 95% CI: 0.87 to 2.75; $p = 0.14$). Likewise, there were no differences in regards to patients' sense of thirst (4 studies, WMD = -0.7; 95% CI: -2.58 to 1.17; $p = 0.46$), the duration of intravenous diuretic treatment (2 studies, WMD = 0.17 days; 95% CI: -1.26 to 1.6 days; $p = 0.81$), the serum creatinine levels (5 studies, WMD = 0.05 mg/dl; 95% CI: -0.16 to 0.26 mg/dl; $p = 0.12$), and serum sodium levels (5 studies, WMD = -0.86 mmol/L; 95% CI: -2.92 to 1.2 mmol/L; $p = 0.41$). By contrast, serum BNP levels were significantly higher in the group with free water intake (4 studies, WMD = 223.76 pg/ml; 95% CI: 158.8 to 288.72 pg/ml; $p < 0.001$).**Conclusions:** In patients with heart failure, liberal fluid consumption does not seem to exert an unfavorable impact on heart failure rehospitalizations or all-cause mortality. However, larger randomized controlled trials are recommended in the future in

order to achieve definitive confirmation of the present findings, which substantially disavow any useful role of fluid intake restriction as a non-pharmacological measure to be adopted in heart failure management.

1245

The effect of a multidisciplinary outpatient heart failure rehabilitation program on the rate of rehospitalization and cost of care in a tertiary Australian center.

J Hanna¹; M Saba²; R Costa²; S Niranjani¹; R Jayasinghe¹

¹Gold Coast University Hospital, Department of Cardiology, Gold Coast, Australia;

²Robina Heart Failure Rehabilitation Service, Gold Coast, Australia

Background: Decompensated congestive cardiac failure is one of the most common causes of hospital admissions in the elderly population. It is associated with a significant financial burden on healthcare budgets worldwide. Objective: To determine the effectiveness of the existing multidisciplinary outpatient heart failure rehabilitation program at decreasing the rate of readmissions.

Methods: We included 155 heart failure patients who were referred to our heart failure rehabilitation program between November 2009 and December 2013. 41 patients were females. We conducted a retrospective analysis comparing rates of all-cause and heart failure related admissions in the same cohort before and after participation in the outpatient multidisciplinary heart failure rehabilitation program. Then we calculated the difference in healthcare spending utilizing the hospital admission coding system used for service reimbursement in the state public health system.

Results: Of 155 patients included, 110 patients had, at least, one hospital admission due to any cause before participation compared to 40 after enrollment (OR 0.1423, CI 0.0863 – 0.2345, $p < 0.0001$). The all-cause admissions and days spent in hospital were significantly lower after enrollment (186 vs. 53) and (715 vs. 120) respectively. Similarly, admissions due to heart failure were lower after participation. 46 patients were admitted due to decompensated heart failure before participating in the program while only 5 needed inpatient treatment after (OR 0.079, CI 0.030 – 0.205, $p < 0.0001$). There were 53 admissions with heart failure as the primary diagnosis before participation and only seven after. The calculated cost of all-cause admissions before enrollment was 1.345897.46 \$ compared to 469739.46\$ after enrollment.

Conclusion: Participating in structured multidisciplinary heart failure rehabilitation program was associated with significant reduction in all-cause hospital admissions, heart failure related admissions, and healthcare cost.

First-in-man trial of Beta-3-adrenoceptor agonist in chronic heart failure - effect on diastolic function

A Anna Axelsson¹; J Hartvig Thomsen¹; R Hasselbalch²; H Soeholm¹; M Soergaard¹; KF Kofoed¹; N Valeur³; F Gustafsson¹; HH Rasmussen⁴; H Bundgaard¹

¹Rigshospitalet - Copenhagen University Hospital, Heart Centre, Department of Cardiology, Copenhagen, Denmark; ²Herlev Hospital - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark; ³Bispebjerg University Hospital, Department of Cardiology, Copenhagen, Denmark; ⁴Royal North Shore Hospital, Department of Cardiology, Sydney, Australia

Introduction: Cardiac myocyte Na⁺ overload contributes to systolic and diastolic dysfunction in heart failure (HF). β_3 -adrenoceptor (β_3 -AR) stimulation activates the cardiomyocyte Na⁺-K⁺-pump, and has been shown to increase contractility in animal models of HF. In addition, since Ca²⁺-efflux via the Na⁺-Ca²⁺-exchanger and thus myocardial relaxation depends on the transmembrane Na⁺-gradient, we hypothesized that β_3 -AR agonist treatment may improve diastolic function.

Methods: In a double-blind trial, we randomly assigned 70 patients with HF (NYHA class II-III) and ejection fraction (LVEF) $< 40\%$ by 2D-echocardiography to receive the β_3 -AR-agonist, Mirabegron (target dose 300 mg daily) or placebo for 6 months, on top of recommended HF therapy. Patients were assessed with 2D-echocardiography and CT at baseline and follow-up.

Results: Baseline and follow-up echocardiographic data were available in 59 patients (59 \pm 12 yrs, 88 % male, 46% ischemic cardiomyopathy). LVEF at baseline was 34 \pm 8% and the majority of patients (93%) were in NYHA class II. As for the LVEF, no difference in change of the grade of diastolic dysfunction based on e' lateral and deceleration time was seen between the treatment arms at follow-up (figure). Neither was there any difference between the groups in change from baseline to follow-up of any single measure of diastolic function (e' lateral for Mirabegron 6.9 \pm 2.4 to 7.5 \pm 2.5 cm/s and for placebo 6.7 \pm 2.0 to 6.5 \pm 2.8 cm/s, mean difference 0.9 cm/s [95% CI -0.3 to 2.0 cm/s], $p = 0.14$, E/e' ratio for Mirabegron 11.2 \pm 5.5 to 10.5 \pm 6.7 and for placebo 11.8 \pm 5.8 to 11.4 \pm 4.8, mean difference

0.8 [95% CI -1.6 to 3.2], $p = 0.51$ or left atrial volume by CT for Mirabegron 68 \pm 15 to 68 \pm 18 and for placebo 60 \pm 24 to 58 \pm 23, mean difference 3 mL/m² [95% CI -4 to 9 mL/m²], $p = 0.40$).

Conclusion: In this first-in-man, double-blind trial of β_3 -AR stimulation in patients with chronic HF and moderately reduced LVEF in addition to recommended heart failure therapy, we did not identify an improvement in diastolic function with Mirabegron compared to placebo. Additional studies are needed to assess the effect in patients with severely reduced LVEF.

Figure. Diastolic dysfunction at baseline and follow-up.

Normal diastolic function: e' lat > 10 cm/s and deceleration time 140-240

Grade I dysfunction: e' lat < 10 cm/s and deceleration time < 140

Grade II dysfunction: e' lat < 10 cm/s and deceleration time 140-240

Grade III dysfunction: e' lat < 10 cm/s and deceleration time > 240

Diastolic function

Survival in HFpEF vs HFrEF patients after beta-blocker titration: New insights from the CIBIS-ELD trial

HD Duengen¹; G Gelbrich²; S Radenovic¹; E Elvis Tahirovic¹; R Wachter³;

J Veskov¹; G Loncar⁴; S Apostolovic⁵; B Pieske¹; F Edelmann¹

¹Charité - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²University of Wuerzburg, Institute of Clinical Epidemiology and Biometry, Wuerzburg, Germany;

³University of Gottingen, Department of Cardiology and Pneumology, Gottingen, Germany; ⁴Health Center "Zvezdara", Department of Cardiology, Belgrade, Serbia;

⁵Clinical Center of Nis, Department of Cardiology, Nis, Serbia

Background: Heart failure (HF) is a leading cause of mortality worldwide. Half of HF patients have preserved ejection fraction (HFpEF), and the other half reduced (HFrEF). Current guidelines provide no disease-specific drug regimen for HFpEF patients, but beta-blockers (BB) are considered excellent candidates.

Purpose: To compare the effects of BB titration on all-cause mortality in HFpEF vs HFrEF.

Methods: In the CIBIS-ELD trial, elderly HF patients were randomized to bisoprolol or carvedilol. BB dose was doubled every two weeks up to the target or maximum tolerated dose within 12 weeks. The long-term follow-up was performed after 4 years. This pre-defined secondary analysis compared HFpEF and HFrEF patients with regards to all-cause mortality during the 4 year follow-up period, according to heart rate (HR) achieved at the end of 12 weeks.

Results: During the 4 year follow-up, 134 patients died and data from 728 patients were available for this analysis (246 HFpEF and 464 HFrEF). Long-term survival was better in HFpEF patients. HFrEF patients with HR < 64 bpm had significantly better survival compared to HR > 64 bpm (hazard ratio = 0.58, 95% confidence interval: 0.39-0.85; $p = 0.006$). Per contra, HFpEF patients with HR < 64 bpm did not have significantly better survival compared to those with HR > 64 bpm (hazard ratio = 0.60, 95% confidence interval: 0.28-1.26; $p = 0.17$). Yet, a trend towards lower all-cause mortality in HR < 64 bpm was observed (Figure).

Conclusions: HFrEF patients with lower HR had significantly better long-term survival. Due to certain limitations of our trial, results regarding HFpEF are still unclear. Therefore, a larger trial of a longer duration is needed to better understand the effects of BB titration on mortality in HFpEF.

Hazard ratios for all-cause mortality

1249

Reduction in early recurrent hospitalisations after discharge for worsening heart failure with ivabradine: a post-hoc analysis of SHIFT

Servier, France

M Michel Komajda¹; L Tavazzi²; K Swedberg³; M Boehm⁴; JS Borer⁵; I Ford⁶
¹AP-HP - Hospital Pitié-Salpêtrière, University Pierre & Marie Curie Paris VI, Dept of Cardiology, Paris, France; ²Maria Cecilia Hospital-GVM Care and Research, Ettore Sansavini Health Science Foundation, Cotignola, Italy; ³Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; ⁴Universitätsklinikum des Saarlandes, Klinik für Innere Medizin III, Homburg/Saar, Germany; ⁵Howard Gilman and Schiavone Institutes, State University of New York Downstate Medical Center, New York, United States of America; ⁶Robertson Centre for Biostatistics, University of Glasgow, Glasgow, United Kingdom

Background and Purpose: Despite use of recommended therapy, readmission rates of patients hospitalised for heart failure (HF) 1 and 3 months after discharge approach 15% and 30%, respectively. This early postdischarge period has been termed the “vulnerable phase”, and represents a major burden for patients, doctors, and society. Therefore an urgent need exists for novel approaches to improve early postdischarge outcomes. Data from the SHIFT study showed that ivabradine reduces the burden of hospitalisations for worsening HF, with a significant reduction of 25 % of total (first and recurrent) HF hospitalisations versus placebo) during a median follow-up of 22.9 months. Here, we examined the effect of ivabradine on the vulnerable phase after HF hospitalisation, by analysing the incidence of early readmission rate up to 90 days after discharge.

Methods and Results: In SHIFT 6505 patients with stable systolic chronic HF, in sinus rhythm, heart rate ≥ 70 bpm, and treated with guideline-recommended therapy were randomized to placebo or ivabradine (2.5 to 7.5 mg bid). The incident rate ratio (IRR) and associated confidence intervals for all hospitalization events in the ivabradine group vs. the placebo group were estimated from a Poisson regression (with correction of overdispersion), and adjusted for beta-blockers or pre-specified baseline prognostic factors. 1186 patients experienced at least one hospitalisation for worsening HF during the study. Within 3 months after the first hospitalization for worsening HF, 131 patients (25%) in ivabradine group vs 203 patients (30%) in placebo group had at least one recurrent hospitalization for any cause. The total number of readmissions was significantly reduced in the ivabradine group versus placebo from the first month.

Conclusions: In patients hospitalised for worsening HF in the SHIFT study, ivabradine reduced the number of recurrent hospitalisations during the vulnerable phase from the first month. This suggests that continuation or early introduction of ivabradine postdischarge will improve early outcomes in HF patients.

Intramyocardial injections of the continuous erythropoietin receptor activator (CERA) in patients with chronic ischemic cardiomyopathy. Results of the randomized study

D Denis Losik¹; A Romanov¹; V Shabanov¹; E Pokushalov¹; O Poveshenko¹; S Artemenko¹; A Strelnikov¹; MW Bergmann²

¹State Research Institute of Circulation Pathology, Novosibirsk, Russian Federation; ²Cardiologicum Hamburg, Hamburg, Germany

Background: Recent stem cell trials have uniformly shown that paracrine mechanisms are responsible for effects on LV function and angiogenesis rather than integration of transplanted cells into muscular tissue or capillaries. We previously found monthly subcutaneous injections of low-dose erythropoietin to improve LV remodeling following PCI. Here we tested the hypothesis, that intramyocardial-guided delivery of C.E.R.A., a long-acting erythropoietin analogue, attenuates LV remodeling in patients with ischemic cardiomyopathy.

Methods: A total of 59 patients with symptomatic heart failure due to ischemic heart disease and left ventricle ejection fraction of less than 45% were randomly assigned to receive either monthly subcutaneous administration of 30U of C.E.R.A. over 6 months (n=29) or intramyocardial application of one 180 U dose (n=30) of C.E.R.A. guided by the NOGA system to ischemic regions defined by unipolar voltage between 6 and 12 mV. Outcome variables were measured at baseline and at 6 months follow up. Primary outcome measure was individual change in ejection fraction as measured by echocardiography. Secondary outcomes included NYHA functional class, 6 minute walk test, end diastolic diameter, end diastolic diameter, left ventricular wall motion, heart failure hospitalization. Patients were followed for 6 month to access primary and secondary outcomes, Results None of the patients developed periprocedural complications following C.E.R.A. injections. Intramyocardial-guided delivery of C.E.R.A. significantly improved left ventricle ejection fraction compared with subcutaneous injections (intra-individual $\Delta EF + 4.2 \pm 1.2\%$ vs $+ 0.7 \pm 0.9\%$, respectively, $p = 0.042$). Intramyocardial delivery resulted in a more pronounced improvement of NYHA class compared to subcutaneous injections ($-0.6 \pm 0.1\%$ vs $-0.2 \pm 0.1\%$, respectively, $p = 0.014$). No significant differences regarding 6 minute walk test, end diastolic diameter, end diastolic diameter and left ventricular wall motion were observed. 4 (13%) patients from intramyocardial C.E.R.A. group and 6 (21%) patients from subcutaneous group required hospitalization due to worsening of heart failure ($p = 0.5$).

Conclusions: Intramyocardial delivery of C.E.R.A. is safe and has positive impact on left ventricle ejection fraction and clinical status in patients with chronic ischemic cardiomyopathy. Extended follow up and larger patient numbers warrants further assessment of the C.E.R.A. effect in this category of patients.

Hemodynamic effects of Levosimendan in patients with reactive pulmonary hypertension

P Severino¹; M Pucci¹; A Fusto¹; A Cinque¹; A D'ambrosi¹; M Mancone¹; F Fedele¹

¹Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrology, Anesthesiology and Geriatric Sciences, Sapien, Rome, Italy

Purpose: Reactive pulmonary arterial hypertension (RPH) has a severe impact on survival of patients with acute decompensated heart failure (ADHF). The aim of our work is to study the hemodynamic effects of Levosimendan (L) in patients with ADHF and RPH.

Methods: 25 patients with ADHF and RPH were enrolled. At baseline and after 6, 12, 24 hours of L treatment we assessed: heart rate (HR); systolic and diastolic blood pressure (SBP,DBP); systolic, diastolic and mean pulmonary arterial pressure (sPAP,dPAP, mPAP); right atrial pressure (RAP); pulmonary wedge pressure (PWP); cardiac output (CO); cardiac index (CI); arterial oxygen saturation (SaO₂), mixed venous oxygen saturation (SvO₂), arterial-venous O₂ difference (ΔAVO_2); systemic vascular resistance (SVR); total, pre-capillary and post-capillary pulmonary vascular resistance (PVR). A p-value < 0.05 was considered significant.

Results: As shown in table 1, mPAP decreased at 6, 12, 24 hours ($p < 0.07$; $p < 0.06$; $p < 0.01$ respectively) compared to baseline. SVR had a significant decline ($p < 0.02$) after 24h L infusion. Total PVR were significantly reduced at 6h ($p < 0.04$), 12h ($p < 0.04$) and 24h ($p < 0.02$); pre-capillary PVR significantly decreased at 24h

60758. Table 1.

	Number of all-cause readmissions		Incident rate ratio (95% CI) p value	
	Ivabradine (n=514)	Placebo (n=672)	Adjusted for beta-blockers	Adjusted for prognostic factors

Long-term administration of ranolazine attenuates diastolic dysfunction and adverse myocardial remodeling in a model of heart failure with preserved ejection fractionA De Angelis¹; D Donato Cappetta¹; E Piegari¹; LP Ciuffreda¹; G Esposito¹; A Rivellino¹; R Russo¹; F Rossi¹; K Urbanek¹; L Berrino¹¹Second University of Naples, Department of Experimental Medicine - Section of Pharmacology, Naples, Italy

Background: Although significant advances have been made in understanding the characteristics of heart failure with preserved ejection fraction (HFpEF), a lot of information is still missing. At the same time none of the pharmacological treatments has shown to be effective in reducing mortality in patients with HFpEF, and most clinical trials have disappointing results. There is a general agreement that extracellular matrix changes, myocyte hypertrophy and altered intracellular calcium homeostasis contribute to a diastolic dysfunction by impaired relaxation and increased stiffness of the left ventricle. One of the potential mechanisms involved in HFpEF pathophysiology is an increase late Na⁺ current in cardiac myocytes. This has created the background for experimental and clinical studies that suggested the benefits of ranolazine (RAN) justifying the need of additional studies.

Purpose: To investigate the effects of chronic administration of RAN on experimental model of HFpEF.

Methods: Seven-weeks old Dahl salt-sensitive rats were fed a high salt diet (8% NaCl) for 5 weeks to induce hypertension. Afterwards, rats continued with a high salt diet and were administered either with vehicle or RAN (20 mg/kg/die, ip) for the following 8 weeks. Control rats were maintained on a low salt diet (0.3% NaCl).

Results: While systolic parameters were not altered, diastolic parameters were changed in high salt animals. Hemodynamic analysis showed a decreased dP/dt min, increased LVEDP, longer time constant and steeper slope of the end-diastolic pressure-volume relationship. Treatment with RAN attenuated these alterations and determined a reduction in mortality. Additionally, the magnitude of myocardial hypertrophy and activation of PI3K/Akt pathway were reduced. Alteration in diastolic compliance as a consequence of elevated myocardial stiffness was confirmed by an increase of collagen deposition and activation of pro-fibrotic TGF- β /SMAD3 signaling. These effects were counteracted by RAN. High salt rats had a decrease in SERCA2 and an increase in Na⁺/Ca²⁺ exchanger (NCX). Treatment with RAN reduced NCX expression and determined an increment of SERCA2. Moreover, the levels of nitrotyrosine and oxidized dihydroethidium were higher in high salt rats. RAN induced a decrement of oxidative stress, supporting the concept that reduction in ROS may mediate beneficial effects.

Conclusions: Our findings support the possibility that diastolic dysfunction can be attenuated by RAN, indicating its ability to affect active relaxation and passive diastolic compliance.

Raf kinase inhibitor protein modulates interstitial and replacement cardiac fibrosis

Deutsche Forschungsgemeinschaft, Bonn, Germany (KA 4024/3-1)

T Meier¹;A Kazakov¹; R Hall²; F Lammert²; M Bohm¹; U Laufs¹¹Saarland University, Department of Internal Medicine III, Cardiology, Homburg, Germany; ²Saarland University, Department of Internal Medicine II, Gastroenterology, Homburg, Germany

Background: Genetic determinants of cardiac fibrogenesis are not completely understood. Quantitative Trait Loci (QTL) analyses in BxD recombinant inbred mouse lines and subsequent characterization of the identified target was applied to identify novel regulators of myocardial fibrosis.

Methods and Results: For genome-wide QTL analysis, 26 BxD lines representing a genetically mosaic but homozygous for all loci genetic reference population were treated with CCl₄ (0.7 mg/kg, 12i.p. injections, 6 weeks) to induce cardiac and systemic fibrosis. The cardiac QTLs linked to collagen accumulation

were screened for potential candidates by expression QTL analyses, availing of transcriptomic data of CCl₄-treated BxDs (Affy 1.0 ST arrays). Cardiac fibrosis in the left ventricle (LV) of BxD lines assessed by picrosirius red staining correlated with LV RKIP mRNA ($R=0.4$; $p=0.05$). 10-week-old male C57/Bl6 wildtype (WT) and C57/Bl6-RKIP-deficient mice (RKIP^{-/-}) were subjected to transverse aortic constriction (TAC, 360 μ m) or sham-operation or treatment with CCl₄ for 6 weeks, untreated mice served as controls ($n=12$ per group). RKIP^{-/-} reduced both CCl₄-induced interstitial- and TAC-induced replacement-LV fibrosis to $75 \pm 9\%$ in CCl₄-treated RKIP^{-/-} and to $61 \pm 12\%$ in RKIP^{-/-}-TAC compared with the respective control groups. Collagen I α 2 mRNA was reduced by approximately 50% both in RKIP^{-/-}-TAC and RKIP^{-/-}-CCl₄. RKIP^{-/-} increased the number of CD31+ endothelial cells to $118 \pm 4\%$ in CCl₄-treated and to $157 \pm 18\%$ in RKIP^{-/-}-TAC per mm², decreased the number of fibroblasts per mm² in TAC mice by $20 \pm 5\%$, the percentage of cycling Ki67+ fibroblasts in CCl₄-treated mice to $23 \pm 18\%$ and the percentage of CXCR4+ fibroblasts in TAC mice to $74 \pm 8\%$. RKIP^{-/-} adult cardiac fibroblasts demonstrated decreased migration capacity and fibronectin production. Expression of pro-angiogenic mediators (angiogenin, DLL4, FGFa, leptin) was increased in RKIP^{-/-}-TAC. RKIP-deficiency diminished cardiomyocyte apoptosis in CCl₄-treated mice to $39 \pm 13\%$ and in TAC mice to $31 \pm 10\%$. Heart weight to tibia length ratio, cardiomyocyte cross-sectional area, oxidative stress in cardiomyocytes and fibroblasts and the percentage of Ki67+ cardiomyocytes were decreased in RKIP^{-/-}-TAC. All effects were significant with $p < 0.05$.

Conclusions: These data identify Raf Kinase Inhibitor Protein as an important regulator of interstitial and replacement cardiac fibrosis.

1254

Aortic tissue proteomic profiling identifies the osmosignaling pathway components aquaporin-1 and tonicity binding protein as molecular biomarkers and mediators of vascular disease in diabetesR Madonna¹; V Doria¹; P Confalone¹; R De Caterina¹¹Institute of Cardiology, "G. d'Annunzio" University, Italy

Macro- and microvascular complications are important causes of morbidity and mortality in patients with type 1 (T1DM) and type 2 diabetes (T2DM), but an understanding of their mechanisms is far from being complete. The hyperosmolar component of hyperglycemia is an important biophysical candidate to mediate glucotoxicity and vascular dysfunction. We hypothesized that the hyperosmotic stress in overt diabetes may contribute to endothelial dysfunction through activation of osmosensing structures, such as aquaporin-1 (AQP-1) and its transcription factor Tonicity Binding Protein (TonEBP), and downstream target such as cyclooxygenase (COX)-2 in human endothelial cells. The current study investigated whether levels and activity of key molecules, such as AQP-1, TonEBP and COX-2, previously shown as causally linked to diabetic microangiopathy, are differentially expressed in human aortic endothelial cells (HAECs) exposed to hyperglycemia-induced hyperosmotic stress and in aortas of a type 1 diabetic mice developing atherosclerosis. We incubated HAECs with glucose or mannitol for 24 h, and tested them for protein levels and in vitro angiogenesis. We used the Ins2Akita mice cross-bred with apolipoprotein E-null (ApoE) mice as a model of type 1 diabetes developing atherosclerosis (along with nondiabetic/nonatherosclerotic and nondiabetic/atherosclerotic controls), to test the in vivo relevance of in vitro observations ($n=8$). Compared with incubations with normal (5 mmol/L) glucose concentrations, cells exposed to both high glucose and high mannitol (at 30.5 or 50.5 mmol/L) increased expression of the water channel AQP1 and COX-2. This was preceded by increased activity of the osmolarity-sensitive transcription factor TonEBP, and enhanced endothelial migration and tubulization in Matrigel, both reverted by treatment with AQP1 and TonEBP siRNA. Compared with nondiabetic/nonatherosclerotic controls, aortas of Ins2Akita, ApoE^{-/-} and Ins2Akita/ApoE^{-/-} mice showed increased levels of a glycosylated AQP1 isoform, while higher levels of COX-2 and TonEBP were found in Ins2Akita and Ins2Akita/ApoE^{-/-} mice (COX-2, and Ins2Akita (TonEBP), respectively (Figure).

The concerted up-regulation of COX-2, which is known to be implicated in excessive angiogenesis characterizing unstable plaques, and the upregulation of hypertonicity stress proteins AQP1 and TonEBP suggest that glucose-related hyperosmolarity may play a role as a biomarker and mediator of the excessive angiogenesis that characterizes diabetic vascular disease, and might constitute a promising new target for therapeutic interventions.

Elamipretide (Bendavia, MTP-131) normalizes cGMP levels in left ventricular myocardium of dogs with advanced heart failure

HN Hani Sabbah¹; RC Gupta¹; V Sing-Gupta¹; K Zhang¹
¹Henry Ford Hospital, Detroit, United States of America

Background: The second messenger cyclic guanosine monophosphate (cGMP) is reduced in heart failure (HF) and is implicated in the progressive deterioration of both LV systolic and diastolic function that characterizes the HF state in patients with reduced ejection fraction (HFrEF). cGMP is also reduced in patients with HF and preserved ejection fraction (HFpEF) and can contribute to progressive worsening of LV relaxation. cGMP generated by guanylyl cyclases (GC) produces its effects by activation of several downstream effectors that include cGMP-dependent protein kinase and cGMP-regulated phosphodiesterases (PDEs). It is well known that the nitric oxide (NO)/soluble GC (NO-sGC) system, once activated, results in the formation of cGMP. In HF, NO generated by endothelial nitric oxide synthase (eNOS) is reduced leading to reduced activation of NO-sGC and, hence, reduced formation of cGMP. Limited activation of eNOS as a result of reduction in cGMP can also negatively impact mitochondrial biogenesis. We previously showed that elamipretide (Bendavia, MTP-131), a novel mitochondria-targeting peptide, improves LV systolic and diastolic function in HF dogs with reduced EF (HFrEF), normalizes maximum rate of ATP synthesis and levels of eNOS.

Purpose / Hypothesis: This study tested the hypothesis that chronic therapy with elamipretide normalizes cGMP levels in LV myocardium of dogs with HFrEF (LV EF ~30%).

Methods: Studies were performed in LV tissue of 14 HF dogs randomized to 3 months therapy with subcutaneous injections of elamipretide (0.5 mg/kg once daily, n = 7) or saline (HF-Control, n = 7). LV tissue from 6 normal (NL) dogs was used for comparisons. cGMP level (pmol/mg protein) was determined using commercially available Elisa kits. Protein level of eNOS was assessed in LV tissue homogenate by Western Blotting and bands quantified in densitometric units (du).

Results: cGMP level in NL dogs was 1.02 ± 0.1 pg/ml and decreased significantly in HF-Control dogs to 0.47 ± 0.05 pg/ml ($p < 0.05$). Treatment with elamipretide restored tissue levels of cGMP to near normal (0.77 ± 0.05 pg/ml) ($p < 0.05$ vs. HF-Controls). eNOS level in NL dogs was 0.68 ± 0.07 du and decreased to 0.19 ± 0.02 du in HF-Controls ($p < 0.05$). Treatment with elamipretide significantly increased protein levels of eNOS to levels closer to normal (0.38 ± 0.03 du) ($p < 0.05$ vs. HF-Controls).

Conclusions: cGMP and eNOS levels are reduced in LV of dogs with advanced HF. Chronic therapy with elamipretide restores cGMP and eNOS levels to near normal. These findings suggest that elamipretide, in addition to being potentially useful for the treatment of HFrEF, may also be useful in the treatment of patients with HFpEF.

Role of intercellular adhesion molecule 1 in mediating pro-atherogenic and pro-fibrotic effects of mineralocorticoid receptor activation

V Marzolla¹; C Mammi¹; A Armani¹; A Antelmi¹; IZ Jaffe²; G Rosano¹; M Caprio¹

¹IRCCS San Raffaele Pisana Hospital, Rome, Italy; ²Tufts Medical Center, Boston, United States of America

Background: In clinical trials, mineralocorticoid receptor (MR) antagonists decrease cardiovascular ischemia and mortality suggesting a beneficial role of MR inhibition in the vasculature. In endothelial cells (ECs) MR activation by aldosterone promoted transcription of Intercellular Adhesion Molecule 1 (ICAM-1) and leukocyte adhesion, an effect that was inhibited by spironolactone and ICAM-1 blocking antibody. These data support that MR activation in human ECs promotes ICAM-1-mediated leukocyte-EC adhesion, an important step in early atherosclerosis lesion formation.

Results To further explore the mechanisms through which MR is able to regulate endothelial ICAM-1 expression, we performed transient transfection experiments in HUVEC. We observed that aldosterone is able to activate (2 fold) a 3 Kb promoter region upstream the transcription start site of human ICAM-1 gene. Such effect was inhibited by co-incubation with spironolactone, confirming the presence of elements responsive to signaling pathway(s) activated by MR. Bioinformatics analysis of this region revealed the presence of three different highly conserved regulatory elements: one NF- κ B binding site, one AP1 binding site and one glucocorticoid/mineralocorticoid responsive element (GRE/MRE). Blocking of either c-Jun or NF- κ B pathway resulted in a marked reduction of the aldosterone effect on ICAM-1 promoter activity, suggesting the involvement of these transcription factors. Selective deletion of the putative MRE/GRE completely abolished promoter activity induced by aldosterone. In order to verify if the development of atherosclerosis and fibrosis induced by MR activation, could be prevented by deletion of ICAM-1, we generated a double knock out ApoE^{-/-}/ICAM-1^{-/-} mouse. In these mice, we examined the aortic root after infusion of aldosterone and administration of atherogenic diet for 4 and 8 weeks. At level of aortic root, we observed a significant reduction in lipid content and activated inflammatory cell area in plaques from ApoE^{-/-}/ICAM-1^{-/-} mice compared to ApoE^{-/-} mice. Moreover, expression of type I and III collagen was reduced in ApoE^{-/-}/ICAM-1^{-/-} mice, after 8 weeks of treatment.

Conclusion(s): These results suggest: - ApoE^{-/-}/ICAM-1^{-/-} mice, fed an atherogenic diet for 4 weeks, are resistant to early atherosclerosis and plaque inflammation induced by aldosterone. - ApoE^{-/-}/ICAM-1^{-/-} mice, fed an atherogenic diet for 8 weeks, are resistant to aldosterone-induced fibrosis - MR-induced ICAM-1 expression requires NF- κ B and c-JUN transcriptional activity. - ICAM-1 has a central role in the development of atherosclerosis induced by aldosterone.

Mechanical stretching on cardiac adipose progenitors upregulates sarcomere-related genes

A Aida Llucia-Vallderas¹; C Soler-Botija¹; C Prat-Vidal¹; C Galvez-Monton¹; S Roura¹; I Perea-Gil¹; R Bragos²; A Bayes-Genis³

¹Health Science Research Institute Germans Trias i Pujol, Badalona, Spain;

²University Polytechnic of Catalunya, Barcelona, Spain; ³Germans Trias i Pujol University Hospital, Badalona, Spain

Background: The cardiac tissue is an unfriendly environment for the implantation of therapeutic cells due to its unavoidable contractility. Cardiac cells respond to mechanical stimuli and adjust their performance accordingly. It is also known that mechanical stimulation of tissue-engineered constructs improves their organization and contraction force.

Purpose: We hypothesize that mechanical conditioning of therapeutic cells could improve their retention and cardiovascular potential, to help in cardiac tissue restoration.

Methods: Cardiac adipose tissue-derived progenitor cells (ATDPCs) were mechanically stretched for 7 days at 1 Hz in 3 different surfaces (vertical, horizontal and smooth) (Figure 1). Gene and protein analysis were carried out for each cell type and condition. Secretome analysis after stimulation was also performed.

Results: A device was designed and validated to effectively apply a ~10% stretch. Mechanically stimulated cardiac ATDPCs increased the expression of cardiac transcription factors (GATA-4 and Tbx5) and structural genes (cTnI and α -actinin) after 7 days of mechanical stimulation. This gene modulation was different depending on the patterned surface, however the secretome analysis revealed that the vertical pattern was the most convenient for cardiac ATDPCs conditioning. Indeed, the secretome of cardiac ATDPCs stretched on vertical patterned surfaces was significantly associated to myocardial infarction, left ventricular extracellular matrix remodelling and the regulation of myoblast differentiation.

Conclusions: Mechanical conditioning of cardiac ATDPCs enhances the expression of early and late cardiac genes related with the cardiac sarcomere, and it is strongly dependent on the culture surface pattern.

Figure 1. Mechanical stimulation device.

Cardiac specific deletion of crif1 results in vulnerable heart function through mitochondrial damage in mice.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education S A Seon Ah Jin¹; JK Oh¹; MJ Kim¹; UL Choi¹; SW Seong¹; KT Ahn¹; SW Choi¹; JO Jeong¹

¹Chungnam National University Hospital, Daejeon, Korea Republic of

Background/Introduction: Mitochondria are key organelles for cellular energy production. Mitochondrial dysfunction is associated with various diseases such as neurodegeneration, neuromuscular disease and diabetes. Although cardiac tissues which require high energy metabolism are most vulnerable, the mechanisms underlying mitochondrial cardiomyopathy are largely unknown. CRIF1-interacting factor-1 (CRIF1) is a critical mitochondrial protein for the synthesis and formation of the OxPhos complex in the inner mitochondrial membrane.

Purpose: We investigated the physiologic role of CRIF1 in the heart and mitochondrial cardiomyopathy through it.

Methods: The CRIF1^{flx}/flox mice were crossed with Myh6-Cre transgenic mice, which harbor cardiac-specific murine alpha myosin-heavy chain (Myh6, heavy polypeptide 6, cardiac muscle, alpha) promoter drives expression of Cre in this transgenic strain. To investigate the physiologic role of CRIF1 in the heart, we used wild type and Myh6-Cre;CRIF1^{flx}/+. Western blot analysis was performed according to standard methods with commercially available antibodies. Oxygen consumption rates (OCR) in cardiomyocytes were measured using a Seahorse XF-24 flux analyzer. Histological and echocardiographic examinations were done before and after isoproterenol infusion with mini-osmotic pump.

Results: Cardiac-specific deletion of CRIF1 leads to mitochondrial dysfunction. In the mutant cardiac muscles, mitochondrial inner structure was altered with lack of cristae. The basal OCR in the CRIF1^{flx}/+ cells showed no significant gap compared to wild type, but was reduced more after oligomycin treatment ($p < 0.001$). It was not recovered after maximal respiration ($p < 0.001$). The mutant cardiomyocytes showed also decreased pSTAT3 and increased pERK. Although mutant cardiomyocytes showed decreased oxygen consumption rates and ATP production, there were no distinguished cardiac phenotyping showing normal cardiac function. To evaluate cardiac phenotyping after injury, the ratio of heart weight-to-body weight was measured at each week after isoproterenol infusion. At 2 weeks, the heart weight-to-body weight ratios of Crif1^{flx}/+ were low significantly ($p < 0.05$). Consistently, the values of deltaEF and deltaFS (difference of ejection fraction or fractional shortening between before and after isoproterenol infusion) at 4 weeks were markedly decreased in the mutant mice ($p < 0.001$).

Conclusions: In conclusion, mutant cardiomyocytes showed decreased rates of oxygen consumption and ATP production, suggesting that CRIF1 plays an essential role in the maintenance of both mitochondrial structure and respiration in cardiomyocytes. Mutant CRIF1 mice showed decreased cardiac hypertrophy and vulnerable heart function after isoproterenol infusion in mice.

Serelaxin effect on cardiac remodeling in an acute myocardial infarction animal model

Study funded by Novartis and fully realized, as a blind study, in Cariology Department of Virgen de la Arrixaca University Hospital, Murcia, Spain MC Asensio-Lopez¹; A Lax¹; J Jesus Sanchez-Mas¹; MJ Fernandez-Del Palacio²; L Caballero¹; MT Perez-Martinez¹; M Navarro¹; I Garrido-Bravo¹; FJ Pastor-Perez¹; DA Pascual-Figal¹

¹University Hospital Virgen De La Arrixaca, Murcia, Spain; ²Department of Animal Medicine and Surgery, Murcia, Spain

Introduction. Relaxin-2 is a natural reproductive hormone that has been associated with anti-inflammatory, anti-fibrotic and angiogenic effects in cardiac ischemia

models. Serelaxin (RLX030), a recombinant form of the relaxin-2 human hormone, has been able to relieve dyspnea and congestion in patients with acute heart failure and to reduce mortality. To date, the effects of RLX030 on cardiac remodeling and function in acute myocardial infarction (AMI) have not been evaluated. Purpose. The objective of the study was to characterize the dose effects of serelaxin on cardiac remodeling and heart function in an animal model of AMI. Methods. Sprague-Dawley rats were subjected to AMI by permanent ligation of the left anterior descending coronary artery. Infarcted animals were divided into an untreated group or a group treated with RLX030 (30 µg/kg/day, i.v.) for 72 h from the time of ligation. The control group was subjected to the same surgery but without ligation. Animals were sacrificed 7 days after surgery. By RT-PCR levels of markers were measured in the infarcted zone including: fibrosis (collagen I, collagen III, TIMP-1, α-SMA and TGF-β), inflammation (IL-6, TNF-α and MCP-1), angiogenesis (VEGF-A and VEGF-B) and remodeling (sST2 and galectin-3). Each value is referred to the control group and is expressed as mean ± standard error. Results. In the histological analysis, the AMI group showed high levels of expression of all fibrosis and inflammation markers and decreased angiogenesis markers compared to the control group. Compared with AMI group, treatment with RLX030 showed lower expression values of IL-6 (16.1 ± 3 vs. 7.4 ± 3.8, AMI vs. AMI + RLX030, $p = 0.04$) and MCP-1 (15.1 ± 2.5 vs. 7.7 ± 1.3, $p = 0.01$) and higher values of VEGF-A (0.73 ± 0.09 vs. 1.1 ± 0.1, $p = 0.02$) and VEGF-B (0.58 ± 0.09 vs. 0.9 ± 0.07, $p = 0.02$). RLX030 treatment did not prevent fibrosis markers increase induced by the AMI, but it reduced sST2 levels (1059 ± 219 vs. 412 ± 163, AMI vs. AMI + RLX030, $p = 0.018$) and galectin-3 levels (98 ± 25 vs. 26 ± 5, AMI vs. AMI + RLX030, $p = 0.04$), suggesting a favorable effect on myocardial remodeling in the longer term.

Conclusions: Our results suggest an early protective effect of RLX030 on AMI by reducing inflammation, promoting angiogenesis and favorably modulating galectin-3 and sST2 remodeling markers

1260

Synchronous electromechanical conditioning of adult cardiac adipose tissue-derived progenitor cells within a fibrin construct drives recovery of cardiac function after myocardial infarction

C Soler-Botija¹; A Lucia-Valldeperas¹; C Galvez-Monton¹; S Roura¹; C Prat-Vidal¹; I Perea-Gil¹; B Sanchez²; R Bragos³; A Bayes-Genis¹

¹Health Sciences Research Institute of the Germans Trias i Pujol Foundation (IGTP), Badalona, Spain; ²Harvard Medical School, Boston, United States of America;

³Polytechnic University of Catalonia, Electronic and Biomedical Instrumentation Group, Barcelona, Spain

Purpose: Cardiac cells are subjected to mechanical and electrical forces, which regulate gene expression and cellular function. Therefore, in vitro electromechanical stimuli could benefit further integration of therapeutic cells into the myocardium. Our goals were: 1) to study the viability of a tissue engineered construct with cardiac adipose tissue-derived progenitor cells (cardiac ATDPs); and 2) to examine the effect of electromechanically stimulated cardiac ATDPs embedded in a fibrin patch within a myocardial infarction (MI) model in mice.

Methods: Cardiac ATDPs were electromechanically stimulated mimicking the physiological heart environment: 2 ms pulses of 50 mV/cm at 1 Hz and 10% stretching during 7 days. Cell viability was evaluated through a Life&Dead assay. The cells were harvested, labelled, embedded in a fibrin hydrogel, implanted over the infarcted area of the murine heart and animals were sacrificed at 21 days post-implantation. 39 mice were randomly distributed: without cells and with stimulated or non-stimulated cells. Echocardiography, gene and protein analysis were also carried out.

Results: Physiologically stimulated ATDPs showed increased expression of cardiac transcription factors, structural genes and calcium handling genes. After 3 weeks of in vitro culture in the fibrin construct, cells exhibited high viability and remained labelled. 21 days post-implantation, cardiac function (measured as left ventricle ejection fraction between pre-sacrifice and post-MI) increased in animals treated with stimulated ATDPs constructs by 5% - 12% relative to unstimulated cells and non-treated animals, respectively. Constructs containing stimulated cells presented vascularization and integration with the host blood supply, resulting in an increased vessel density in the infarct border region. Histology analysis showed cell proliferation and cardiac markers expression of implanted cardiac ATDPs, but also scarce migration to the mouse myocardium.

Conclusions: Trained cells within the implanted fibrin patch expressed main cardiac markers, and migrated into the underlying ischemic myocardium. Thus, synchronous electromechanical conditioning prior to cell implantation emerges as a promising therapeutic strategy for cardiac regeneration after myocardial infarction.

Perinatal adaptation to the extrauterine life involves a gradual decrease in the sensitivity for oxidative titin modifications in cardiomyocytes of the rat

B Beata Bodi¹; ET Pasztorne¹; L Nagy¹; A Toth¹; Z Papp¹

¹University of Debrecen, Division of Clinical Physiology, Debrecen, Hungary

Purpose: During the first weeks of postnatal life cardiomyocytes undergo a maturation process whereby embryonic proteins are gradually replaced by those of the adult myocardium. Along this process, the N2BA titin isoforms are switched for N2B titin isoforms leading to an increase in sarcomeric passive force (F_{passive}) to coordinate left ventricular (LV) diastolic function. Here we attempted to reveal how titin isoform composition and oxidative insults (SH oxidation, carbonylation) influence F_{passive} of LV cardiomyocytes following birth.

Methods: Experiments were performed at different stages of postnatal development (at 0, 7 and 21 days) of control Wistar rats. F_{passive} was measured in single permeabilized LV cardiomyocytes. The effects of SH oxidation and carbonylation of the two titin isoforms on F_{passive} were evaluated following in vitro exposures to an oxidative agent, dithiodipyridine (DTDP, 10 mM) or Fenton reagents (50 μM FeSO_4 , 1.5 mM H_2O_2 , 6 mM ascorbic acid) in cardiomyocytes followed by the application of the antioxidant dithiothreitol (DTT, 10mM). Titin isoform composition was analyzed by SDS-gel electrophoresis, while Western-blot analyses were carried out for the semiquantitative determination of SH groups (by biotinylation) and carbonyl groups (by OxyBlotTM) in titin isoforms.

Results: F_{passive} was significantly increased with age in a range of sarcomere lengths (SL, 1.9-2.5 μm) along with an antiparallel change in the N2BA/N2B ratio ($80 \pm 1\%/20 \pm 1\%$, $41 \pm 1\%/59 \pm 1\%$, $10 \pm 1\%/90 \pm 1\%$ in 0-, 7-, and 21-day-old rats, respectively, $n = 5-7$). DTDP and Fenton reagents significantly increased F_{passive} in 0- and 7-day-old rats, but to a lesser extent in 21-day-old animals (DF F_{passive} of DTDP: $99 \pm 26\%$; $65 \pm 23\%$ vs. $39 \pm 21\%$; DF F_{passive} of Fenton: $138 \pm 33\%$; $55 \pm 13\%$ vs. $27 \pm 8\%$ $P < 0.05$ in 0-, 7-day-old vs. 21-day-old groups, SL: 2.3 μm , $n = 7-8$). The effects of oxidative insults were completely reverted by the application of DTT in the same age groups. The relative extents of DTDP-evoked SH oxidations and Fenton-evoked carbonylations declined with cardiomyocyte age for both titin isoforms (N2BA(DTDP): $80 \pm 1\%$, $71 \pm 1\%$, $64 \pm 1\%$, N2B(DTDP): $74 \pm 1\%$, $62 \pm 2\%$, $53 \pm 2\%$; N2BA(Fenton): $157 \pm 6\%$, $134 \pm 4\%$, $35 \pm 3\%$ N2B(Fenton): $190 \pm 10\%$, $158 \pm 4\%$, $74 \pm 4\%$ in 0-, 7- and 21-day-old rats, respectively, $P < 0.05$, $n = 4-20$).

Conclusion: Cardiomyocyte differentiation is accompanied by a gradual decrease in the oxidative sensitivity of F_{passive} due to the sarcomeric maturation of N2BA and N2B titin isoforms.

CLINICAL CASE CORNER 4: WHEN THE HEART IS BURNING: CASES OF INFLAMMATORY CARDIAC INVOLVEMENT – PART I

A heart with no legs to run: giant cell myocarditis in a patient with bilateral leg amputation after giant cell vasculitis.

A Alberto Aimò¹; A D'asciano²; A Pucci²; A Giannoni³; G Vergaro³; A Barison³; L Innocenti³; C Passino¹; M Emdin¹

¹Sant'Anna School of Advanced Studies, Pisa, Italy; ²University of Pisa, Pisa, Italy; ³Gabriele Monasterio Foundation, Pisa, Italy

A 23-year old woman with a history of dystimia and drug abuse developed ulcerative skin lesions in her lower limbs. Such lesions which were excruciatingly painful, spread out, merged, and became rapidly infected. The histological findings led initially to a presumptive diagnosis of granulomatous slack skin disease, an extremely rare subtype of T-cell cutaneous lymphoma. A temporary treatment with steroids and cyclophosphamide was therefore undertaken, but the response was partial, partly because of poor patient compliance. One year later, a bilateral above-knee amputation was mandatory.

Several months after the amputation, the patient presented with progressive oedema, complained of dyspnoea at rest, orthopnoea, and paroxysmal nocturnal dyspnoea. After admission to an Emergency Department, cardiac function deteriorated rapidly until cardiogenic shock supervened; she was treated with aortic counterpulsation, combined norepinephrine and levosimendan infusion, and non-invasive mechanical ventilation. An ischaemic aetiology was excluded by coronary angiography. Cardiac magnetic resonance documented 25% left ventricular ejection fraction (LVEF), diffuse hypokinesia, and myocardial oedema; this last finding, together with a marked increase of the inflammatory markers, suggested an acute myocarditis. Discharged with a low-dose bisoprolol, valsartan, with furosemide and spironolactone treatment, she underwent repeated hospitalizations, till, after 3 months, she was transferred to our Cardiology Department with pulmonary congestion, bilateral pleural effusion, anasarca, and fever. At echocardiogram, a 18% LVEF was estimated. After unloading treatment with levosimendan and intravenous furosemide, left heart catheterization was undertaken, and a myocardial biopsy allowed to diagnose giant cell myocarditis. Methylprednisolone and cyclosporine were then started.

In the following two months, bisoprolol, ramipril, and aldosterone antagonist were up-titrated. serial echocardiograms documented a slow but steady recovery of systolic function. Meanwhile, a the former skin lesion biopsy was re-evaluated, and the evidence of macrophages with the appearance of giant cells in the context of skin granulomas, allowed a diagnosis of small vessel vasculitis. At discharge, the patient did not display any signs or symptoms of heart failure, and had a 25% LVEF. One month later, the reverse remodeling was further advanced, with 35% LVEF, while NT-proBNP had dropped from 20728 to 3684 ng/L. This case confirms the association between giant cell myocarditis and other autoimmune manifestations. Furthermore, the evidence of giant cells in both skin and heart biopsies suggests common pathogenesis for cutaneous and cardiac lesions, a concept that has never been proposed so far. With regard to treatment, our case demonstrates that a relatively rapid recovery of cardiac function can be achieved by integrating an immunosuppressive strategy with optimal heart failure management.

1263

An 18 year old man with severe left ventricular systolic dysfunction and mysterious intracardiac masses. What is the diagnosis?

G Georgiana Tamasescu¹; S Iancovici¹; M Dan¹; A Aexandrescu¹; M Dorobantu¹

¹Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania

The imaging of left ventricular masses can be very spectacular but establishing the aetiology and choosing a right treatment can be challenging. We present the case of an 18-year-old man admitted to our clinic for new acute heart failure. The patient had a history of recent respiratory tract infection with high fever followed by

persistent cough and shortness of breath for which he underwent empiric antibiotic treatment. On admission, the patient was severely dyspnoea at rest and ineffective cough. Chest X-ray revealed cardiomegaly and bilateral confluent opacities in the inferior lung fields. ECG showed sinus tachycardia without other changes. Blood tests revealed marked leucocytosis, inflammatory syndrome and very high natriuretic peptides. Transthoracic echocardiography (TTE) showed a very dilated left ventricle (LV) with severe systolic dysfunction (LVEF 10%) and multiple large and mobile masses with a hypo echogenic core, occupying the whole LV apex. No spontaneous contrast was seen in the LV. Moderate functional mitral regurgitation was observed. The CT scan confirmed bronchopneumonia and intracardiac masses. The patient was admitted in the intensive care unit and received standard heart failure treatment. The sputum samples were repeatedly negative, blood serology was positive for acute cytomegalovirus infection. The differential diagnosis was between extensive intracardiac thrombosis in a dysfunctional dilated LV, newly discovered cardiac tumours, atypical vegetations in a patient with pulmonary infection and Löffler's syndrome, but no eosinophilia was detected. The MRI, initially postponed due to patient's clinical status, confirmed diagnosis of acute myocarditis and intraventricular thrombosis with no criteria of non-compaction cardiomyopathy. The cardiac imaging performed didn't give a straight answer about the aetiology of these masses and a clinical decision had to be made before having a clear diagnosis in order to avoid embolic complications and unfractionated heparin treatment was initiated. Several days after starting Heparin, subsequent echocardiographic evaluation showed complete resolution of these masses under anticoagulant treatment proving it was LV thrombosis. We concluded it is a rare case of acute myocarditis with severe LV dilatation and systolic dysfunction and signs and intraventricular thrombi following a respiratory infection with CMV. Sometimes, in the acute setting, multimodality imaging cannot be performed completely and the treatment decisions have to be made before having a clear diagnosis in order to avoid complications. In this particular case the evolution under anticoagulant treatment revealed better the aetiology than the cardiac imaging alone.

Exercise induced pulmonary hypertension in unexplained dyspnea due to scleroderma left heart diastolic dysfunction

V Valentina Labate¹; F Bandera²; G Generati²; V Donghi²; M Guazzi²

¹IRCCS Policlinico San Donato, heart failure unit, San Donato Milanese, Italy;

²IRCCS Policlinico San Donato, University of Milan, Heart Failure Unit, San Donato Milanese, Italy

Introduction-Case report description: Almost half of patients with heart failure have preserved ejection fraction (HFpEF). According to consensus recommendations, a diagnosis of HFpEF can be obtained when signs and symptoms of HF, normal left ventricular (LV) systolic function and impaired LV relaxation and compliance are met simultaneously. Some HFpEF patients, however, may be misclassified, because they have virtually normal diastolic function and filling pressure at rest, compared with controls. We report a case of a patient with unexplained dyspnea

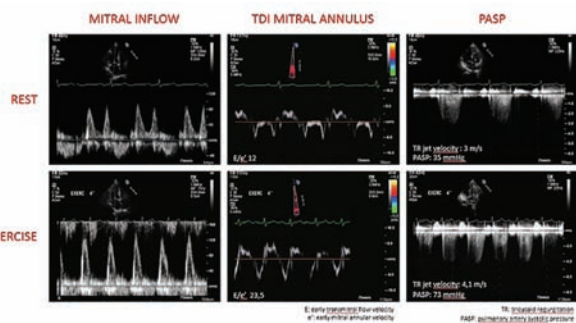

and suspected HFpEF evaluated by a combined approach using cardiopulmonary test (CPET) simultaneously with exercise stress echocardiography (ESE).

A 76-year-old mild hypertensive woman was referred to our center for evaluation of exertional dyspnea. She referred a rapid progression of dyspnea during effort (NYHA II class). Raynaud's phenomenon was also referred. Rest echocardiography revealed normal biventricular structure and function and initial diastolic dysfunction (LV ejection fraction 77%, E/e' 12, TAPSE 24mm, PASP 35 mmHg).

Description of the problem, procedures, techniques and/or equipment used Dyspnea is a common unspecific symptom and can be caused by many different conditions. Not only multiple systems are involved and interact synergistically in the complex pathophysiology of dyspnea but dynamic changes in cardiac function and pulmonary pressure can play a key role in the genesis of this symptom. Based on these considerations a dynamic evaluation by means of CPET combined with ESE using a tiltable ergometer was performed (incremental ramp of 12 W/min). CPET showed a reduced peak VO₂ (12.2 ml/kg/min, 61% of predicted), characterized by the flattening of $\Delta\text{VO}_2/\Delta\text{Work Rate}$ relationship (mean slope 7.2). The ventilatory efficiency was normal (VE/VCO₂ slope of 29.2). During exercise rapid increase of LV filling pressure (E/e' 25.3) associated with severe dynamic pulmonary hypertension (PH) (PASP 73 mmHg) and dynamic mitral regurgitation (MR) was detected.

Answers-Discussion: In patients with early stage HFpEF with diastolic dysfunction that has not yet caused an increase in left atrial pressure, E/e' could be normal at rest, whereas it could increase only during a 'diastolic stress', such as exercise. Additional effort abnormalities, i.e. reduced exercise capacity, exercise-induced PH, dynamic MR a steeper VE/VCO₂ slope can support the diagnosis of HFpEF.

Conclusions-Implications for clinical practice: Traditional echocardiographic indices may be insensitive for the diagnosis of HFpEF because they try to identify patients with breathlessness during exercise, using only resting diagnostic criteria. Diagnosis may therefore remain challenging, especially in the earlier stages when symptoms occur just during exercise. Exercise appears the ideal physiological condition to monitor simultaneously cardiac filling pressure by ESE and symptoms by CPET making early diagnosis of HFpEF more likely.

dynamic echocardiographic evaluation

Heart failure, heart rate and myasthenia gravis

E Elia Venturini¹; L Magni¹; R Testa¹

¹Department of Cardiology - Civic Hospital, Cecina (LI), Italy

Introduction: Myasthenia gravis (MG) is an autoimmune neuromuscular disorder causing muscle weakness and fatigue. The treatment of cardiac disorders that affect patients with MG can be a challenge because many drugs induce or worsen symptoms of the disease. Case report description: we report the case of a 76-year-old male with late-onset MG who developed systolic heart failure. The patient (P) was referred by her general practitioner for tachycardia and effort dyspnea (NYHA IIb class). At the age of 71 years he had bilateral ptosis, hyposthenia and weakness of upper limb muscles. A diagnosis of MG was made. Physical examination showed arterial blood pressure of 150/85 mmHg, heart rate (HR) of 116/min, regular a holosystolic murmur (2/6 Levine scale) and a III sound (ventricular gallop). There were ankle edema and rales at lung bases bilaterally. The ECG showed sinus tachycardia, a first-degree atrioventricular block and left bundle branch block and the echocardiogram a reduction of ejection fraction (EF: 30%) with diffuse hypokinesia. The brain natriuretic peptide was increased (BNP 878 pg/mL; normal value 0-100) and the chest X-ray confirmed cardiomegaly. Due to the concomitant MG was started treatment with ACE inhibitors and diuretics. After about one month, exertional dyspnea improved (NYHA IIa) and also HR was reduced (90 /min) as well as the BNP (638). Therefore ivabradine (IVA) was added and the dose was gradually increased to 7.5 mg x 2. Was tolerated with no worsening of MG symptoms. At a 6 months follow up the p is asymptomatic with no signs or symptoms of HF, in normal sinus rhythm (HR 70/min). The BNP is 218. Also the EF (40%) is improved. Discussion and implications for clinical practice: ryanodine and titin receptors are expressed in striated muscles and in the heart. This may cause a cross immunogenicity and lead to the

HF sometimes preceded by an autoimmune myocarditis. Also serum antibodies against adrenergic receptors present in P with MG can be involved. Beta-blockers are a cornerstone in the treatment of heart failure, but are contraindicated in MG. The clinical case confirmed another observation that IVA is a good alternative to reduce the HR in patients with systolic HF and sinus rhythm. Its efficacy is also demonstrated by the improvement in EF and the reduction of the BNP. IVA is effective in improving clinical outcome in HF (cardiovascular death, hospitalizations, worsening HF) in P without MG. Is a HR-lowering agent which acts specifically on the sino-atrial node and inhibits the If current of cardiac pacemaker cells, with no effects on other cardiac ionic currents, like those of the neuromuscular junction. The HF is rare in MG and the overlapping of symptoms between the two conditions may delay the diagnosis. The echocardiogram and the BNP are valid diagnostic tools. IVA is a useful, effective, and well-tolerated drug for systolic HF in MG in sinus rhythm.

Non-infective endocarditis in a patient with fever

D Daniela Teferici¹; A Lloji²; A Idrizi³; Y Themeli⁴; M Luzati⁵

¹University Hospital Center Mother Theresa, Tirana, Albania; ²University Hospital Center Mother Theresa, Internal Medicine, Tirana, Albania; ³University Hospital Center Mother Theresa, Service of Nephrology, Tirana, Albania; ⁴Diagnostic Center Med.al, Tirana, Albania; ⁵University Hospital Center Mother Theresa, Cardiology - Cardiac surgery, Tirana, Albania

Introduction: Libman Sacks endocarditis (LSE) is present in 1 on every 10 patients with systemic lupus erythematosus (SLE). The diagnosis of LSE becomes challenging in differentiating it from infective endocarditis (IE). Case: This is a 16 year old female who presents with fatigue, fever, shortness of breath. History of present illness stated 2 weeks ago. On physical examination she presented increased central venous pressure, tachypnea, tachycardia, temperature 38.8°C, BP150/90mmHg, a grade V/VI pansystolic mitral murmur. 3 pairs of blood culture samples were collected from different sites and all had negative results. A cardiac ultrasound revealed large pericardial effusion (PE) and the decision of pericardiocentesis was made. The patient's laboratory work up revealed high creatinine levels, proteinuria, abnormal LFTs, hemolytic anemia, thrombocytopenia, WBC 10900, CRP 38.8g/L. Work up showed positive antinuclear antibody (ANA), anti-dsDNA, anti-ENA screen and slightly depressed serum complement levels. According to the diagnostic criteria the diagnosis of SLE was made and the patient started treatment with methylprednisolone and cyclophosphamide. A transthoracic echo (TTE) revealed: diffuse infiltration of anterior mitral leaflet and a nodular thickening on it, sized 20x10mm (Fig. 1), severe mitral regurgitation, concentric hypertrophy of LV, normal size and systolic function of both ventricles. A small amount of PE was detected. Considering a possible IE, elevated CRP and WBC levels, ampicillin and gentamycin for 2 weeks was added. As the urea and creatinine levels raised up and the patient became oliguric, she was transferred to nephrology ward; hemodialysis was started. Under the above mentioned treatment, her symptoms improved; afebrile, creatinine level after reaching 7mg/dl went down up to 3mg/dl. TTE studies have yet to be repeated as of writing this article. Discussion: This is a case report of a young patient with SLE, who presented with progressive dyspnea, (caused by PE) and fever. The patient had an aseptic vegetation in the mitral valve with severe MR. The most commonly involved valve in LSE, is the mitral valve. The vegetation seen on TTE, was on the anterior mitral valve leaflet, with infiltration of the entire leaflet. Laboratory parameters can be useful in distinguishing IE from LSE. 3 laboratory data are important: white blood cell count, c-reactive protein (CRP) and blood cultures. The leukocytes tend to decrease during lupus activity and the opposite occurs in IE. Very high CRP levels suggest an infectious cause; for a definitive differential diagnosis, the blood cultures are more important. In the present case, a diagnosis of LSE was more probable, as the leukocyte count was slightly elevated, the CRP was not highly elevated and blood culture samples had negative results. **Conclusion:** Patients with SLE will be more likely to develop cardiac manifestations of lupus, such as valvular regurgitation and possible LSE.

1267

Infiltrative cardiomyopathy: a novel aetiologyTG Moon¹; K O'gallagher¹; D Sado¹¹King's College Hospital, Department of Cardiology, London, United Kingdom

Introduction and case report description: Cardiomyopathy is a common condition encountered by the cardiologist but clinicians should be vigilant to rarer causes. We present the case of a 52-year-old gentleman presenting with pulmonary oedema secondary to an infiltrative histiocyte cardiomyopathy caused by Rosai-Dorfman Disease (RDD).

Description of the problem, procedures, techniques and/or equipment used

A 52-year-old Afro-Caribbean male presented with a 6-month history of dyspnoea, decreasing exercise tolerance and paroxysmal nocturnal dyspnoea. Clinically he was in pulmonary oedema. He had a history of RDD and chronic hepatitis B. There was no previous cardiac history. Transthoracic echocardiography (TTE) demonstrated biventricular hypertrophy with suggestion of a right atrial mass. At this point the cardiac diagnosis was unclear.

Questions, problems or possible differential diagnosis

What are the differential diagnoses for biventricular hypertrophy with a right atrial mass? What technique would you use to confirm the diagnosis? How would you manage this patient?

Answers and discussion

The differential diagnoses included amyloidosis, sarcoidosis or hypereosinophilic syndrome but subsequent cardiovascular magnetic resonance (cMR) imaging was not consistent with any of these. cMR imaging revealed thickening of all four cardiac chambers. No right atrial mass was seen, however the right atrial wall was grossly thickened. There was normal gadolinium kinetics and no late enhancement. The patient proceeded to an endomyocardial biopsy. Histological assessment demonstrated a lymphocytic and histiocytic infiltration with emperipolesis and positive S100 staining. These findings are characteristic of RDD. To our knowledge this is the first case describing infiltration of all four cardiac chambers secondary to RDD. The patient received cisplatin, etoposide and dexamethasone as medical therapy for RDD. Serial cMR demonstrated improvement in myocardial infiltration and a reduction in cardiac mass, but progressive infiltration of the aortic valve and initially moderate, then severe aortic regurgitation. An intended aortic valve replacement has not been possible due to ongoing gastrointestinal and respiratory complications of immunosuppression.

Conclusions and implications for clinical practice

Originally described in 1969, RDD is a rare, non-clonal proliferative disorder of histiocytes of unknown aetiology which typically causes bilateral painless cervical lymphadenopathy. Extra-nodal involvement most commonly involves the skin, nasal cavity, paranasal sinuses, orbit, upper respiratory tract and bone. Cardiac involvement is rare, occurring in <1% of cases. To our knowledge, this is the first description of RDD involving all four cardiac chambers. This case highlights the need to be vigilant to rare causes of cardiomyopathy and the role of endomyocardial biopsy in diagnosing cardiomyopathies of uncertain aetiology.

cMR- Rosai Dorfman Cardiomyopathy

Introduction: Myocarditis is an inflammatory disease of the myocardium with a wide range of clinical presentations, from subclinical disease to sudden death. Viral infection is the main aetiology and its treatment may require immune therapy when an unstable presentation occurs. Case report: A 39-year old white female without previous cardiovascular history was admitted to the coronary unit because of chest pain. A stage IVA follicular lymphoma was diagnosed six months before admission. The patient completed a first line regimen with rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone. No completed remission was achieved after treatment, starting a second line regimen with rituximab, etoposide, methyl-prednisolone, cytarabine and cisplatin. The patient developed pericardial chest pain, hypotension and fever a few hours after the second cycle. On examination, blood pressure was 72/50 mmHg and heart rate was 92 bpm. Heart sounds were rhythmic without murmurs. An electrocardiogram showed an ST-segment elevation in the inferior leads and an echocardiogram was performed revealing a mild left ventricular systolic dysfunction with inferoseptal akinesia. Troponin I levels raised up to 50,1 ng/ml. A computerized tomography coronary angiogram was performed, showing normal coronary arteries. A cardiovascular magnetic resonance found the presence of late gadolinium enhancement involving the inferoseptal epicardium and mid myocardium. Left ventricular ejection fraction (LVEF) was 39%. PCR for detection of enterovirus was positive in pharyngeal and blood samples. According to these results an acute enterovirus myocarditis was suspected. After stabilizing the patient with inotropic agents, immune therapy consisting of intravenous methyl-prednisolone and immunoglobulin was initiated. A new echocardiogram revealed a deterioration of the LVEF down to 34% and severe functional mitral regurgitation. The patient developed dyspnoea, starting treatment with diuretics with an initial good response. Ten days after diagnosis the patient suffered a ventricular fibrillation, return of spontaneous circulation (ROSC) was achieved after thirty minutes of cardiopulmonary resuscitation. Cardiogenic shock resistant to inotropic agents and intraaortic balloon pump occurred and the patient was deceased after 48 hours.

Discussion and conclusion: Acute myocarditis may associate in a minority of patients a poor prognosis. The differential diagnosis includes ischemic heart disease, valvular heart disease, congenital heart disease, other cardiomyopathies and pulmonary disease. Rituximab is a monoclonal antibody directed against the CD20 antigen on B-lymphocytes, which modifies the humoral immune response increasing viral infections. Lethal enterovirus myocarditis associated with rituximab is an extremely unusual condition described in the medical literature and its treatment should include haemodynamic support, immune therapy and mechanical support in unstable patients.

Cardiovascular magnetic resonance

1269

A rare cause of polyserositis with constrictive pericarditisPD Pitic¹; PI Petre¹; DM Dan¹; DM Dorobantu¹¹Emergency Clinical Hospital Floreasca, cardiology, Bucharest, Romania

Constrictive pericarditis is a rare cause of chest pain. The patients present usually with signs and symptoms of right heart failure, without any history of heart disease and with normal systolic function. The etiology remains the most important challenge.

We present the case of a 47 years old man, smoker who came in the emergency department complaining in the last month of cough and constrictive chest pain, improved by leaning forward. He associated also a pharyngeal infection, self-treated with nonsteroidal anti-inflammatory drug and antibiotic therapy; under this medication the symptoms were solved briefly.

At the emergency room a fast echocardiography was done, revealing circumferentially pericardial fluid. The patient was admitted in the cardiology department for further investigation. A CT (computed tomography) scan of the chest and abdomen with intravenous contrast was done. The result was polyserositis- thickening of the pericardium with a small amount of pericardial fluid, bilateral pleural effusion and peritoneal fluid. Also moderate increased volume of the liver was found; no pathological masses were detected. The blood work revealed the presence of a

1268

Lethal enterovirus myocarditis associated with rituximabO Oscar Gonzalez Fernandez¹; T Lopez Fernandez¹; C Alvarez Ortega¹; R Mori Junco¹; P Meras Colunga¹; V Rial Baston¹; J Irazusta Cordoba¹; E Lopez De Sa¹; M Moreno Yanguela¹; JL Lopez Sendon¹¹University Hospital La Paz, Cardiology, Madrid, Spain

inflammatory syndrome and a moderate elevation of the hepatic transaminases (with the predominance of the aspartate aminotransferase); the cardiac enzymes (creatin kinase and creatine phosphokinase-MB) were normal.

At this point, corroborating the clinical and paraclinical data, the differential diagnosis was made between an infection with a systemic implication, neoplasia or an autoimmune disease.

Colchicine (one milligram per day) and Ibuprofen (six hundred milligrams every eight hours) were administered. Under this treatment, during the second day of the admission the patient became febrile, so hemocultures were taken and Ciprofloxacin was added to the treatment.

The echocardiography was repeated, bringing important information: medium size pericardial fluid with adhesions between the visceral and parietal layer, septal bouncing and significant respiratory variations of mitral and tricuspid flow velocity with preservation of myocardial velocities (tissue Doppler). These findings were conclusive for effusive-constrictive pericarditis.

Because of the persistent fever, the history of pharyngeal angina, acute inflammatory syndrome and polyserositis the presence of an infectious disease was strongly suspected. The patient was transferred to the Infectious Disease Hospital, where a rare form of pharyngeal infection with *Yersinia enterocolitica* was found; after 3 weeks of antibiotics, Colchicine and Ibuprofen treatment the echocardiography was normal.

We consider this case of a rare form of infection with *Yersinia enterocolitica*, leading to polyserositis and a transient form of constrictive-effusive pericarditis. Particular, the cardiac symptoms led to the diagnosis and cure of the infection.

¹University Hospital La Paz, Cardiology, Madrid, Spain; ²University Hospital La Paz, Internal Medicine, Madrid, Spain

We present the case of a 27-year-old man from Paraguay who was referred to our centre because of pain, paresthesias and ulcerated lesions in both lower limbs. An arteriogram showed diffuse arterial disease with areas of stenosis and occlusion as well as important collateral circulation. With the diagnosis of advanced lower extremity peripheral artery disease, medical treatment was started, but he finally required a left limb supracondylar amputation.

During the postoperative period, he suffered an acute pulmonary edema requiring intravenous diuretics and non invasive mechanical ventilation. An echocardiogram was performed, revealing severe left ventricular dysfunction with global hypokinesia and a diastolic restrictive pattern, secondary severe mitral regurgitation and mild right ventricular dysfunction.

Several complementary tests were performed, finding a constant elevation of eosinophiles and IgE levels. A cardiac resonance revealed circumferential subendocardial late gadolinium enhancement in both ventricles, suggesting endomyocardial fibrosis, without areas of edema in STIR sequences.

A wide differential diagnosis was attempted, dismissing most common etiologies. We ruled out infectious diseases, mainly parasitic infections, but also HIV, Lyme and Chagas disease, among others. We also considered celiac disease and other endocrinal diseases or nutritional deficits, Buerger disease, sarcoidosis, amyloidosis, hemochromatosis and acute myocarditis. Coronary artery disease was ruled out with an angio-CT.

Hypereosinophilic syndrome (HES) is a multisystemic disease as a result of maintained blood elevation of eosinophiles and IgE. Primary causes (hematologic disease) were dismissed by means of a bone marrow biopsy, as well as secondary causes (hypersensitivity, atopia, parasite infection, autoimmune disease, collagen disease, malignancy, eosinophilic pulmonary diseases, hyper-IgE syndrome, etc.). Finally, an idiopathic HES with cardiac and vascular – but also pulmonary and hematologic – involvement was diagnosed.

We initiated treatment with bisoprolol, enalapril, eplerenone and ivabradine. We also started corticosteroids and, later on, azathioprine, with analytical improvement but with no impact on left ventricular ejection fraction. A CRT-D was implanted for primary prevention of sudden cardiac death. The patient is currently in a stable situation with good functional class and no hospital readmissions.

Collaboration among different specialties is mandatory for the management of these patients with complex multisystemic diseases.

Hip to be square: cardiomyopathy of unknown origin

F Enseleit¹; M Frank¹; M Naegele¹; AJ Flammer¹; F Ruschitzka¹

¹University Hospital Zurich, Zurich, Switzerland

Background: The pathogenesis of cardiomyopathies is very complex and variable, since genetic factors, post-translational alterations, endocrine abnormalities, microbial infections, and environmental factors can lead to the phenotype of dilated cardiomyopathy. Therefore, the work-up for the initial presentation of a patient with cardiomyopathy of unknown origin still remains a diagnostic challenge in clinical practice. We here describe a patient with signs of heart failure, neurological impairment and liver failure.

Case presentation: A 66-year old male was referred to our tertiary hospital with signs of heart failure (fatigue, dyspnea on exertion, orthopnea) and neurological impairment (loss of vision and hearing), as well as weight loss during the last months. Medical history included hypertension since 10 years and bilateral hip replacement with chronic left hip pain. Six months ago hypothyroidism was treated with levothyroxine and heart failure was diagnosed. Echocardiography at that time point showed a reduced left ventricular ejection fraction (LVEF = 38%), heart failure therapy was started. Initial laboratory findings at our institution showed reduced kidney function and elevated liver enzymes. Initial ECG was unremarkable, additional diagnostics including screening for vasculitis, amyloidosis, infectious or mitochondrial diseases were negative. Cardiac biopsy showed features of dilated cardiomyopathy including interstitial fibrosis with no evidence for an infiltrative or inflammatory process. The patient deteriorated rapidly and died despite maximal inotropic therapy. Autopsy revealed toxic cardiomyopathy by cobalt poisoning.

Summary and Conclusion: Cobalt intoxication was initially reported in the literature in the 1960s as beer-drinkers cardiomyopathy. Since then some cases have been described, mainly documenting cobalt toxicity from hip arthroplasties. In a patient presenting with heart failure, hypothyroidism, liver failure and a history of hip arthroplasty and ongoing hip pain, the work-up for DCM should include toxicological screening.

with restrictive filling pattern (E/A 2.7). Right ventricular function was normal. In a right and left heart catheterization, significant coronary artery disease was excluded. Left ventricular end diastolic pressure (LVEDP) was elevated (LVEDP 30 mmHg). For further diagnostic work-up, endomyocardial biopsy was performed. The histopathologic examination excluded other cause such as amyloidosis, myocarditis or an acute vasculitic process. The examination showed Myocytes with numerous cytoplasmic vacuoles and low-grade diffuse interstitial fibrosis (Figure 1). Based on these findings, the diagnosis of HCQ-induced cardiomyopathy was confirmed. The drug was immediately discontinued and heart failure medication was initiated.

Conclusion: HCQ-induced cardiomyopathy is a rare but significant complication of HCQ-therapy and should be strongly suspected in patients developing conduction abnormalities or heart failure. To the best of our knowledge, this is one of the rare cases of HCQ-induced cardiomyopathy.

Figure 1

1294

Hydroxychloroquine-induced cardiomyopathy in a patient with limited cutaneous systemic sclerosis

A Abdin¹; J Poess¹; J Reil¹; G Fuernau¹; R Kandolf²; H Thiele¹

¹University Hospital of Schleswig-Holstein, Heart Center Lubeck, Lubeck, Germany; ²University Hospital of Tübingen, Tübingen, Germany

Introduction: Hydroxychloroquine (HCQ) is a widely used medication in the management of many connective tissue diseases. Cardiac toxicity is a rare but serious complication related to the chronic use of HCQ. Possible manifestations are the development of cardiomyopathy or of conduction abnormalities. Herein, we present the case of a 58-year-old female with limited cutaneous systemic sclerosis who was admitted to our institution with HCQ-induced cardiotoxicity.

Case presentation: A 58-year-old woman with a 2-year history of limited cutaneous systemic sclerosis was referred to our institution for further work-up of progressive dyspnea (NYHA class 2–3) over a period of 2 months. Her cardiac history before admission includes a dual chamber pacemaker implantation (in 1993 due to complete AV-block). Her other medical history includes peripheral artery disease and cardiovascular risk factors such as arterial hypertension and hyperlipidemia. She was taking HCQ, sildenafil and a Iloprost. Physical examination revealed bilateral lower leg swelling. The electrocardiogram was normal. Initial investigations at the time of admission revealed an elevated NT-pro-BNP (17825ng/l). Transthoracic echocardiography revealed concentric LV hypertrophy (LV septal and posterior wall thickness measuring 1.9 cm and 1.4 cm, respectively) with a severely reduced systolic ejection fraction (EF) of 30% and an elevated filling pressure (E/E' 17)

Creatine phosphokinase utility in diagnosing new onset heart failure

A Yehya¹; RM Martin²; VP Polsani³; BS Stambler⁴

¹Piedmont Heart Institute, Advanced Heart Failure and Heart Transplant, Atlanta, United States of America; ²Piedmont Heart Institute, Marcus Heart Valve Center, Atlanta, United States of America; ³Piedmont Heart Institute, Cardiac Imaging, Atlanta, United States of America; ⁴Piedmont Heart Institute, Cardiac Electrophysiology, Atlanta, United States of America

Introduction: creatine kinase is one the diagnostic laboratory testing that should be performed in all patients with cardiomyopathy according to the European Society of Cardiology (ESC) but not in the American College of Cardiology (ACC) and the Heart Failure Society of America (HFSA) guidelines.

Case report: a 21 year previously healthy, asymptomatic college student male referred to our clinic after his primary care physician auscultated irregular heart sounds. The patient denied palpitations, limitation of activities, dizziness, syncope or presyncope. His ECG demonstrated sinus rhythm with premature atrial contractions (PAC). To evaluate his PAC, a Holter monitor and a transthoracic echocardiogram (TTE) were ordered. His Holter monitor revealed moderate PAC burden (10.5% in 24 hours) and the TTE revealed global hypokinesis of the left ventricle (LV), with an estimated ejection fraction (EF) 35-40%. A CPK was ordered and was notably elevated at 6180 mcg/L (normal 24-204). Goal directed medical

therapy (GDMT) was initiated and a cardiac MRI was ordered after 3 months of GDMT demonstrating mild global hypokinesis with LVEF 48%. (Fig 1-4) Our patient was referred to a rheumatologist to rule out primary connective tissue disorder. Muscular dystrophy was suspected and genetic testing was performed revealing a hemizygous, in-frame deletion in the Duchenne muscular dystrophy gene. The clinical picture is most consistent with Becker's muscular dystrophy associated cardiomyopathy.

Conclusion and Implication: CPK testing was instrumental in establishing the etiology of the newly diagnosed cardiomyopathy in our patient. It was also important for defining his clinical management and overall prognosis. This underscores the importance of having CPK as part of the routine testing in our cardiomyopathy patients and calls for ACC and HFSA to include it in our initial diagnostic laboratory panel as the ESC does.

Hyponatremia- possible factor in biventricular pacing abnormalities

R Raluca Sosdean¹; R Macarie¹; B Enache¹; C Tutuianu¹; F Goanta¹; C Mornos¹; A Ionac¹; S Pescariu¹

¹University of Medicine Victor Babes, Cardiology, Timisoara, Romania

Introduction and case report description: Hyperkalemia is an established cause of biventricular device malfunction, but data in the literature about hyponatremia is scarce. Reporting unusual causes is worthwhile for an appropriate management. We report the case of a 59-year-old patient implanted with a CRT cardioverter defibrillator (DDD, lower rate of 50beats/minute) two weeks before, with congestive heart failure symptomatology and generalized muscle weakness. The electrocardiogram (ECG) revealed sinus rhythm with a heart rate of 70bpm with only intermittent pacing spikes followed by biventricular capture. The patient had metabolic acidosis, with normal potassium and calcium levels but a significantly low serum sodium concentration (116mEq/l).

Description of the problem, procedures, techniques: QRS complexes, both paced and non- paced, were larger compared to his previous ones and a new first degree atrioventricular block was detected. The interrogation confirmed intermittent loss of atrial sensing leading to loss of biventricular pacing even at the highest sensitivity on the atrial lead. Atrial capture was absent even at the highest pacing voltage and impulse duration. The atrial lead impedance and radiological position and the ventricular pacing and sensing thresholds were normal. The problems improved after initiation of sodium replacement therapy and metabolic acidosis correction, but completely resolved only after reaching a sodium level of 127mEq/l. The paced QRS complex width returned to normal, atrial sensing was constant, the atrial pacing threshold improved and also the patient status improved significantly.

Questions, problems or possible differential diagnosis: The cause of CRT failure was unclear and initially we suspected an atrial lead problem- displacement, local inflammation or lead injury. Metabolic acidosis has also been described to induce pacing problems in certain conditions.

Answers and discussion: The normal impedance and radiological aspect made atrial lead problems unlikely but could not exclude local inflammation. The close temporal association between sodium correction and reversal of the pacing and conduction problems suggests that hyponatremia, added to metabolic acidosis, played an important role. A small amount of preclinical and clinical data suggests that hyponatremia can produce conduction disturbances and also pacing malfunction by altering fast sodium currents. It is highly unlikely that metabolic

acidosis alone was the cause of malfunction, as all reports describe it along with high extracellular potassium levels, which was not the case in our patient.

Conclusions and implications for clinical practice: Hyponatremia is likely to play an important role in cardiac device malfunction. The physician should be aware of this possible issue in order to avoid a delay in diagnosis, unnecessary medication and/or interventions, and potentially fatal hemodynamic deterioration.

Enterocutaneous fistula as a complication of left ventricular assist device after heart transplant

J Jesus Velasquez Rodriguez¹; E Zatarain-Nicolas¹; I Sousa-Casasnovas¹; A Villa-Arranz¹; J Fernandez-Yanez¹; M Juarez-Fernandez¹; G Cuerpo-Caballero²; JM Barrios-Gutierrez³; A Gonzalez-Pinto²; F Fernandez-Aviles¹

¹University Hospital Gregorio Maranon, Cardiology, Madrid, Spain; ²University Hospital Gregorio Maranon, Cardiac Surgery, Madrid, Spain; ³University Hospital Gregorio Maranon, Anaesthesiology, Madrid, Spain

Introduction: Left ventricular assist devices (LVAD) have changed end-stage heart failure prognosis. Most devices require abdominal wall transgression and create a potential for abdominal complications.

Case report: A 58-year-old male underwent uncomplicated implantation of a paracorporeal pulsatile-LVAD (PP-LVAD) for an end-stage ischemic cardiomyopathy as a bridge to heart transplantation (HT). He had several episodes of gastrointestinal bleeding during support. After a severe rectorrhagia an abdominal computed tomography (CT) showed active bleeding at the ascending colon, but colonoscopy and angiography could not localized the bleeding point for treatment. The inner cannula was directly in contact with splenic angle of colon but no signs of complication were observed. One month later, patient received a HT after 104 days of support. The inner cannula was difficult to remove due to intense fibrosis. It was done after graft implantation, in order to avoid lack of time because the graft arrival. The treatment after HT was basiliximab (one single dose at the first day), steroids, micophenolate mofetil from the beginning and tacrolimus was started the 14th day. The 11th day after surgery, fecaloid secretion started to drain through the wound of the inner cannula; CT confirmed the existence of an enterocutaneous fistula from the splenic flexure of the colon that was neither connected to the peritoneal cavity nor to thoracic cavity after injection of iodide contrast (picture). The CT also evidence the presence of a supradiaphragmatic retrosternal collection. Surgical drainage of the thoracic collection was decided and surgical exploration did not find connection with abdominal cavity. The microbiologic culture of the thoracic samples and wound samples were positive for *Enterococcus faecium*. The enterocutaneous fistula was decided to be treated by medical approach first, because there was no drainage of intestinal content to peritoneal cavity and the patient was without infection signs. Soon after the patient had respiratory deterioration with pulmonary distress and repeated atelectasis, oliguric renal failure and progression to septic shock. The patient had a poor outcome with severe sepsis refractory to proper antibiotic treatment and there were no chance to abdominal surgery due to instable situation so unfortunately he died.

Clinical implications: Intestinal complications related to LVAD during support are already described in literature. This is the first description of enterocutaneous fistula after HT due to removal of PP-LVAD support. The withdrawal of the cannula at the moment of HT can be complex because the intense fibrosis of the scar. Those patient may benefit from imaging diagnosis of the anatomic relationships of the cannula before HT. Early surgical approach may help to avoid future septic complications due to enterocutaneous fistula, even if there is no evidence of active infection at that moment.

An unusual treatment strategy and an infrequent comorbidity in chronic heart failure with reduced ejection fraction

D Denes Vagany¹; B Muk¹; L Rokusz²; CS Dzsini³; T Borsanyi¹; Z Varga¹; J Pinter⁴; ZS Majoros¹; RG Kiss¹; N Nyolczas¹

²Medical Centre, Hungarian Defence Forces, Internal Medicine, Budapest,

Hungary; ³Medical Centre, Hungarian Defence Forces, Vascular Surgery,

Budapest, Hungary; ⁴Medical Centre, Hungarian Defence Forces, Radiology,

Budapest, Hungary

Background: Chronic heart failure with reduced ejection fraction (HFrEF) is a complex clinical syndrome with significant morbidity and mortality. Patients with severe therapy-refractory heart failure often require prolonged hospitalization. Considerable attention is needed to handle all comorbidities and iatrogenic diseases.

Case report: We report the case of a 71-year-old cachectic man who was admitted to our department with refractory HFrEF (LVEF: 15%), in NYHA III-IV functional class. He had a history of COPD and a preceding continuous hospitalization for 5 months because of advanced HFrEF. At the time of admission he did receive neither ACEi nor beta blocker because of intolerance. But in the effect of the direct vasodilator regime (dihydralazine and nitrate) the patient later was able to tolerate an ACEi and a BB. We could even successfully titrate the doses of these drugs and it was possible to reach the optimal medical treatment of HFrEF. During hospitalization we took some blood cultures because of persistently elevated inflammatory markers (CRP: 54.4 mg/L, ESR: 100 mm/h, WBC: 9.5 G/L), which were positive for MRSA. CT

angiography (CTA) conducted as part of our investigation of significant weight loss, persistent atypical chest pain and MRSA bacteraemia revealed a pseudo-aneurysm (PA) of the descending thoracic aorta. After a negative result of a TOE a PET-CT scan was done for the detection of MRSA bacteraemia source as part of complex investigation. It visualized the PA as the only positive region. Based on the results of the afterwards performed control CTAs, PA size progression was confirmed. Because of the MRSA infected PA of descending thoracic aorta an aorta stent graft implantation was proposed by the interdisciplinary consultation (vascular surgeon, infectologist and cardiologists) after a six-week course of antibiotic (IV vancomycin). After the successful operation and a further six-week targeted treatment with antibiotics (IV vancomycin and gentamicin) the patient was discharged in clinically stable condition on optimal medical treatment of HFrEF and on triple combination of oral antibiotics (rifampicin, doxycycline, sulfamethoxazole/trimethoprim). Three months after the stent graft implantation follow-up tests verified normal conditions, and control CTA showed the graft in normal position without sign of inflammation. One year after the procedure the patient is still in stable condition both from the cardiology and infectology point of view (LVEF: 35%, NYHA I-II, CRP: 5.5 mg/L, WBC: 5.9 G/L, ESR: 20 mm/h).

Conclusions: The care of HFrEF patients is a complex problem and requires special attention. Comorbidities can be encountered frequently, which have great impact on hospitalizations and mortality. MRSA aortitis is a life-threatening disorder. Rapid and accurate diagnosis of the disease can be a challenge for the clinicians. Close collaboration between different medical professions is essential for proper treatment.

Non-invasive lung impedance-guided preemptive treatment in chronic heart failure patients: a randomized controlled trial (impedance-HF trial)

M Michael Shochat¹; A Shotan¹; I Kleiner²; I Dahan¹; D Blondheim¹; M Kazatsker¹; A Asif¹; J Weinstein²; S Meisel¹

¹Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; ²Saroka Medical Center, Cardiology, Beer Sheva, Israel

Background: Previous investigations have suggested that lung impedance (LI)-guided treatment reduces hospitalizations for heart failure (HF). A single-blind two-center trial was performed to evaluate this hypothesis.

Methods: Study population included 256 patients with Chronic Heart Failure (CHF), Left Ventricle Ejection Fraction $\leq 35\%$ in New York Heart Association class II-IV. Patients were randomized (1:1) to a control group treated by clinical assessment and a monitored group whose therapy was also assisted by LI. Noninvasive LI measurements were performed with a new high-sensitive device. The primary efficacy endpoint was HF hospitalizations. Secondary endpoints were all-cause hospitalizations and mortality. For statistical analyses were used Cox proportional-hazards, Poisson and negative binominal models.

Results: The mean follow-up was 48 ± 32 m (5221 visits, 511 patient-years follow-up, 10.6 visits/ patient-year) in the monitored group, and 39 ± 26 m (4351 visits, 411 patient-years follow up, 10.6 visits/ patient-year) in the control group ($p=0.01$). The groups were similar with respect to baseline characteristics. There were 67 vs. 158 HF hospitalizations during the first year (HR=0.51, 95% CI 0.38-0.68, $p<0.0001$, Number Needed to Treat [NNT]=1.4) and 211 vs. 386 HF hospitalizations (HR=0.63, 95% CI 0.53-0.75, $p<0.0001$, NNT=1.9) during the entire follow-up among the monitored and control patients. All-cause mortality during the follow-up period included 42 patients in the monitored group and 59 patients in the control group (rate: 0.08 vs. 0.14 per patient-year follow-up, HR=0.52, 95% CI: 0.35-0.78, $p=0.002$, NNT=7.5). Cardiovascular (CV) death occurred in 26 and 47 patients, (rate 0.05 vs. 0.11, HR=0.41, 95% CI: 0.25-0.67, $p<0.0001$, NNT=6.1) in the monitored and control group, respectively. During the entire study period there were 13 deaths due to HF in the monitored and 31 HF deaths in the control groups (rate 0.03 vs. 0.08, HR=0.30, 95% CI: 0.15-0.58, $p=0.0001$, NNT=7.1). There was no significant difference in the incidence of non-CV deaths.

Conclusion: The IMPEDANCE-HF is the first trial demonstrating that LI-guided pre-emptive therapy of worsening pulmonary congestion, prevents HF hospitalizations in CHF patients and reduces all- cause, CV and HF mortality in these patients.

Diagnostic relevance of diastolic stress-test echocardiography in patients with suspicion of heart failure with preserved ejection fraction

E Belyavskiy¹; E Kraigher-Krainer¹; DA Morris¹; M Uri-Michitsch²; Aravind K Radha Krishnan¹; M Kropf¹; R Kraft¹; A Meinitzer³; A Schmidt²; B Pieske¹

¹Charite - Campus Virchow-Klinikum (CVK), Department of Internal Medicine and Cardiology, Berlin, Germany; ²Medical University of Graz, Department of Cardiology, Graz, Austria; ³Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria

Aim: The purpose of this study was to assess the diagnostic relevance of diastolic stress-test echocardiography (DST) in patients with suspicion of heart failure with preserved ejection fraction (HFPEF).

Methods: Patients with suspicion of HFPEF (undetermined dyspnea NYHA class I-II, septal E/e' at rest $9 - 14$, and NT-proBNP at rest $125 - 220$ pg/ml) and a control group constituted by asymptomatic patients with hypertensive heart disease (HHD) and healthy subjects were included. All patients were analyzed by conventional and 2D speckle-tracking echocardiography (STE) at rest and during exercise.

Results: Fifty six subjects were included in the final analysis (13 with suspicion of HFPEF, 21 asymptomatic with HHD and 22 healthy subjects). Patients with

suspicion of HFPEF had significantly lower values of LV global longitudinal systolic strain (GLS), higher values of septal E/e', tricuspid regurgitation (TR) velocity and NT-proBNP during exercise than hypertensive and healthy subjects (GLS $-18.7 \pm 4.2\%$ vs $-21.6 \pm 3.8\%$ and $-22.4 \pm 3.9\%$; E/e' 14.0 ± 3.1 vs. 8.8 ± 1.7 and 8.1 ± 1.4 ; TR velocity 2.52 ± 0.67 m/s vs. 2.07 ± 0.47 m/s and 2.01 ± 0.21 m/s; NT-proBNP 125.6 ± 92.4 pg/ml vs. 68.7 ± 49.2 pg/ml and 73.5 ± 38.1 pg/ml). In line with these findings, 46.1 % of patients with suspicion of HFPEF had evidence of HFPEF during exercise, which was detected by DST (i.e. dyspnea and septal E/e' during exercise ≥ 15). Moreover, using a criteria of HFPEF as dyspnea + TR during exercise > 2.8 m/s or dyspnea + GLS during exercise $\geq -16\%$, 46.1% and 38.4% of patients with suspicion of HFPEF had evidence of HFPEF during exercise, respectively.

Conclusion: The findings of this study suggest that diastolic stress-test using both conventional and speckle-tracking echocardiography could be of great usefulness to diagnose HFPEF in patients in the diagnostic "grey zone".

1346

Left ventricular dimension, but not reverse remodeling, predict the occurrence of malignant ventricular tachyarrhythmias in CRT patients.

A Alessandro Paoletti Perini¹; I Ricceri¹; P Pieragnoli¹; G Ricciardi²; L Padeletti²

¹Careggi Hospital, Clinica Medica Department, Florence, Italy; ²University of Florence, Florence, Italy

Introduction: In chronic HF, CRT reduces hospitalizations and mortality, and improves LV performance by inducing left ventricular (LV) reverse remodeling. Burden of malignant ventricular arrhythmias (i.e. Ventricular Fibrillation (VF) and Ventricular Tachycardia (VT)) after CRT is reduced in responder patients.

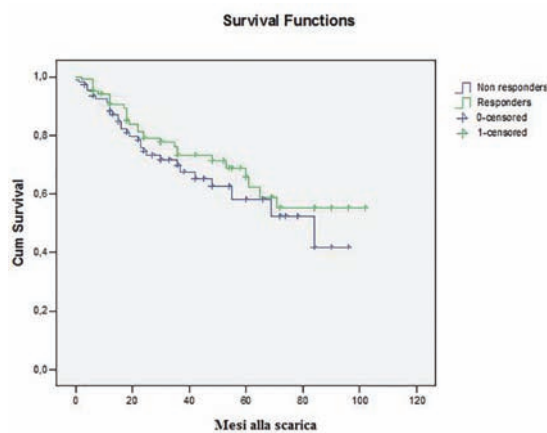

Purpose: aim of the present study is to evaluate the association between pre-implant LV dimensions, response to CRT and the long-term development of ventricular tachyarrhythmias requiring Implantable Cardioverter-Defibrillator (ICD) intervention, to assess whether initial LV size may help guide the implantation and programming of ICD associated with CRT.

Methods: We enrolled 258 consecutive CRT-D patients implanted according to International Guidelines. An echocardiogram was performed at baseline and after 6 months. Occurrence of appropriate therapies (both shocks and ATPs) delivered by the device was assessed at each FU. According to previous literature, patients were regarded as responders if LV end systolic volume (LVESV) reduction was $\geq 15\%$ at 6-month evaluation.

Results: out of 258 CRT-D patients (76% males, mean age 69 ± 9), 69 (27%) experienced at least 1 appropriate ICD therapy for VT/VF at a mean FU of 37 ± 24 months (213 total events). At baseline, VT patients had greater LV dimensions than

non-VT ones (LV End Diastolic Diameter (LVEDD) 70 ± 8 vs 67 ± 8 mm, $P = 0.009$; LV end systolic diameter (LVESD) 59 ± 8 vs 55 ± 8 mm, $P = 0.001$); similarly, at 6 months, LV size was statistically related to appropriate ICD intervention (LVEDD 68 ± 8 vs 64 ± 8 mm, $P < 0.001$; LVESD 55 ± 1 vs 51 ± 9 mm, $P = 0.003$). A similar percentage of responders and non-responders, as traditionally defined, had at least 1 arrhythmic ventricular episode (48% vs 52%, $P = 0.470$). In a multivariable Cox regression model comprehending age, gender, QRS duration, use of beta-blockers, etiology and baseline LV diameters, LVEDS (HR 1.034, $p = 0.048$), ischemic etiology (HR 2.316, $P = 0.003$) and female gender (HR 2.499, $P = 0.021$) had independent association with ICD delivered-therapies. In a model comprehending age, gender, QRS duration, use of beta-blockers, etiology, responder status and 6 month LV diameters, both LVEDD (HR 1.054, $P = 0.002$) and LVESD (HR 1.039, $P = 0.013$), together with etiology and gender ($P < 0.05$ for all), were associated to outcome, while responder status was not (HR 1.121, $P = 0.682$).

Conclusion: In CRT-D patients, occurrence of appropriate ICD intervention show independent association to baseline and 6-month LV dimensions, rather than to the occurrence of LV reverse remodeling, traditionally defined as LVESV reduction $\geq 15\%$ at 6-month FU.

Incidence of VF/VT

1347

Axial-flow left ventricular assist device pump speed increase is associated with increased peak exercise cardiac output and VO₂, postponed anaerobic threshold and improved ventilatory efficiency

A Del Torto¹; C Vignati²; N Corrieri¹; F Nicolì¹; S Farina²; M Conti²; E Salvioni²; P Palermo²; A Apostolo²; P Agostoni¹

¹University of Milan, Milan, Italy; ²Cardiology Center Monzino IRCCS, Milan, Italy

Background: An increased cardiac output (CO) at peak exercise is associated with a larger oxygen consumption (VO₂), provided that the arteriovenous difference of O₂ ($\Delta(\text{Ca-Cv})\text{O}_2$) remains unchanged. At the anaerobic threshold, VO₂ depends on CO.

Purpose: To show that, in patients with chronic heart failure (HF) who underwent implantation of a continuous axial-flow left ventricular assist device (LVAD), a sharp increase in CO, achieved by changing the LVAD pump speed, is associated with an increase in VO₂ at the anaerobic threshold (AT) and at peak exercise.

Methods: Twenty patients with advanced HF who underwent LVAD implantation were enrolled; 15 patients successfully completed the measurements at peak exercise. Cardiopulmonary exercise tests were performed with simultaneous measurement of CO with the inert gas rebreathing technique at rest and at peak exercise, on two separate days, with the LVAD pump speed randomly set at 8000 rpm or 11000 rpm.

Results: A higher LVAD pump speed was associated with an increase in CO at rest (from 3.4 ± 0.9 to 3.8 ± 1.0 L/min, $p = 0.04$) and at peak exercise (from 5.3 ± 1.3 to 5.9 ± 1.4 L/min, $p < 0.01$). Similarly, VO₂ increased from 788 ± 169 to 841 ± 152 mL/min ($p = 0.01$) at peak exercise and from 568 ± 116 to 619 ± 124 mL/min ($p = 0.02$) at the anaerobic threshold. The arteriovenous difference of O₂ did not vary significantly, while ventilatory efficiency improved (VE/VCO₂ slope from 39.9 ± 5.4 to 34.9 ± 8.3 , $p < 0.01$) [Table 1].

Conclusion: In LVAD recipients, an increase in CO due to a higher LVAD pump speed is associated with a significant increase in peak VO₂, anaerobic threshold and ventilatory efficiency.

Table 1

	Lower speed	Higher speed	P value
Peak VO ₂ (mL/min)	788 ± 169	841 ± 152	0.01
Peak VO ₂ (mL/kg/min)	10.0 ± 1.6	10.8 ± 2.0	0.01
Maximum ventilation (L/min)	39 ± 7	36 ± 10	NS
CO at rest (L/min)	5.3 ± 1.3	5.9 ± 1.4	< 0.01
$\Delta(\text{Ca-Cv})\text{O}_2$ at rest (mL/100 mL)	11.4 ± 4.5	9.9 ± 2.7	NS
$\Delta(\text{Ca-Cv})\text{O}_2$ at peak (mL/100 mL)	15 ± 3.9	15.1 ± 3.6	NS
Resting HR (bpm)	76 ± 9	72 ± 9	0.05
Peak HR (bpm)	101 ± 19	101 ± 19	NS
VE/VCO ₂ slope	39.9 ± 5.4	34.9 ± 8.3	< 0.01
VO ₂ AT (mL/min)	568 ± 116	619 ± 124	0.02
VO ₂ AT (mL/kg/min)	7.3 ± 1.3	8.1 ± 1.6	0.01

1348

The heart mate risk score identifies patients with similar mortality risk across all INTERMACS classes in a large multicenter analysis: low INTERMACS class should not be a contraindication to LVAD

L Luigi Adamo¹; Y Tang²; M Nassif¹; E Novak¹; PG Jones²; S Larue¹; JA Spertus²; DL Mann¹

¹Washington University School of Medicine, Cardiovascular Division, Department of Medicine, St. Louis, United States of America; ²St. Luke's Mid America Heart Institute, Kansas City, United States of America

Background: The Heart Mate Risk Score (HMRS) was recently proposed as a simple tool for risk stratification of LVAD recipients but has had conflicting estimates of its validity.

Purpose: To assess the performance of the Heart Mate Risk Score in a large multi-center cohort of patients, with a focus on its heterogeneity as a function of disease severity.

Methods: We performed a retrospective, longitudinal, comparative study using the INTERMACS database. We included all recipients of a primary continuous flow left ventricular assist device (CF-LVAD) with pre-implant data available to calculate the HMRS and excluded patients with CF-LVAD implant less than 90-day prior to database query or, CF-LVAD implant to replace previously placed VAD. Correlation with mortality was calculated with Cox models with an interaction by INTERMACS class (1 vs 2 vs 3+). Results - We identified 10,847 patients meeting inclusion criteria. 60.5% of patients were between the age of 50 and 69, 78.9 % were male, 14.1% were in INTERMACS class 1 and 37.3% were in INTERMACS class 2. HMRS showed a moderate discrimination with both short- (90 day, C-index 0.62) and long-term (5-year, C-index 0.59) mortality with no significant difference between axial and centrifugal devices. In fully-adjusted models, the Hazard for mortality comparing high HMRS and low HMRS categories was 2.92 ($p < 0.001$) at 90 days and 1.85 at 5 years ($p < 0.001$). Importantly, the HMRS had similar performance across INTERMACS classes and had better discrimination for mortality than INTERMACS classes (INTERMACS c-statistic = 0.58 at 90-day, 0.54 at 5-year). While INTERMACS class maintained a correlation with mortality after adjusting for HMRS level, calculation of a Net Reclassification Index (0.29 at 90 day, $p < 0.05$) showed that addition of the HMRS to INTERMACS class appropriately reclassified mortality risk in up to 30% of patients. Patients with INTERMACS class 3+ and high HMRS had greater 90-day mortality risk than INTERMACS class 2 patients with low HMRS (9.6 vs 5.4% , $p < 0.001$) and patients with mid-HMRS had similar 1-year and 2-year mortality risk independently of their INTERMACS category ($p > 0.18$).

Conclusion: The HMRS is a valid tool to risk-stratify patients in all INTERMACS classes and may be more accurate than traditional INTERMACS classification. Risk stratification with the HMRS showed that patients within each INTERMACS class have a wide spectrum of mortality risk and low INTERMACS class should therefore not be considered per se a contraindication to mechanical support.

1349

The novel non-invasive ultrasound device for detection an early change in the brain in patients with heart failure.

R Olszewski¹; W Dobkowska-Chudon²; E Frankowska³; A Arkadiusz³; M Wrobel⁴; A Dabrowski⁴; P Karłowicz⁵; A Nowicki⁶

¹Military Institute of Medicine, Cardiology and Internal Medicine, Warsaw, Poland;

²District Hospital, Cardiology, Radom, Poland; ³Military Institute of Medicine, Radiology, Warsaw, Poland; ⁴SoNovum A.G., Leipzig, Germany; ⁵Sonomed sp. z o.o., Warsaw, Poland; ⁶IPPT, Polish Academy of Science, Department of Ultrasound, Warsaw, Poland

Background: Cognitive impairment has been described as a consequence of heart failure (HF). The exact mechanisms remain unclear probably it is due to embolic stroke or chronic cerebral hypoperfusion. It has been described that HF patients have more severe white matter hyperintensities (WMHs) when compared to healthy non-cardiac and cardiac controls. Acoustocerebrography (ACG) is a novel, noninvasive, transcranial ultrasound method that could potentially help to diagnose early stages of brain changes. ACG measure multispectral ultrasound signals that are propagated through the brain tissue, including: absorption coefficient, frequency dependent attenuation, speed of sound and tissue elasticity.

Aim: The aim was to compare the brains ACG signal with Magnetic Resonance (MRI) in patients in early stage of heart failure (EsHF) with WMHs.

Methods: From the group 352 Pts we selected 54 (age of 66 ± 6.7) with EsHF treated with B-blocker 92.72%, ACE/ARBs 74.54%, Diuretics 43.63%. According to MRI data the patients (when WMHs was found) were assigned into four groups based on the number of WMHs: “L0”[0 to 4] WMHs, “L5”[5 to 9] WMHs, “L10”[10 to 29] WMHs and “L30”[≥ 30] WMHs.

Results: It was proved that the ACG method could clearly differentiate a group of WMHs. (Fig. 1) For the patients with 0 to 4 WMHs (L0) and a group of patients with 30 and more WMHs (L30) this correlation is highly significant ($p < 0.001$).

Conclusions: ACG is a new, effective method for detecting WML in patients with EsHF. The ACG measurement methodology may become increasingly useful to diagnose and to stratify patients with EsHF in order to individualize their treatment and maybe important to reduce their risk of cognitive impairment.

Mortality in patients implanted with cardiac resynchronisation therapy with or without a defibrillator

S Monga¹; G Atton¹; D Haigh¹; Q Pang¹; S Ramcharitar¹; P Foley¹; B Chandrasekaran¹

¹The Great Western Hospital, Wiltshire cardiac centre, Swindon, United Kingdom

Background: The role of Cardiac Resynchronisation Therapy (CRT) in reducing morbidity and mortality in patients with heart failure is well established. However, incremental benefit of CRT-D (defibrillator) over CRT-P (pacemaker) remains uncertain.

Purpose: To evaluate whether in a standard UK District General Hospital population of heart failure patients implanted with CRT-P would have benefitted additionally from a defibrillator.

Method: This was a retrospective single-centre observational study comparing 267 patients implanted with either CRT-D or CRT-P devices between 2011 and 2015 at our institution. Data was collected from patient electronic records and follow-up visits. The median follow up duration was 2.2 (1.2-3.3) years.

Results: The patients implanted with CRT-P were older, had more advanced heart failure with more females (Table 1). The mortality was higher in the CRT-P group primarily due to non-cardiac causes 5.7% vs 15.6% ($P < 0.001$) (Table 1). There were more documented ventricular arrhythmias in the CRT-D group and 12% received appropriate therapy, however in multivariate analysis Age > 75 years was the only independent predictor of survival (OR 4.0 CI 1.7-9.5).

Conclusions: The higher mortality in patients implanted with CRT-P is mainly due to a higher age at implant and comorbidities. Therefore, on current selection criteria, CRT-P patients are unlikely to gain incremental benefit from the addition of a defibrillator.

Patient Characteristics			
	CRT-D	CRT-P	P-value
Number of Patients	145	122	
Mean Age yrs mean (SD)	70.6 (9.7)	79.2 (7.8)	$P < 0.0001$
> 75 yrs	39%	79%	$P < 0.0001$
Female	13%	24%	$P < 0.03$
NYHA III/IV	73%	85%	$P < 0.03$
Upgrade from chronic RV pacing	19.3%	27.9%	$P = 0.09$

Myocardial scar on surface ECG: high eelvester score, but not QRS fragmentation, impairs response to cardiac resynchronization therapy.

A Paoletti Perini¹; S Cartei¹; M Nesti¹; L Checchi¹; R Bani¹; I Ricceri¹; P Pieragnoli¹; G Ricciardi¹; G Mascioli²; L Padeletti³

¹Careggi University Hospital (AOU), Heart and Vessels Department, Arrhythmic Diseases Unit, Florence, Italy; ²Clinical Institute Humanitas Gavazzeni, Bergamo, Italy; ³University of Florence, Florence, Italy

Background: Burden and transmural extension of myocardial scar impair response to Cardiac Resynchronization Therapy (CRT). Its presence may be assessed on surface ECG by either the Selvester Score (SSc) or the detection of QRS fragmentation (fQRS). True Left Bundle Branch Block (LBBB) has recently been identified as a pre-requisite for positive outcome after CRT, providing higher clinical benefit than LBBB as traditionally defined.

Purpose: To compare the prognostic significance of both scores in terms of left ventricular (LV) reverse remodeling (primary end-point) and major clinical events (secondary end-point), in the same cohort of CRT patients with true-LBBB on pre-implant surface ECG.

Methods: We retrospectively calculated the SSc and assessed the presence of fQRS on pre-implant ECGs of 178 consecutive patients with low left ventricular ejection fraction (LVEF $\leq 35\%$), true-LBBB and NYHA class II-III despite optimal medical treatment, who underwent CRT-D implantation. Median value of SSc was chosen as cut-off for the analysis. Echocardiographic response to CRT (LV end-systolic volume reduction $\geq 15\%$ or LVEF increase $\geq 10\%$) was assessed six months after implantation. Clinical events comprehended cardiac mortality, hospitalizations due to heart failure (HF) and occurrence of ventricular arrhythmias requiring ICD intervention.

Results: Out of 178 consecutive patients with true LBBB, males were 120 (70%); mean age at implantation was 70 ± 10 years; mean QRS duration was 161 ± 18 ms; etiology was mostly not-ischemic (64%). Median SSc was 7; fQRS was present in 74 patients (41.6%). At 6 months, echocardiographic response occurred in 106 patients (59.5%). At multivariable analysis, SSc > 7 was negatively associated with response (OR: 0.327; 95% C.I. 0.155-0.689; $p = 0.003$), while fQRS showed no association (OR: 1.133; 95% C.I. 0.539-2.381; $p = 0.742$). Response was independently associated also with female gender, absence of Diabetes Mellitus, Sinus Rhythm at implantation, and lower LVEF before CRT. Over a median follow-up of 24 (9-48) months,

28 deaths occurred (16%), of which 18 (10%) were diagnosed as cardiac deaths. Thirty-four patients (19%) were hospitalized for HF and 25 (14%) experienced at least one appropriate ICD intervention. At univariate Cox regression analysis no correlation was found between either SSc or fQRS and mortality, HF-hospitalizations, ventricular arrhythmias and a composite of these major adverse cardiac events (MACE).

Conclusion: SSc > 7 independently predicts non-response to CRT in true-LBBB HF patients undergoing CRT with defibrillation backup, and should be preferred to fQRS when looking for myocardial scar before implantation. However, neither SSc nor fQRS are associated with cardiac death, ventricular arrhythmias, HF-hospitalization or MACE.

1352

De novo aortic regurgitation after continuous flow left ventricular assist device implantation: a meta analysis

H Hrvoje Gasparovic¹; T Kopjar¹; L Svetina¹; M Petricevic¹; M Cikes¹; D Lovric¹; D Milicic¹; B Biocina¹

¹University Hospital Centre Zagreb, Zagreb, Croatia

Background: Continuous flow left ventricular assist devices (cf-LVAD) have become the standard of care for patients with advanced heart failure. De novo aortic regurgitation (AR) may occur after cf-LVAD implantation, and it harbors potential to adversely impact device performance and subsequently clinical outcomes.

Purpose: We aimed to determine the incidence of de-novo AR among cf-LVAD recipients, as well as to identify variables that are in correlation with its development. Odds ratios (OR) for dichotomous data and weighted mean differences (MD) with 95% confidence intervals (CI) for continuous data were calculated.

Methods: We performed a systematic search of PubMed and Cochrane Library for articles reporting on the incidence and predictors of de novo AR among patients with cf-LVAD. Significant AR was defined as more than mild in 5 studies, and as mild or greater in one.

Results: Six trials with a total of 468 patients were identified in the meta-analysis (Heartmate II 295 patients, HeartWare LVAD 130 patients, VentrAssist 2 patients, Jarvik 2000 3 patients, Evaheart 24 patients, Duraheart 14 patients). The combined incidence of de novo AR across the analyzed studies was 39%. Patients who developed de novo AR after cf-LVAD placement were older (MD 7.16 [95% CI 5.04, 9.29], $P < 0.001$, $I^2=39\%$), were less likely to be male (OR 0.49 [95% CI 0.29, 0.81], $P=0.006$, $I^2=0\%$) and had lower body surface area (BSA) (MD -0.13 [95% CI -0.18, -0.07], $P < 0.001$, $I^2=0\%$). Furthermore, they were more likely to have a persistently closed aortic valve (OR 5.82 [95% CI 3.69, 9.16], $P < 0.001$, $I^2=0\%$) and longer duration of support (208.06 [95% CI 116.68, 299.44], $P < 0.001$, $I^2=56\%$). Neither preoperative dimensions of the left ventricle (LV) nor LV ejection fraction had an impact on the development of de novo AR. Diabetes mellitus, hypertension or ischemic cardiomyopathy antedating cf-LVAD implantation had no effect on the subsequent development of de novo AR.

Conclusions: This meta-analysis illustrates that de novo AR occurs frequently after cf-LVAD implantation. Factors influencing its development and progression are older age, female gender, lower BSA, non-opening of the aortic valve and duration of cf-LVAD support.

1353

Effect of QRS narrowing after cardiac resynchronization therapy on functional mitral regurgitation

O Karaca¹; O Omaygenc¹; B Cakal¹; SD Cakal¹; B Boztosun¹; F Kilicaslan¹

¹Medipol University Faculty of Medicine, Cardiology Clinic, Istanbul, Turkey

Purpose: 1) To evaluate the predictors of FMR improvement after CRT, 2) To assess whether CRT-induced change in QRS duration (Δ QRS) might have an impact on FMR response after CRT.

Methods: 110 CRT recipients were enrolled. CRT response (≥ 15 reduction in LVESV) and FMR response (absolute reduction in FMR volume) were assessed with echocardiography before and 6-months after CRT. The study end-points included all-cause-death or hospitalization assessed in 12 ± 3 months (range 1-18).

Results: A total of 71 (65%) patients responded to CRT at 6 months. FMR response was observed in 49 (69%) of the CRT responders and 8 (20%) of the CRT non-responders ($p < 0.001$). The paced QRS durations were shorter ($p = 0.012$) and the Δ QRS values were higher ($p = 0.003$) in FMR responders. There was a linear correlation between Δ QRS and change in regurgitant volume ($r = 0.49$, $p < 0.001$). At multivariate analysis, Δ QRS ($p = 0.028$) independently predicted FMR response.

Conclusion: QRS narrowing after CRT independently predicts FMR response. A Δ QRS ≥ 20 ms after CRT is associated with a favorable outcome in all clinical end-points.

Clinical outcome based on Δ QRS

	Δ QRS < 20 ms (n = 68)	Δ QRS \geq 20 ms (n = 42)	p value
Improvement in NYHA class	30 (44%)	28 (66%)	0.027
Response to CRT	36 (53%)	35 (83%)	0.005
Reduction in FMR	22 (32%)	35 (83%)	< 0.001
Hospitalization	33 (49%)	9 (21%)	0.021
All-cause-death	14 (21%)	2 (5%)	0.022

QRS narrowing and FMR after CRT

Cardiac resynchronization therapy combined with coronary artery bypass grafting in ischemic heart failure patients: long-term results of the RESCUE study

V Shabanov¹; D Denis Losik¹; A Romanovov¹; D Prokhorova¹; Y Syrtceva¹; J Bis²; A Cherniavsky¹; E Pokushalov¹; MW Krejca²; M Deja²

¹State Research Institute of Circulation Pathology, Novosibirsk, Russian Federation; ²Medical University of Silesia, Katowice, Poland

Aims: Totally epicardial cardiac resynchronization therapy (CRT) is a novel treatment modality for patients with heart failure and systolic dyssynchrony undergoing coronary artery bypass grafting (CABG). In this study we have prospectively evaluated the long-term outcomes of totally epicardial CRT.

Methods: Between September 2007 and June 2009, one hundred seventy eight patients were randomly assigned to the CABG alone group (n = 87) and CABG with concomitant epicardial CRT implantation (n = 91). The primary endpoint of the study was all-cause mortality in the two groups between the day of surgery and August 13, 2013 (common closing date). The secondary outcomes included mode of death, adverse cardiac events and lead performance.

Results: The mean follow-up was 55 ± 10.7 months. According to per-protocol analysis with treatment as a time-dependent variable to account for conversion from CABG to CABG+CRT, there were 24 deaths (35.8%) in the CABG group and 17 deaths (15.3%) in the CABG+CRT group. As compared to CABG alone, concomitant CRT was associated with reduced risk of both all-cause mortality (hazard ratio (HR) 0.43, 95% confidence interval (CI) 0.23 to 0.84, $p = 0.012$) and cardiac death (HR 0.39, 95% CI 0.21 to 0.72, $p = 0.002$). Eleven (12.6%) sudden deaths were observed in the CABG group in comparison to 4 (4.4%) in the CABG+CRT group ($p = 0.048$). Hospital re-admission was required for 9 (9.9%) patients in CABG + CRT group and for 25 (28.7%) patients in CABG group (ER = 0.001). There were 4 (1.5%) epicardial lead failures.

Conclusion: The results of our study suggest that the procedure of coronary artery bypass grafting and totally epicardial CRT system implantation is safe and significantly improves the survival of patients with heart failure and dyssynchrony during long-term follow up.

Cardiac resynchronisation therapy in octogenarians

P Pieter Martens¹; FH Vebrugge¹; P Nijst¹; PB Bertrand¹; M Dupont¹; W Mullens¹

¹Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium

Background: Despite the high prevalence of chronic heart failure in octogenarians, these patients are systematically under-represented in clinical trials testing efficacy of cardiac resynchronization therapy (CRT).

Purpose: To evaluate clinical and echocardiographic response and long-term outcome after CRT in octogenarians.

Methods: A total of 687 consecutive CRT-recipients between October 2008 and July 2015 were retrospectively analyzed. Patients were dichotomous divided in octogenarians and non-octogenarians. Clinical improvement was analyzed as change in NYHA-class, echocardiographic response as change in ejection fraction (EF) and left ventricular end diastolic dimension (LVEDD) all at six month follow-up. For octogenarians annual death probability was calculated and compared with the general age-matched population using national actuarial life tables.

Results: A total of 166 octogenarians (83.3 ± 3.1 years) were compared with 459 non-octogenarians (68 ± 9.3 years). Both groups exhibited similar clinical response with equal change in NYHA-class (-0.88 ± 0.70 vs -0.89 ± 0.70; P = 0.88). Echocardiographic response was similar, with equal change in EF (12.6 ± 11.2% vs +12.9 ± 12.8%; P = 0.82) and LVEDD (-9.2 ± 12.5% vs -8.8 ± 16.9%; P = 0.82). Overall follow-up was 3.04 ± 1.89 years. Calculated annual mortality rate for octogenarians receiving CRT was 7.0% versus 7.5% for aged matched octogenarians in the general population (see figure 1; survival curve with age matched octogenarians plotted in red).

Conclusion: Despite advanced age, octogenarians retain the ability to mount clinical and echocardiographic response to CRT. Translating into an annual life-expectancy matching octogenarians in the general population.

Survival curve

1356

The impact of persistent electrical dyssynchrony on predicting ventricular arrhythmias following cardiac resynchronization therapy

O Karaca¹; O Omaygenc¹; B Cakal¹; SD Cakal¹; F Kilicaslan¹; B Boztosun¹

¹Medipol University Faculty of Medicine, Cardiology Clinic, Istanbul, Turkey

Background: Although response to cardiac resynchronization therapy (CRT) has been conventionally assessed with LV volume reduction, ventricular arrhythmias (VT/VF) are associated with poor outcome even in the “super-responders”.

Purpose: To evaluate the predictors of VT/VF and the association of post-CRT persistent electrical and mechanical dyssynchrony with follow-up VT/VF.

Methods: Ninety-five patients receiving CRT were followed-up for 9 ± 3 months. A post-CRT prolonged QRS interval was defined as electrical dyssynchrony (ED). A Yu index ≥ 33 milliseconds was used to identify patients with persistent mechanical dyssynchrony (MD). Presence of both ED and MD was defined as electro-mechanical dyssynchrony (EMD). The first VT/VF episode defined as non-sustained VT on device interrogation and/or appropriate anti-tachycardia therapy for VT/VF were the end-points of the study.

Results: Forty-five patients who reached the study end-points had significantly

lower mean ΔQRS (baseline QRS – post-CRT QRS) intervals than those without VT/VF (-20.8 ± 28.9 ms vs. -6.6 ± 30.7 ms, p = 0.022). The baseline and post-CRT QRS intervals, and the Yu index values were not different in two groups. Patients with VT/VF were statistically more likely to have persistent ED (38% vs. 9%, p = 0.021). Kaplan-Meier curves showed that a negative ΔQRS was associated with a higher incidence of VT/VF during follow-up (p = 0.016). A multivariate Cox model revealed that QRS prolongation was an independent predictor of VT/VF after CRT (p = 0.029).

Conclusions: A negative ΔQRS, also called persistent ED is associated with VT/VF at follow-up. The narrowest possible QRS interval might be a reliable goal of both implantation and optimization of devices to reduce arrhythmic events after CRT.

Kaplan-Meier curves for prediction VT/VF

Multimodality Imaging in ICD Implantation Decision Making in Heart Failure Patients: Role of 123-Iodine Metaiodobenzylguanidine Imaging and Cardiac MRI

LI Birtolo¹; P Paola Scarparo¹; N Salvi¹; C Calvieri¹; P Severino¹; S Calcagno¹; V Frantellizzi²; M Mancone¹; G De Vincentis²; F Fedele¹

¹Sapienza University of Rome, Department of Cardiovascular and Respiratory Sciences, Rome, Italy; ²Sapienza University of Rome, Department of Radiologic, Oncologic and Pathological Anatomy sciences, Rome, Italy

Background: According to guidelines, ICD therapy is recommended in prevention of sudden cardiac death (SCD) in heart failure (HF) patients (pts). Guidelines have several limitations because ICD indication is based mainly on left ventricular ejection fraction (EF). Recently, 123-iodine metaiodobenzylguanidine imaging (123-I MIBG), associated with cardiac magnetic resonance imaging (MRI), seems to identify, in pts candidate to ICD and independently from EF, pts at high risk of SCD (heart/mediastinum (H/M) ratio <1.6 and a summed score (SS) > 26).

Purpose: Our aim is to assess the role of 123-I MIBG combined with cardiac MRI to predict ventricular arrhythmia (VA) causing ICD shock in HF pts

Methods: we enrolled 69 pts, consecutively admitted to our hospital with diagnosis of HF and EF ≤ 35%, who underwent 123-I MIBG imaging and cardiac MRI. SS > 26 was used as cut-off to identify high risk (group1) versus low risk (group2) pts. Late gadolinium enhancement (LGE) was evaluated in the 2 groups. All pts of both groups underwent to ICD implantation. We assessed VA events and appropriate ICD therapy at 12 months follow-up.

Results: 21 pts were included in group 1 and 48 pts in group 2. All baseline characteristics were similar in 2 groups apart from the HF etiology. In group1, H/M ratio was 1.47 ± 0.24 and in group2 21.63 ± 0.27 (p = 0.015). The percentage of the pts with LGE was 70.9% in group1 vs 39.1% in group2 (p = 0.023). At 12 months follow-up malignant VA events in group1 were 19.05% vs 4.17% in group2 (p < 0.037). Moreover VA events were statistically recorded greater in pts with both SS > 26 and LGE compared to pts with only SS > 26 (46.7% vs 19.6%, p = 0.046)

Conclusion: Our results seem to confirm that reduced 123-I MIBG uptake and presence of LGE are associated with the occurrence of life-threatening VA in HF pts independently from EF. The use of integrated imaging could be a useful tool in the future to increase the specificity of the selection of pts for ICD therapy.

Table 1

	Group 1 SS > 26 (n = 21)	Group 2 SS ≤ 26 (n = 48)	P value
H/M	1.47 ± 0.24	1.63 ± 0.27	0.015
Hypertension (%)	76.19	66.70	-
Diabetes (%)	23.81	16.67	-
Ischemic CM (%)	65.02	28.30	0.003
Idiopathic DCM (%)	34.98	68.90	0.003
EF %	26.05 ± 5.66	31.79 ± 10.30	0.005
ICD implantation	100%	100%	-
Malignant ventricular arrhythmia	4 (19.05%)	2 (4.17%)	0.037

Potential candidates to percutaneous left atrial decompression through interatrial shunt implantation among patients under evaluation for heart transplantation.

LH Varela-Falcon¹; IJ Ignacio Jesus Amat Santos¹; J Tobar¹; S Vera¹; A Recio-Platero¹; J Lopez¹; L De La Fuente¹; J Castrodeza¹; C Cortes-Villar¹; JA San Roman¹

¹University Hospital of Valladolid, ICICOR, Valladolid, Spain

Introduction: Recently, a new approach for the treatment of advanced heart failure (HF) based on reducing left atrial pressure through a percutaneously implanted interatrial shunting device (IASD) has been demonstrated safe and effective. **Aim:** To evaluate the potential number of patients among those who underwent right heart catheterization (RHC) during evaluation for heart transplantation (HT) that met criteria for the use of and potential benefit from this new technology.

Methods: All patients sent to the HF clinic in our institution in the last 3 years who underwent RHC as part of the evaluation for HT were included. Clinical and hemodynamic parameters were gathered for all patients. Hemodynamic inclusion criteria for the subset of patients who may benefit from IASD within the first-in-man study included: Wedge pressure ≥ 15 and ≤ 18 mmHg, right atrial pressure (RAP) ≥ 4 and ≤ 11 mmHg, and systolic pulmonary artery pressure < 70 mmHg.

Results: A total of 107 patients (84.1% males, 56.8 ± 10.9 years of age) were included in this study. Of them, 74 patients (69.2%) were medically treated; 25 patients (23.4%) received HT; and 8 patients (7.4%) underwent an IASD implantation. Main reasons to avoid HT were adequate functional status (61.7%) and presence of comorbidities (36.4%). RHC mean parameters included RAP of 10.7 ± 7.7 mmHg, systolic pulmonary artery pressure of 47.3 ± 16.6 mmHg, wedge pressure of 22.3 ± 9.3 mmHg, cardiac index of 2.2 ± 0.62 L/min/m², and pulmonary vascular resistance of 2.8 ± 1.8 WU. Patients who underwent HT presented comparable RHC parameters to the other 2 groups, but worse NYHA class (III–IV in 100% vs. 82.7%, $p = 0.034$). Up to 24 patients (22.4% of the study population) presented criteria for IASD implantation. Of them, 7 underwent HT (29.2%), 8 underwent IASD implantation (33.3%), and 9 (37.5%) were medically treated. At a mean follow-up of 1.5 years, 22 patients had died (16.3%) but none of them among patients who had undergone IASD implantation.

Conclusions: Patients evaluated for HT through RHC were finally medically treated in 3 out of 4 cases. One third of this subset of patients may benefit from percutaneous implantation of interatrial shunting devices according to RHC measurements. Indeed, initial experience with these devices was successfully performed in many of these cases.

1359

Tri-ventricular pacing improves long-term survival and freedom from ventricular arrhythmias in advanced heart failure: results from a propensity-matched comparison.

R Providencia¹; D Rogers¹; N Papageorgiou¹; A Ioannou¹; G Babu¹; S Ahsan¹; O Segal¹; M Lowe¹; P Lambiase¹; AW Chow¹

¹Barts Health NHS Trust, London, United Kingdom

Background: Bi-Ventricular pacing (Bi-V) is an important adjunctive treatment in advanced heart failure, but almost one third of patients are non-responders. Adding a third ventricular lead (Tri-Ventricular pacing –Tri-V) has shown to be feasible and provide favourable acute results when assessed by echocardiographic, haemodynamic and clinical endpoints. However, long-term impact of this approach on survival and hard outcomes is unknown.

Purpose: We aimed to assess the long-term effects of Tri-V pacing and its impact on long-term survival.

Methods: Single-centre propensity score-matched cohort study comparing 34 advanced heart failure patients implanted with Tri-V devices with 34 controls treated with Bi-V comparing clinical outcomes (complications, survival and incidence of appropriate or inappropriate therapies) over a 10-year time interval.

Results: During a median of 2,478 days (IQR = 1,183–3,214) Tri-V patients presented with a comparable incidence of complications: lead dislodgement (Tri-V 0.86 vs. Bi-V 1.10 per 100 patient-years; $P = 0.742$), device-related infection (Tri-V 1.83 vs. Bi-V 1.76 per 100 patient-years; $P = 0.996$) and refractory phrenic nerve capture (Tri-V 0.48 vs. Bi-V 1.84 per 100 patient-years; $P = 0.341$). However, Tri-V presented with a trend for shorter battery longevity (time to Box change: Tri-V $1,758 \pm 360$ vs. Bi-V $1,993 \pm 408$ days; $P = 0.072$). Ventricular arrhythmia episodes requiring implantable cardioverter-defibrillator intervention occurred more frequently in the Bi-V group (Tri-V 6.55 vs. Bi-V 16.88 per 100 patient-years; adjusted HR = 0.31, 95%CI 0.14–0.66, $P = 0.002$). Lower all-cause mortality and heart transplant was observed in the Tri-V group (Tri-V 6.99 vs. Bi-V 11.92 per 100 patient-years; adjusted HR = 0.44; 95%CI 0.23–0.85, $P = 0.015$).

Conclusion: Tri-V displayed a similar safety profile when compared with Bi-V and was associated with potential benefits regarding long-term survival and ventricular arrhythmia burden. Further randomized controlled studies are required to confirm these promising results.

Adhere to clinical guidelines concerning implantable cardioverter defibrillator deactivation?

Supported by Public Health Agency NI (Research & Development) and ESC/HFA Nurse Training Fellowship Grant 2014

LM Hill¹; LM Hill²; SJ McIlpatrick³; SJ McIlpatrick³; BJ Taylor¹; T Jaarsma⁴; A Stromberg⁴; D Fitzsimons¹; D Fitzsimons²; D Fitzsimons³

¹University of Ulster, Jordanstown, United Kingdom; ²Belfast Health and Social Care Trust, Belfast, United Kingdom; ³All Ireland Institute of Hospice and Palliative Care, Belfast, Ireland; ⁴Linköping University, Linköping, Sweden

Background: An increasing number of heart failure patients receive an implantable cardioverter defibrillator (ICD) to prevent premature cardiac mortality. There is growing evidence that many patients receive multiple futile shocks from their device when nearing end-of-life. Recent studies indicate ICD deactivation is infrequently discussed with expert clinical guidelines not being implemented in practice.

Purpose: To examine the attitudes of healthcare professionals' through-out Europe regarding the discussion and deactivation of an ICD at end-of-life.

Methods: The factorial survey combines the strengths of experiment (random manipulation of variables) and survey design (improved recruitment), making it an ideal methodology to explore and measure the impact of implicit factors on decision-making. Data from a systematic literature review, retrospective case note review and ten case studies were refined to determine nine factors or Independent Variables (IV). The factorial survey consisted of a short demographic questionnaire followed by six unique clinical vignettes which embedded the IVs. The anonymised survey was distributed electronically through a secure IT platform to healthcare professionals in Europe involved in the management of patients with an ICD. Statistical analysis included multiple regression and ANOVA.

Results: A total of 1,518 vignettes were completed by 253 professionals (cardiologists, specialist nurses and cardiac physiologists). Preliminary results showed the majority of professionals agreed the cardiologist should initiate the discussion, although specialist nurses felt equipped to undertake this responsibility. Professionals in post for more than six years were found to be more confident in initiating the discussion ($p=0.001$). There was diversity of opinion on when a discussion about deactivation should take place with an overall reluctance by professionals to discuss prior to device implantation. Consensus was found among professionals, and in line with guidelines, that deactivation should be discussed when death was imminent. Clinical indicators of severe heart failure ($p<0.0005$), presence of malignancy ($p<0.0005$) and a patient receiving multiple ICD shocks ($p=0.004$) were associated with an increased likelihood of a discussion. In terms of the decision to deactivate an ICD, professionals believed patients should be involved with many wishing for inclusion of next of kin.

Conclusions: Professionals are missing opportunities to inform patients and enable shared decision-making regarding their ICD. Innovative strategies across Europe require to be developed that aim to improve professionals' adherence to expert guidelines and ultimately benefit patient care.

Impact of ICD/CRT-D implantation on healthcare resources utilization: an Italian cohort study

F Achilli¹; F Madotto²; LG Mantovani²; M Landolina³; M Lunati⁴; A Curnis⁵; M Marzegalli⁶; A Proclemer⁷; C Fornari²; G Cesana²

¹San Gerardo de' Tintori Hospital, Cardiovascular Department, Monza, Italy; ²University of Milano-Bicocca, Research Centre on Public Health (CESP), Monza, Italy; ³Major Hospital, Cardiology Department, Crema, Italy; ⁴Niguarda-Cà Granda Hospital, Cardiology Department, Milano, Italy; ⁵Civili Hospital, Cardiology Department, Brescia, Italy; ⁶Maddalena Grassi Foundation, Milano, Italy; ⁷University Hospital Santa Maria della Misericordia, Udine, Italy

Introduction: Given the high burden of cardiovascular diseases, is crucial from a payer perspective to understand outcomes and costs of medical device use in clinical practice. We assessed clinical outcomes and the related healthcare resources utilization in patients (pts) implanted with ICD or CRT-D devices in an Italian Region.

Methods: Merged Lombardy Healthcare Administrative Databases (LHAD) information and clinical data recorded in the National ICD/CRT-D Registry (IRCAB) were used to identify pts implanted from 2000 to 2010 by means of indirect patient identifiers. Using this approach, 85.8% of LHAD pts have been linked with IRCAB files. Hospitalizations identified by ICD-9 codes, outpatient visits and drug consumption occurring within 3 years before and 8 years after device implantation were assessed.

Results: From 2003 to 2010, 12,525 pts (81.6% males, mean age 65.4+/-11.9 years) underwent a first device implantation (35.4% with single-chamber ICD, 29.4% with dual-chamber and 35.2% with CRT-D); 11,189 pts (89.4%) had dilated cardiomyopathy (44.2% ischemic, 45.1% idiopathic) and 49.0% had LVEF less than 30%. The number of first implantations increased over time being less than 135 implants in 2000 and more than 1850 implants/year from 2007 onwards; primary prevention indication increased from 12.8% in 2000 to 60% from 2007 onwards. Implant rate in 2005-2010 was 232.5/mln of person-years, whereas replacement rate was 10/100 pts-years. Pts were implanted after a median of 2 days [IQR: 1-7] from hospital admission (length of stay 6 days [IQR: 3-12]) in primary prevention and after 6 days [IQR: 2-11] (length of stay 10 days [IQR: 5-16]) in secondary prevention ($p<0.05$). The mean annual cardiovascular (CV) hospitalization rate/100 patients decreased from 95.7 (CI 95%: 93.5-97.9) in the year before implant to 47.5 (CI 95%: 45.7-49.3, $p<0.05$) in the 2nd year after the implant in ICD pts and from 107.0 (CI 95%: 103.9-110.2) to 52.2 (CI 95%: 49.6-54.9, $p<0.05$) in CRT-D pts. The total annual/pt costs for CV hospitalizations, outpatients visits and drugs significantly decreased from 5,441 € (CI 95%: 5,308€ - 5,613€) in the year before the implant to 2,525 € (CI 95%: 2,423€ - 2,621€) in the 2nd year after the implant.

Conclusions: ICD/CRT-D implantation appears to be effective not only in improving outcomes, but also in reducing CV costs both in ICD and CRT-D pts.

1362

Cost utility of real-time pulmonary artery pressure monitoring using an implantable wireless pressure sensor from the perspective of the united kingdom national health service

M R Cowie¹; M Marcus Simon²

¹Imperial College London, London, United Kingdom; ²SJM International, Inc., Zaventem, Belgium

Introduction: Heart failure treatment guided by physicians with access to real-time pressure measurement from a wireless implantable pulmonary artery pressure (PAP) sensor has previously been shown to reduce hospital admissions for heart failure in the CHAMPION trial of 550 US heart failure patients. Cost effectiveness has also been previously demonstrated from the US health system perspective with an incremental cost effectiveness ratio (ICER) of \$30,167/QALY. PurposeThe system is CE marked but not yet reimbursed in Europe. Although demonstrably effective, uncertainty remains regarding the value of the system in European health systems where healthcare costs are significantly lower than in the US. We present a cost effectiveness analysis using treatment effects from the CHAMPION RCT to model the potential benefit to UK patients and value to the National Health Service.

Methods: A Markov cohort model consisting of two health states (stable heart failure and dead) was developed to estimate the cost effectiveness of PAP pressure guided treatment of heart failure using the CardioMEMS (St Jude Medical Inc) implantable pressure sensor compared to usual care strategies. Cost effectiveness was measured as the incremental cost per QALY gained. The time horizon was 10 years and no effect on mortality was modelled after 5 years. Mortality and hospitalisation rates

for usual care were taken from the literature, costs were calculated based on UK reference costs, quality of life values were modelled from the Champion trial and costs and QALYs were discounted at a rate of 3.5% a year. Distributions were assigned to model input variables in order to enable probabilistic sensitivity analysis to be performed to estimate uncertainty. Results In the base case analysis PAP guided heart failure therapy increased cost of treatment by £12,289 from £6,599 to £18,887 over the 10 year time horizon. Quality adjusted life years (QALY) per patient for usual care were 2.89 and 3.56 for PAP guided patients - an incremental increase in effectiveness of 0.67 QALYs. The resultant incremental cost effectiveness ratio is £18,291 per QALY gained. Varying the hazard ratio for mortality across the 95% confidence interval resulted in an ICER between £10,475/QALY and £59,276/QALY. The model was less sensitive to changes across the CI for the hazard ratio reduction in risk of heart failure hospitalisation where the ICER ranged from £17,293/QALY to £20,540/QALY. Assuming a willingness to pay threshold of £20,000 the system is cost effective in 81% of simulations.

Conclusion: The analysis indicates that integrating wireless pulmonary artery pressure monitoring into the management of UK heart failure patients is likely to be a cost effective addition to the heart failure treatment pathway for appropriate patients.

1363

A cost analysis of HFPEF Vs HFREF in the first year following index hospitalization and enrollment in a disease management programme.

TM Murphy¹; M Ledwidge¹; DW Waterhouse¹; S James¹; J Gallagher¹; E O'Connell¹; R O'Hanlon¹; K McDonald¹

¹Heart Failure Unit, St. Vincents University Hospital, Dublin, Ireland

Background: The index admission with heart failure (HF) is a milestone in the progression of the disease, often resulting in higher intensity medical care and ensuing readmissions. Whilst there is evidence to support enrolling patients in a heart failure disease management program (HF-DMP), there is a scarcity of literature differentiating costs based on ejection fraction.

Purpose: To investigate the financial landscape of the first year following index hospitalization with HF and enrollment in an intensive 3-month hospital based HF-DMP, comparing HFREF with HFPEF.

Methods: 1292, consenting, consecutive patients admitted with a primary diagnosis of HF were enrolled in a hospital based, HF-DMP and categorized as HFPEF (EF ≥ 45%) and HFREF (EF < 45%). In addition to primary care and medication costs, DMP costs were evaluated using an assessment of scheduled and unscheduled DMP clinic visits, telephonic contact and medication changes over 3 months in addition to admissions to hospital over 1 year. Direct costs were included using a combination of casemix and microcosting techniques from the provider perspective.

Results: The total average cost per patient was higher in HFREF €13,011 (12011, 14078) than HFPEF, €12,206 (11009,13518) although confidence intervals overlapped. The cost of running a DMP was approximately 11% of the total annual cost of HF, with the majority of the expenditure allocated to hospitalizations, mainly the index admission and subsequent readmissions. Within the DMP, HFREF patients average cost was significantly greater than HFPEF patients, costing €8.78 a day versus €7.70 during a 90 day intensive DMP and €2.74 versus €2.16 a day for the remaining 9 months. The majority of the cost was associated to scheduled and titration visits. Table 1, Figure 1.

Conclusion: The majority of the financial outlay in the first year following index admission of HF is associated with hospitalization. The cost associated with the clinical workload in a HF-DMP is significantly higher amongst patients with HFREF than HFPEF.

Average (95% CI) cost per-patient Euros	HFREF (n = 879)	HFPEF (n = 413)
Index Admission (LOS based)	7660 (7047,8354)	6302 (5673,7004)
Readmissions	4287 (3574,5042)	5396 (4390,6494)
DMP Clinical Workload (0-3m)	791 (764,819)	693 (660,728)
DMP Clinical Workload (3-12m)	751 (701,802)	593 (533,655)
Medications	596 (579,613)	527 (505,550)
GP visits	594 (582,608)	569 (551,587)
All Costs	13011 (12011,14078)	12206 (11009,13518)

National trends and predictors of readmissions after HF hospitalization in Slovenia

D Daniel Omersa¹; J Farkas¹; I Erzen¹; M Lainscak²

¹National Institute of Public Health, Ljubljana, Slovenia; ²General Hospital Celje, Department of Cardiology, Celje, Slovenia

Introduction: In addition to high mortality, patients with HF are frequently hospitalized and have high readmission rates. There are few studies with nationwide data regarding readmissions after HF hospitalizations, especially for central and east European countries. Thus our aim was to evaluate trends and predictors for HF readmission after HF hospitalization.

Methods: We recorded all HF hospitalizations from the Slovenian national hospital discharge registry between 2004 and 2012 where HF was coded in any diagnose fields. First HF hospitalization was defined as the first HF hospitalization of an individual after 4 years of observational period and 30-, 60-, 90-day and 1-year HF readmission as well as age, sex, year of admission and comorbidities were recorded. Annual readmission proportions were calculated and trends were assessed using ANOVA. Predictors for readmissions were evaluated using multiple log binomial regression analyses.

Results: A total of 156,900 HF hospitalizations in 79,865 patients were recorded (median age 77 yr., 54.3% women). Between 2008 and 2012 there were 43,636 (47.8%) first HF hospitalizations. In 11.7%, 17.2%, 20.9% and 37.5% of those first HF hospitalizations, 30-, 60-, 90-day and 1-year HF readmission followed, respectively. Between 2008 and 2011 increasing trends in annual HF readmission proportions were seen for all readmission endpoints (P < 0.05 for all). Male sex, myocardial infarction, cancer and chronic kidney disease were the most important independent predictors for all readmission endpoints (P < 0.001 for all, Figure). As predictors for HF readmission, myocardial infarction turned out to be less important predictor for 1-year HF readmission whereas chronic obstructive pulmonary disease (COPD) became significant only for 1-year HF readmission.

Conclusion: This retrospective observational study demonstrated increased trends in HF readmissions after HF hospitalization that were associated with specific comorbidities.

Predictors of HF readmission. *per 1 yr.

Global variations in heart failure outcomes: INTER-CHF

Novartis

H Dokainish¹; K Teo¹; S Yusuf¹

¹McMaster University, Hamilton Health Sciences, Hamilton, Canada

Background: Heart failure (HF) is a global health problem. Most HF data comes from North America and Europe, with scant information from the rest of the world.

Methods: INTER-CHF is a prospective, longitudinal cohort study of 5823 participants conducted in 108 centers from 16 countries in Africa, Asia, the Middle East and South America. Patients with a clinical diagnosis of HF were prospectively enrolled over 17 months. Demographic features, risk factors, investigations and therapies were recorded at enrolment, and patients were followed for one year to determine mortality and HF hospitalization. Differences in mortality between regions were examined after adjustment for 12 key clinical variables (Model 1) and additionally for medication use (Model 2) and for socioeconomic variables (Model 3), using Cox proportional hazards analysis.

Unadjusted outcomes at one-year

Variable	China n = 991	India n = 858	SE Asia n = 811	Middle East n = 1000	Africa n = 1294	South America n = 869	P-VALUE
Death at 1 Year (%)	7.1	19.9	13.9	8.9	26.4	8.4	<.0001
HF hospitalization at 1 Year (%)	27.5	16.3	17.6	25.1	24.3	16.1	<.0001
Death or HF hospitalization at 1 Year (%)	31	26.7	24.9	28.8	39	20.4	<.0001

HF=heart failure; SE=Southeast

Results: Among 5823 HF patients recruited, there were 858 deaths (14.7%) at one year. The unadjusted one-year mortality/HF hospitalization or mortality rates ranged from 26.4%/39% in Africa to 8.4%/20% in South America ($p < 0.001$, Table). Adjusting for clinical variables (Model 1) and comparing to patients in South America as the reference, patients from Africa and India [hazard ratio (HR)=3.3 [confidence interval (CI)=2.3-4.8 for both] had the highest mortality, with intermediate risk [HR=2.5 (CI=1.7-3.8) for patients in Southeast Asia and no excess risk for patients in China [HR = 0.75 (CI = 0.5-1.2)] or the Middle East [HR=1.2 (CI = 0.8-1.8)]. After additionally adjusting for medication use, followed by socioeconomic variables, the significantly higher mortality rates in Africa and India remained [HR=3.3 (CI=2.2-4.8) and HR=3.2 (CI=2.1-4.7), respectively].

Conclusions: Heart failure patients in Africa and India have markedly higher one-year mortality rates compared to patients from South America, China and the Middle East, even after adjustment for key clinical variables, medication use, and socioeconomic variables. Understanding the reasons for excess mortality in HF patients from these regions is crucial to improving patient care.

1366

Interpretability of the European Heart Failure Self-care Behaviour scale score

KP Wagenaar¹; BDL Broekhuizen¹; FH Rutten¹; A Stromberg²; AW Hoes¹; T Jaarsma²

¹University Medical Center Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands; ²Linköping University, Department of Social and Welfare Studies, Linköping, Sweden

Background: The European Heart Failure Self-care behaviour scale (EHFScB) is a validated patient-reported outcome questionnaire to measure self-care behaviour of heart failure (HF) patients. It is primarily used in research. It is, however, unknown how its score should be interpreted.

Purpose: To enhance better use, we aimed to assess the interpretability of the EHFScB scale.

Methods: We used cross-sectional data with 12 months follow up of 1,023 HF patients from the COACH study, a randomized trial on effects of support with a disease management program in HF patients (mean age 71 (SD 11) years, 63% male). At baseline demographic characteristics were measured. At baseline, and after 12 months all participants filled out questionnaires on self-care (EHFScB), HF related quality of life (Minnesota Living with Heart Failure Questionnaire (MLHFQ)), while the HF nurse or cardiologist assessed New York Heart Association functional classification (NYHA). In addition, during follow-up hospitalizations and mortality were registered. Interpretability refers to the meaning of score results and changes within. We operationalised interpretability by evaluating distributions of EHFScB scale scores across relevant subgroups by eyeballing, and by defining a threshold. The scale has a standardized score from 0-100, with a higher score meaning better self-care. The distribution of scores across the scale was explored in subgroups of a) severity of HF, b) duration of HF, c) LVEF, d) age, e) gender, f) depressive symptoms, g) knowledge on, and h) education in HF. A threshold of ≥ 70 was defined as adequate self-care, and < 70 as inadequate self-care. The risk on hospitalisations and mortality using the threshold was tested with a Chi2 test.

Results: The distribution of the EHFScBs scores showed a similar pattern in the relevant subgroups with a mean between 57.8 (SD 18.0) and 70.0 (SD 23.6). The 559 HF patients with inadequate self-care (score < 70) had significantly more all-cause hospitalizations than the 464 patients with adequate self-care (score ≥ 70).

Conclusion: Scores on the EHFScBs were equally distributed in relevant HF subgroups. A single threshold of '70' seems to discriminate between adequate and inadequate self-care.

1367

The caregiver burden inventory in evaluating the burden of heart failure patients' caregivers: a multicenter study

A Andrea Greco¹; M Sala¹; L Pancani¹; D Baretta¹; M D'addario¹; A Petruzzio²; R Alvaro²; P Steca¹; E Vellone²

¹University of Milan-Bicocca, Department of psychology, Milan, Italy; ²University of Rome Tor Vergata, Rome, Italy

Background: The importance of caregiver (CG) in the management of many diseases has been well documented, especially for chronic illnesses, as heart failure (HF). For this reason, the maintenance of an acceptable healthy condition and the avoidance of CGs' burden have been underlined as topic issues. Many studies have highlighted that CGs' burden negatively impacts on the quality of life of patients. Many instruments have been validated to measure CGs' burden in different illness contexts but very few have been validated in HF patients' CGs. Purpose. The aim of this study was dual: 1) to provide a psychometric validation of the Caregiver Burden Inventory - CBI in a cohort of HF patients' CGs; 2) to identify determinants of CG burden, considering socio-demographic, clinical, and psychological variables, measured both for patients and their CGs.

Methods: This was a cross-sectional study on Italian HF patients and their CGs, enrolled from different outpatient centers in 28 Italian provinces. CG was defined as the unpaid person, inside or outside the family, who provides the most informal care, as well as designated by the patients. CG strain, quality of life, perceived social support, and contributions to self-care, and patient comorbidities, cognitive function, contributions to self-care, activities of daily living, physical and emotional quality of life, as well as sociodemographic characteristics, duration, severity, and type of HF were measured. Confirmatory factor analyses (CFA) were used to evaluate the structural models of CBI dimensionality and multiple regression analyses were conducted to investigate determinants of CG burden.

Results: In total, 505 HF patients (44.6% female, mean age 75.6 ± 10.7 years) and their CGs (52.2% female, mean age 56.9 ± 14.8 years) were enrolled. CFA showed the items clustered into the original five factors proposed by Novak and Guest (1989): time-dependence, developmental, physical, social and emotional burden. This five-factor model fitted good ($\chi^2(242)=513.287$, $p < .001$; CFI=.95; RMSEA=.047; SRMR=.067), better than other different models, and the dimensions showed high internal consistency (Cronbach's alphas were .908, .917, .875, .893, and .925 respectively). Regression analyses revealed that CG quality of life, CG perceived social support, CG contributions to self-care, and patients disability in activities of daily living, as well as disease severity were the major predictors of CBI dimensions.

Conclusions: CBI proved to be a valid and reliable multidimensional instrument for evaluating the impact of burden of HF patients' CGs. This tool and the identified determinants of CG burden can be considered to tailor interventions aimed at improving CG outcomes. Finally, this study also suggest that the comparison of burden of CGs of patients with different disease is possible using this questionnaire.

CLINICAL CASE CORNER 5: WHEN THE HEART IS BURNING: CASES OF INFLAMMATORY CARDIAC INVOLVEMENT PART II

Acute tetraplegia in idiopathic necrotizing eosinophilic myocarditis

E Edda Bahlmann¹; HS Van Der Schalk¹; AG Ghanem¹; ID Dotz¹; DL Lassner²; UG Gross²; HS Schultheiss²; DK Kivelitz¹; CT Terborg¹; KK Kuck¹

¹Asklepios Clinic St. Georg, Hamburg, Germany; ²Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany

We report a 59-year old man admitted after a motorcycle accident with a left-sided fracture of the tibial head Morre V, treated surgically. Four weeks later laboratory testing revealed increasing inflammatory markers and shortly later he presented confusion, fever, paresis of the right arm, angina and elevated troponin. Coronary angiography ruled out artery stenosis. Clinical signs of right- and soon after left-sided hemiplegia and aphasia followed. Cranial MRI revealed an extensive neurocranial infarction combined with small subcortical hemorrhage. Transesophageal echocardiography confirmed left ventricular (LV) hypertrophy with preserved ejection fraction but was negative for intracardial thrombi, endocarditis, foramen ovale or aortic atherosclerosis. Besides pneumonic infiltrations and congestion, thoracic CT scans revealed new onset and rapid progression of LV wall thickness and subendocardial ischemia. Soon after the patient was resuscitated due to ventricular fibrillation. In cardiac MRI late enhancement particularly in the inner layers probably consistent with myocarditis and apical appositional thrombus formation was found. LV endomyocardial biopsy samples confirmed the diagnosis of a severe active necrotizing eosinophilic myocarditis with endocardial thrombus apposition (figure). Intubation and tracheotomy became necessary because of persistent tetraplegia with dysphagia. Immunosuppressive therapy with prednisolone was immediately initiated and Azathioprine was added and resulted in fast recovery of serum hyper eosinophilia. In addition therapeutic anticoagulation was initiated. The patient was discharged to a neurorehabilitation centre. Discussion: Acute necrotizing eosinophilic myocarditis is a very rare, unclear and potentially fatal condition with variable clinical presentations. Association with parasitic infections, drugs, hypersensitivity reaction, hyper eosinophilic syndrome and paraneoplastic occurrence is reported. This case report is the first reporting a patient with acute necrotizing eosinophilic myocarditis complicated by tetraplegia. Our patient did not present with typically described heart failure symptoms due to cardiac dysfunction. Arrhythmias as in our patient is reported in some cases. The diagnosis is based on endomyocardial biopsy with apparent eosinophilic and lymphocytic infiltration with cell necrosis. Cardiac recovery after immunosuppression is described in patients with impaired left ventricular function. Clinical recognition in this scarce and untreated fatal condition is important to avoid most frequent diagnosis in post-mortem examinations. Figure. Endomyocardial biopsy specimen shows: A endothelium of the endocardium (E), thrombus (T) after necrosis of endothelium, necrosis (N) of myocytes (My) and dense infiltration of inflammatory cells, especially eosinophils; B dense infiltration of inflammatory cells, especially eosinophils (Eo) and macrophages (M) affecting myocytes (My) and necrosis (N).

Figure

1369

Acute necrotizing eosinophilic myocarditis possibly triggered by anti-migraine drug as an uncommon cause of acute heart failure

G Bem¹; F Hehn¹; A Maulaz²; P Schvartzman³; C Astigarraga⁴; J Stiff⁵; BA Duso⁵; M Kronfeld¹; L Luis Beck Da Silva¹

¹Federal University of Rio Grande do Sul - Hospital Clinicas of Porto Alegre, Porto Alegre, Brazil; ²Hospital Moinhos de Vento, Neurology, Porto Alegre, Brazil;

³Hospital Moinhos de Vento, Radiology, Porto Alegre, Brazil; ⁴Hospital Moinhos de Vento, Hematology, Porto Alegre, Brazil; ⁵Hospital Moinhos de Vento, Gastroenterology, Porto Alegre, Brazil

A 29 years-old previously healthy woman walked in to ER with a 14-day history of significant epigastric pain, which had become more intense and associated with retrosternal pain. An upper gastric endoscopy was normal 5 days prior to admission. She did not smoke and had no history of illicit-drug abuse. She was on no regular medication but had repeatedly been taking a combination of Isometheptene 30 mg, Dipyrone 300 mg and caffeine 30 mg (up to six pills a day) for recurrent migraines. Her first ECG, performed while patient was in pain, showed 1 mm ST segment depression in the anterior wall. Troponin was high in 13.0 ng/ml (normal < 0.16 ng/ml) and a first echocardiography had normal left ventricular function. On the first day, white cell count presented eosinophilia up to 19%. Stool exam negative for parasites. A cardiac MRI was suggestive for Myocarditis due to edema and midwall fibrosis on the lateral wall, basal, mid and apical segments of the septal wall and apical segment of the anterior wall. Borderline left ventricular global contractility. Viral markers and tests for autoimmunity were negative or inconclusive. Serum troponin plateau from day 3 to 4, when she was transferred to ICU due to signs of heart failure (HF), BNP >1200 pg/ml, orthopnea, dizziness and chest pain. Treatment for HF was initiated. On day 5, an empirical treatment with prednisone 60 mg/day PO was started, which brought relief of symptoms of HF and of chest pain. On day 7, patient reported a more intense than usual headache. Head MRI revealed multiple lesions involving the white matter of both hemispheres, with pitting and linear enhancement, associated with micro bleeding spots. The association with the additional clinical data and acute myocarditis suggested the possibility of systemic vasculitis with involvement of the central nervous system. A lumbar puncture revealed mild increase in liquor protein. A presumptive diagnosis was Central Nervous System (CNS) vasculitis but we could not exclude the possibility of being a reaction to the vasoconstrictor effects of patient's anti-migraine medication: Isometheptene. On day 8, it was performed an endomyocardial biopsy. Diagnosis of Acute Necrotizing Eosinophilic Myocarditis. (picture). Pulse therapy was started with Methylprednisolone 1g daily, IV, for 5 days. The patient has improved overall clinical status by day 1 of pulse therapy and tolerated well all the infusions. After therapy, troponin levels were reduced to normal (< 0.16 ng/ml), BNP reduced from 1200 to 400 pg/ml and echocardiography showed normal LV function. MRI control performed immediately after pulse therapy showed significant reduction in myocardial edema, preserved LV function and few apical foci of fibrosis. Patient was discharged in good general condition, without clinical manifestations of heart failure and with normal left ventricular function. Four months Cardiac MRI showed preserved LV function and minimal apical foci of fibrosis.

Endomyocardial biopsy and MRI follow-up

Acute rheumatic valvulitis post-streptococcal glomerulonephritis

H A Hafisyatul Aiza Zainal Abidin¹; MK Mohd Arshad¹; JR Ismail¹; ZO Ibrahim¹; CW Lim¹; E Abdul Rahman¹; N Chua¹; RN Khir¹; S Kasim¹

¹ Universiti Teknologi MARA, Cardiology Department, Selangor, Malaysia

Introduction: Acute rheumatic fever is still prevalent in developing countries. Cardiac involvement during the acute phase will lead to chronic sequelae of rheumatic heart disease. We report an unusual case of acute rheumatic fever post-streptococcal glomerulonephritis. Case report: A 14 year-old boy was admitted with a six weeks history of fever, vomiting and worsening shortness of breath. He was diagnosed with post-streptococcal glomerulonephritis a week prior to the onset of symptoms. On presentation, he was in left sided heart failure requiring intubation. Auscultation revealed a loud pansystolic murmur. White cell count was markedly raised as well C-reactive protein level. Echocardiography showed severe regurgitation of the mitral, aortic, tricuspid and pulmonary valves with rheumatic appearance (Figure 1). Left ventricular systolic function was depressed with ejection fraction of 45%. He was started with empirical intravenous benzylpenicillin and high dose hydrocortisone. He responded temporarily to therapy but rapidly deteriorated over a two week period. Description of the problem: This is a case of acute heart failure secondary to acute rheumatic valvulitis refractory to medical therapy. Mortality rate is high if not treated. Urgent surgical intervention during active rheumatic process is questionable. Questions and differential diagnosis: The diagnostic dilemma exists as there was a suspicious vegetation of the tricuspid valve. This raised a concern of concomitant infective endocarditis of the tricuspid valve. Is there a different outcome of valve replacement in patient with infective endocarditis as compared to acute rheumatic carditis?

Answers and discussion: Acute rheumatic fever is diagnosed with Jones criteria; evidence of antecedent streptococcal infection (required criteria), carditis (one major criteria) and fever and raised inflammatory markers (two minor criteria). Echocardiography examination is essential to diagnose cardiac involvement in the acute phase particularly rheumatic valvulitis. Features seen on transesophageal echocardiography strongly point the diagnosis towards rheumatic pathogenesis. This patient has severe heart failure due to hemodynamic derangements produced by severe regurgitation. Emergency valve replacement could potentially be life saving in this case.

Conclusion and implication to clinical practice: The decision for surgical intervention should be based on the severity of the haemodynamic disturbance rather than the active or inactive state of the rheumatic activity. Successful case has been reported although evidence is scarce.

Rheumatic valvulitis

1371

A case of idiopathic aortitis with clinical presentation consisting in acute decompensated heart failure: diagnosis, treatment, follow-up and pathophysiological considerations

R De Vecchis¹; C Ariano¹

¹ Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy

Case description: A 61 year old woman came to our attention with an acute decompensated cardiac insufficiency (ADHF). The findings of the physical examination were a III-IV holodiastolic murmur loudest at the left upper sternal border plus a clinical picture of dyspnea from minimal efforts, rales in the mid-basal lung fields, jugular distention, painful hepatomegaly and peripheral edema. Diagnostic and therapeutic techniques There was a fusiform aneurysm with a diameter of 62 mm involving the ascending aorta, identified by chest computed tomography. Moreover, an echocardiogram showed moderate aortic regurgitation and a dilated aortic root with substantially intact aortic valve, in the presence of preserved left ventricular ejection fraction (EF). Mainly based on these findings, the patient underwent surgical valve-sparing aortic root replacement. Her aortic histopathology revealed medial necrosis with an inflammatory infiltrate consisting of lymphocytes, plasma cells, macrophages and neutrophils. Rheumatologic and infectious laboratory tests were unremarkable, including antinuclear antibodies, anti-neutrophil cytoplasmic antibodies, rheumatoid factor, rapid plasma reagin, fluorescent treponemal antibodies and complement levels. She had no bacterial growth in blood, urine, and stool cultures. Diagnosis Given the pathologic findings in her aorta and lack of an identifiable secondary cause, the patient was diagnosed with idiopathic aortitis (IA). She was observed prospectively with periodic imaging and vascular examinations. At her three-month follow-up, she remained asymptomatic. Discussion In the case of our patient, her IA led to aneurysmal development and subsequent aortic root dilation. Over time, the dilation caused incompetence of the aortic valves, leading to worsening aortic regurgitation and high left ventricular filling pressures, leading to decompensation. The aortic valve itself was not compromised by the aortitis and surgical repair of the dilated root led to cure of the aortic regurgitation and, by association, of the heart failure. Pathophysiology There is some debate between scholars as to whether IA is a distinct entity or merely an early manifestation of systemic rheumatologic disease. Furthermore, management of IA is widely debated, because the decision to adopt a therapy with glucocorticoids or immunosuppressant agents would have a sound rationale only if an immunological origin has been proven. For this reason, in patients with suspected aortitis the European Society of Cardiology recommends periodic imaging and vascular examinations, as well as trending inflammatory biomarkers. Closing remarks a) Patients with suspected aortitis should undergo rheumatologic and immunologic assessments before making the diagnosis of idiopathic aortitis b) The modality of clinical presentation of our case was unusual, because it consisted of an ADHF clinical picture c) Glucocorticoid therapy in patients with IA remains controversial.

Recurrent infection-myocarditis: is there an immunological memory leading to acute cardiac dysfunction, even after complete resolution in previous episodes?

O Barrett¹; JM Weinstein²; A Shalev²; H Abu Kaf³; A Kassem³

¹ Soroka University Medical Center, ¹Department of Medicine D, ² clinical research center, Beer Sheva, Israel; ² Soroka University Medical Center, cardiology division, Beer Sheva, Israel; ³ Soroka University Medical Center, Department of Medicine D, Beer Sheva, Israel

Introduction: Acute myocarditis is an inflammatory disease of the myocardium that manifests in an otherwise healthy person. Various triggers can be accountable, including infectious and noninfectious diseases. Recurrence of myocarditis is infrequent, and in respect to infection-associated myocarditis the rate of recurrence is unknown and described sporadically in a few case reports.

Case report: We present a case of recurrent myocarditis associated with different primary sites of infection and involvement of various pathogens. A 35 year-old healthy male presented to the emergency department (ED) with chest pain, three days after he was diagnosed with Group A streptococcus (GAS) pharyngitis. Past history included two prior episodes of infection-associated myocarditis, with similar clinical presentation. Left ventricular function was normal in Echo studies in both previous episodes, and the patient made a complete recovery. Patient presented with 1 mm ST segment elevation in lateral leads (I, aVL, V6), (figure 1). Troponin T was elevated at 66 ng/l (normal <14). A second troponin was markedly elevated, at 526 ng/l. C-Reactive protein at 121 mg% (normal <0.5). During first day of admission, he had a drop of BP to 85/60 mmHg. Echo demonstrated mild to moderate global LV systolic hypokinesia, and a borderline hypokinetic right ventricle. Under treatment with acetylsalicylic, amoxicillin, ramipril and bisoprolol symptoms have improved. A consecutive echo performed five days later showed recovery of cardiac function, with LV ejection fraction of 60%. He was released with complete resolution of his chest pain. ECG returned to baseline with normalization of troponin and CRP.

Discussion: Our patient was admitted three times with similar clinical presentation. His cardiac echo was normal in two first episodes, whereas on his last admission, he presented with evidence of cardiac dysfunction accompanied by hypotension. In this latest episode, CRP level was markedly elevated, compared with levels seen in the previous episodes. In patients with chronic myocarditis it has been demonstrated that the appearance of antimyosin autoantibodies correlate with development of systolic and diastolic LV dysfunction, and the question is whether recurrent episodes of myocarditis can lead to the expression of similar autoantibodies or other immune factors which are not expressed during remission, but can lead to intensification of response in subsequent exposures, resulting in more extensive myocardial damage. Study in that area is needed to evaluate whether immunological memory plays a role in magnification of cardiac damage during subsequent episodes of acute myocarditis. This knowledge may promote therapeutic approaches and help in identifying patients that might benefit from prophylactic immunosuppressive therapy

Severe dilated cardiomyopathy in myasthenia gravis requiring cardiac transplantation

P M Haydock¹; P J Cowburn¹; A S Flett¹

¹University Hospital Southampton NHS Foundation Trust, Cardiology, Southampton, United Kingdom

Myasthenia Gravis (MG) is a rare autoimmune disorder of neuromuscular transmission, characterized by weakness and early fatigability. Cardiac involvement is rare, but case reports have described an association with Giant Cell Myocarditis (GCM), and Takotsubo Cardiomyopathy. We describe a case of dilated cardiomyopathy in a 17 year old male with MG and a thymoma, ultimately requiring cardiac transplantation and concurrent thymectomy.

The patient initially presented to the neurology service, following the onset of weakness over 1 year. There was no significant past medical or family history. He had features of early fatigability and markedly elevated serum acetylcholine receptor antibody levels. A CT scan demonstrated a thymoma in the anterior mediastinum. Pyridostigmine treatment was commenced to good effect and a plan was made for surgical resection. However, he re-presented with worsening fatigue, felt to be relapsing MG. He was thus admitted for intravenous immunoglobulin (IVIg) therapy. Examination revealed no neurological signs but his vital capacity was significantly reduced. Following the administration of IVIg the patient deteriorated and was found to be in acute heart failure. Echocardiography confirmed severe bi-ventricular dilatation and systolic dysfunction. His ECG is shown. The patient was transferred to the CCU for ongoing treatment. Cardiac MRI demonstrated a severely dilated left ventricle (LV) with an ejection fraction of 16%. The right ventricle (RV) was similarly dilated, and contained thrombus. Late gadolinium enhancement revealed extensive scar throughout both ventricles. Active infection was excluded and treatment with pulsed methylprednisolone for probable GCM was administered. Formal confirmation via endomyocardial biopsy was considered too risky in the context of RV thrombus and anticoagulation. The patient was subsequently assessed for cardiac transplantation but judged to be stable and discharged for ongoing review. One month later he had deteriorated and was placed on the active transplant waiting list. Given the high risk of intercurrent sudden death, a transvenous ICD was implanted. The implant proved challenging due to poor parameters despite multiple attempted lead positions - likely the result of the extensive scarring of the RV. Over six weeks the patient further deteriorated and was readmitted and listed acutely for transplantation. This was performed without the need for interim mechanical support and his thymoma was resected at the same time. Pathology from the explanted heart did not demonstrate any features of GCM and the findings were in keeping with idiopathic dilated cardiomyopathy (DCM).

This case is, to our knowledge, unique in describing a transplant, with concurrent thymectomy, for DCM in Myasthenia Gravis. It also demonstrates the importance of the awareness of potential heart failure where the clinical condition of Myasthenic patients deteriorates.

Multiple pseudotumorous crystalline deposits in small intestine, mesentery and lungs in terminal heart failure patient without gouty arthritis

VS Moiseev¹; AA Shavarov¹; VA Varshavsky²; VV Reshetin³

¹Peoples' Friendship University of Russia, Moscow, Russian Federation; ²I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation;

³City Clinical Hospital No 64, Moscow, Russian Federation

Introduction: Atypical clinical manifestation of gout can vary from unusual disease progression to tophaceous deposits in atypical parts of the body, which can mimic other disease processes. We report a rare case of a patient with tophaceous gout affecting small intestine, mesentery and lungs.

Case report: A 52-year-old man with a past history of two myocardial infarction, arterial hypertension and anemia was admitted for terminal chronic heart failure. One year before patient was hospitalized for severe iron deficiency anemia and colonoscopy revealed tuberosus mass lesion with diameter of 3 sm in ileocecal valve region. Cytologic samples was suggestive of gastrointestinal stromal tumor. On current admission physical examination revealed abdominal mass. Laboratory test indicated hemoglobin of 43 g/l. On the 6th hour of hospitalization, despite the use of inotropic treatment, it was impossible to maintain hemodynamic stability, and the patient died. On postmortem examination multiple soft round-shaped outpouchings along the wall of the small intestine with focal luminal narrowing with approx 70% stenosis were found. Multiple deposits of mesentery coalesced into tumor-like mass (17x12 sm). Multiple round-shaped soft deposits were also observed in all lobes of both lungs. One year before result of chest computed tomography was considered normal. Histologically, the lesional tissue of lung (fig. 1A) and intestine (fig. 1B) exhibited granuloma formation and numerous giant cells. Possible differential diagnosis: Based on the clinical findings and histopathology, the differential diagnoses considered were tumor, tophaceous gout, tuberculosis. Answers and discussion: Histopathologic investigations revealed pink-colored urate crystals surrounded by granulomatous inflammation with foreign-body giant cells. Polarizing light microscopy of grey-brown ointment-like content of deposits in lungs, intestine and mesentery viewed negatively birefringent, needle-shaped monosodium urate crystals. Tuberculosis is characterized by the presence of epithelioid granuloma with Langhans giant cells, which were not observed. No other findings suggestive of gouty arthritis or tumor were obtained from the patient's pathological examination. Severe anemia was related to chronic hemorrhage from multiple intestine lesions.

Conclusion: We demonstrate a rare, if not unique, case of tophi presenting as a mesentery mass, multiple intestinal and especially pulmonary deposits in terminal heart failure patient without gouty arthritis.

Adaptive servo-ventilation in heart failure: results of a randomized, controlled clinical trial

C O'Connor¹; D Whellan²; M Fiuzat³; A Benjafield⁴; H Woehrle⁴;

N Punjabi⁵; K Anstrom³; A Amy Blase⁴; J Lindenfeld⁶; O Oldenburg⁷

¹Inova Heart and Vascular Institute, Falls Church, United States of America;

²Thomas Jefferson University Hospital, Philadelphia, United States of America;

³Duke Clinical Research Institute, Durham, United States of America; ⁴ResMed,

San Diego, United States of America; ⁵Johns Hopkins University of Baltimore,

Baltimore, United States of America; ⁶Vanderbilt University, Nashville, United

States of America; ⁷Heart and Diabetes Center NRW, Bad Oeynhausen, Germany

Background: Sleep disordered breathing is common in heart failure (HF) patients and is associated with worse outcomes in this patient population. The Cardiovascular Improvements with Minute Ventilation-targeted Adaptive Servo-Ventilation (MV-ASV) Therapy in Heart Failure (CAT-HF) trial was designed to examine whether MV-ASV improved outcomes in hospitalized HF patients. During the course of CAT-HF, new results from the Treatment of Predominant Central Sleep Apnea by Adaptive Servo Ventilation in Patients with Heart Failure (SERVE-HF) study indicated ASV therapy may be harmful in patients with left ventricular ejection fractions $\leq 45\%$ and predominant central sleep apnea, a subgroup of patients enrolled in CAT-HF; as a result, enrollment in CAT-HF was discontinued.

Purpose: The CAT-HF Study was designed to evaluate the safety and efficacy of MV-ASV in addition to optimized medical therapy versus optimized medical therapy alone at 6 months, initiated in patients after a hospitalization for ADHF.

Methods: CAT-HF was a prospective, randomized, controlled, multicenter clinical trial (NCT: 01953874) in HF patients with either reduced or preserved ejection fraction and an Apnea-Hypopnea Index (AHI) ≥ 15 events per hour (obstructive or central) randomized to usual care or active treatment in a 1:1 ratio. 215 patients were intended to be randomized following a hospitalization for acute decompensated HF. The primary endpoint is a global rank composite of death, cardiovascular hospitalizations, and six minute walk distance at 6 months. Secondary endpoints include changes in functional parameters, biomarkers, quality of life, and sleep parameters. Results are expected to be completed by January 22, 2016.

Results: At the time of discontinuation, 126 patients were randomized. Mean age was 62 years, 26% were women, and 41% were African-American. At baseline, 81% had left ventricular ejection fraction $\leq 45\%$, the mean six minute walk distance was 206 meters, and the mean AHI was 35 events/hour.

Conclusions: The CAT-HF study was designed to assess the efficacy and safety of MV-ASV treatment in patients with obstructive or central sleep apnea after a hospitalization for acute decompensated HF. The results of this study will provide information regarding treatment in HF patients, and inform future clinical trials.

Clinical significance of tricuspid regurgitation severity in heart failure

D Doron Aronson¹; J Lessick¹; S Yalonsky¹; Y Agmon¹; ZS Azzam¹;

W Darawsha¹; D Mutlak¹

¹Rambam Health Care Campus, Haifa, Israel

Background: Hemodynamically significant tricuspid regurgitation (TR) is common in patients with heart failure (HF) and has been reported to portend poor prognosis. However, it is still unknown whether TR is a surrogate marker of advanced myocardial and valvular heart disease or a mediator of disease progression.

Methods: We studied 623 patients admitted for HF. TR severity was assessed by echocardiography according to ESC guidelines. Congestion was assessed with a 10-point scale. The study endpoint was all-cause mortality with a median follow-up of 2 years.

Results: Higher TR grade was associated with several clinically significant cardiac abnormalities including LVEF $< 45\%$, moderate or severe mitral regurgitation, RV dysfunction and pulmonary artery systolic pressure (PASP) > 50 mm Hg (All

$P < 0.001$). The median PASP was 35, 49, 58 and 60 mm Hg in patients with none/trivial, mild, moderate and severe TR, respectively ($P < 0.001$). There was a graded increase in the number of signs of congestion with increasing TR severity ($P < 0.001$). In addition, higher TR grade was associated with higher BNP, worse renal function and abnormal liver function tests. Kaplan-Meier analysis showed a graded increased probability of mortality during follow-up with increasing TR severity (Figure). However, in a multivariable Cox model adjusting for clinical and echocardiographic parameters, TR was not associated with increased mortality risk. Compared with patients with none/trivial TR, the adjusted hazard ratio for mortality was 0.88 (95% CI 0.53-1.47), 1.12 (95% CI 0.64-1.96) and 1.61 (95% CI 0.86-3.00) in patients with mild, moderate and severe TR, respectively.

Conclusion: In patients with HF, the association between TR and mortality can be explained by associated co-morbidities.

1412

A simple score to discriminate pulmonary hypertension due to HFpEF

E Berthelot¹; D Montani²; C Dreyfuss¹; V Algarrondo³; D Chemla²; O Sitbon²;

M Humbert²; P Assayag¹

¹Hopital Bicetre, AP-HP - Service de Cardiologie, Université Paris-Sud, Le

Kremlin-Bicetre, France; ²Hopital Bicetre, AP-HP - Service de Pneumologie et

Soins Intensifs, Université Paris-Sud, Le Kremlin-Bicetre, France; ³Hopital Antoine

Beclere, cardiology, Clamart, France

Background: Right heart catheterization (RHC) is the gold standard technique to discriminate post capillary pulmonary hypertension due to heart failure with preserved ejection fraction (PH-HFPEF) from precapillary pulmonary hypertension (precapillary PH). Whether clinical exam and cardiac echocardiography could predict the catheterization results is still unknown.

Purpose: this study aims to identify clinical and echographic parameters that best discriminate PH-HFPEF from precapillary PH.

Methods: clinical exam and echocardiography were analyzed and compared to results from RHC in 158 patients referred to the french PH referral center for PH evaluation. RHC identified 78 PH-HFPEF patients that were compared to 78 precapillary PH patients (group 1 and 4 of PH classification).

Results: After the logistic regression analysis, a predictive model of PH-HFPEF was built using the following predictor characteristics: presence of diabetes mellitus (2 points), presence of atrial fibrillation (3 points), left atrial area (from 0 to 4 points), right ventricular diastolic area (from 0 to 2 points) and left ventricular mass index

(from 0 to 4 points). the score was internally validated using the bootstrap technique and showed good predictive characteristics: the C-index of Harrel was 0.94 and the calibration slope was 1.01 (0.75–1.30). With a score > 9, the sensitivity to diagnose PH-HFPEF was 100%. A score < 3 would predict 100% of precapillary PH.

Conclusion: By combining simple clinical and echographic parameters, as diabetes mellitus, atrial fibrillation, left atrial area, left ventricular mass index, right ventricular diastolic area, a score could predict accurately PH-HFPEF from precapillary PH.

Diabetes is associated with long-term adverse clinical outcomes in a multinational cohort of ambulatory patients with chronic heart failure. Results from the ESC-HFA Long-Term Heart Failure Registry.

M Dauriz¹; G Targher¹; C Laroche²; PL Temporelli³; L Alonso-Pulpon⁴; V Celic⁵; AJ Coats⁶; MG Crespo-Leiro⁷; A P Aldo Pietro Maggioni⁸; L Tavazzi⁹

¹University and Azienda Ospedaliera Universitaria Integrata of Verona, Division of Endocrinology, Diabetes and Metabolism, Department of Medicine, Verona, Italy;

²European Society of Cardiology, EURObservational Research Programme, Sophia-Antipolis, France; ³IRCCS Fondazione Salvatore Maugeri, Cardiology Division, Veruno, Italy; ⁴Hospital Universitario Puerta de Hierro, Department of Cardiology, Madrid, Spain; ⁵University Clinical Hospital Center "Dr Dragisa Misovic-Dedinje", Cardiology Department, Belgrade, Serbia; ⁶University of Warwick, Coventry, United Kingdom; ⁷Complejo Hospitalario Universitario A Coruna, CHUAC, Unidad de Insuficiencia Cardiaca Avanzada y Trasplante Cardiac, La Coruna, Spain; ⁸ANMCO Research Center, Florence, Italy; ⁹Maria Cecilia Hospital, GVM Care & Research – ES Health Science Foundation, Cotignola, Italy

Background: Diabetes mellitus (DM) is associated with an increased risk of cardiovascular disease (CVD) and death. As the prevalence of DM has achieved pandemic proportions worldwide and chronic heart failure (CHF) is becoming increasingly common with ageing population, it is timely to evaluate the impact of DM on long-term adverse outcomes among patients with CHF.

Purpose: Currently, there is continuing debate on this topic, and therefore it warrants in-depth investigation.

Methods: We prospectively evaluated the impact of DM status and glycaemic control (as provided by haemoglobin A1c, HbA1c) on the risk of 1-year all-cause death, CVD death and hospitalization for HF in a multinational cohort of 9,428 ambulatory patients with CHF enrolled in the ESC-Heart Failure Long-Term Registry.

Results: Patients with known or newly diagnosed DM represented a considerable proportion of the study cohort (36.5%, n=3,440). Compared with patients without DM, those with DM showed higher cumulative rates of 1-year all-cause death (9.4% vs. 7.2%; adjusted-HR [95% CI] 1.31 [1.10–1.56], p<0.005), 1-year CVD death (4.8% vs. 3.8%; adjusted-HR 1.28 [1.00–1.63], p<0.05) and 1-year HF hospitalization (13.8% vs. 9.3%; adjusted-HR 1.43 [1.23–1.65], p<0.001). These adverse outcomes occurred independently of age, sex, body mass index, smoking, hypertension, estimated glomerular filtration rate, LV-ejection fraction, HF etiology, statin use, prior stroke or chronic obstructive pulmonary disease. Among the patients with CHF and DM, suboptimal glycaemic control was significantly associated with increased 1-year CVD death (adjusted-HR: 3.44 [1.06–11.15]), but not with 1-year all-cause death or hospitalizations for HF.

Conclusions: These results indicate that the presence of DM is associated with an increased risk of long-term adverse outcomes, independently of multiple clinical risk factors, among ambulatory patients with CHF. Since suboptimal glycaemic control is also closely associated with increased CVD mortality among patients with CHF and DM, a more effective and personalized treatment of diabetes should be considered in this high-risk patient population.

1414

In anaemic heart failure patients abnormal erythropoietin is related to disease severity and renal impairment, but neither inflammation nor iron deficiency

M Tkaczyszyn¹; P Van Der Meer²; I Flinta³; C Enjuanes⁴; W Banasiak⁵; AA Voors²; P Ponikowski⁶; J Comin-Colet⁴; EA Jankowska¹

¹Wrocław Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wrocław, Poland; ²University Medical Center Groningen, Department of Cardiology, University of Groningen, Groningen, Netherlands; ³Wrocław Medical University, Department of Physiology, Wrocław, Poland; ⁴Hospital del Mar, Department of Cardiology, Barcelona, Spain; ⁵Military Hospital, Cardiology Department, Centre for Heart Diseases, Wrocław, Poland; ⁶Wrocław Medical University, Department of Heart Diseases, Wrocław, Poland

Introduction: Significant proportion of anaemic heart failure (HF) patients present with abnormal endogenous erythropoietin (EPO) levels and underlying pathomechanism are not fully explained. We investigated the adequacy of endogenous EPO levels in HF patients with anaemia and evaluated whether abnormal EPO levels are associated with iron deficiency (ID).

Methods: Study population comprised of 1821 chronic HF patients from Poland, Spain and the Netherlands. EPO was available in 1026 subjects, of whom 435

(mean age: 74 ± 10 years; men: 60%; New York Heart Association class I/II/III/IV: 9/30/50/11%; HFrEF: 49%) had anaemia (haemoglobin < 12.0 g/dL for women and < 13.0 g/dL for men). The adequacy of endogenous EPO levels was evaluated using the observed/predicted (O/P) ratio. Predicted level of EPO was calculated with the following formula: $\log_{10}(\text{EPO}) = 4.640 - [0.274 \times \text{haemoglobin concentration}]$. Patients with EPO levels higher than expected for a given haemoglobin (Hb) concentration (O/P ratio > 1.087) were considered EPO resistant, whereas EPO levels lower than expected (EPO O/P ratio < 0.916) indicated EPO deficiency. ID was defined as serum ferritin < 100 µg/L or serum ferritin 100–299 µg/L with transferrin saturation < 20%.

Results: EPO deficiency was found in 250 (57%) patients, 95 (22%) subjects were EPO resistant, and remaining 90 patients had adequate EPO levels (as expected for a given Hb level; O/P ratio: 0.916–1.087). Mean Hb in these 3 groups of patients was 10.7 ± 1.1, 12.0 ± 0.8, and 11.4 ± 1.0 g/dL, respectively (p < 0.001 for ANOVA). In the multivariable linear regression model, higher EPO O/P ratio was independently associated with advanced HF symptoms (higher NYHA class), higher plasma NT-proBNP, reduced LVEF, and concomitant ID, whereas lower EPO O/P ratio correlated with worse renal function (reduced eGFR calculated using a MDRD equation) (all p < 0.05). Patients identified as EPO resistant compared to subjects with adequate EPO levels had more severe HF symptoms (NYHA class III–IV: 75 vs. 59%, p = 0.02), higher plasma NT-proBNP (median 3670 vs. 2223 pg/ml, p = 0.03) and lower LVEF (37 ± 17 vs. 43 ± 16%, p = 0.008), whereas eGFR, serum C-reactive protein (CRP) and the prevalence of ID were similar in these 2 groups. Conversely, patients with EPO deficiency had worse renal function (median eGFR 68 vs. 84 ml/min/1.73 m², p = 0.007) than subjects with adequate EPO levels, but these 2 groups did not differ regarding NYHA class, LVEF, NT-proBNP, CRP or the prevalence of ID.

Conclusions: More than half of HF patients with anaemia develop relative EPO deficiency, which is primarily due to renal impairment. Being the feature of advanced HF, EPO resistance is less prevalent pathology. ID does not contribute significantly to abnormal endogenous EPO levels.

1415

Right ventricular dyssynchrony and exercise capacity in idiopathic pulmonary arterial hypertension

R Badagliacca¹; R Poscia¹; B Pezzuto¹; M Reali¹; S Papa¹; G Manzi¹; S Sciomer¹; F Fedele¹; CD Vizza¹

¹Sapienza University of Rome, Dept. of Cardiovascular and Respiratory Science, Rome, Italy

Background: In idiopathic pulmonary arterial hypertension (IPAH), characterized by a severe functional limitation due to right heart failure, indices of resting right ventricle (RV) systolic function are not always able to explain the impairment of exercise capacity.

Purpose: Aim of our study was to evaluate if RV dyssynchrony at rest is related to effort tolerance measured by cardiopulmonary exercise test (CPET) and can explain reduced exercise capacity in patients with preserved RV systolic function.

Methods: One-hundred and five consecutive stable IPAH patients (majority NYHA class III, severe PH) underwent echocardiographic study and symptom limited CPET. RV dyssynchrony was evaluated by 2D speckle-tracking echocardiography calculating the standard deviation of the times to peak-systolic strain for the 4 mid-basal RV segments (RV-SD4). Patients were grouped by the median value of RV fractional area change (RVFAC, 38%) and compared for RV echocardiographic and CPET parameters.

Results: Patients with a RVFAC > 38% presented better morphological and functional echocardiographic parameters and CPET values than the other group. Analyzing the relationship between RVFAC and peak VO₂, we found that a significant portion of patient with preserved RVFAC (> 38%) presented low peak VO₂. Plotting RV-SD4 and peak VO₂, is evident that most of the patients with preserved RVFAC and low peak VO₂ show significant RV dyssynchrony. Evaluating the VO₂ peak determinants by logistic analysis, model 1, considering only hemodynamic variables, showed cardiac index, right atrial (RA) pressure and pulmonary compliance as the independent predictors, with low predictivity (r² 0.31; p < 0.01). In model 2, considering only echocardiographic variables, and excluding RV dyssynchrony, RVFAC and RA area resulted as independent predictors, with low predictivity comparable to model 1 (r² 0.35; p = < 0.01). Adding dyssynchrony analysis to model 2, RV dyssynchrony significantly improved the power of the predictive model, emerging together with RVFAC and RA area as independent predictor of VO₂ peak (r² 0.48; model 3 vs model 1, p < 0.001; model 3 vs model 2, p < 0.001).

Conclusions: Our data show that RV dyssynchrony at rest is an independent predictor of peak VO₂ and may explain reduced exercise capacity in patients with preserved RV systolic function.

Ventricular recovery after bilateral lung transplantation for pulmonary arterial hypertension: a cardiac magnetic resonance study

T M Gorter¹; E A M Verschuuren²; D J Van Veldhuisen¹; E S Hoendermis¹; M E Erasmus³; H J Bogaard⁴; A Vonk Noordegraaf⁴; R M F Berger⁵; J P Van Melle¹; T P Willems⁶

¹University Medical Center Groningen, Cardiology, Groningen, Netherlands;

²University Medical Center Groningen, Lung Transplantation, Groningen, Netherlands; ³University Medical Center Groningen, Thoracic Surgery, Groningen, Netherlands; ⁴VU University Medical Center, Pulmonology, Amsterdam, Netherlands; ⁵University Medical Center Groningen, Paediatric Cardiology, Groningen, Netherlands; ⁶University Medical Center Groningen, Radiology, Groningen, Netherlands

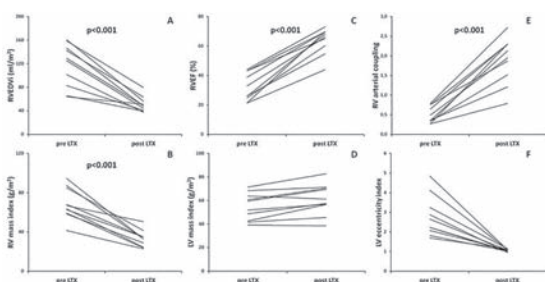

Background: Pulmonary arterial hypertension (PAH) is a serious and often fatal disease and many end-stage PAH patients require lung transplantation (LTX). Timing and type of LTX (i.e. lung versus heart-lung transplantation) is subject of intense debate yet reliable data regarding the effects of LTX on ventricular recovery are scarce. Given the shortage of organs for transplantation, more study on this topic is urgently needed.

Purpose: To investigate the effects of bilateral LTX on ventricular function in patients with severe PAH using cardiac magnetic resonance (CMR) imaging.

Methods: We studied patients with PAH who underwent bilateral LTX between 2000 and 2015 at our institution and in whom CMR was available both pre- and post-LTX. Right ventricular (RV) and left ventricular (LV) volumes, function and mass were measured and RV-arterial coupling, LV-eccentricity index and RV / LV ratio were calculated.

Results: We investigated 10 patients with PAH; their mean age was 41 ± 15 years and pulmonary vascular resistance was 1020 dynes-sec-cm⁻⁵. After LTX, RV ejection fraction increased from 32 to 64% ($p < 0.001$), RV volume decreased from 118 to 51 ml/m² ($p < 0.001$), RV mass decreased from 69 to 33 g/m² ($p < 0.001$) and RV-arterial coupling increased from 0.5 to 1.9 ($p < 0.001$). In addition, LV mass significantly increased after LTX, from 55 to 61 g/m² ($p = 0.005$). LTX resulted in a normalization of LV eccentricity index ($p < 0.001$) and of RV / LV volume ($p < 0.001$) and mass ratio ($p < 0.001$) in all patients.

Conclusion: RV function and morphology markedly improved and also left-sided parameters returned toward normal after bilateral LTX for severe PAH. These results may potentially affect the discussion regarding lung versus heart-lung transplantation in these patients.

Ventricular recovery after LTX

1417

Mid-regional pro-atrial natriuretic peptide predicts unfavorable clinical course in heart failure patients undergoing cardiac resynchronization therapy

M Mattia Arrigo¹; QA Truong²; J Szymonifka²; M Rivas Lasarte¹; H Tolppanen¹; E Gayat¹; A Mebazaa¹

¹Inserm UMR-S 942, Paris, France; ²Weill Cornell Medical College, New York, United States of America

Aims: Cardiac resynchronization therapy (CRT) may improve outcome of patients with chronic heart failure (HF), but despite accurate selection, at least one third of patients receiving CRT remain non-responders. Aim of the study was to assess the properties of NT-proBNP, MR-proANP and MR-proADM to predict CRT response.

Methods and Results: A total of 137 chronic HF patients undergoing CRT device implantation were prospectively included. Blood was collected at the time of CRT implantation and after 6 months. CRT-response at 6 months and major adverse cardiovascular event (MACE) during 2 years were assessed. Baseline levels of MR-proANP and MR-proADM were lower in CRT responders compared to CRT non-responders (202 vs. 318 pmol/L, $p = 0.009$, and 843 vs. 1112 pmol/L, $p = 0.02$, respectively). A similar trend was observed also for NT-proBNP (1019 vs. 2227 pg/mL, $p = 0.06$). At 6 months, CRT responders showed a decrease in MR-proANP levels, compared to an increase in CRT non-responders (-32 vs. $+7$ pmol/L, $p = 0.02$). High baseline MR-proANP levels were associated with reduced likelihood of CRT-response (OR 0.41, 95% CI 0.24-0.71, $p = 0.002$). Furthermore, levels of NT-proBNP, MR-proANP and MR-proADM were associated with increased risk of 2-year MACE (all $p < 0.001$). Patients with MR-proANP levels < 250 pmol/L, compared to patients with higher levels, had higher CRT response (74% vs. 46%, $p = 0.003$) and lower MACE (10% vs. 39%, $p < 0.001$).

Conclusions: Peripheral levels of MR-proANP show strong properties to predict adverse clinical course in HF patients receiving CRT.

1418

Blood urea nitrogen to creatinine ratio in the general population and patients with acute heart failure

Y Matsue¹; P Van Der Meer¹; K Damman¹; JR Teerlink²; CM O'Connor³; SJ Bakker⁴; MM Givertz⁵; RT Gansevoort⁴; DJ Van Veldhuisen¹; AA Voors¹

¹University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands; ²University of California San Francisco, San Francisco, United States of America; ³Duke University Medical Center, Durham, United States of America; ⁴University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands; ⁵Brigham and Women's Hospital, Boston, United States of America

Background: The BUN/Creatinine ratio has been proposed as clinically relevant in acute heart failure, but data on the normal range/value of the ratio are lacking.

Purpose: Aim of this study is to define the normal range of BUN/Creatinine ratio and to investigate the clinical significance of BUN/Creatinine ratio in acute heart failure patients.

Methods: In 8692 subjects of the Prevention of Renal and Vascular End-stage Disease (PREVEND) cohort, we assessed the normal values of the BUN/Creatinine ratio. Based on these normal values, we derived a higher and lower than normal range of BUN/Creatinine ratio, exceeding 95% prediction intervals. We applied this normal range of BUN/Creatinine ratio to 2033 acute heart failure patients (PROTECT cohort).

Results: In the PROTECT cohort, 482 (24.6%) and 28 (1.4%) patients were classified into higher and lower than normal range groups, respectively. Patients with higher than normal range of BUN/Creatinine showed significantly worse survival (Log-rank: $P < 0.001$). In Cox regression analysis, higher than normal range of BUN/Creatinine ratio group was an independent predictor for all-cause death through 180 days (HR: 1.86, 95% CI: 1.30-2.67, $P < 0.001$) and death or cardiovascular or renal rehospitalization through 60 days (HR: 1.38, 95% CI: 1.03-1.83, $P = 0.029$) even after adjustment for other prognostic factors including both creatinine and BUN.

Conclusions: BUN/Creatinine ratio is an age- and sex-related biomarker. BUN/Creatinine ratio is higher in acute HF patients compared with the general population, and a higher than normal range of BUN/Creatinine ratio is associated with worse prognosis independently from both creatinine and BUN.

BUN/Creatinine ratio higher than normal range	482	427	394	370	355	344	277
BUN/Creatinine ratio lower than normal range	1446	1394	1363	1326	1298	1273	1062
BUN/Creatinine ratio within normal range	28	28	28	27	27	27	20

Background: Hospital length of stay (LOS) is a key determinant of heart failure hospitalization costs. Longer LOS is associated with lower performance on quality of care measures and higher rates of subsequent readmission and mortality. Right ventricular (RV) dysfunction predicted poor outcomes in patients with stable chronic HF, however, its prognostic value in the setting of acute decompensated heart failure (ADHF) patients has not been sufficiently clarified.

Purpose: To investigate the prognostic value of RV dysfunction in predicting longer LOS in ADHF patients. **Methods:** A prospective cohort study was conducted in our hospital to all patients admitted with ADHF and had data on baseline RV functions

assessed by tricuspid annular plane systolic excursion (TAPSE). Detailed clinical, laboratory and echocardiographic data were collected on admission. Clinical comorbidities including malnutrition, concomitant pneumonia and worsening renal function (WRF) were monitored during hospitalization. The primary outcome was hospital LOS. Cox regression analysis was used to identify independent predictors for longer LOS.

Results: Two hundred and fifty-nine patients presenting to the emergency department with the diagnosis of ADHF were included in this cohort study. On time-to-event analysis, diastolic blood pressure (HR 1.011, 95% CI 1.004–1.018, $p=0.002$), hemoglobin levels (HR 1.102, 95% CI 1.045–1.162, $p<0.001$), RV dysfunction (measured by TAPSE) (HR 0.659, 95% CI 0.506–0.857 $p=0.002$), WRF (HR 2.015, 95% CI 1.520–2.670, $p<0.001$) and malnutrition (HR 5.965, 95% CI 4.402–8.082, $p<0.001$) were associated with longer LOS. In a multivariate Cox regression model, RV dysfunction (HR 0.515, 95% CI 0.303–0.874, $p<0.02$), WRF (HR 2.989, 95% CI 2.160–4.135, $p<0.001$) and malnutrition (HR 8.211, 95% CI 5.883–11.459, $p<0.001$) were the sole independent predictors of longer length of hospital stay.

Conclusions: Right ventricular dysfunction is an important predictor of longer length of hospital stay. Routine assessment of the right ventricle should be considered in the evaluation of patients with ADHF.

Objective: Heart failure (HF) patients often have multiple chronic conditions (MCCs). In the current study, we examined incremental impact of MCCs in patients with HF and reduced ejection fraction (HFrEF).

Methods: Of the 2707 patients with advanced HF and EF $<35\%$ in the Beta-Blocker Evaluation of Survival Trial (BEST), 59% had coronary artery disease (CAD), 37% had chronic kidney disease (CKD), 36% had diabetes mellitus (DM) and 24% had atrial fibrillation (AF), and 17.4%, 33.0%, 29.8%, 16.2% and 3.6% had none, 1, 2, 3, or all of these conditions. Using multivariable-adjusted Cox regression models, we examined association of having 1 to 4 morbidities with outcomes during an average of 2 years of follow-up, compared with no morbidity.

Results: Patients had a mean age of 60 years, 22% were women and 23% African American. Association of MCCs with all-cause hospital admission and all-cause mortality are displayed in Table. Similar associations were observed for HF hospitalizations. These associations appeared more pronounced among those <65 years than among those ≥ 65 years.

Conclusion: In patients with advanced HFrEF, there appears to be a graded association between number of morbidities and outcomes, which appear to be more pronounced among younger patients.

Obstructive sleep apnea increases the risk of heart failure: a population-based follow-up study.

P-H Pao-Hsien Chu¹; Y-S Lin²

¹The First Cardiovascular Department, Chang Gung Memorial Hospital, Chang Gung University, Taipei, Taiwan ROC; ²Linkou Chang Gung Memorial Hospital, Cardiology, Tao-Yuan, Taiwan ROC

Background: Obstructive sleep apnea (OSA) is related to heart failure (HF) is not clear. We aim to clarify the relationship between OSA and incidence of HF.

Methods: The population-based cohort study consisted of patients with newly diagnosed OSA between 2000 and 2009. The comparison cohort was matched for age, sex, diabetes mellitus and hypertension. All subjects previously been diagnosed with acute or chronic kidney disease were excluded. The primary end point was newly diagnosed with HF during the study period.

Results: We identified 6,866 subjects with OSA followed up for a median of 4.4 years. The median follow-up year from OSA to HF is 3.2 years with 2.5 months earlier than non-OSA cohort. Hazard Ratios (HR) for risk of HF with OSA versus non-OSA were 2.4 (95% CI, 2.07–3.44; $p=0.045$) and 2.3 (95% CI, 2.0–2.6; $p=0.019$) among those without hypertension or diabetes.

Conclusion: Our data provides the first prospective evidence that obstructive sleep apnea is significantly related to the occurrence of HF even without hypertension and diabetes.

RV-fwLS/PAP* (%/mm Hg)	0.04 (0.01-0.09)	< 0.001	0.76	0.26 (0.08-.85)	0.025	0.86

*Ratio calculated on the basis of absolute values of right ventricular strain measures. †Multivariate models separately included right ventricular systolic function parameters due to collinearity.

The aim of this study was to evaluate right ventricular (RV) ventriculararterial coupling by 2-dimensional (2-D) strain and estimated right ventricular systolic pressure in order to assess their role in predicting mortality in chronic heart failure (CHF).

Methods: We enrolled 315 outpatients (77% males, 64 ± 13 years, NYHA class 2.2 ± 0.7 , left ventricular ejection fraction, LVEF $33 \pm 9\%$) with CHF (ESC criteria), in stable clinical conditions (>1 month) and in conventional therapy. All patients underwent a clinical evaluation, a routine chemistry and an echocardiogram. A right focused four-chamber view was analyzed by 2-D speckle tracking to evaluate the longitudinal strain of RV free wall (RV-fwLS). Moreover, the tricuspid annular plane systolic excursion (TAPSE), by mono-dimensional echo, and estimated right ventricular systolic pressure(PAPs) were measured. Ventriculararterial coupling was evaluated as the ration between the parameters of RV systolic function and PAPs.

Results: During a mean follow-up of 36 ± 26 months, 69 patients died. As shown in the table, at Cox univariate regression analysis TAPSE and RV-fwLS as well as their relative parameters of ventriculararterial coupling, i.e. TAPSE/PAP and RV-fwLS/PAP, were all associated to mortality. However, only RV-fwLS/PAP showed the greatest accuracy assessed by C-index value. Finally, RV-fwLS/PAP but not TAPSE/PAP remained significantly associated to events when separately included in multivariate Cox models with age, LVEF, logNTproBNP, glomerular filtration rate, NYHA class, mean arterial pressure. Figure shows Kaplan Meier curves according to RV-fwLS/PAP quartiles.

Conclusions: Our results suggest the possible usefulness of 2-D strain derived measures in order to evaluate right ventriculararterial coupling and to stratify patients' prognosis in CHF. RV systolic shortening assessed by 2-d strain combined to PAPs seems to allow a more accurate estimation of the length/force relationship than TAPSE/PAP.

Mean velocity of the pulmonary artery estimated by cardiac MRI as a prognostic indicator in heart failure with reduced ejection fraction

B Trejo Velasco¹; F Ridocci Soriano¹; O Fabregat Andres¹; MP Garcia Gonzalez¹; DC Perdomo Londono¹; C Albiach Montaniana¹; GN Chacon Hernandez¹; L Higuera Ortega¹; JP Cardenas¹; S Sanchez¹

¹University General Hospital of Valencia, Cardiología, Valencia, Spain

Introduction: Pulmonary hypertension (PH) implies a worse prognosis in chronic heart failure (HF) specially when right ventricular dysfunction overcomes. Although cardiac catheterization is the gold standard technique for the diagnosis of PH as it allows to directly measure the pressure at the pulmonary artery Cardiac MRI permits an accurate evaluation of pulmonary pressure through vascular peripheral resistance

estimation, which have already shown their prognostic value in heart failure. However, their calculation requires of multiple measurements that can limit its utility in daily practice.

Purpose: the aim of this study was to establish more simple parameters that permit a precise assessment of pulmonary artery pressure through cardiac MRI and to evaluate their prognostic value in HF.

Methods: we prospectively included 151 patients (mean age 64.6 ± 12.7 years, 71% male) admitted for acute HF with left ventricular dysfunction (LVD) (ejection fraction <40%). We measured the mean velocity at the pulmonary artery (mvPA) with cardiac MRI and divided our sample in two groups according to the optimal cutoff value for event prediction calculated by ROC curve (mvPA = 10cm/s). We considered readmission for HF and total mortality as primary events in the follow up and performed a survival analysis with a Kaplan-Meier survival curve.

Results: 67 patients had mvPA value <10cm/s. There were no differences in baseline characteristics between the two groups. During a mean follow up period of 13 months there were 66 events in the total sample; 47 of them in the group with lower mvPA (Log Rank 18.82, $p < 0.0001$); Figure 1. We identified mvPA and atrial fibrillation as independent predictors in Cox multivariable analysis (CI 95%, $p < 0.008$), Table 1. Right ventricular dysfunction was not an independent prognostic predictor in multivariable analysis.

Conclusion: mvPA below 10cm/s by cardiac MRI indicates a worse prognosis in patients with HF and LVD, independently of right ventricular function. Therefore this parameter could act as an early prognostic indicator in these patients.

Multivariable analysis		
Variable	HR(IC 95%)	p value
Late gadolinium enhancement	0.88 (0.47-1.66)	$p = 0.7$
Ischaemic cardiomyopathy	0.83(0.46-1.50)	$p = 0.55$
Severe left ventricular dysfunction < 30%	1.12 (0.63-2.02)	$p = 0.31$

Prognostic impact of iron deficiency in heart failure with preserved and reduced ejection fractionB Borut Jug¹; D Kosuta¹; D Omersa²; M Lainscak³¹Dept. of vascular diseases, University clinical center, Ljubljana, Slovenia; ²National institute of public health, Ljubljana, Slovenia; ³General Hospital Celje, Celje, Slovenia**Background:** Iron deficiency is associated with impaired exercise tolerance and symptom progression in patients with heart failure.**Purpose:** To assess the prognostic impact of iron deficiency on heart failure-related events in outpatients with chronic, stable and optimally managed heart failure.**Methods:** Consecutive patients referred for heart failure outpatient management at three centres were prospectively enrolled. Iron deficiency was defined as ferritin <100 mcg/L or ferritin 100–300 mcg/L and transferrin saturation <20%. Patients were followed for a minimum of six months for heart failure related events (i.e. death or hospitalization).**Results:** A total of 469 patients (mean age 74 ± 11 years, 39% females, 47% with preserved left ventricular ejection fraction) were included; 119 (25%) experienced an event during a median follow up of 236 (interquartile range 85–411) days. In multivariate Cox model, iron deficiency emerged as a strong predictor of heart failure-related events (odds ratio /OR/ 2.062; 95% confidence interval /95%CI/ 1.234–3.445; $p=0.006$), even after adjustment for age, gender, NYHA class, ischemic etiology, natriuretic peptides, kidney function, and anemia. A significant trend for iron deficiency to predict heart failure-related events was retained in both, patients with reduced and (alas to a lesser extent) with preserved ejection fraction: OR 2.366 (95% CI 1.247–4.488, $p=0.008$) and OR 1.880 (95% CI 0.917–3.861, $p=0.085$), respectively (figure).**Conclusions:** Iron deficiency is a predictor of adverse events in outpatients with both, heart failure with reduced and with preserved ejection fraction.

Iron deficiency and survival in HF

Early systolic anterior motion of interventricular septum due to increased right ventricular dyssynchrony predicts accurately impaired right ventricular ejection fractionV Vladislavs Sokalskis¹; D Peluso¹; V Spadotto¹; P Aruta¹; D Muraru¹; L Badano¹¹University of Padova, Padua, Italy**Background:** Besides right ventricular (RV) ejection fraction (EF) <35%, RV dyssynchrony was described as an independent parameter of clinical outcome in pulmonary hypertension (PH) patients.**Purpose:** This study examines a relation between RV dyssynchrony, RV EF and interventricular septum (IVS) motion patterns.**Methods:** 24 men (63 ± 12 years), 68 women (66 ± 14 years) with pre-capillary PH were retrospectively studied. RV dyssynchrony was quantified as a standard deviation of time to peak systolic strain of basal and mid segments of RV free wall and IVS. Septal kinetics were assessed by M-mode. RVEF was quantified from 3D echo data sets. Post-systolic shortening (PSS) was quantified as a relation between max time to peak systolic strain of abovementioned RV segments to pulmonary valve closure time.**Results:** PH patients with increased RV dyssynchrony (Table 1) showed early systolic anterior motion (ESAM) of IVS (Fig. A) that occurred within/after QRS complex and its peak was after the R-wave. It appeared in all patients with (positive) PSS in contrast to patients with end diastolic anterior motion (EDAM) (Fig. B). ESAM pattern showed 89% sensitivity and 96% specificity in detecting RV EF <35% (AUC 0,98; $p<0,001$), being more accurate than TAPSE <17 mm (67% sensitivity, 73% specificity; AUC 0,69; $p=0,021$). Although RV dyssynchrony correlated well with mPAP, RV free wall strain and RV EF ($r=0,55$, $r=0,7$, $r=-0,85$, all $p<0,01$), in the multi-variable analysis only the latter was an independent predictor ($\beta=-0,63$, $p<0,01$).**Conclusions:** Increased RV dyssynchrony and, thus, PSS strongly correlated with the early systolic anterior motion of IVS. This M-mode sign could be applied as a stratification tool to detect the impaired RV ejection fraction.

POSTER SESSION 3

Monday 23 May 2016

Location: Poster Area

ACUTE HEART FAILURE

P1426

Repeated echocardiography in patients with inferior myocardial infarction and acute heart failure

I Imad Meray¹; LA Babaeva¹; AF Safarova¹; MA Teterina¹; AS Pizaruk¹; VS Moiseev¹

¹ Peoples Friendship University of Russia (RPFU), Moscow, Russian Federation

Background: Acute mitral regurgitation (AMR) is a frequent reason of acute heart failure (AHF) in patients with acute inferior myocardial infarction (AMI) and usually underdiagnosed.

Purpose: To examine the frequency of AMR as a reason of AHF in patients with first inferior ST elevation AMI.

Methods: In the study 62 patients with first acute inferior ST elevation myocardial infarction and signs of AHF on admission were included, 40 patients with moderate and 22 with severe AHF. Echocardiography was done every day in the first 3 days.

Results: AMR was diagnosed in 30 patients (48.4%). The reasons of AMR was papillary muscles dysfunction in 21 (16.1%) patients and papillary muscle rupture in 9 (14.5%) patients. The left ventricle ejection fraction was more than 40% in all patients with AMR. In the first day AMR was diagnosed in 15 patients, 11 and 4 patients in the second and third days consequently.

Conclusion: The reason of AHF in patients with first inferior ST elevation AMI was AMR in about half of the patients usually diagnosed in the first 3 days.

P1427

Performance of dynamic change of cardiac output in the diagnosis of acute heart failure (AHF) in patients with acute dyspnea. Comparison between patients with reduced and preserved left ventricular

WAFA Zhani¹; KAOUTH Beltaief¹; HBIB Grissa¹; NIZAR Fredj¹; ADEL Sekma¹; NASRI Bzouiech¹; HAMDY Boubaker¹; WAHID Bouida¹; SEMIR Nouira¹

¹ fattouma bourguiba hospital, emergency department, monastir, Tunisia

Aim of study: To evaluate the diagnostic performance of cardiac output (CO) change with dynamic and pharmacological maneuvers in the diagnosis of AHF in patients with acute dyspnea, and to study the difference between those with reduced and preserved LVEF.

Materials and Methods: A prospective study conducted in the emergency department (ED) of our hospital including patients over 18 years admitted for acute dyspnea. We measure CO using thoracic bioimpedance : at baseline supine position (SP), during leg rising (LR), in sitting position(S), during Valsalva maneuver (VM) and after administration of sublingual nitroglycerin (NTG test). Heart failure (HF) is defined on the basis of clinical examination, serum levels of pro-BNP and echocardiographic findings. Patients were divided into three groups: control group including patients without HF (HF -), group with reduced LVEF (<50%) and group with preserved LVEF (≥50%).

Results: 291 patients were included in this study with an average age of 64 years and a sex-ratio (M / F) 0.62. In patients with HF and LVEF <50%, only NTG test is associated with a significant different change of CO compared to control group (respectively -23% versus -36%, $p < 0.01$) figure 1. In patients with HF and LVEF ≥50%, only VM is associated with a significant different change of CO compared to control group (respectively -21% versus -31%, $p < 0.01$) figure 2.

Conclusion: In patients presenting to the ED for acute dyspnea, HF can be detected by CO change with NTG test in patients with reduced LVEF and VM in patients with preserved LVEF.

Figure 1: Cardiac output change with dynamic maneuvers in patients with reduced LVEF

Figure 2: Cardiac output change with dynamic maneuvers in patients with preserved LVEF

Value of diagnostic investigations in the emergency room in patients suspected of having heart failure

N Nuria Farre¹; R Olivero²; I Rodriguez-Costoya²; N Sancho³; P Moliner⁴; C Enjuanes⁴; S Ruiz²; J Comin-Colet⁴

¹Hospital del Mar, Municipal Institute for Medical Research (IMIM), Barcelona, Spain; ²Hospital del Mar, Department of Cardiology, Barcelona, Spain;

³Autonomous University of Barcelona, Barcelona, Spain; ⁴Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain

Background/Introduction: Diagnosis of heart failure (HF) cannot be solely based on signs or symptoms due to its low specificity or insensitivity. Therefore, the 2012 ESC HF Guidelines recommends that HF diagnosis be supported with diagnostic investigations in these patients. In the acute setting, the optimal exclusion cut-off point for NT-proBNP is set at 300 pg/mL.

Purpose: To analyse the sensitivity (S), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of diagnostic investigations in a contemporary cohort of patients with suspected HF.

Methods: Retrospective analysis of all patients admitted into the emergency department (ED) between January 1st - December 31st 2014 who had an NTproBNP determination for suspected HF. Diagnosis of HF was done according to the 2012 ESC HF Guidelines.

Results: A total of 820 patients were analysed. Mean age was 77.9 years, 52% were women. Comorbidities were frequent: 41% of patients had diabetes mellitus, 82% hypertension. Chronic kidney disease, chronic pulmonary disease, ischemic

heart disease or valve disease had a prevalence of around 25% each. Nine percent of patients had dementia and 14% had had a stroke. All patients had a chest X-ray and ECG done in the ED. HF was diagnosed in 64% of patients. Although NTproBNP was higher in patients with HF (median 4620 [p25-p75: 2085-9535] pg/mL vs 1307 [401-4070] in non-HF patients), 91% of the whole cohort had NTproBNP levels ≥ 300 pg/mL (98% in HF vs 79% in non-HF patients, $P < 0.001$). Value of diagnostic investigations are shown in Table 1.

Conclusions: The presence of pulmonary oedema and pleural effusion on chest X-ray had a high specificity for the diagnosis of acute HF. An abnormal ECG did not help to establish the diagnosis of HF. In a contemporary cohort of unselected elderly patients with comorbidities, an NTproBNP value of 300 pg/mL has little diagnostic value.

Table 1

	Frequency in the whole cohort, n (%)	S	Sp	PPV	NPV
Abnormal ECG	681 (85)	82%	14%	34%	58%
Cardiomegaly on chest X-ray	415 (51)	61%	67%	77%	49%
Pulmonary oedema on chest X-ray	108 (13)	18%	95%	86%	39%
Pleural effusion on chest X-ray	235 (29)	34%	80%	75%	41%
NTproBNP ≥ 300 pg/mL	749 (91)	88%	21%	69%	46%

P1429

Heart failure diagnosis in the emergency department: are classical signs and symptoms useful?

N Nuria Farre¹; I Rodríguez-Costoya²; R Olivero²; N Sancho³; C Enjuanes⁴; P Moliner⁴; S Ruiz²; J Comin-Colet⁴

¹Hospital del Mar, Municipal Institute for Medical Research (IMIM), Barcelona, Spain; ²Hospital del Mar, Department of Cardiology, Barcelona, Spain; ³Autonomous University of Barcelona, Barcelona, Spain; ⁴Hospital del Mar, Department of Cardiology, Municipal Institute for Medical Research (IMIM), Barcelona, Spain

Background/Introduction: Diagnosis of heart failure (HF) is challenging because most of its signs and symptoms lack specificity or are insensitive. The diagnostic value of classical HF signs and symptoms has seldom been evaluated in contemporary cohorts that include old or comorbid patients.

Purpose: To analyse the sensitivity (S), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of classical HF signs and symptoms in a contemporary cohort.

Methods: Retrospective analysis of all patients admitted into the emergency department (ED) who had an NTproBNP determination for suspected HF from January 1st to December 31st 2014. Diagnosis of HF was done according to the 2012 ESC HF Guidelines.

Results: A total of 820 patients were analysed. Mean age was 77.9 years, 52% were women. Comorbidities were frequent: 41% of patients had diabetes mellitus, 82% hypertension. Chronic kidney disease, chronic pulmonary disease, ischemic heart disease or valve disease had a prevalence of around 25% each. Nine percent of patients had dementia and 14% had had a stroke. HF was diagnosed in 64% of patients. Diagnostic value of key signs and symptoms are described in Table 1. Presence or absence of hepatomegaly and third heart sound (gallop rhythm) were seldom documented on medical charts.

Conclusions: Only 2/3 of patients with suspected HF in the ED are diagnosed with HF. Breathlessness was the main complaint but specificity was low. The presence of paroxysmal nocturnal dyspnoea had the highest specificity.

Table 1

Signs/symptoms	Frequency in the whole cohort, n (%)	S	Sp	PPV	NPV
Breathlessness	720 (88)	96%	26%	70%	78%
Orthopnoea	330 (40)	52%	81%	83%	49%
Paroxysmal nocturnal dyspnoea	191 (23)	32%	92%	87%	43%

Clinical characteristics of acute decompensated heart failure patients hospitalized in the intensive care unit of internal medicine department

A Alice Balaceanu¹; C Diaconu²; M Fronea³; G Dediu³; C Despan³; M Ciocan³; C Voiculet¹; G Aron¹; I Dina¹

¹UMF Carol Davila, Emergency Clinical Hospital Sf. Ioan, Internal Medicine Clinic, Bucharest, Romania; ²UMF Carol Davila, Emergency Clinical Hospital Floreasca, Internal Medicine Clinic, Bucharest, Romania; ³Emergency Clinical Hospital Sf. Ioan, Internal Medicine Department, Bucharest, Romania

Introduction: A large number of patients are hospitalized for acute decompensated heart failure in the internal medicine department of emergency hospital.

Purpose: to evaluate the prevalence and in-hospital characteristics of acute decompensated heart failure in patients consecutively admitted in the intensive care unit of Internal Medicine Clinic, from a university emergency hospital.

Methods: A retrospective study was conducted on 98 patients admitted for acute decompensated heart failure, from January 2013 to December 2014. Hemoglobin, BUN, serum creatinine, eGFR, uric acid, glycaemia, sodium and potassium levels, and acid-base balance were monitored. Transthoracic echocardiography was performed.

Results: 53% of patients were male and 47% were female. Mean age was 76.7+/-12.56 for males and 82.8+/-8.27 for females. Acute respiratory failure with dyspnea was the reason for admission in all patients. Hypertension was present in 66% of patients, diabetes mellitus in 30.61% and COPD in 19.38% of patients. Arterial acid-base balance was evaluated in 82.65% patients in the first day of admission. 41.83% of patients had acidosis. Respiratory acidosis associated to heart failure was prevalent, despite chronic kidney disease who was present in 55.10% of patients. LVEF <45% was measured in 73.46% of cases. 17.34% of patients had hyponatremia on admission. Uric acid was increased in 24.48% of patients. 26.53% of patients with acute decompensated heart failure had at least one infection in the first day of admission. The most prevalent bacteria were *Klebsiella* spp (34.61%).

Conclusions: Acute respiratory failure with acidosis was the principal reason for admission in acute decompensated heart failure.

Critical analysis of a plasma NT-proBNP led acute heart failure service at our institution over 1 year

J Draper¹; J Jessica Webb¹; Y Yiu¹; S Piper²; C Plymen²; T Mcdonagh²; S Kapetanakis¹; R Rajani¹; G Carr-White¹

¹St Thomas' Hospital, Cardiology Department, London, United Kingdom; ²King's College Hospital, Cardiology Department, London, United Kingdom

Background: Recent guidelines have suggested that patients presenting acutely with symptoms and signs of symptomatic heart failure should have NT-proBNP testing to exclude heart failure and help rationalise echo usage. We therefore evaluated such a system in a large tertiary centre cardiac unit. All patients presenting with possible heart failure underwent NT-proBNP testing. Those with values above 400ng/l automatically received an echocardiogram with a dedicated heart failure sonographer and a heart failure consultant review.

Methods: All consecutive patients who had plasma NTpro-BNP requested between 10/09/2014 and 09/09/2015 were included. Hospital databases and records were used to identify diagnoses, length of stay and inpatient mortality. Outpatient mortality was confirmed using Summary Care Records (range 4-16 months). Data was collected as part of our Institution's approved Clinical Audit.

Results: In total, 2144 patients had plasma NTpro-BNP testing because of the clinical suspicion of heart failure. 1791 patients (85%) had a NT-proBNP over 400ng/litre. 156 patients were discharged before the heart failure team could see the patients. These patients had a mortality rate of 9.6%. The average time for the heart failure team to review for heart failure patients was 1.01 days (SD 0.51). 1153 (70%) patients were reviewed within two days by the heart failure team and 1456 (89%) within three days. 737 patients had echocardiography to facilitate the heart failure review; the study was not repeated if it had been performed within 6 months. 34 patients were sent home with arrangements made for echocardiography within two weeks – of these, 6 patients had heart failure. In total, 605 patients had heart failure; 398 patients had Left Ventricular Systolic Dysfunction (LVSD) (65.7%), 138 patients had Heart failure with preserved Ejection Fraction (HFpEF) (22.8%), and 69 patients had Right Heart Failure (RHF) (11.4%). This represents an increase compared to results from 2013/2014. Patients with LVSD had a mortality rate of 25.8%, compared to 12.5% in HFpEF, 22.1% in RHF and 24% in patients without heart failure. Readmissions with heart failure was common; 79 patients presented twice, 20 patients presented three times, 5 patients presented 4 times, 2 patients presented 5 times during the year and 1 patient presented 6 times. However, the mortality for patients who readmitted was increased (LVSD 35.4%, HFpEF 27.6%, RHF 35.7%).

Conclusions: Our data suggests a NT-proBNP led acute heart failure service with a dedicated heart failure physiologist does diagnose patients with heart failure in a timely fashion. In our unselected cohort of over 2000 consecutive inpatients with

suspected heart failure over a year, only 31% of those with a raised NT-proBNP level ended up with a clinical diagnosis of heart failure. Of these patients 67% had LV systolic dysfunction. This raises questions as to whether peptide testing as an acute screen is not specific enough.

P1432

High risk clinical profiles in severe forms of acute heart failure syndrome

V Enache¹; AC Nechita¹; I Iordache¹; SC Stamate¹; MM Vintila¹

¹University of Medicine and Pharmacy Carol Davila, Emergency Hospital St. Pantelimon, Bucharest, Romania

Introduction: Acute heart failure (AHF) is a syndrome with still high in-hospital and early post-discharge mortality. A lot of clinical and paraclinical parameters with prognostic value come from national and international registries. Just a few data related to clinical forms.

Purpose: identifying high risk clinical profiles for in-hospital mortality (IHM) in patients with severe clinical forms of AHF syndrome.

Methods: 228 patients with two severe forms of AHF syndrome: Chronic Decompensated Acute Heart Failure NYHA IV class (CDAH NYHA IV class) and non-Acute Coronary Syndrome Pulmonary Edema (nonACS APE), admitted in an Emergency Hospital – Cardiology between 01.01-31.12.2013; divided and analyzed by etiology and clinical form. Biologic, clinic and echocardiographic parameters with prognostic value were established for each form; risk profiles were defined.

Results: 136 patients CDAH NYHA IV class, 92 patients nonACS APE. Males, CDAH vs non ACS APE 55.88% vs 45.65%, similar mean age (73 years). Significant statistical differences ($p < 0.001$) for cardiovascular risk factors incidence, higher for nonACS APE (hypertension - 89.13% vs 69.12%, dyslipidemia - 76.09% vs 39.71%, type II diabetes mellitus 45.65% vs 32.35%) and for some comorbidities ($p < 0.05$), higher in CDAH NYHA IV class for atrial fibrillation (33.82% vs 19.56%) and history of HF (100% vs 80.43%). IHM was 17.54%, statistically significant associated with non ACS APE at admission (non ACS APE vs CDAH, 9.64% vs 7.89%, $RR=1.14$, $p=0.005$). Regardless of etiology, for CDAH NYHA IV class, the following parameters proved to have independent prognostic value for IHM: urea > 67 mg/dl ($p < 0.001$), sodium < 130 mEq/l ($p=0.007$), systolic blood pressure at presentation < 100 mmHg ($p=0.004$), right atrio-ventricular gradient > 41 mmHg ($p=0.005$) and $E/E' > 20$ ($p=0.006$), and for nonACS APE: sodium < 130 mEq/l ($p=0.002$), EDT < 196 ms ($p=0.03$), diastolic left ventricular diameter (DLVD) > 54 mm ($p=0.15$).

Conclusions: There are enough clinical and paraclinical data to help us to define a high risk clinical profile in severe clinical forms of AHF syndrome. Our analysis highlighted a high risk for IHM for nonACS APE as clinical form ($p=0.005$, $RR=1.14$), for CDAH NYHA IV class with hypotension at admission, hyponatremia (< 130 mEq/l) and high blood urea (> 67 mg/dl) and echo with high filling pressure and pulmonary hypertension and for non ACS APE associated with hyponatremia (< 130 mEq/l), high filling pressure (EDT < 196 ms) and dilated left ventricle (DLVD > 54 mm). Larger groups of patients are needed for risk score development, taking into account all of these parameters.

P1433

Relationship between clinical and hemodynamic presentation of heart failure deterioration and left ventricular ejection fraction - preliminary report

AG Galas Agata¹; PK Krzesinski Pawel¹; KP Piotrowicz Katarzyna¹; RR Ryczek Robert¹; GG Gielerak Grzegorz¹; AS Skrobowski Andrzej¹

¹Institute of Military Medicine, Department of Cardiology and Internal Diseases, Warsaw, Poland

Background: Treatment of patients with heart failure (HF) deterioration is one of the most challenging problems in acute cardiovascular care. However, cardiovascular risk of the ones with mildly impaired and preserved left ventricular ejection fraction (LVEF) might be underestimated. The use of simple, noninvasive methods of hemodynamic assessment such as impedance cardiography (ICG), can support the hemodynamic assessment and adequate treatment strategy of those high risk patients.

Aim: We aimed to evaluate the clinical and hemodynamic status of patients with HF deterioration with respect to LVEF.

Methods: The study was performed in a group of 45 patients (37 men; mean age 73.1 years, mean LVEF 37.6%) hospitalized in the cardiology department because of HF deterioration (NYHA class 4; $n=17$). Clinical evaluation at admission included: NYHA class, NT-proBNP concentration and hemodynamic assessment of i.e. systolic and diastolic blood pressure (SBP, DBP), cardiac index (CI), systemic vascular resistance index (SVRI) and thoracic fluid content index (TFCI), measured by ICG. The analysis focused on comparison between patients with severe left ventricular systolic dysfunction (LVEF $\leq 35\%$; mean LVEF 27.6%; $n=22$) and mild or no left ventricular systolic dysfunction (LVEF $> 35\%$; mean LVEF 47.1%; $n=23$).

Results: The main differences between subgroup with LVEF $\leq 35\%$ and LVEF $> 35\%$ were: percentage of males (96% vs 70%; $p=0.023$) and age (80.0 vs 69.0 years; $p=0.004$). The prevalence of resting dyspnea (NYHA 4) was almost equal

(41% vs 35%; $p=0.671$). The only statistically significant hemodynamic distinctions were: lower SBP (128.5 vs 142.8 mmHg; $p=0.030$) and CI (2.77 vs. 3.34 l/kg/m²; $p=0.008$). The trend to higher TFCI (19.6 vs. 17.5 l/kg/m; $p=0.138$) and NT-proBNP concentration (5710 vs 4486 pg/mL; $p=0.151$) was also observed, but there was no significant difference in SVRI (2372 vs 2239 dyn*s/m²/cm⁵; $p=0.589$).

Conclusions: The severity of clinical state and hemodynamic alterations in patients with HF deterioration are not related to great extent to LVEF. The early use of ICG in HF deterioration provides complex hemodynamic monitoring and seems to be justified.

P1434

The correlation between pressure gradient on tricuspid valve regurgitation and cardiac function in patient with left ventricular systolic dysfunction

J-P Jong-Pil Park¹; S-H Lee²; D-Y Lee²; J-E Song²; S-H John²; J-Y Rhew²; J-Y Lee²; W-J Kim⁴

¹Presbyterian Medical Center, Jeonju, Korea Republic of; ²Presbyterian Medical Center, Jeonju, Korea Republic of; ³Kangbuk Samsung Hospital, Seoul, Korea Republic of; ⁴CHA University, Seongnam, Korea Republic of

Background and Purpose: It is known that assessment of pulmonary artery pressure (PAP) can be a monitoring tool for managing heart failure (HF). However, the correlations between change of pressure gradient (PG) on tricuspid valve regurgitation (TR) as an indirect monitoring tool of PAP and functional change of left ventricular (LV) systolic function in patients with systolic dysfunction are not well known

Methods: From our echocardiographic laboratory database, we searched for and reviewed total 99 patients (59 males, 40 females; mean age 68 ± 13 years) who had LV systolic dysfunction under 50% of ejection fraction (EF) on initial transthoracic echocardiography (TTE) and underwent follow up TTE consecutively two times. TTE data included evaluation of systolic function, pressure gradient of TR. Patients were subdivided into two groups and compared with percent changing of LVEF between 3rd and 1st TTE (Group 1 showed improvement over 30% of PG between 2nd and 1st TR ($n=50$) and the Group 2 showed under 30% improvement or aggravated PG of TR ($n=49$)). And, the linear regression was applied to determine the relationships between percent change of PG of TR (between 2nd and 1st) and percent change of EF of LV (between 3rd and 1st).

Results: The initial mean EF of LV was $31.9 \pm 10.6\%$ and 2nd and 3rd follow up mean EF showed significant improvement of EF (45.5 ± 12.2 and $52.4 \pm 12.2\%$, $p < 0.001$). The initial mean PG of TR was 35.6 ± 14.6 mmHg and 2nd and 3rd follow up mean PG of TR showed significant improvement (24.8 ± 12.2 and 26.4 ± 12.2 mmHg, $P < 0.001$). The percent change of LVEF between 3rd and 1st TTE was significantly higher on Group 1 ($43.8 \pm 17.7\%$ vs. $31.8 \pm 19.9\%$, $p=0.003$). There was a negative correlation between percent change of PG (2nd and 1st TTE) and change of LVEF (3rd and 1st TTE) ($r = -0.313$, $p=0.008$).

Conclusions: When patients presented acute heart failure with LV systolic dysfunction, the improvement of PG of TR on follow up TTE could be an important marker of final improvement of LV systolic function.

Medium term prognosis of Egyptian patients hospitalised with acute decompensated heart failure

R Reham Awad¹; BASSEM Ibrahim¹; OSAMA Louis¹; RANIA Hanna¹; HOSSAM Abd-El Aliam¹

¹National Heart Institute, heart failure unit, Cairo, Egypt

Background: Heart failure represents a serious heart muscle disease that is associated with a bad outcome. Predictions the Middle East will be witnessing a growing epidemic in the next decade.

Purpose: To study different biochemical, electrophysiological, clinical and pharmaceutical parameters that affect heart failure prognosis in patients hospitalized with any form of decompensated heart failure.

Methods: We analyzed available inpatient data collected from Apr to Oct 2013 by heart failure unit in National Heart Institute in Egypt. The unit is the first heart failure unit nation wide with the largest number of admissions. Our study included 100 consecutive patients who were admitted with different forms and etiologies of decompensated heart failure. We assessed clinical, laboratory, electrocardiographic and echocardiographic indices with follow up 6 months for clinical status, re-hospitalization, death and major cardiovascular events.

Results: The mean age of our patients was (51.3 ± 14.9) years which is less than the mean age of heart failure patients in developed countries. Male patients were 66 and females were 34. We also found that heart failure secondary to ischemic heart disease represent the major cause of admission (54%) and the valvular heart disease was not uncommon (11%). Other etiologies were DCM (15%), HFpEF (8%), PPCM (6%), congenital heart disease (2%), chemotherapy induced cardiomyopathy, restrictive cardiomyopathy and tachyarrhythmia induced heart failure. 42% of our patients had a history of previous hospitalization due to heart failure. 86% were currently on heart failure treatment measures, of which (25.5%) were non compliant to medical treatment, (12%) of patients were not on treatment and (2%) were

first diagnosed as heart failure patients. On discharge, (75%) of discharged patients were on ACE-I or ARBs, (54%) were on BB, (91%) were on spironolactone and (65%) were on digoxin. Mortality was 9 and 18 during hospitalization and follow up period respectively giving a total mortality of 27. It was found that, patients who died in-hospital had significantly higher liver enzymes ALT (366 ± 839 vs. 29.4 ± 22.5 U/L, $p < 0.001$), and AST (276.7 ± 637 vs. 29.4 ± 22.5 U/L, $p < 0.001$) and significantly higher CK-MB. Cumulative re-hospitalization rate was 37 (40.6%) and (27%) of them were re-hospitalized more than once. Regarding 6 month mortality and rehospitalization : it was higher in the elderly patients, diabetics, and AF, those who were hypotensive, hyponatremic on admission and those who showed rising creatinine levels during hospitalization. Less mortality was noticed in patients receiving digoxin and BB.

Conclusion: Heart failure patients in Egypt have a different clinical profile, a lower mean age and worse prognosis compared with patients in western countries. Valvular heart disease is still responsible of significant proportion of heart failure. We probably need to improve our prescription increasing BB and decreasing digoxin.

P1436

Clinical outcomes of patients with decompensated heart failure

LR Moraes¹; LM Gomez¹; CB Terhoch¹; HF Moreira¹; SM Ayub-Ferreira¹; SG Lage¹; MT Oliveira¹; VS Victor Sarli Issa¹; EA Bocchi¹

¹Heart Institute (InCor) do Hospital das Clínicas da Faculdade de Medicina da Universidade São Paulo, Sao Paulo, Brazil

Introduction: Heart failure is major source of morbidity and mortality in Latin America; however, demographic data, etiology, clinical presentation and prognosis have not been systematically analyzed in recent cohorts.

Methods: We analyzed a cohort of 409 patients admitted for decompensated heart failure in a tertiary hospital dedicated to cardiology from August 2013 through December 2015; demographic data, etiology (including Chagas' disease), clinical presentation and prognosis were reviewed.

Results: Mean age was 55.3 ± 15 years and 254 (62.1%) patients were male; left ventricle ejection fraction was $30 \pm 12\%$; 102 (24.9%) patients had ischemic heart disease, 97 (23.7%) Chagas' cardiomyopathy, 74 (18.1%) idiopathic dilated cardiomyopathy and 48 (11.7%) hypertensive disease. At admission BNP level was 1486 ± 1297 pg/dL and creatinine 1.96 ± 1.2 mg/dL. During hospital admission 45 (11%) patients were submitted to heart transplant and 128 (31.3%) died. 85 (20.7%) patients received an intraaortic balloon pump (IABP) and 54 died (63.5% mortality); patients with Chagas disease that received IABP had lower mortality as compared to other etiologies (51% vs 71%, $P = 0.06$)

Conclusion: Patients with decompensated heart failure have a high mortality rate. The use of IABP is of limited use in these circumstances.

P1437

The value of a simplified lung ultrasound protocol at hospital discharge in patients with acute heart failure

A Frigy¹; IA Szabo²; I Kocsis¹; L Fehervari¹; L Mathe¹

¹University of Medicine of Targu Mures, Targu Mures, Romania; ²Clinical County Emergency Hospital Mures, Cardiology, Targu-Mures, Romania

Optimal timing of hospital discharge in patient with acute heart failure (AHF) is an important factor of preventing rehospitalizations. Our aim was to evaluate the value of a simplified lung ultrasound (LUS) protocol in assessing pre-discharge status of patients with AHF, correlating the LUS findings with the values of NT-proBNP.

Methods: 24 patients (18 men, 6 women, mean age 68,2 years) hospitalized with acute heart failure underwent LUS examination in the afternoon of the day before hospital discharge. In the next morning the NT-proBNP value was also determined. We applied a simplified LUS protocol using on the right three basal (anterior, lateral and posterior) and on the left two basal (lateral and posterior) examination areas. The LUS score was represented by the sum of B lines. The correlation between LUS findings and NT-proBNP values was analyzed using Fisher's exact test (significant $p < 0,05$).

Results: 6 patients had < 15 B lines, 16 patients had >15 B lines and 2 patients had pleural effusion on LUS, while 16 patients had the value of NT-proBNP >1000pg/ml at discharge. The results of LUS correlated significantly ($p = 0,0022$) with the NT-proBNP values – only one patient not having increased NT-proBNP in the group with >15 B lines.

Conclusions: Despite a relatively good clinical status, the majority of patients had high NT-proBNP values at the time of hospital discharge. LUS proved to be a useful tool in identifying patients with subclinical congestion reflected by the high NT=proBNP levels. These patients may need a prolongation of hospitalization and/or a more careful follow-up to prevent early readmission.

P1438

Correlation between low body mass index and clinical safety outcome measures of patients with congestive heart failure: perspective of a single-centre, prospective pilot study

S Khaled¹; L Faour¹; K Khaled Salem¹

¹King Abdullah Medical City, Cardiology Departement. Heart failure program, Makkah, Saudi Arabia

Background/Introduction: The correlation between low body mass index (BMI) and congestive heart failure (obesity paradox) has been described in the literature; however, the association between BMI and clinical outcome measures is not well characterized.

Purpose: This study aimed to describe the correlation among BMI and myocardial infarction (MI)/cerebrovascular accident (CVA)/mortality composite outcome, combined infection/bleeding and combined CVA/transient ischaemic attacks (TIA)/unexplained syncope outcome measures of patients with heart failure with reduced ejection fraction (HFrEF).

Methods: Retrospective analysis of prospectively collected data of a single centre heart failure registry in Saudi Arabia.

Results: Of 167 patients with HFrEF, 41 (25%) had BMI of ≤ 24 kg/m². The low BMI group had higher composite MI/CVA/mortality (19% vs 3%; $P = 0.014$) and composite infection/bleeding (12% vs 19%; $P = 0.016$) rates compared with those with BMI of >24 kg/m². Moreover, the study revealed that lower the BMI, higher the CVA/TIA/unexplained syncope (23.9, 5.5 vs 28.7, 6.2; $P = 0.01$), higher the composite MI/CVA/mortality (26.4, 5.6 vs 29, 6.3; $P = 0.014$) and lower the combined infection/bleeding (27.7, 5.8 vs 31.3, 7.3; $P = 0.01$) rates.

Conclusion: Patients with HFrEF having BMI of ≤ 24 kg/m² had a higher incidence of MI/CVA/mortality, higher combined CVA/TIA/unexplained syncope incidence and lower combined incidence of bleeding/infection compared with those having BMI of >24 kg/m².

CVA/TIA/syncope and BMI correlation

Gender and racial differences in surgical outcomes among adult patients with acute heart failure

CM Arslanian-Engoren¹; JJ Sferra²; MC Engoren³

¹University of Michigan School of Nursing, Health Behavior and Biological Sciences, Ann Arbor, United States of America; ²ProMedica, Surgery, Sylvania, Ohio, United States of America; ³University of Michigan Health System, Anesthesiology, Ann Arbor, Michigan, United States of America

Background: Approximately three million U.S. adult females, age 20 and older, are living with heart failure (HF). While both males and females are affected by this cardiac syndrome, females are more likely than males to develop it, be discharged from the hospital for HF and to die from it compared to males. Black females have the highest prevalence of HF compared to White females and Black males. However, little is known about racial and gender differences in 30-day perioperative outcomes in patients with new or acute/worsening HF.

Purpose: To describe gender and racial differences in 30-day surgical morbidity and mortality outcomes among adult patients with new or acute/worsening HF.

Methods: A secondary analysis of 2012-2013 National Surgical Quality Improvement Program (NSQIP) data was conducted to compare 30-day morbidity (e.g., infection, myocardial infarction) and mortality of adults patients with new or acute/worsening HF undergoing surgical procedures (e.g., cardiac, orthopaedics, vascular).

Results: A total of 9548 NSQIP patients had HF of which 6827 (72%) were White and 1470 (15%) were Black; 5155 (54%) were male and 4393 (46%) were female. Males were more likely to be of White race, have diabetes mellitus, smoke, undergo vascular surgery, and be functionally independent. Females tended to be older and more likely to undergo general or orthopaedic surgery.

By multivariate analysis, females were more like to have a postoperative urinary tract infection (OR=2.012, 95% CI=1.497-2.704, $p<.001$) and bleed excessively (OR=1.130, 95% CI=1.004-1.271, $p=.043$), while males were more likely to suffer a cardiac arrest (OR=1.524, 95% CI=1.190-1.951, $p=.001$) or myocardial infarction (OR=1.373, 95% CI=1.012-1.864, $p=.042$). 30-day mortality rates did not differ by gender (670 males (13%) vs 558 females (13%), $p=.690$), but did by race. Blacks were less likely to die compared to Whites (OR=0.691, 95% CI=0.552-0.866, $p=.001$), but were more likely to develop renal failure (OR=1.567, 95% CI=1.107-2.218, $p=.011$) and to require admission within 30 days (OR=1.175, 95% CI=1.007-1.372, $p=.041$).

Conclusions: Gender and racial differences in 30-day surgical outcomes were noted for adults with acute HF. Further study is needed to identify the factors that lead to these differences.

P1440

In-hospital mortality in patients hospitalized for acute heart failure: comparison between actual and predicted

Novartis Farma provided a grant for statistical analysis

MV Bertao¹; I Marques¹; B Ferreira²; RL Ramos¹; S Abreu¹; J Lopes¹; S Nunes³; D Mendonça⁴; L Teixeira⁴

¹Hospital Center of Porto, Internal Medicine Department, Porto, Portugal; ²Hospital da Luz da Arrábida, Internal Medicine Department, Vila Nova de Gaia, Portugal;

³Hospital Center of Entre Douro and Vouga, Polyvalent Intensive Medicine

Department, Santa Maria da Feira, Portugal; ⁴University of Porto, Population Studies Department, Institute of Biomedical Sciences Abel Salazar, Porto, Portugal

Introduction: Clinical models predicting in-hospital mortality risk in patients hospitalized for acute heart failure (AHF) have been developed. Acute Decompensated Heart Failure National Registry (ADHERE) risk tree provides clinicians with a practical bedside tool using systolic blood pressure, creatinine and blood urea nitrogen obtained at hospital admission. Nonetheless, can not estimate accurately mortality in certain real-world populations.

Purpose: This study aims to compare in-hospital mortality risk predicted by ADHERE risk tree and the actual mortality in patients hospitalized for AHF.

Methods: Retrospective observational study that enrolled all patients hospitalized for AHF and discharged from an internal medicine department in 2012. Clinical records were queried for data collection from the 429 enrolled patients. Ten patients were excluded for lack of data to estimate ADHERE risk group. Chi-square test or Fisher's Exact test were performed to compare in-hospital mortality risk predicted by ADHERE risk tree and the actual mortality in patients hospitalized for AHF.

Results: Thirty four patients (7.9%) died during AHF hospitalization. Comparing this study population with the validation cohort of ADHERE risk tree, the first had higher mortality in Low Risk, Intermediate Risk 2 and Intermediate Risk 1 groups (4.5% vs 2.3%, $p=0.017$; 12.5% vs 5.6%, $p=0.024$ and 40.0 vs 13.2%, $p=0.003$, respectively).

Conclusions: Patients hospitalized for AHF in our department experienced higher global in-hospital mortality than patients enrolled in ADHERE validation cohort, reported as 4%. Nevertheless, our mortality rate is similar to recent observational surveys. When analysing groups of risk given by ADHERE risk tree, certain patients are more prone to die, presenting in-hospital mortality rate which is the double in Low Risk and Intermediate Risk 2 and fourfold in Intermediate Risk 1, comparing with ADHERE validation cohort stratification groups. These results improve our knowledge and should influence patient management since the very first hours at emergency room. Although a simple tool for managing these patients, ADHERE risk tree is not readily applicable and needs to be validated to specific populations and clinical scenarios.

P1441

The evolution of endothelial dysfunction, serum uric acid and NTproBNP in decompensated chronic heart failure

M Madalina Ababei¹; A Campeanu¹; D Nistorescu¹; T Nanea¹

¹University of Medicine and Pharmacy Carol Davila, Internal Medicine "Prof. Th. Burghel" Hospital, Bucharest, Romania

Background: The complex hemodynamic and neurohumoral hyperactivation mechanism implied by heart failure pathophysiology has led to revolutionary treatments in the past 15-20 years. Furthermore, new pathophysiological models, such as endothelial dysfunction or oxidative stress, are being pursued, aiming for new risk and prognostic markers.

Purpose: Analyzing the relationship between endothelial dysfunction and serum uric acid (SUA) and NTproBNP for patients suffering from acute de novo and decompensated chronic heart failure. **Method:** The study was based on data from 50 patients with an average age of 70.84 ± 8.72 years suffering from decompensated chronic heart failure caused by ischemic cardiomyopathy. The most common causes for decompensation were ischemia aggravation and medication or sodium diet non-compliance. The cardiac function has been evaluated echocardiographically. The flow mediated vasodilatation method was used to evaluate endothelial function, values below 10% indicating cases of endothelial dysfunction. Also, the

dynamics of SUA and NTproBNP has been studied. Hyperuricemia, defined by values above 7 mg/dL in males and above 6 mg/dL in females, was found in 54% of the subjects. A decrease in the averages was observed during hospitalization both for SUA - 7.22 ± 2.77 mg/dL at admission vs. 5.94 ± 1.86 mg/dL at discharge - and NTproBNP - 4935 ± 4861 µg/dL at admission vs. 2660.62 ± 3442 µg/dL at discharge. Results: A significant improvement in the endothelial function was observed during hospitalization, vasodilatation levels rising from an average of $9.56\% \pm 6.25\%$ at admission to an average of $17.80\% \pm 8.57\%$ at discharge ($p<0.0001$). While 29 of the subjects (58%) presented endothelial dysfunction at admission, the dysfunction was only present at discharge in 8 of the cases (16%) ($p=0.01$). Significant correlations have been found both between the vasodilatation and SUA evolution ($r=0.32$, $p=0.025$) and between the vasodilatation and NTproBNP evolution ($r=0.349$, $p=0.015$).

Conclusions: Interdependency between the endothelial function and the evolution and prognostic biological parameters seems to be present. The results suggest a connection between the endothelial dysfunction and acute and decompensated chronic heart failure pathophysiology. These parameters could lead to new risk and prognostic indicators.

Introduction: Heart rate (HR) is a modifiable risk factor of death and early hospitalizations in patients (pts) with systolic heart failure (HF). However recommended treatment optimization with the aim to achieve target HR (<70 beat per minute -bpm-), is still unsatisfactory after acute HF hospitalization.

Purpose: To investigate the proportion of patients eligible for ivabradine treatment after an acute decompensated HF (ADHF) hospitalization and at the first outpatient appointment.

Methods: We evaluated retrospectively 309 consecutive pts discharged from 3 Italian hospitals with a HF dedicated team, between January 2012 and the end of September 2015, with a left ventricular ejection fraction (LVEF) $\leq 40\%$. Pts eligible for ivabradine were defined based on LVEF $\leq 35\%$, sinus HR ≥ 70 bpm, NYHA class II-IV.

Results: At discharge 71 pts (23.0%) were eligible for ivabradine. Among them 10 pts were discharge with ivabradine, 2 pts were already on this drug, and 59 pts (19.1%) although eligible did not receive ivabradine. Characteristics of 59 pts not on ivabradine at discharge were: age 65 ± 14 years, female 32%, ischemic etiology 35.6%, median LVEF 28% (interquartile range -IQR: 25-30%), 40.7% were de novo cases, NYHA class III-IV 32.2%, with a mean systolic blood pressure of 109 ± 18 mmHg, median HR 75 bpm (IQR: 72-84 bpm, a previous episode of atrial fibrillation (AF) in 32.2%, on beta-blockers 86.4% (median carvedilol dosage 15.6 mg/day; median bisoprolol dosage 2.5 mg/day), on amiodarone 37.3%, on digoxin 3.4%. At first outpatient appointment (after a median time of 3 months, IQR: 2-6 months) only 28 (9.1%) pts were still eligible for ivabradine. During the time between discharge and the first appointment we reported 2 deaths, 6 HF rehospitalizations, and 6 pts were lost at follow up. At the first appointment in 5 pts ivabradine was started, thus 24 (7.8%) pts were still without proper HR control without ivabradine prescription. The characteristics of this population not on ivabradine was 68 ± 14 years, female 42%, ischemic etiology 37.5%, median LVEF 30% (interquartile range -IQR: 25-32%), NYHA class III-IV 20.8%, with a mean systolic blood pressure of 120 ± 24 mmHg, median HR 78 bpm (IQR: 75-83 bpm, a previous episode of AF in 29.2%, on beta-blockers 79.2% (median carvedilol dosage 12.5 mg/day; median bisoprolol dosage 2.5 mg/day), on amiodarone 33.3%, on digoxin 8.3%. **Conclusion(s):** Even in HF specialized centers, 19.1% of pts discharged after an ADHF event were not on ivabradine although suitable for this treatment. At first outpatient appointment the proportion of pts still eligible for ivabradine was 7.6%. It must be noted that up to 32% of pts not on ivabradine at discharge had a previous episode of AF, and titration of beta-blockers could also be pursued. The attractive hypothesis that a more rapid achievement of HR target could reduce early events after an ADHF needs perspective validation.

Diastolic dysfunction has differential impact on clinical outcomes of diabetic versus non-diabetic patients hospitalized with acute heart failure: a population based study

This research was supported by grants from the National Institutes of Health: PO1 HL 76611, R01 HL 84155

H Horng Chen¹; SH Wan¹; JP Slusser¹; D Hodge¹

¹Mayo Clinic, Rochester Mn, United States of America

Background: The association between diastolic dysfunction (DD) severity and clinical outcomes in patients hospitalized for acute heart failure (AHF) with and without

diabetes remains undefined. Our objective is to compare the clinical characteristics, echocardiographic characteristics, and clinical outcomes of those with and without diabetes hospitalized with AHF based on severity of DD.

Methods: Retrospective analysis of 428 adults residing in a County hospitalized from 2005 to 2008 for primary diagnosis of AHF and who had sufficient Doppler echocardiographic data to classify diastolic grade according to the American Society of Echocardiography (ASE) classification. Those with indeterminate diastolic grade were excluded. Demographic, clinical, laboratory, and echocardiographic data were collected. AHF was identified from ICD-9 codes. Mean follow up was 6.5 ± 3.2 years.

Results: Of 428 subjects who had characterization of diastolic grade during hospitalization, 186 (43.5%) had diabetes mellitus (DM) and 242 (56.5%) did not have diabetes. Among those with both AHF and DM, 81.2% had moderate or severe DD (grade 2 or greater), whereas among those with AHF but not DM, 68.6% had moderate or severe DD. In subjects with both AHF and DM, those with moderate or severe DD had higher HbA1c levels (6.9 ± 1.4 , $p = 0.036$) compared to those with normal diastolic function (6.0 ± 1.2) or with mild DD (6.2 ± 0.9). Ejection fraction was similar among all diastolic grades (average 45.8%, $p = 0.49$). Among those with AHF and DM, the severity of DD was associated with increased risk of cardiac and heart failure rehospitalization ($p < 0.05$). However, among those with AHF but without DM, there was no association with diastolic grade and cardiac or heart failure rehospitalization.

Conclusions: Among those hospitalized for AHF, those with DM had a greater prevalence of moderate or severe DD compared to those without DM. Those with the most severe diastolic grade in the DM group were more likely to have higher HbA1c levels. Among those with both AHF and DM, there was an association between diastolic grade severity and cardiac and heart failure rehospitalization. This association is not seen among those without DM.

Non-recovery of renal function in acute heart failure is an independent predictor of long-term mortality

J Joao Carmo¹; P Freitas¹; MJ Baldo²; R Morais²; P Vicente²; A Leitao²; F Marques²; I Araujo²; L Campos²; C Fonseca²

¹Hospital de Santa Cruz, Lisbon, Portugal; ²Hospital de Sao Francisco Xavier, Lisbon, Portugal

Background: Renal dysfunction is one of the strongest risk marker in acute heart failure (AHF). Although admission serum creatinine (SCr) and worsening of SCr during hospitalization have been reported as risk predictors, significance of recovery of renal function at discharge is uncertain.

Methods: One hundred and thirty-five consecutive patients were admitted to our Heart Failure Unit with AHF. SCr was obtained on admission, during hospitalization and at discharge. Worsening of renal function (WRF) was defined as an increase of SCr > 0.3 mg/dL during hospitalization when compared to admission SCr. The recovery of renal function was defined as a decrease of SCr > 0.3 mg/dL at discharge, when compared to peak SCr. All cause mortality during long-term follow-up was assessed as clinical endpoint.

Results: The population had a mean age of 75 ± 12 years, 53% were female and 54% presented at class IV NYHA. In patients with WRF during hospitalization ($n = 46$), total mortality during mean follow-up of 20 months was 55.6% versus 28.9% in patients without WRF (log rank 0.001). Cox proportional hazard models identified non-recovery of renal function at discharge (hazard ratio HR 5.94, CI 95% 2.64 to 13.38, $p < 0.001$), age (HR 1.04, 1.00 to 1.07, $p = 0.048$), chronic obstructive pulmonary disease (HR 2.03, 1.03 to 3.98, $p = 0.040$), use of a renin angiotensin system inhibitor (HR 0.27, 0.13 to 0.57, $p = 0.001$), urea (HR 1.01, 1.00 to 1.02, $p = 0.001$) and albumin (HR 0.41, 0.19 to 0.87, $p = 0.019$) as independent predictors of long-term mortality. There was no significant difference in mortality between patients with WRF and recovery of renal function ($n = 28$) and those without WRF ($n = 89$) (HR 1.53, 0.74 to 3.16, $p = 0.253$).

Conclusion: In patients with AHF, non-recovery of renal function is the strongest independent predictor of all-cause mortality at long-term follow-up.

P1445

Short term prognostic factors in patients hospitalized with acute heart failure

ML Barbu¹; IL Bruckner¹; A Mihailescu¹; DV Spataru¹; AL Gurghean¹

¹Coltea Clinical Hospital, Bucharest, Romania

Background: The perpetually growing burden of cardiovascular disease is one the most important socioeconomic aspects of modern medicine. Hospitalization for heart failure symptoms is on the rise, because of an increase in incidence and the difficulties of managing such patients, both on the short and long term. There is a need to properly define the factors that impact the prognosis of patients, so as to implement new strategies of better care which might improve survival and quality of life.

Purpose: The purpose of our descriptive study was to analyze the records of the patients admitted for acute heart failure (AHF) in our cardiology unit, with a focus on certain parameters which influence treatment options and the decision to discharge.

Material and methods: From the total number of admissions in our secondary cardiology unit in 2014, almost 30% were for decompensated heart failure. The total number of patients was 189, a fifth of whom had multiple readmissions. Less than 4% of admissions were for acute pulmonary edema; the vast majority of patients had acutizations of chronic heart failure (NYHA class IV). The median age of the group was 76, with an even distribution on sexes. More than half of the patients had heart failure with preserved ejection fraction.

Results: The main underlying etiology was ischemic heart disease, with half of the patients also having valvular disease (mitral or aortic). For 20% of the subjects, the underlying pathology was hypertensive cardiopathy, while two thirds of the group had atrial fibrillation. More than half of the cases associated pulmonary hypertension.

Looking at relevant comorbidities, we found the prevalence of type II diabetes to be 36%. Half of the patients had chronic kidney disease, with 20% of them being stage 4. Important subgroups of patients were the 10% with persistent hypotension and also the cases which associated significant electrolyte disturbances.

The median hospitalization length was 8 days. We found no significant correlation between neither the NT-proBNP value, nor the degree of systemic congestion and the duration of admission. The only clear predictors of a longer hospital stay were hypotension and hyponatremia. By the end of the study period, 5% of the total number of patients had died in our clinic.

Conclusions: Hospitalization and discharge were mostly decided by the severity of dyspnea. Better ambulatory management is needed, as most patients admitted failure to adhere to medication and diet. The most important factors which influenced management during hospitalization were hyponatremia and hypotension.

Comparison of the effects between urapidil and nitroglycerin in patients with heart failure with preserved ejection fraction

Q Qi Hua¹; XAOYE Yuan¹; JING Li¹; JIAN Qin¹; YUJIE Zhou²; YAN Fu³; SHU Qin⁴; XM Chen⁵; JC Guo⁶; DEZHAO Wang⁷

¹Xuan Wu Hospital, Capital Medical University, Department of Cardiology, Beijing, China People's Republic of; ²Beijing Anzhen Hospital, Department of Cardiology, Beijing, China People's Republic of; ³Tong Ren Hospital, Capital Medical University, Emergency Department, Beijing, China People's Republic of; ⁴First Affiliated Hospital, Chongqing University, Department of Cardiology, Chongqing, China People's Republic of; ⁵Ningbo First Hospital, Department of Cardiology, Ningbo, China People's Republic of; ⁶Luhe Hospital of Beijing Tongzhou District,, Department of Cardiology, Beijing, China People's Republic of; ⁷Mentougou District Hospital, Department of Cardiology, Beijing, China People's Republic of

Background: Nowadays, heart failure (HF) is a common clinical syndrome with high morbidity and mortality. HF with preserved ejection fraction (HFPEF) presently accounts for approximately 40% of HF diagnoses, with a rising incidence, mortality and morbidity is rising.

Objective: The aim of this study was to evaluate whether an alpha1-adrenergic blocker (a1-blocker), urapidil, provides additional therapeutic benefits compared to nitroglycerin (NG) in treatment of different classification of HFPEF.

Methods: All patients enrolled met the following criteria: satisfied the standard diagnostic criteria for hypertension and acute HFPEF (Killip \geq II grade; NYHA \geq II grade). 102 patients suffered from acute HFPEF patients were assigned into two groups according to cardiac function: ejection fraction (EF) $\geq 50\%$; N-terminal pro-B-type natriuretic peptide (NT-proBNP) were 450 ng/L, 900 ng/L, 1800 ng/L according to the age < 50 years, 50-70 years, > 70 years, respectively. That were Killip group ($n = 51$; age, 69.760 ± 11.870 years; EF, $59.643 \pm 6.291\%$; NT-proBNP, 3895.882 ± 3419.372 ng/L) and NYHA group ($n = 51$; age, 69.650 ± 12.270 years; EF, $62.777 \pm 7.810\%$; NT-proBNP, 4744.882 ± 3577.651 ng/L). Each group randomized to receive different treatment with urapidil or NG., respectively. Doses of urapidil and NG were administered to patients based on the standard protocols used for regular administration regimes for acute HF patients. Patient's blood pressure (BP) was constantly monitored during administration to provide constant information that might warrant adjustment of the dose rate and delivery time. Urapidil was administered at a rate of 50 or 100 mg/min for

an initial 6 hours and then adjusted to 300 mg/min for the remaining administration time. Accordingly, NG was administered at a rate of 10 mg/min for the initial 6 hours and then adjusted to a maximum rate of 20 mg/min for the remaining administration time. All patients were monitored for systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR) and received test for N-terminal pro-B-type natriuretic peptide (NT-proBNP) at different time points (0 hours, 48 hours and 7 days) after treatment.

Results: SBP ($F=133.386, p<0.05$), DBP ($F=71.583, p<0.05$), HR ($F=35.796, p<0.05$) and NT-proBNP ($F=75.754, p<0.05$) decreased significantly in each group. Without regard to Killip and NYHA, patients receiving urapidil showed significantly lower SBP at 48 hours ($F=5.031, p<0.05$) and 7 days ($F=5.811, p<0.05$), and significantly reduced levels of NT-proBNP at 48 hours ($F=4.199, p<0.05$) and 7 days ($F=4.094, p<0.05$) were observed than them of counterparts treated with NG. DBP of patients with urapidil in Killip group more decreased from baseline at 48 hours ($p<0.05$) and 7 days ($p<0.05$) compared to them in NYHA group.

Conclusions: Urapidil demonstrated better efficiency than NG on lowering SBP and NT-proBNP of patients suffered with HFPEF. More attention, it also could effectively reduce DBP of these cases classified by Killip.

Place of care is the main determining factor for outcome in acute heart failure patients

N Norildin Al-Refaie¹; M Ashton²; S Lucas-Jones²; M Phillips¹; J Goodfellow²; A Wong²

¹Princess of Wales Hospital, Bridgend, United Kingdom; ²Princess of Wales Hospital, Cardiology Department, Bridgend, United Kingdom

Introduction: Acute heart failure is associated with high in-patient mortality. UK national heart failure audit has shown poorer outcome in patients who didn't have cardiology specialist input.

Purpose: Aim of the study is to determine the factors that predict poorer outcome in patients admitted with acute heart failure.

Method: Retrospective analysis of data on 250 patients who were discharged with the primary diagnosis of heart failure from year 2014-2015.

Results: There's no significant mortality rate difference in patients received cardiology specialist input, however mortality rate is significantly lower if it's divided according to the place of care. (Cardiology ward: 12.5% versus other medical wards: 25%, P value = 0.006)

Demographic data, co-morbidities, investigations and medications are shown in the table below.

Incidence of LV systolic dysfunction and ischemic heart disease is higher in cardiology ward patients.

Conclusions: There's significant lower mortality rate in heart failure patients treated in cardiology ward despite the presence of more significant co-morbidities. These findings are likely to be attributed to better investigations and optimisation of medical treatment.

Cardiology versus other wards' patients

	Cardiology ward n = 158	Other medical wards n = 92	P value
Inpatient mortality	12.5%	25%	0.006
Age	78 years	82 years	
Hypertension	69%	70%	0.5
Diabetes	42%	45%	0.3
Ischemic heart disease	56%	45%	0.04
Asthma or COPD	30%	40%	0.08
Haemoglobin level	12	11.5	
Creatinine level	135	126	
ECG	97%	88%	0.0002
Atrial fibrillation	47%	60%	0.02
Echo or equivalent	92%	68%	0.0001
LV systolic dysfunction	47%	18%	0.0001
Triple therapy	24%	24%	0.4
ACE inhibitors/ACE blockers	70%	67%	0.3
Beta blockers	77%	67%	0.04
Spironolactone/Eplerenone	46%	37%	0.09
Medically stable on oral therapy	76%	55%	0.03

Ivabradine administration in cardiogenic shock is associated with cardiac stroke work index improvement

I Ilaria Battistoni¹; M Marini¹; L Angelini¹; MV Matassini¹; M Francioni¹; A Gili¹; S Moretti¹; GP Perna¹

¹University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy

Background: Cardiogenic shock (CS) is the most severe form of acute heart failure associated with poor prognosis. Among compensatory mechanisms to overcome cardiac output reduction, tachycardia is the first activated. However, tachycardia is accompanied by oxygen consumption increase that may further impair cardiac contractility.

Purpose: the aim of this observational, single-center study was to assess if administration of 5 mg ivabradine bid to patients with CS, receiving inotropes and vasopressor, was associated with improvement of echocardiographic hemodynamic parameters

Methods: Of 18 patients admitted for CS (M 42%, 67 ± 11.9 years, LVEF $29 \pm 6\%$), 9 patients were treated with ivabradine on top of optimal therapy while the others represented the control group. Patients were evaluated at baseline, after 24 h, 48 h, 72 h and 120 h with clinical and echocardiographic assessments.

Results: Baseline characteristics of groups were similar. There were no significant differences in HR and systolic blood pressure variations nor in cardiac index or stroke volume index over time between groups. However, ivabradine group presented a significant higher increase in stroke work index (from baseline 17.8 to 55 at 120 h) when compared to control group (from baseline 22.3 to 29 g/m/m2) ($p=.034$).

Conclusions: Ivabradine use in patients with cardiogenic shock was associated with a significant increase in stroke work index that is an expression of cardiac mechanic work and contractility.

P1449

Management of heart failure after non-ST elevation MI; use of mineralocorticoid receptor antagonists and implications for devices.

Supported by the Bristol NIHR Cardiovascular Biomedical Research Unit O Buckledee¹; Y Ismail²; A K Angus K Nightingale²

¹University of Bristol, School of Clinical Sciences, Bristol, United Kingdom; ²Bristol Heart Institute, Department of Cardiology, Bristol, United Kingdom

Background: The presence of heart failure following a non-ST elevation myocardial infarction (non-STEMI) is associated with a worse prognosis. Current UK and European Guidelines recognise the importance of identifying these higher risk patients and offering them disease modifying therapies including drugs and devices.

Purpose: We wanted to find out if these guidelines were being followed in a busy Heart Attack Centre in the South West of England; in particular, whether a mineralocorticoid receptor antagonist (MRA) was being prescribed to those with impaired LV function and either diabetes or signs of heart failure.

Methods: We performed a retrospective audit of consecutive patients identified as having non-STEMI on the MINAP database from April 2014 to March 2015. We assessed: 1. How many received an echocardiogram during their index admission; 2. Compliance with NICE recommended post MI medications on discharge; 3. Implications for device implantation rates according to NICE and ESC guidelines.

Results: 176 patients (mean age 70 years, 64% male) were recorded on the MINAP database with non-STEMI in the study period. 71% (125/176) had an echocardiogram during the index admission. 42% (53/125) had good left ventricular (LV) function and 30% (38/125) had moderately or severely impaired LV function (EF < 40%). Of those with impaired LV function post non-STEMI, 82% (31/38) either had diabetes or signs of pulmonary oedema; 6 of these had a documented contra-indication to a MRA. 56% (14/25) were prescribed a MRA in accordance with the NICE guidelines compared to > 95% compliance with guidelines recommending ACEi/BB/statin/antiplatelet agents. Mean length of stay for those with impaired LV function was 7.9 days. 71% (27/38) of the impaired LV function patients were followed up by our cardiology team with 11 referred back to their local hospital for follow up. 41% (11/27) had a repeat echo after at least one month to reassess LV function and assess requirement for implantable devices.

Conclusions: Nearly a third of patients had significantly impaired LV function following non-STEMI. Whilst most post-MI drugs were prescribed > 95% in compliance with the NICE guidelines, MRAs (spironolactone and eplerenone) were only prescribed in around half of suitable cases. The reasons for this could include poor documentation of contra-indication to MRA or lack of awareness of the guidelines. Follow-up reassessment of LV function after at least a month to detect functional recovery or indication for device therapy was also poor. Opportunities to prevent sudden death or worsening heart failure by implanting ICD or CRT devices could therefore have been missed. Management of non-STEMI patients complicated by heart failure might benefit from a closer link between the acute coronary syndrome and the heart failure teams to improve outcomes and reduce length of stay for patients.

P1450

The prognostic value of Nt pro BNP and echocardiographic markers in patients with intermediary high risk pulmonary embolism

A Ion¹; M Raileanu¹; D Craciunica²; C Andrei¹; V Chioncel¹; C Sinescu¹
¹University of Bucharest Carol Davila, Bagdasar Arseni Emergency Hospital, Cardiology Department, Bucharest, Romania; ²Bagdasar-Arseni Emergency Hospital, Cardiology, Bucharest, Romania

Purpose: Intermediary risk pulmonary embolism (PE) represents a severe medical condition. The thrombolytic treatment for this condition is a debated subject, as there are few studies that prove the positive effect on hemodynamic stability. The ESC guidelines 2014 on the management of PE recommend the thrombolytic therapy on patients with intermediary – high risk PE. Method We selected 65 patients with intermediary risk PE, defined by both biochemical (Nt pro BNP) and echocardiographic markers (myocardial contraction velocity by TDI (MCV), tricuspid annulus pick systolic excursion (TAPSE), right ventricle diastolic diameter (RVD)) of right ventricle pressure overload. We divided the patients in two groups, a study group – 28 patients-, receiving thrombolytic therapy – 10mg t-PA bolus followed by 90 mg t-PA in 2 hours- and a control group -37 patients- which received only unfractionated heparine. The patients from study group did not have any contraindications for thrombolysis, were younger than 75 y.o., did not have severe renal failure (creatinine clearance > 30ml/min) and did not have anemic syndrome. The patients were assessed regarding the biochemical and echocardiographical signs of RV pressure overload on admission and on 48 hours after therapy and the results were compared between the two groups. Results All the echocardiographic markers had a statistically significant better improvement in the study group compared to control group. TAPSE increased with 56.49% in the study group compared to 31.44% in the control group (p 0.01), MCV increased with 23.12% in the study group compared to 14.2% in the control group (p 0.03) and RVD decreased with 21.59% in the study group compared to 11.21% in the control group (p 0.02). Meanwhile Nt pro BNP decreased with 71.59% in the study group compared to 52.07% in the control group (p 0.005). Referring to the correlation to the mortality rate Nt pro BNP was the only marker significantly statistical correlated with mortality, a cut-off value of 2423pg/ml being associated with increased mortality rate (p 0.015) with a 95% confidence interval. Regarding bleeding risk the bleeding rate in the study group was 10.23 % while in the control group it was 5.4% but there was only one case of major bleeding in the study group.

Conclusions: The positive effect of thrombolytic therapy on the prognosis of patients with intermediary-high risk PE is proven by the effect of thrombolysis on the echocardiographic and biochemical markers of RV dysfunction.

P1451

Characterisation of serelaxin pharmacokinetics using a population pharmacokinetics approach

The study was sponsored by Novartis Pharma AG, Basel, Switzerland
 A Soubret¹; Y Pang²; M Dahlke¹

¹Novartis Pharma AG, Basel, Switzerland; ²Novartis Institutes for BioMedical Research, Cambridge, United States of America

Purpose: Serelaxin, a recombinant human relaxin-2, is in development for treatment of acute heart failure (AHF). This model-based covariate analysis aimed to investigate the impact of covariates (patient demographics, markers of kidney and liver function, inter-trial variability) on serelaxin pharmacokinetics (PK).

Methods: Pooled data from 8 randomised, single-dose serelaxin infusion trials: CRLX030A1201, CRLX030A2201, CRLX030A2202, CRLX030A2101, CRLX030A2102, CRLX030A2103, CRLX030X2201 and RLX.CHF.003 were used for developing the PK model. The model consisted of a 3-compartment disposition with linear elimination calibrated by a non-linear mixed effect approach using Monolix version 4.3.2 (Lixoft Inc.). Covariates on different model parameters such as clearance and volume of distribution were selected and ranked based on their predictive power using correlation-adjusted (marginal) correlation (CAR) scores. A backward elimination step was performed to obtain the best model with the least number of covariates and maximum explanatory power according to the Bayesian information criterion.

Results: The analysis included data from 416 subjects. Population estimates of clearance (central: CL; inter-compartmental: Q2, Q3) and volume of distribution (central: Vc; peripheral: Vp2, Vp3) for a typical Caucasian subject without HF were as shown in the table below. Based on the covariate analysis, eGFR and BMI were selected to explain the variability in CL and serelaxin concentration at steady state (Css). Correlation of eGFR with clearance implied that 15–20% of serelaxin clearance might be through renal clearance. The total volume of distribution (Vc+Vp2+Vp3) was markedly larger in the subjects with AHF (567 mL/kg) and chronic HF (461 mL/kg), compared with the population estimate (350 mL/kg) in those without HF. These differences may be due to abnormal fluid retention conditions commonly observed in patients with HF.

Conclusion: This population approach with a 3-compartment disposition model adequately characterises the serelaxin PK. Correlations were observed between

some of the covariates and serelaxin PK. The impact on serelaxin PK was moderate and thus considered to have no clinical relevance.

	CL (mL/h/kg)	Q ₂ (mL/h/kg)	Q ₃ (mL/h/kg)	V _c (mL/kg)	V _{p2} (mL/kg)	V _{p3} (mL/kg)
Population estimate (± SD)	89.9 (± 1.5)	126.4 (± 6.8)	8.0 (± 0.4)	73.3 (± 4.5)	176.5 (± 7.8)	100.3 (± 3.2)
Coefficient of variation (%)	31.0	33.0	37.0	70.0	27.0	22.0

Impact of furosemide dosages on in-hospital and post-discharge outcomes in acute heart failure diabetic patients: a DAD-HF II sub-study

G Giamouzis¹; G Karayannis²; G Giannakoulas³; E Petrou¹; J Xirogiannis¹; A Xanthopoulos¹; H Karvounis³; J Butler⁴; J Skoularigis¹; F Triposkiadis¹

¹University General Hospital of Larissa, Department of Cardiology, Larissa, Greece;

²Harefield Hospital, London, United Kingdom; ³Ahepa University Hospital, Cardiology, Thessaloniki, Greece; ⁴Emory University Hospital, Atlanta, United States of America

Background: The role of the addition of low-dose dopamine on top of low- or high-dose furosemide infusion in patients with acute decompensated heart failure (ADHF) has been assessed in the DAD-HF II trial and was found not to be associated with any beneficial effects in relation to renal parameters as well as survival end-points. Its role, however, in ADHF patients with diabetes, which portends increased incidence of worsening renal function with the use of diuretics during hospitalization, has never been evaluated.

Purpose: To assess the effect of these combinations in the subgroup of DAD-HF II patients with a history of diabetes mellitus.

Methods and Results: 161 ADHF patients (mean age, 78.1 years; 46% female; ejection fraction 30.9%) were randomized to 8-hour continuous infusions of: a) high-dose furosemide [HDF, n=50, diabetics n=24 (48%), 20 mg/h], b) low-dose furosemide and low-dose dopamine [LDFD, n=56, diabetics n=23 (41%), 5 mg/h and 5 µg kg⁻¹ min⁻¹ respectively], or c) low-dose furosemide [LDF, n=55, diabetics n=31 (56%) 5 mg/h]. The main outcomes were 60-day and one-year all-cause mortality (ACM) and hospitalization for HF (HHF). Dyspnea relief (Borg index), serum creatinine and length of stay (LOS) were also assessed.

The urinary output at 2, 4, 6, 8, and 24h was not significantly different in diabetics vs. non-diabetics in the three groups. No differences in the Borg index or LOS were noted. Baseline creatinine did not differ between the study groups in both diabetics and non-diabetics. However, peak creatinine was significantly higher in diabetic patients of the HDF group compared to LDF group (2.12 vs. 1.48 mg/dL, P=0.017). Neither the ACM at day 60 or at one year nor the HHF at day 60 or one year differed between HDF, LDFD, and LDF diabetic-subgroups groups, respectively.

Conclusions: In ADHF diabetic patients, treatment with HDF is associated with increased risk of worsening renal function as compared with lower doses of furosemide, regardless concomitant dopamine administration. This finding, however, is not associated with a worse short- and long-term prognosis.

P1453

Effect of baseline characteristics on mortality in the SURVIVE trial comparing levosimendan and dobutamine in acute heart failure: sub-analysis of the Finnish patients

T Tarvasmaeki¹; M Kivikko²; P Pollesello²; T Sarapohja²; V-P Harjola¹; MS Nieminen¹

¹Helsinki University Central Hospital, Cardiology, Helsinki, Finland; ²Orion Pharma, Critical Care, Espoo, Finland

Background: In the SURVIVE study [Mebazaa A. JAMA. 2007;297:1883-91], in 1327 acute heart failure patients from 9 countries, there was no statistically significant difference between levosimendan and dobutamine in the 180-day all-cause mortality. Country-specific differences in outcome were, however, present. In the Finnish sub-population, mortality was significantly lower in levosimendan treated patients.

Purpose: We aim to understand the reasons for this disparity.

Methods: The risk factors for all-cause mortality were identified in the whole study population using multivariable Cox proportional hazards regression analysis. Those factors were evaluated in the Finnish 95 patients.

Results: The treatment by country interaction for mortality in Finland vs. other countries was significant, p=0.029 (see Figure). Levosimendan treated patients had a lower mortality compared to dobutamine; 8/47 (17%) vs. 19/48 (40%), Hazard ratio [95% CI] 0.38 [0.17, 0.88], p=0.023. Baseline variables predicting survival in the whole SURVIVE population included age, systolic blood pressure, heart rate,

myocardial infarction during admission, levels of NT-pro-BNP, glucose, creatinine, and alanine transferase, use of ACE inhibitors and β -blockers, oliguria, time from hospital admission to randomization, history of cardiac arrest, and left ventricular ejection fraction. Finnish patients were more frequently treated with β -blockers (88% vs. 52%, $p < 0.0001$), their study drug treatment was started earlier (mean \pm SD 41 ± 40 h vs. 81 ± 154 h; $p < 0.0001$), and acute myocardial infarction was more common at admission (39% vs. 16%, $p < 0.0001$).

Conclusions: The significantly lower mortality in the Finnish patients treated with levosimendan was possibly due to different baseline characteristics, such as higher use of beta-blockers, higher frequency of myocardial infarction at admission, and to shorter delay between randomization and start of treatment.

180-day mortality in SURVIVE trial

Acute hemodynamic effects of caval counterpulsation balloon in heart failure patients

J E Herrera¹; G Dempaire²; J A Octavio²; B Finizola¹; E Garcia¹; L Velasco¹; W Torres¹; J A Herrera¹; R Levine³; I Palacios³

¹Ascardio, Barquisimeto, Venezuela; ²Hospital de Clinicas Caracas, Caracas, Venezuela; ³Massachusetts General Hospital, Interventional Cardiology, Boston, United States of America

Background: Up to the present, preload reduction in congestive heart failure (CHF) patients is performed with high potency diuretics. Last year, we reported in TCT/ACC U.S.A 2015 the hemodynamic changes of the first 6 CHF cases in humans, using Percutaneous Transluminal Caval Flow Restriction (PTCR) procedure achieved with caval counterpulsation balloon (CCPB). This innovative method reduced preload in CHF. In this study we are reporting the results of the 6 consecutive patients with CHF, treated with intermittent preload reduction of caval flow with CCPB, guided by the respiratory phases.

Methods: 6 patients with CHF who met our protocol criteria, were evaluated. 4 were ischemic, and 2 non ischemic. The mean age was 58 ± 9 . 4 male mean age 55 ± 6 years, and 2 female mean age 63 ± 4 . We performed baseline Doppler echocardiography, coronary angiography and right heart catheterization. Subsequently caval flow restriction was started, through the right femoral vein, catheter balloon was introduced in the femoral vein and echo guided, placed just before hepatic vein drainage. The balloon was inflated according to previous calculations, to cover Inferior Vena Cava (IVC) remaining area completing 100% (total occlusion), and 70% during expiration (sub-occlusion), assuming 30% inspiratory collapse, resulting intermittent flow. The balloon was kept inflated for 30 minutes, right catheterization and echocardiography were repeated during inflated balloon. The balloon was removed and deflated.

Results: Table 1. Hemodynamic Variables

Conclusion: We are reporting our hemodynamic and echocardiography experience in 6 patients with CHF treated with intermittent reduction of preload with CCPB. Hemodynamic and echocardiographic changes obtained in these patients, including preservation of cardiac output suggest, that this innovative approach can play a role in the treatment of CHF patients.

Prognostic utility of lung ultrasound pocket device in acute heart failure.

M Manuel Lobo Gonzalez¹; I Mendez¹; R Hidalgo¹

¹University Hospital of Virgen Macarena, Cardiology, Seville, Spain

Background and purpose: Heart failure (HF) increases the risk of death during myocardial infarction (AMI) and the risk increases with severe symptoms of HF; It is necessary to develop rapid HF diagnosis techniques to improve management and minimized morbimortality. The aim of this study is to evaluate the short term prognostic significance of lung ultrasound performed at bedside with a pocket device (PD) in patients with heart failure in the acute myocardial infarction context.

Methods: 109 patients with AMI and HF symptoms, admitted to our coronary care unit and studied at bedside with PD were included. The interstitial lung water was determined by counting the B-lines according to BLUE and FALLS protocol. The management of patients was made according to European clinical practice guidelines. The primary endpoint was a composite of all-cause death or HF hospitalisation at 3 months from discharge.

Results: 76 of 109 patients included were men, the mean age was 70 ± 15 years. The primary endpoint was observed in 22 patients (20,7%). Patients with events were older (79 ± 6 vs 67 ± 4 years, $p < 0.001$) and had more risk factors (hypertension 72% vs 49% and diabetes 74% vs 32%). No other significant differences in the clinical characteristics of the patients were found. The mean B-lines count was 10,5 (5-39) Patients who presented the primary endpoint had more B-lines (32 [12-40]) compared to those patients without events (13 [7-20], $p < 0.001$). In the univariate analysis B-lines > 30 was associated with the occurrence of the primary endpoint at 3 months (odds ratio : 1.5 [1.1-2.1], $p = 0.002$). This relationship remained despite the inclusion of cardiac systolic function, NT-proBNP, age, hypertension and diabetes in the multivariate analysis (OR 1.7 [1.2-2.6], $p = 0.009$).

Conclusion: Lung ultrasonography assessed with a PD may represent a useful diagnostic tool in AHF, and may help with prognostic including prediction of mortality of the patients. These suggestions should be validated in large studies.

CHRONIC HEART FAILURE

P1456

Hyperbaric oxygen therapy and correction of platelet aggregation in patients with chronic heart failure

V Victor Ruzov¹

¹Ulyanovsk state University, medicine, Ulyanovsk, Russian Federation

Objective: To determine the influence of hyperbaric Oxygen Therapy on the aggregation of platelets in patients with chronic heart failure (CHF). Materials and

Methods: The study involved 50 patients with ischemic etiology of CHF, the average age of 55.4 ± 8.58 let taking (57%) and receiving (43%) at a dose of 75mg cardiomagnil in the treatment of CHF. Before and after 5 sessions HBO mode 1.2 ATA 40minut exposure for 5 days, the platelet aggregation on a laser analyzer.

Results: The use of HBO accompanied by changes in the functional activity of platelets in 17% of patients receiving and not receiving 20% Cardiomagnil. This normalization of increased or decreased platelet aggregation was detected in 18% of patients taking Cardiomagnil and only 8% had never accept Cardiomagnil. At the same time maintained the increased platelet aggregation in 6% of patients on the background Cardiomagnil and 23% - not taking Cardiomagnil.

Conclusion: The use of HBO in the treatment of heart failure has a more pronounced effect on platelet aggregation, taking Cardiomagnil.

P1457

Influence of revascularization methods in acute myocardial infarction on the level of brain natriuretic peptide and development of congestive heart failure in patients with post-MI

AI Chesnikova¹; ES Godunko¹; OE Kolomatskaya¹; VA Safronenko¹; AV Khripun¹; VP Terentyev¹

¹State Medical University of Rostov-on-Don, Rostov-on-Don, Russian Federation

One of the highly topical problems of practical cardiology is the development of congestive heart failure (CHF) in patients with myocardial infarction (MI). It is important to measure the concentration of Brain Natriuretic Peptide (BNP) to confirm heart failure. BNP secretion increases in accordance with the intensity of post-infarction heart changes. The aim of the study was to investigate the impact of revascularization methods in acute myocardial infarction on the level of BNP and the development of congestive heart failure in patients with post-MI.

Methods: 101 patients with acute MI with ST-segment elevation were enrolled in the study. Their clinical symptoms of congestive heart failure were evaluated during discharge and over 1 year; echocardiography was assessed, as well as the level of BNP was determined. Mean age was 56 ± 9.99 years; with 81.9% of men. All the patients depending on revascularization method in acute MI were divided into 3 groups: Group 1 ($n=28$; 27.7%) consisted of patients who underwent thrombolytic therapy (TLT), Group 2 ($n=42$; 41.6%) of patients with percutaneous coronary intervention (PCI), and Group 3 included patients without myocardial revascularization ($n=31$; 30.7%).

Results: Analysis of the results revealed that 74.7% of patients had BNP level exceeding the threshold. $BNP \geq 125$ pg/ml was found in 76.2% of patients in Group 1, in Group 2 - in 69% of cases, in Group 3 in 85% of patients. The average concentration of BNP was significantly lower in patients who underwent PCI (150 ± 90 , 1 pg/ml), compared with an average level of $BNP 270 \pm 117$, 6 pg/ml in patients of Group 3 ($3-2=0.000$). In addition, there is a clear tendency towards accuracy by comparing the average BNP level of Groups 1 and 2 ($2-1=0.072$) with the lowest value in patients with a history of PCI. Analysis of BNP concentration in patients with $EF > 50\%$ revealed that values of $BNP \geq 125$ pg/ml were observed in 19.07% of patients in Group 1, in Group 2 in 21.45%, and in Group 3 in 20% of patients, which allowed us to confirm a likely probability of congestive heart failure with preserved EF in those patients. However, in 9.53% of patients in Group 1, in 21.45% - in Group 2 and 15% of patients in Group 3 with an index $EF > 50\%$ BNP concentration was < 125 pg/ml.

Conclusions: A lower BNP level was registered after a year of observation in patients with PCI in acute myocardial infarction. $EF > 50\%$ in patients with congestive heart failure is higher in patients with revascularization. The absence of reperfusion contributes to a more severe course of post-MI heart failure.

P1458

Infiltrative cardiomyopathy: a novel aetiology

N/A

TG Moon¹; K O'gallagher¹; D Sado¹

¹King's College Hospital, Department of Cardiology, London, United Kingdom

A 52-year-old Afro-Caribbean male presented with a 6-month history of dyspnoea, decreasing exercise tolerance and paroxysmal nocturnal dyspnoea. Clinically he was in pulmonary oedema. He had a history of Rosai-Dorfman disease (RDD) and chronic hepatitis B. There was no previous cardiac history.

Transthoracic echocardiography (TTE) demonstrated biventricular hypertrophy with suggestion of a right atrial mass. Cardiovascular magnetic resonance (cMR) imaging revealed thickening of all four cardiac chambers. No right atrial mass was seen, however the right atrial wall was grossly thickened. There was normal gadolinium kinetics and no late enhancement.

At this point the cardiac diagnosis was unclear. The cMR features were not consistent with a diagnosis of amyloidosis, sarcoidosis or hypereosinophilic syndrome.

The patient proceeded to an endomyocardial biopsy. Histological assessment demonstrated a lymphocytic and histiocytic infiltration with emperipolesis and positive S100 staining. These findings are characteristic of RDD. A diagnosis of cardiac RDD was therefore made.

The patient received cisplatin, etoposide and dexamethasone as medical therapy for RDD. Serial cMR demonstrated improvement in myocardial infiltration and a reduction in cardiac mass but progressive infiltration of the aortic valve and initially moderate, then severe aortic regurgitation. An intended aortic valve replacement has not been possible due to ongoing gastrointestinal and respiratory complications of immunosuppression.

Originally described in 1969, RDD is a rare, non-clonal proliferative disorder of histiocytes of unknown aetiology which typically causes bilateral painless cervical lymphadenopathy. Extra-nodal involvement most commonly involves the skin, nasal cavity, paranasal sinuses, orbit, upper respiratory tract and bone. Cardiac involvement is rare, occurring in $< 1\%$ of cases.

To our knowledge, this case is unique as it is the first description of RDD involving all four cardiac chambers.

cMR: Infiltration of all four chambers

P1459

Depression in patients with heart failure

G Caminiti¹; G Marazzi¹; G Campolongo¹; G M C Giuseppe M C Rosano¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Background: Re-hospitalisation represent a high burden in heart failure (HF). Fatigue is one of the most common complaint in patients with HF and depression is a frequent psychological symptom in these patients.

Aim: We assessed the relation between fatigue and depression and their impact on HF hospitalization rates in 1216 patients with HF admitted at a tertiary hospital. Patients were diagnosed based on ICD-9 codes and prescription of antidepressants: no symptom, fatigue, depression, and fatigue and depression.

Results: The hospitalisation rates were higher in women with depression and fatigue (OR 3.2, 95% CI 2.1-4.3). No difference was found between patients reporting fatigue and those reporting fatigue and depression in the re-hospitalisation rates.

Conclusion: Depression is a frequent occurrence in women with HF and when coupled with fatigue is associated with an increased risk or re-hospitalisation.

P1460

Oscillatory breathing and respiratory muscles strength during exercise in congestive heart failure patients

PI Pietro Palermo¹; VS Sassi¹; AA Apostolo¹; MC Contini¹; SF Farina¹; CV Vignati¹; PA Agostoni¹

¹Cardiology Center Monzino IRCCS, Milan, Italy

Background/Introduction: Congestive Heart failure (CHF) patients often have breathing abnormalities due to increase of pulmonary stiffness. Oscillatory breathing (OB) is observed in part of these patients but we do not know if this is associated to respiratory muscles fatigue.

Purpose: Aim of this study was to evaluate effort of respiratory muscles in CHF patients. We selected patients with CHF in stable conditions. Inclusion criteria were $LVEF < 40\%$ and presence of OB at cardiopulmonary exercise test (CPET).

Methods: We analyzed 45 CHF patients (41 males, 4 females, age 68.4 ± 10.6 years) who presented OB at CPET and we measured, with a dedicated device, Maximal Expiratory Pressure (MEP) and maximal inspiratory Pressure (MIP) at rest (before CPET) and immediately after exercise. We calculated normal values of MIP and MEP by Black & Hyatt formula.

Results: MIP at rest was $87 \pm 31\%$ of predicted, while right after effort $83 \pm 25\%$. MEP was at rest $65 \pm 18\%$ of predicted and right after effort $63 \pm 19\%$. We observed a slight reduction after physical exercise, not statistically significant. This suggests that muscles do not get more tired after effort. Study population was then subdivided in 2 groups according to persistence of OB (group B, 18 patients) or its disappearance during effort (group A, 27 patients). In group A, MIP at rest was $94 \pm 30\%$ of predicted, while after effort $89 \pm 26\%$. MEP was $69 \pm 17\%$ at rest and $67 \pm 18\%$ after effort. In group B MIP at rest was $74 \pm 30\%$ of predicted

while after effort $70 \pm 17\%$. MEP was $58 \pm 17\%$ at rest and 57 ± 20 after effort. The difference between absolute values within the two groups (A vs B) resulted statistically significant: for MIP at rest $p = 0.003$, while after effort 0.002, for MEP at rest $p = 0.01$ while after effort 0.02. Functional evaluation showed that the study population reached 43% of work predicted measured in watt, Group A 49% and group B 33% ($p = 0.001$). Also, statistically significant difference between the two groups has been observed in VO_2 peak values: in group A 14.67 ± 3.44 ml/kg/min vs. 10.96 ± 2.73 ml/kg/min in group B ($p < 0.001$). In terms of VE/VO_2 slope we observed also a significant difference: 31.90 ± 6.01 (A) vs. 43.45 ± 13.88 (B) ($p < 0.001$).

Conclusion: In CHF patients the respiratory muscles are compromised at rest probably because of major stiffness and imbibition of pulmonary tissue. Our data showed differences in CHF patients with persistent OB. In particular, these data suggest that those patients are more compromised and have a worse prognosis. In fact significant differences have been found in terms of lower working capacity, lower VO_2 peak, higher VE/VO_2 slope, lower MIP and MEP and higher mortality.

P1461

Impaired gas diffusion in heart failure identifies patients with impaired right ventricle contractile reserve

V Valentina Labate¹; V Donghi¹; G Generati¹; PL Laforgia¹; F Bandera¹; M Guazzi¹

¹IRCCS Policlinico San Donato, heart failure unit, San Donato Milanese, Italy

In heart failure (HF) patients, an altered gas diffusing capacity for carbon monoxide (DLCO) is a marker of lung capillary injury that bears relevant clinical and prognostic information. It is unknown whether an impaired right ventricular contractile reserve is linked to an impaired gas diffusion and may become synergic in causing exercise limitation and ventilation inefficiency.

Methods: 23 HF patients (mean age 64 ± 10 ; male 75%; NYHA II-III; mean left ventricular (LV) ejection fraction $34 \pm 9\%$) underwent DLCO measurements with assessment of membrane component (DM) and capillary blood volume (V_c) and maximal cardiopulmonary exercise testing (CPET, tilt-ergometer, personalized ramp protocol) combined with Echo-Doppler assessment of right ventricular function by assessing tricuspid annular peak systolic excursion (TAPSE) and pulmonary systolic pressure (PASP).

Results: Patients exhibited an abnormal gas diffusion (mean DLCO 17.3 ± 4.2 ml/min/mmHg) with depressed alveolar-capillary membrane diffusing capacity (DM) component (mean 24.3 ± 8.5 ml/min/mmHg) and elevated capillary volume (mean 102.8 ± 57.3 ml) along with significant functional limitation (mean peak VO_2 12.8 ± 3.8 ml/kg/min) and ventilatory inefficiency (mean VE/VO_2 slope: 32.6 ± 6.1 and mean end-tidal of CO_2 mean 32.4 ± 4.7 mmHg).

Population was divided into two groups according to mean value of DM: patients with an DM < 25 ml/min/mmHg ($n = 10$, group A) and patients with DM ≥ 25 ml/min/mmHg ($n = 12$, group B).

As shown in figure, group A exhibited an unfavorable TAPSE versus PASP relationship suggesting an impairment of RV contractile reserve. Group A presented with a lower peak VO_2 (mean peak VO_2 11.8 ± 3.7 ml/kg/min) and a higher VE/VO_2 slope (mean VE/VO_2 slope: 34.5 ± 7.2).

Conclusions: Our findings show a link between gas diffusion abnormalities and RV contractile reserve suggesting that interventions aimed at targeting the alveolar-capillary gas diffusion capacity and functional performance in HF population have to ideally combine a modulatory effect on right heart function.

P1462

Serum phosphorus level predicts worse outcome in patients with heart failure and vitamin D deficiency but not in patients with normal vitamin D status.

J Joanna Wisniewska¹; A Drohomirecka¹; T Rywik¹; M Sobieszczanska-Malek¹; A Tarnowska¹; T Zielinski¹

¹National Institute of Cardiology, Warsaw, Poland

Background: Recently there is growing interest in the calcium-phosphorus imbalance in heart failure patients. The aim of the study was to evaluate the impact of vitamin D insufficiency and its results on clinical prognosis in patients with systolic heart failure. **Material and**

Methods: 138 consecutive patients (aged 49.7 ± 11.3 years, 24 women, 114 men) with left ventricular ejection fraction-LVEF $\leq 45\%$ (mean $28.1 \pm 8.4\%$) were included in the study. Patients were divided according to the 25-hydroxyvitamin D [$25(OH)D$] status into two groups: patients with low concentration of $25(OH)D$ (< 20 ng/ml, $n = 93$, 67%) and control group (≥ 20 ng/ml, $n = 45$, 33%). Patients were followed up for median 326.5 days (IQR 163-521). Any death or heart transplantation were considered as an end point ($n = 11$).

Results: A higher level of parathormon (59 vs 48 pg/ml, $p = 0.005$) and phosphorus (1.17 vs 1.1 mmol/l, $p = 0.003$) was observed in patients with concentration $25(OH)D < 20$ ng/ml compared to the control group. Cumulated event-free-survival was 85%. The $25(OH)D$ level showed no influence on survival. However, after exclusion of NT-pro-BNP from the analysis, serum phosphorus level was the strongest predictor of worse prognosis (HR 7.1/0.1 mmol/l, $p = 0.02$) independently of renal function. The relationship was not seen in the control group.

Conclusion: Vitamin D deficiency is common among patients with systolic heart failure and it could impair the prognosis through calcium-phosphorus imbalance.

P1463

Degree of improvement in ejection fraction after coronary artery bypass grafting in patients with low preoperative left ventricular ejection fraction

F Lopez Valdivieso¹; J Joffrey Eduardo Lujan Valencia¹; C Velazquez Velazquez¹; J Hernandez Campo¹; JC Tellez Cantero¹; MA Gutierrez Martin¹

¹Virgen Macarena University Hospital, Sevilla, Sevilla, Spain

Objective: To determine if there is any degree of improvement in the left ventricular ejection fraction at one year after performance of coronary artery bypass grafting in patients with low preoperative ejection fraction.

Methods: A retrospective observational study was performed comparing the variability of ejection fraction in patients who had low preoperative ejection fraction (less than 45 percent) versus the left ventricular ejection fraction at one year after the surgery in all patients who underwent coronary artery bypass grafting in the period from 2010 to 2014 and we divide the variability at one year in 5 degrees of improvement: No improvement from 0 to 4%, mild improvement from 5 to 8%, moderate improvement from 9 to 12%, great improvement if it was higher than 12% and worsening if there was regression in the ejection fraction. From 479 coronary artery bypass grafting done, 43 were done in patients with low ejection fraction and the year follow up was available in a total of 34 patients.

Results: From the total of 34 patients selected for the study, 28 patients where men (82.4%) and had a mean age of 62.42 ± 3.59 years. The mean preoperative ejection fraction was $36.12 \pm 2.19\%$ been the lowest value 25%. In all patients was performed a complete revascularization. After one year of follow up the mean ejection fraction was $45.56 \pm 3.05\%$. The mean of the difference between preoperative ejection fraction and control ejection fraction was $10.44 \pm 2.70\%$ that was statistically significant with a $p < 0.0001$. From the 34 patients 1 had no improvement (2.94%), 8 patients had mild improvement (23.53%), 9 patients had moderate improvement (38.24%) and 13 patients had great improvement (38.24%). Three patients had a reduce in their ejection fraction (8.82%) at one year follow up, and was only one death after one year.

Conclusion: Coronary artery bypass grafting is a safe procedure in patients with low left ventricular ejection fraction with very low mortality and a great improvement of ejection fraction after the surgery with the majority being in mild to great improvement over the preoperative ejection fraction.

P1464

Physical activity improved diastolic function in spinal cord-injured subjects

G De Rossi¹; L G T Zacharias¹; W Cirillo¹; W Nadruz Jr¹; J R M Jose Roberto Souza²

¹FCM-UNICAMP, Campinas, Sp, Brazil; ²UNICAMP - State University of Campinas, Department of Cardiology, Campinas, Brazil

Purpose: Subjects with spinal cord injury (SCI) have been reported to present impaired left ventricular (LV) diastolic function in comparison with able-bodied (AB) ones. The present study investigated the effect of regular physical activity on the cardiac structure and function of SCI subjects.

Methods: Fifty-eight SCI men (29 sedentary [SCI-S] and 29 athletes [SCI-A]) and 29 AB men were cross-sectionally evaluated by clinical, laboratory, hemodynamic, and

echocardiographic analysis. All enrolled subjects were normotensive, nondiabetic, nonsmoker, and normolipemic, and the studied groups presented similar age and body mass index.

Results: SCI-S presented similar LV structural and systolic parameters but higher E/Em (8.0 ± 0.5) and lower Em/Am (1.18 ± 0.09) ratios than SCI-A and AB (E/Em = 6.4 ± 0.3 and 5.9 ± 0.3 , respectively; Em/Am = 1.57 ± 0.12 and 1.63 ± 0.08 , respectively; all $P < 0.05$ compared with SCI-S). Analysis of SCI individuals according to injury level revealed that tetraplegic athletes had similar features compared with sedentary tetraplegic subjects, except for higher Em (10.9 ± 0.6 vs 8.6 ± 0.7 cm s, $P < 0.05$) and lower E/Em ratio (6.3 ± 0.4 vs 8.8 ± 0.8 , $P < 0.05$), whereas paraplegic athletes had similar features compared with sedentary paraplegic individuals, except for higher LV end-diastolic diameter (49.4 ± 1.4 vs 45.0 ± 1.0 mm, $P < 0.05$) and Em/Am ratio (1.69 ± 0.20 vs 1.19 ± 0.08 , $P < 0.05$) and lower LV relative wall thickness (0.330 ± 0.012 vs 0.369 ± 0.010 , $P < 0.05$) and heart rate (67.1 ± 4.2 vs 81.9 ± 2.8 bpm, $P < 0.05$).

Conclusion: Regular physical activity is associated with improved LV diastolic function in SCI subjects and might exert distinct cardiac structural effects in tetraplegic and paraplegic subjects.

P1465

Acutely decompensated chronic heart failure treatment in an elderly population

E Emma Weiss¹; D Penes¹; E Badila¹; D Bartos¹

¹Clinical Emergency Hospital Bucharest, Internal Medicine Department, Bucharest, Romania

Purpose: To describe pharmacotherapy recommended on discharge in a population of elderly (80+ yrs) chronic heart failure (HF) patients admitted for an acute decompensation secondary to a hypertensive urgency in the clinical setting of an emergency hospital.

Methods: We included 270 consecutive patients admitted to the Internal Medicine Clinic from January through December 2015, separated in two groups – HF with reduced ejection fraction (HF-REF, 53 pts) and HF with preserved ejection fraction (HF-PEF, 217 pts) to compare the two groups in terms of cardiovascular medication recommended upon discharge.

Results: Beta-blockers were recommended more in patients with HF-REF ($p < 0.01$), but in only 2/3 of HF-REF hypertensive patients and in >50% of those with HF-PEF. Those with REF were recommended more diuretics (furosemide) than those with PEF ($p < 0.01$). Spironolactone was frequently recommended in both groups, however more in the hypertensive elderly HF-REF population ($p < 0.01$).

Conclusions: Elderly patients admitted for chronic HF acutely decompensated by a hypertensive urgency had in 80% of the cases HF-PEF, and most patients were admitted in NYHA class III. Use of both beta-blockers and spironolactone (recommended more in the CKD patients) was suboptimal, while loop diuretics were recommended on discharge in >50% of HF-REF patients.

	HF-REF NYHA III	HF-PEF NYHA IV	NYHA III	NYHA IV
No pts (total 270)	53 (19.62%)	217 (80.37%)

The combination drug valsartan/sacubitril (LCZ696) reduced pulse wave velocity and aortic systolic blood pressure in patients with stable heart failure with reduced ejection fraction

Z Kobalava¹; S Villevalde¹; E Tyukhmenov¹; O Olga Lukina¹; L Babaeva¹; E Zharikova¹

¹Peoples Friendship University of Russia, Moscow, Russian Federation

Objective: Dual neprilysin inhibition and angiotensin receptor blockade with LCZ696 has been shown therapeutic benefits in chronic heart failure (CHF) patients. The aim of the study was to assess LCZ696 effects on parameters of arterial stiffness in stable heart failure with reduced ejection fraction (HFrEF).

Methods: In the open-label follow-up to PARADIGM HF study 18 patients with stable HFrEF (16 male, 69 ± 9 years ($M \pm SD$), arterial hypertension 83%, previous myocardial infarction 89%, diabetes mellitus 39%, dyslipidemia 56%, LVEF $32 \pm 4\%$, serum creatinine 118 ± 21 $\mu\text{mol/l}$, eGFR 56 ± 13 ml/min/1.73m², potassium 4.45 ± 0.35 mmol/l) were enrolled. Patients received a stable background treatment for at least a month (ACEI 94%, beta-blockers 100%, aldosterone receptor antagonists 83.3%, loop diuretics 72.2%). ACEI treatment was interrupted for 36 h and replaced with LCZ696 100 or 200 mg (11 patients) BID according to baseline brachial BP (mean dose 185.7 ± 36.3 mg BID). Applanation tonometry was performed baseline and after 6 month LCZ696 therapy. Wilcoxon test was considered significant if $p < 0.05$.

Results: Baseline brachial BP decreased from $137.1 \pm 22.0/83.4 \pm 11.8$ to $120.5 \pm 13.5/75.1 \pm 9.3$ mmHg (Δ $-16.6 \pm 14.2/-8.3 \pm 10.3$ mmHg, $p < 0.05$), heart rate did not change (78 ± 12 vs 75 ± 15 beats/min (Δ -2.7 ± 14.7 beats/min, $p > 0.05$). Valsartan/sacubitril therapy was associated with significant decrease of carotid-femoral pulse wave velocity (11.5 ± 2.9 vs 10.2 ± 2.9 m/s, $p < 0.05$), central systolic (125 ± 16 vs 116 ± 15 mmHg, $p = 0.005$) and diastolic (78 ± 7 vs 74 ± 9 mmHg, $p < 0.05$) blood pressure. Central pulse pressure (45 ± 11 vs 41 ± 16 mmHg), augmentation pressure (16 ± 7.1 vs 13.8 ± 8.4 mmHg), augmentation index (29 ± 7 vs $28 \pm 11\%$), time to reflected wave (128 ± 8 vs 132 ± 7 ms) did not change significantly ($p > 0.05$ for all comparisons).

Conclusion: In stable patients with heart failure with reduced ejection fraction 6 month valsartan/sacubitril therapy was associated with significant decrease of aortic systolic pressure and pulse wave velocity.

P1467

Audit of a tertiary heart failure outpatient service to assess compliance with practice guidelines

K Guha¹; C Allen¹; H Pryse-Hawkins¹; L Fallon¹; V Chambers¹; A Vazir¹; A Lyon¹; MR Cowie¹; RK Sharma¹

¹Royal Brompton Hospital, Cardiology Department, National Heart and Lung Institute, London, United Kingdom

Background/Introduction: The National Institute of Health and Care Excellence (NICE) updated guidelines for chronic heart failure (HF) in 2010; incorporating an electronic audit tool to measure outpatient care delivery. Previous local audit described high prescription rates of established therapies, monitoring and specialist follow-up; contrasting with a significant omission in inadequate access to cardiac rehabilitation.

Purpose: This re-audit assessed interim improvement.

Methods: Patients with HF (preserved and reduced ejection fraction) attending a tertiary cardiac centre in London between 01/01/2013 and 31/12/2014 were audited. The electronic format covered all HF clinics; capturing demographic data, aetiology of HF, prescribed medication, heart rhythm and rate, measures of clinical follow-up and compliance with rehabilitation.

Results: Five hundred and thirteen patients were included. Compared with 2011, there was an identical male preponderance (71%) and age profile (68 ± 14 years, (Mean \pm SD)). Seventy-three percent lived outside of London. Predominant HF aetiologies included ischaemic heart disease (37% vs 40% in 2011), idiopathic dilated cardiomyopathy (26%, 20%) and primary valve disease (13%, 12%). Eighty-five percent ($n = 434$) had left ventricular systolic dysfunction (LVSD). For these patients, medication included 89% (77%, 2011) taking a beta-blocker, 91% (86%, 2011) an ACE-inhibitor or angiotensin receptor antagonist and 56% (44%, 2011) an aldosterone antagonist. Twenty-nine (6%) patients were prescribed Ivabradine. All patients (100%) received monitoring of mandatory indices (functional status, rhythm, biochemistry etc.) at least six-monthly.

Access to rehabilitation remained low. While 100% of patients were educated about the beneficial effects of exercise in HF, only 21 (4%) were enrolled in a supervised group exercise programme.

Conclusion(s): This audit demonstrated that a tertiary HF service has high rates of documentation, follow-up and compliance with guideline-based medical therapies. A notable omission was that access to rehabilitation remains poor. This may be influenced by the fact most patients reside outside London. Further lobbying with regional and national commissioners for HF based exercise services is imperative moving forward. Alternative strategies such as telehealth and multidisciplinary education for junior team members continue to be explored.

Figure 1 - LVSD medication rates

P1468**Metolazone therapy in heart failure patients**H Hunain Shiwani¹; MM Anwar¹; N Ansari¹; DS Bulugahapitiya¹¹Bradford Teaching Hospitals NHS Trust, Department of Cardiology, Bradford, United Kingdom**Background:** Metolazone (MTZ), a thiazide-like diuretic is used together with loop diuretics in the management of refractory congestive heart failure.**Aim:** The aim of this study was to study the demographics of the heart failure population prescribed MTZ and to identify the event rates in this group.**Method:** A retrospective analysis of data was taken of patients prescribed MTZ at Bradford Foundation Teaching Hospitals. The time period of prescription was from 1/1/14 to 31/12/14 and the 30 day and 1 year event rates in this group was studied.**Results:** In the 12 month period, 50 patients were prescribed MTZ. 18 (36%) patients had Atrial Fibrillation, 18 (36%) had Chronic Kidney Disease, 20 (40%) had Diabetes, 15 (30%) had Hypertension, 23 (46%) had known ischaemic heart disease, 6 (12%) had an ICD/Bi-vent in-situ and 3 (6%) had a previous/current malignancy. The average number of concomitant factors was 2.5.

38 patients (76%) were Caucasian, 9 (18%) were South-Asian and 3 (6%) were Afro-Caribbean.

The mean age of patients receiving MTZ was 79.2 years (standard deviation - 14.25) ranging from 32-95.

23 patients (46%) had one or more readmission(s) within 12 months of which 13 patients (26%) were readmitted due to heart failure. 5 patients (10%) were readmitted within 30 days.

9 patients (18%) died within their first 30 days from admission and 26 patients (52%) who took MTZ died within 1 year. 14 patients (28%) died in hospital.

The average time to death was 102 days from the first dose of MTZ to the day of death.

Conclusion: 1. MTZ treatment is predominantly used in the elderly population in our local practice.

2. MTZ prescription is associated with a high readmission and mortality rate at 30 days and 1 year.

P1469**Are clinicians influenced by cognitive biases when investigating chronic heart failure?**This work was supported by the National Institute of Health Research Cardiovascular Biomedical Research Unit at the Bristol Heart Institute A K Angus K Nightingale¹; Y Yanagisawa¹; T Tallis²; D G Wilson¹; Y Ismail¹; A G Dastidar¹; P Jeetley³; M Goonewardene⁴; B Whalley⁵¹Bristol Heart Institute, Department of Cardiology, Bristol, United Kingdom;²Weston Area Health Authority, Department of Child and Adolescent Psychiatry,Bristol, United Kingdom; ³Royal Free Hospital, Department of Cardiology, London,United Kingdom; ⁴Papworth Hospital NHS Trust, Department of Cardiology,Hinchingbrooke Hospital, Cambridge, United Kingdom; ⁵University of Plymouth, School of Psychology, Plymouth, United Kingdom**Background:** ESC guidelines for management of chronic heart failure (CHF) recommend non-invasive stress imaging to decide who should be investigated with coronary angiography and then undergo revascularization. We hypothesised that, like an addict who can't resist chocolate, cardiologists have cognitive biases that might influence their choice of investigations and treatment.**Purpose:** First, we wanted to know whether these CHF guidelines were being followed. Secondly, we wanted to see if a cognitive bias (availability bias) might explain why clinicians request an angiogram without first performing a non-invasive stress imaging test in patients with CHF but no angina.**Methods:** We performed a retrospective audit of 133 patients with CHF and no angina at a University Hospital in England who were listed for diagnostic coronary angiography. 97 were excluded as the angiogram was carried out during an admission with acute heart failure. 35 patients (21M, 14F), mean age 67 years old, were included. We carried out a survey of 35 cardiologists to assess attitudes and

behaviours towards investigations and treatments in CHF using 3 case scenarios. We also asked the 35 cardiologists and 50 GPs to choose a snack and then observed the impact of the availability of chocolate cake on their decision making.

Results: Non-invasive stress imaging was performed in only 23% (8/35) of CHF patients prior to angiography showing low compliance with the ESC guidelines. A further two had these tests after the angiogram. 60% (21/35) had normal coronary arteries or only mild atheroma. 9% (3/35) underwent coronary revascularization. Coronary angiography (CA) was viewed as much more readily available to cardiologists than non-invasive stress imaging such as stress echo (SE), myocardial perfusion scintigraphy (MPI) or stress perfusion cardiac MRI (weighted score of perceived availability CA 4.8 v SE 3.4 v MPI 3.9 v MRI 3.9). 88% (60/75) of clinicians said they would choose a healthy snack when writing a shopping list but only 37% (28/75) would still choose a healthy snack when offered chocolate cake as an additional option.**Conclusions:** Coronary angiography is widely carried out in CHF patients without prior non-invasive stress imaging contrary to current ESC guidelines. One factor that could account for this is the greater perceived availability of coronary angiography compared to non-invasive stress imaging tests. Other cognitive factors that we did not investigate include financial pressures, prestige and the desire for action. In the same way that chocolate can change people's behaviour, we need to aware that the availability and status of coronary angiography can influence how clinicians investigate patients with CHF. Cognitive biases may account for some of the reasons why clinicians struggle to follow international clinical guidelines.**P1470****Effect on depression and anxiety on risk of death and hospitalisation in patients with congestive heart failure.**JL Begrambekova¹; MY Drobizhev²; VY Mareev¹¹M.V. Lomonosov Moscow State University, Medical Research and EducationCenter, Moscow, Russian Federation; ²I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation**Background:** Many studies have shown an independent effect of depression on the prognosis of heart failure. Most Experts' communities recommend routine screening for depression in patients with cardiovascular disease and the subsequent directions of their psychiatrist for consultation for the appointment of therapy. Nevertheless so far there is no conclusive evidence of the effect of psychologic methods and antidepressants treatment on the course of heart failure.**Purpose:** of the study was to analyze effect of anxiety and depression on primary end point of the randomized clinical trial - mortality and hospitalization in patients with heart failure.**Material and methods:** In 730 pts with CHF (NYHA III - IV) included in CHANCE (Congestive Heart failure: A multidisciplinary Non-pharmacological approach for Changing in re-hospitalization and prognosis), depression and anxiety was assessed by the Russian version of the Hospital Anxiety and Depression Scale (HADS). Using an integrated univariate and multivariate analysis we studied relationship between the depression and anxiety, as well as other clinical characteristics and non-pharmacologic multidisciplinary Disease Management Program (DMP), consisted of structured education and regular phone calls the mortality and hospitalization during 12 months follow-up.**Results:** In univariate analyze have been found direct connection between HADS depression scale points with mortality OR 1.09 [95% CI: 1.02 - 1.16]. Presence of severe depression (HADS > 10) also significantly associated with higher mortality 1.24 (95% CI: 1.04 - 1.48). Neither depression nor anxiety demonstrates the connection with hospitalization in the univariate analysis. In multiple logistic regression we have include clinical variables typical for CHF pts, which have demonstrated the strong correlation with mortality in univariate analyze plus to depression and anxiety symptoms. Main independent predictors of prognosis (death and hospitalization of CHF) remain: NYHA FC - OR of 4.13 [95% CI: 2.54 - 6.72], history of myocardial infarction, OR 2.54 (95% CI: 1.50 - 4.28) and inclusion in active care group (DMP) - OR - 0.61 [95% CI: 0.37 - 0.99]. When included in a multiple logistic regression depression and anxiety have lost their connection with mortality.**Conclusion:** In this study, depressive and anxiety disorders showed no independent effect on prognosis in patients with NYHA FC III-IV, while non-pharmacologic DMP significantly reduce risk of death plus hospitalizations**P1471****Drug therapy recommendations at discharge in patients with heart failure - do we follow ESC guidelines in Estonia**T Pern¹; P Poder¹; A Adoberg¹; L Hein¹; E-M Lotman¹; R Lubi¹; R Majas¹;K Puvi¹; P Teppand¹; T Marandi¹¹North Estonia Medical Centre, Tallinn, Estonia**Background/Introduction:** ESC published the latest guidelines for management of heart failure (HF) in 2012, which recommends the use of beta-blockers (BB), angiotensin-converting-enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB), mineralocorticoid receptor antagonists (MRA), loop-diuretics (D) and digoxin

in HF patients with reduced ejection fraction. These guidelines were endorsed by Estonian Society of Cardiology and translated as a pocket version to be used in everyday practice.

Purpose: To evaluate if drug recommendations at discharge for patients hospitalized with HF into biggest tertiary care centre in Estonia were in concordance with ESC guidelines.

Methods: All data were collected retrospectively from electronic discharge summaries by trained readers using pre-specified worksheet. Local guidelines of data protection were followed. We included all patients that were discharged from departments of cardiology with diagnosis of HF (codes I50.0-I50.9, ICD-10) from 01/10/2014 to 30/09/2015. Data about sex, age, length of stay in hospital, NYHA class and treatment recommendations at discharge for BB, ACEi or ARB, MRA, D and digoxin were collected. Data collection method did not allow differentiating between reduced and preserved ejection fraction HF patients. Data were analysed using MS-Excel 2013.

Results: There were 2182 patients (1251 men/931 women) discharged during the study period, mean age was 70 (19-99) years and mean length of stay 6.35 (0-40) days. For 98% of patients at least one drug was recommended at discharge. Patients with higher NYHA class were recommended more drug groups (Table1). Metoprolol, ramipril or telmisartan, torasemide and spironolactone were most commonly used BB, ACEi or ARB, D and MRA, respectively.

Conclusion(s): Due to the wide variability of grading NYHA class (i.e NYHA 0) and drug recommendations at discharge we recommend reassessing criteria for diagnosing and treating HF in our institution.

Table 1

	NYHA 0 (n=2)	NYHA I (n=139)	NYHA II (n=1128)	NYHA III (n=718)	NYHA IV (n=96)	NYHA N/A (n=99)	Total n=2182 (100%)

Do we use beta-blockers in elderly patients with heart failure and reduced ejection fraction as we should?

M Mikel Taibo Urquia¹; M Cortes Garcia¹; A Garcia Ropero¹; A Romero Daza¹; JA Palfy¹; ML Martin Mariscal¹; M Lopez Castillo¹; JA Franco Pelaez²; S Briongos Figueroa²; J Farre Muncharaz¹

¹Foundation Jimenez Diaz, Cardiology, Madrid, Spain; ²University Hospital Infanta Leonor, Madrid, Spain

Background: Several reports have demonstrated the benefits of using beta-blockers (BB) when treating elderly patients with heart failure and reduced ejection fraction (HF-REF).

Purpose: In this study we aim to address the use of BB in an elderly population of our area with HF-REF.

Methods: We studied patients aged ≥ 75 years with a left ventricular ejection fraction $\leq 35\%$ referred to our echocardiography laboratory between January 2008 and December 2013.

The following information was recorded: mortality, cardiac events (defined as cardiac death or hospitalization due to heart failure) and medication use by the patient by the end of the follow up.

Our study also analysed those cases in which the heart failure treatment was not optimized according to the latest Guidelines in order to identify the reasons that could explain this situation.

The follow up consisted of a monitoring of the patient's electronic medical history, as well as a telephone interview when needed.

Results: 802 patients were included, 33,8% females. The median age of the group was $82 \pm 4,9$ years, and the median LVEF was $28 \pm 6,5\%$ at the moment of the inclusion.

The aetiology of the ventricular dysfunction was ischaemic in the 51,1% of the cases. With a median follow up of $32,7 \pm 22,6$ months, 496 (61,8%) cardiac events and 381 (47,5%) deaths took place.

71,7% of the patients were treated with BB. Multivariate survival analysis using the Cox regression model, showed that use of BB was associated with statistically significant lower total mortality rate (OR: 0,53; 0,39-0,71) and with less number of cardiac events (OR: 0,70; 0,54-0,90).

When analysing the reasons to avoid starting BB or to stop using them, the main cause we found was the presence of chronic lung disease (31,4%), followed by bradyarrhythmia (10,5%), asthenia (4,5%) and deterioration of HF. However, up to 30% of the patients that were not on BB did not present any formal contraindication for their use.

Conclusion: The use of BB in elderly patients with HF-REF was associated with a better prognosis. Nevertheless, we found a significant number of patients in which BB are not used as a therapeutic option even when there was no contraindications for their use. Awareness among professionals about the benefits of using BB in this kind of patients is needed in order to promote their use when possible.

Gender specific clinical indicators of congestive heart failure in the middle east: Data from a single centre heart failure registry

K Khaled Salem¹; D Fallata¹; K Sheeren¹; O Elkhateeb¹

¹King Abdullah Medical City, Cardiology Departement. Heart failure program, Makkah, Saudi Arabia

Background/Introduction: Clinical outcome measures are the mainstay of cardiology trials. Congestive heart failure (CHF) measures have traditionally focused on average length of stay (LOS) and rehospitalisation and mortality rates.

Purpose: We aimed to identify the significant factors of gender variability of CHF patients with a reduced ejection fraction (HFrEF).

Methods: We performed gender comparison of statistically relevant variables using prospectively collected data of HFrEF patients hospitalised over a 12-month period.

Results: Of 174 consecutive patients, 135 (78%) were males and 39 (22%) were females. Compared to males, females had a statistically significant older age (64 vs. 58; $P < 0.001$), higher ejection fraction (EF) (28% vs. 23%; $P = 0.023$) and no history of active smoking (0% vs. 16%; $P = 0.005$) and less use of beta blockers (76% vs. 93%; $P = 0.006$), digitalis (2% vs. 12%; $P = 0.009$) and mineralocorticoid receptor antagonist drugs (35% vs. 55%; $P = 0.025$). After one year, both males and females had similar all-cause and heart failure hospitalisation and re-hospitalisation rates. Females showed no differences in in-house mortality, combined in-house mortality/30-day re-hospitalisation rates and composite myocardial infarction/stroke rates, compared to males. Males were more likely to require defibrillator device implantation (34% vs. 12%; $P = 0.008$).

Conclusion: Our findings showed that female HFrEF patients had similar LOS; in-house mortality, hospitalisation and rehospitalisation rates; less utilisation for implantable devices.

Gender specific characteristics

Baseline characteristics	Males (n = 135), mean, (SD)	Females (n = 39), mean, (SD)	P-value	95% CI for difference
Age	58 (13.5)	54 (9)	< 0.001	(-10.4, -3.03)
EF	23 (9.2)	28.2 (12.8)	0.02	(-9.61, -0.75)
Smoking	16%	0%	0.01	(0.09, 0.21)
Beta blockers upon discharge	93%	76%	0.01	(0.025, 0.30)
MRAs upon discharge	55%	35%	0.03	(0.024, 0.36)
Digitalis upon discharge	12%	2%	0.01	(0.02, 0.17)
Warfarin upon discharge	25%	10%	0.02	(0.02, 0.26)
CVA or TIA rate	21%	5%	< 0.001	(0.06, 0.26)
Annual Device implantation rate	34%	12%	0.01	(0.08, 0.35)

CVA, cerebrovascular accident; TIA, transient ischemic attack; MRAs, mineralocorticoid receptor antagonist drugs

Characteristics and co-morbidities of older UK heart failure patients treated with ivabradine: baseline data from the multi-centre live: life prospective cohort study

The Live Life study is funded by Servier Laboratories Ltd (UK).

D Donah Zachariah¹; D Stevens²; N Rowell³; J Taylor⁴; PR Kalra¹

¹Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; ²Servier Laboratories UK, Slough, United Kingdom; ³South Tees Hospitals NHS Foundation Trust, Middlesbrough, United Kingdom; ⁴Glasgow Royal Infirmary, Glasgow, United Kingdom

Background: The effects of ivabradine on cardiovascular mortality, hospitalisation and quality of life (QoL) in chronic heart failure (CHF) patients with left ventricular systolic dysfunction (LVSD) have been described (SHIFT mean age 60 ± 11 yrs). Characteristics of older patients being initiated on ivabradine and its effects are limited.

Purpose: LIVE:LIFE is a UK Phase IV, multi-centre, open-label, prospective observational cohort study assessing QoL in patients aged ≥70 yrs over 6 months following clinically indicated initiation of ivabradine for CHF (NYHA II-IV, LVSD and sinus rhythm heart rate > 75 bpm). We describe the baseline characteristics of patients recruited.

Methods: Consenting patients in whom Ivabradine was initiated for clinical reasons were enrolled. Demographic, clinical, QoL (SF12, Minnesota Living with Heart Failure Questionnaire, MLWHFQ) & 6-minute walk test (6MWT) data were collected at baseline, 2 and 6 months.

Results: Between 17 December 2013 and 31 March 2015, 241 patients were recruited from 44 UK centres. 42% were female and 28% aged ≥80 yrs (mean 76 ± 6 yrs). Ischaemia was the commonest aetiology (63%) and 57% had been diagnosed for <2 yrs. Mean heart rate was 83 ± 10bpm, systolic blood pressure 124 ± 22mmHg, 52% were NYHA class III and 53% had severe LVSD. 54% received beta-blockers (39% intolerant) with a bisoprolol equivalent dose 4.0 ± 3.2 mg. Starting dose of ivabradine was 2.5mg bid in 56% of patients (44% 5mg bid). Baseline QoL: MLWHFQ total score 43 ± 24, physical 24 ± 12, emotional dimension 10 ± 8; SF-12 scores- Physical Component Summary: 35.73, Mental Component Summary: 45.15; 6MWT(n = 102) 253 ± 172m.

Conclusions: These contemporary observational data highlight the burden of complexity of comorbidities suffered by typical elderly patients initiated on ivabradine. Just over 50% patients are on beta-blockers, but use of ACEi/ARB is high. Polypharmacy is common and patients have impaired QoL and exercise capacity. Further data will help define the tolerability and impact of ivabradine on this real life population.

Comorbidities and medication

Comorbidity	N (%)	Medication	N (%)

Identifying barriers to a nurse-led heart failure team

British Heart Foundation

J Jayne Masters¹; PJ Cowburn¹; I Anton-Solanas²

¹University Hospital Southampton NHS Foundation Trust, Cardiology, Southampton, United Kingdom; ²University of San Jorge, Zaragoza, Spain

Background: Heart failure (HF) is a chronic condition that has adverse effects for the sufferer in terms of mortality, morbidity and quality of life. A substantial body of evidence exists to support the treatment of HF in left ventricular systolic dysfunction (LVSD). Registry studies show that HF patients are more likely to be given such treatment if under the care of specialists i.e. cardiologists and HF specialist nurses.

Purpose: Our hospital has employed a predominantly nurse-led HF team since 2008. However, not all patients get referred to the team. This study set out to understand referral practices, to identify barriers and facilitate better access by all HF patients to specialist HF services.

Methods: The study used a mixed methods approach. Quantitative methods involved database interrogation, development, piloting and distribution of a HF referral questionnaire. All consultant physicians, cardiologists and their registrars, responsible for patients with a primary diagnosis of HF from 2012-2013

were identified and sent the questionnaire. Semi-structured interviews were conducted on a theoretical sample of the participants; qualitative analysis using grounded theory methods was undertaken to gain a better understanding of the results.

Results: The questionnaire identified answers from 13 physicians and 15 cardiologists (40% response). Analysis of the questionnaires revealed that 4 clinicians referred all HF patients to the specialist MDT. Cardiologists referred for education and follow up and did refer complex patients. Six physicians referred complex patients. Geriatricians felt that patients with frailty and multiple co-morbidities could not be managed by disease specific teams. Other reasons given for non-referral were: HF is easily managed without specialist input, HF nurses do not add anything to hospital management, confident in own management of HF; do not understand referral criteria, role or objectives of the team.

Conclusion: The study provided valuable information about the referral practices of clinicians responsible for the care of HF patients admitted to a large UK hospital. The main barrier to referrals to the inpatient HF team was lack of understanding of the roles, aims and objectives of the team, patient age and complexity.

P1476

Haemodynamic determinants of the biological variation of NT-proBNP in patients with stable chronic heart failure

This work was supported by non-restricted grant of Roche diagnostics International AG, Switzerland

T Tobias Taeger¹; A-K Wiedergruen¹; H Froehlich¹; R Cebola¹; A Horsch²; G Hess²; K Slottje¹; HA Katus¹; FH Wians³; L Frankenstein¹

¹University Hospital of Heidelberg, Department of Cardiology, Heidelberg, Germany; ²Roche Diagnostics International, Basel, Switzerland; ³Park University Ext, LAFB, 15027 Iron Horse Way, Helotes, United States of America

Background: Biological variation of amino-terminal probrain natriuretic peptide (NT-proBNP) in chronic heart failure (CHF) may affect blood levels and risk stratification. The sources of NT-proBNP variation are largely unknown.

Methods and Results: We performed NT-proBNP measurements, clinical and haemodynamic assessment in 50 patients with CHF who met criteria for clinical stability at 2 time intervals (1-week and 2-weeks). Haemodynamic variables were measured using inert gas rebreathing and impedance cardiography. Stability of heart rhythm was continuously monitored with external ECG event recorders throughout the complete study. Determinants of NT-proBNP-levels, and both absolute (ΔNT-proBNPabs.) and relative changes (ΔNT-proBNP%) were identified using univariable and stepwise multivariable linear regression analyses, respectively. Clinical and haemodynamic variables did not change significantly between study visits. Independent predictors of NT-proBNP levels were diastolic blood pressure (DBP) (β=33.23, SE=8.55, P=0.0002) and estimated glomerular filtration rate (β=-21.19, SE=3.52, P<0.0001). While ΔNT-proBNPabs. depended from change in left cardiac work index (ΔLCWlabs.; β=154.09, SE=54.47, P=0.0077), ΔNT-proBNP% was determined by relative changes of thoracic fluid content index (ΔTFCI%; β=1.75, SE=0.62, P=0.008) and DBP (ΔDBP%; β=1.41, SE=0.54, P=0.013). Overall, the forced common model including all hemodynamic and clinical variables determined 19% of absolute and 32% of relative variation of NT-proBNP.

Conclusions: Changes of LCWI, DBP, and TFCI are determinants of the biological variation of NT-proBNP. However, they account for only 20-30% of NT-proBNP variation

P1477

Use of common treatment regimens advocated by ESC guidelines for patients with chronic heart failure in Germany: a retrospective study of the Health Risk Institute healthcare claims database

This research was funded by Novartis Pharma AG, Basel, Switzerland

S Hupfer¹; F Calado²; D Souto²; R Handrock¹; J Jacob³; J Walker³; S Klebs¹

¹Novartis Pharma GmbH, Nuernberg, Germany; ²Novartis Pharma AG, Basel, Switzerland; ³Elsevier, Berlin, Germany

Background: ESC guidelines provide recommendations for the treatment of patients with chronic heart failure (CHF) with reduced ejection fraction; similar medications may be given to those with preserved ejection fraction. Few data are available, however, regarding use of the recommended medications in German clinical practice. A retrospective study of anonymized healthcare claims data from the Health Risk Institute database was therefore conducted.

Purpose: The objectives were to investigate how patients with CHF are treated in Germany, and to describe patient characteristics and outcomes according to whether or not they received treatment regimens advocated by ESC CHF guidelines effective in 2011.

Methods: Data from patients with at least two recorded CHF-related diagnoses based on ICD-10 German Modification codes for CHF in a hospital or ambulatory setting in 2011 were analysed; about half of these patients were expected to have reduced ejection fraction. Use of guideline-compatible

treatment regimens was defined by the prescription of appropriate medication for the respective New York Heart Association (NYHA) classification, in two scenarios. Minimum requirements for the stricter regimen were: NYHA I, ACEI/ARB; NYHA II, ACEI/ARB + β -blocker + loop/thiazide diuretic; NYHA III–IV, ACEI/ARB + β -blocker + loop/thiazide diuretic + spironolactone/epplerone. A second, less stringent regimen was defined as above except that it did not include spironolactone/epplerone for NYHA III–IV.

Results: Of 123 925 patients identified, 25 863 (21%) had a specified NYHA classification. Only 45.1% (n = 11 669) of these individuals were treated according to the stricter regimen; 93.4% of patients with NYHA I and about half (55.7%) with NYHA II received such treatment. This fell to about one in five with NYHA III (20.6%) or NYHA IV (18.4%). The proportion of individuals treated in line with the stricter regimen declined with increasing age, falling from 53.4% of patients aged 55–59 years to 28.3% of those aged over 90 years, and was slightly higher in men (47.9%) than in women (42.2%). Similar proportions of patients were hospitalized whether treated according to the stricter regimen or not (62.7% and 65.3%, respectively). Mortality was lower among those treated according to the stricter regimen versus those who were not (6.7% vs. 16.2%). Compared with the stricter regimen, a greater proportion of patients received treatment with the less stringent regimen (45.1% vs 65.0%, respectively), especially those with NYHA III (66.5%) or NYHA IV (62.4%).

Conclusions: Use of treatment regimens advocated by ESC CHF guidelines may be further increased in German clinical practice, particularly when treating older patients and those with advanced disease.

P1478

Management of patients with chronic systolic heart failure at heart failure outpatient clinic improves survival after CRT and/or ICD implantation

P Peter Bogyi¹; ZS Majoros¹; D Vagany¹; B Muk¹; M Dekany¹; B Polgar¹; ZS Bari¹; GZ Duray¹; RG Kiss¹; N Nyolczas¹

¹Medical Center of Budapest, Cardiology, Budapest, Hungary

Backgrounds: Despite novel medical and device treatment of patients with chronic systolic heart failure (HFREF), mortality still remains high.

Aim: The aim of the study was to investigate the effect of management at heart failure outpatient clinic on mortality among HFREF patients after device (CRT and/or ICD) implantation.

Patients and methods: We followed 195 HFREF patients (150 male, mean age: 65.3 ± 10.6 years, NYHA: 2.4 ± 0.8, EF: 27.1 ± 6.8%, ischaemic etiology: 57.4%) who received ICD (33.3%) CRT-P (14.9%) or CRT-D (51.8%) according to current guidelines, between 2010 and 2014. Every patient received optimal medical therapy and was followed at our electrophysiology clinic. The possibility of management at our heart failure outpatient clinic was offered for every patient, 116 of them accepted it. We compared the mortality of patients who participated at heart failure management and who did not, using Kaplan Meier method and log-rank test. The impact of heart failure management was evaluated with Cox regression.

Results: During follow-up period (mean: 41.7 ± 19.8 months) 72 patients died. Survival of patients who managed at heart failure outpatient clinic proved to be better significantly than who did not. (HR:0.493 CI:0.310–0.784 p=0.003) The survival benefit remained statistically significant (HR:0.409 CI:0.238–0.703 p=0.001), after adjustment with relevant baseline parameters (age, diabetes, ischaemic/non-ischaemic etiology, type of implanted device, LVEF, LVEDD, difference in ACEi and BB use and dosage).

Conclusion: Heart failure patients with CRT-P, CRT-D or ICD have survival benefit from management at heart failure outpatient clinic besides controlling their devices by electrophysiologists.

P1479

Chronic heart failure management with cardiac resynchronisation therapy - an evaluation of current practice in a tertiary centre

D Daniela Cassar Demarco¹; M Mercieca Balbi¹; O Aquilina¹; RG Xuereb¹; N Calleja²; V Grech¹; M Sammut¹

¹Mater Dei Hospital, Tal-Qroqq, Malta; ²University of Malta, Health Information and Research, Msida, Malta

Introduction: Heart failure causes significant morbidity and mortality, besides being an important economical burden on healthcare provision. When lifestyle advice and medical treatment is not enough, further management with cardiac resynchronisation therapy (CRT) may be indicated.

Aim: The aim of this study was to investigate the current management of Maltese heart failure patients who require CRT, in order to optimise service provision and ultimately long term patient care.

Methods: A retrospective cohort study was carried out. Data was collected from the clinical notes of 100 patients who had a CRT device system implanted in the local general hospital until 2012. Demographic data, together with indications for CRT, device used and technique of implantation, complications, patient symptomatology and re-admissions with heart failure after implantation, and mortality data was collected. Pearson Chi2 and 2-sample t-test analysis was performed together with survival assessment.

Results: Descriptive analysis showed that there were more frequent implantation of devices in patients who had moderate to severe heart failure symptoms, prolonged QRS duration >130ms and an EF <35%, despite optimal medical therapy. This was consistent with current recommendations. Analysis with Pearson Chi2 testing did not show statistical significance when the patients who were readmitted to hospital were analysed also for mortality (p 0.266). 2-sample t-test analysis of variables recorded for readmissions with heart failure and mortality showed that out of all the comorbidities investigated, there was a correlation with impaired renal function (p < 0.001).

Conclusion: In most cases, current recommendations for CRT in Malta are being followed. The current pre-assessment clinic will undoubtedly re-enforce adequate patient selection for the device with extra care towards renal patients, and introduction of a specific follow-up device clinic is recommended to optimise the care of chronic heart failure patients.

Comorbidity	P-value Morbidity (Readmissions)	P-value Mortality
Diabetes mellitus	0.266	0.483
Ischaemic Heart Disease	0.192	0.203
Hypertension	0.416	0.096
Atrial Fibrillation	0.084	0.137
Renal Impairment	0.008	<0.001
Cardiomyopathy	0.336	0.157
Alcoholic	0.942	0.627

View on in-hospital heart rate control in patients with heart failure with reduced ejection fraction in Russian Federation.

E A Lyasnikova¹; M YU Sitnikova¹; MA Trukshina¹; AV Yurchenko¹; DV Duplyakov²; R A Libis³; EV Shlyakhto¹

¹Federal Almazov Medical Research Centre, Heart Failure Department, St-petersburg, Russian Federation; ²Samara Regional Cardiology Dispanser, Samara, Russian Federation; ³Orenburg State Medical Academy, Orenburg., Russian Federation

Purpose: The aim of this study is to analyses the frequency of use of ivabradine and digoxin in patients with systolic HF in Russian hospital clinical practice (from the Russian hoSpital Heart Failure Registry (RUS-HFR)).

Methods and Results: The RUS-HFR is a prospective, multicentre, observational study conducted in 3 Cardiac centers (No.1-St.Petersburg, No.2-Samara, No.3-Orenburg). Inclusion criteria: HF NYHA I–IV, LVEF≤40%, age 18–75 yrs. From Oct 2012 to Jan 2014, 524 patients were enrolled. Age 60.0±9.6 yrs; 80.5% men; most patients with HF III NYHA. Mean LVEF was 28.8%. AF was present in 43.2/46.2/47.4% and eGFR<60 mL/min/1.73 m² in 26.6/43.1/41.5% of the patients, respectively. The use of RAS blockers, β -AB, MRAs and diuretics at hospital discharge was comparable with European registers and did not differ between the centers. Only 4.6/0.8/0.7% and 6.6/1.5/3.7% patients were receiving ivabradine prior to admission and much more at discharge, respectively. Digoxin prior to admission was taken in 9.7/12.3/5.2% cases, including 1.9/2.3/0.17% of patients in sinus rhythm. 4.6/33.1/51.9% of patients were on digoxin at hospital discharge, including 0/13.1/17.0% of patients in sinus rhythm. Only in the center No.1 has been observed reduction in the frequency of digoxin use and the absence of this drug in patients in sinus rhythm at discharge. Check of digoxin blood levels in centers was not performed.

Conclusion: There was a problem of adequate rate control in patients with CHF, especially in the period of decompensation. The RUS-HFR showed that ivabradine for heart rate control in HF patients with reduced ejection fraction in Russia was not as widely used as recommended. The prescription of digoxin, mostly in atrial fibrillation, remained high and increased in some centers multiplies in times during the period from admission to discharge and decreased only in specialized heart failure center. There is a heterogeneous approach in the application of digoxin, especially in sinus rhythm, among the Russian cardiological centers.

P1481

Optimising heart failure management: peritoneal dialysis for selective advanced heart failure patients has shown reduction in hospital readmissions and decrease in annual health care cost.

M Maureen Leyser¹; L Vitou²

¹St. Mary's General Hospital, Cardiology, Kitchener, Canada; ²Grand River Hospital, Nephrology, Kitchener, Canada

Background/Introduction: Heart failure (HF) is a complex chronic syndrome with significant morbidity and mortality. Success with HF is improving patient's quality

of life (QOL) by (a) controlling their symptoms and (b) avoiding hospitalizations. Healthcare practitioners are required to heighten their awareness to improve the quality care of advance stage HF and close the gap between practice and clinical outcomes. Peritoneal dialysis (PD) has been proposed as a therapeutic alternative for patients with refractory HF and has resulted in effective HF management by reducing hospital readmissions and reducing annual healthcare costs.

Purpose: To determine if PD is a therapeutic option for patients with refractory HF by assessing for clinical outcomes such as hospitalizations and mortality. An examination of cost-benefit ratio of PD treatment versus traditional HF therapy will be analyzed to determine a reduction in annual health care costs while improving QOL for HF patients.

Methods: A retrospective chart review was conducted at a cardiac center on advanced HF clinic patients (NYHA class III/IV) not responding to conventional HF therapy. All patients had a minimum of two emergency room (ER) visits or hospitalization for HF within a year prior to PD therapy. A comparison of this patient population 18 months prior to PD and 18 months post PD was analyzed to determine if PD was an effective approach to improve HF management, reduce hospital readmissions, and annual healthcare costs.

Results: The advanced HF patients (n = 15) had NYHA Class 3-4 symptoms with renal dysfunction (average GFR 25mls/min). The average age was 74.5 years old with 53% having non-ischemic cardiomyopathy. Many patients had three co-morbidities (n = 12: 80%). The overall mortality according to the Kaplan-Meier survival curve revealed a life expectancy of 86%, 68% and 39% after 12, 18 and 24 months of PD therapy respectively. Prior to receiving PD, these 15 patients had 98 urgent cardiac clinic visits, 27 ER visits, 14 hospitalizations (Length of stay (LOS) = 278 days), 200 cardiac clinic telephone calls and 20 renal clinic visits. During PD therapy there were significant reductions in hospitalizations, ER visits, telephone and clinic visits. This resulted in 1 ER visit, 1 hospitalization (LOS = 14 days), 4 clinic telephone calls, 21 routine cardiac clinic visits and 48 routine PD renal clinic visits. There were no documented peritonitis cases. The economic analysis indicated a cost-benefit ratio of 2.32 revealing a financial savings to the health care system.

Conclusions: Despite a small sample size, these results demonstrated that PD may be an effective means of improving HF management by reducing readmission and hospital resources. QOL gains have not been considered in the analysis but should be considered as a part of a more complete economic analysis. Further research should also focus on improve identification for patients to benefit from palliative PD therapy.

P1482

MultiSENSE patient diary use versus HF decompensation

Boston Scientific

G Molon¹; JB Boehmer²; R J Robert Sweeney³; YZ Zhang³; QA An³; VA Averina³

¹ Sacred Heart Hospital of Negrar, Negrar-Verona, Italy; ² Penn State Milton S. Hershey Medical Center, Hershey, PA, United States of America; ³ Boston Scientific CRM, Rhythm Management Research, St Paul, MN, United States of America

Background: Standard management of heart failure (HF) involves teaching patients to adhere to medical therapy, monitor weights and symptoms to detect early HF, and then to take action once early HF is detected. In a clinical trial that included recording weight, medications and symptoms in a diary, we hypothesized that greater diary use would be associated with fewer worsening HF events (WHE).

Methods: The Multisensor Chronic Evaluations in Ambulatory Heart Failure (Multi-SENSE) study is a prospective, observational study where patients' CRT-D devices were converted to devices capable continuous ambulatory measurements of trans-thoracic impedances, heart sounds, body acceleration and respiration values in addition to existing CRT-D measurements. Patients were asked to complete a diary to record daily weights and medication changes and weekly self-assessment of symptoms. WHE were collected and were adjudicated by a panel of clinicians. Data from 500 patients were characterized by how frequently they completed diary responses as either never answered (Never), answered <50% of the time (<50), or answered ≥50% of the time (≥50) in each of weights, medications changes or symptoms. A WHE event rate (WHE rate) for each patient was the number of adjudicated WHE divided by the patient's duration in study. The WHE rates were compared among groups for weight, medication change, and symptom responses.

Results: For each characterization group, Table 1 shows number of patients (N Pts) and the average WHE rate (WHEavg) for weight, medication and symptom diary use. p values are Wilcoxon test for differences among the three groups. Note, only whether a patient responded is considered and not the actual response value.

Conclusion: Patients that consistently answered the weight (p = 0.02) and symptom (p = 0.0003) questions in the diary had fewer WHE than those that did not. However, consistently recording medications (p = 0.29) was not associated with fewer WHE. It may be that patients that actively pay attention to their weights and especially symptoms do not decompensate as frequently.

Table 1 WHE rate versus responses

Group	Weights		Medications		Symptoms	
	N Pts	WHEavg	N Pts	WHEavg	N Pts	WHEavg
Never	44	0.52	100	0.38	84	0.60
<50	146	0.34	170	0.26	170	0.21
≥50	310	0.22	230	0.25	246	0.22
P		0.023		0.290		0.0003

The patients are grouped by % responses (never, <50 and ≥ 50) for the three diary components. Average WHE rates are compared (p is Wilcoxon difference among groups).

P1483

How the elderly patients with chronic heart failure are treated in clinical practice? - the analysis of DATA-HELP registry.

Merck Serono.

JM Justyna Maria Krzysztofik¹; W Banasiak²; B Kurian³; P Ponikowski¹; EA Jankowska⁴

¹ Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland; ² 4th Military Hospital, Cardiology Department, Centre for Heart Diseases, Wroclaw, Poland; ³ Merck, Warsaw, Poland; ⁴ Wroclaw Medical University, Department of Heart Diseases, Laboratory for Applied Research on Cardiovascular System, Wroclaw, Poland

Background: Systolic heart failure (HF) represents a cardio-geriatric syndrome. Advanced age is a known risk factor for HF development and poor outcome in HF. Importantly, the implementation of the ESC guidelines in the elderly patients may be challenging in the everyday clinical practice.

Purpose: The aim of our study was to assess an implementation of the ESC guidelines regarding the management of systolic HF across different age groups.

Methods: We analyzed 5289 outpatients (mean age: 67 ± 11, 63% of men) from the DATA-HELP registry, that comprises a contemporary, representative group of patients with stable, systolic HF treated in Poland.

Results: There was the following age distribution in examined patients: <50 (5%), 50-64 (37%), 65-79 (43%), ≥80 years (14%). Management across age-groups is presented in the Table.

Conclusions: Elderly patients represent big population of patients with systolic HF. Disease-modifying evidence-based therapies are less frequently applied in target doses in the elderly, whereas symptomatic treatments usually is used more often than in other age groups.

Applied treatment in studied groups:

	WOMEN				MEN			
	<50	50-64	65-79	≥80	<50	50-64	65-79	≥80
Age group (years old)								
Number of patients, n (%)	64 (3)	586 (29)	930 (46)	396 (20)	224 (6)	1404 (41)	1403 (41)	382 (11)

Icelandic heart failure patients at time of economic crisis: patient reported outcomes

Landsþítali University Hospital Research Fund, The Icelandic Nurses' Association Research Fund, The research fund of Maria Finnsdóttir

AK Ketilsdóttir¹; BI Ingadóttir²; TJ Jaarsma³

¹Landsþítali University Hospital, Department of Cardiology, Reykjavík, Iceland;

²Landsþítali University Hospital, Department of Surgery, Reykjavík, Iceland;

³Linköping University, Department of Social and Welfare Studies, Linköping, Sweden

Introduction: Since 2008 the economic crisis has hit many European countries hard. There are indications that economic crises directly affect the health of the public. In general, patients with chronic diseases such as heart failure (HF) use a high proportion of healthcare and it might therefore be expected that they suffer most from economic hardship, potentially leading to decline in health status.

Purpose: To describe the characteristics, health status, social and economic status of patients who attend a HF outpatient clinic and assess if there is a relationship between health status and economic factors.

Methods: In this cross sectional study data was collected with mailed questionnaires and from electronic patient journals in 2014. Patient reported outcomes were measured with nine previously validated and structured instruments on self-care (European Heart Failure Self-care Scale-EHFScB), heart-failure related knowledge (Dutch Heart Failure Knowledge Scale-DHFKS), symptoms (Edmonton Symptom Assessment System-ESAS), anxiety and depression (Hospital Anxiety and Depression Scale-HAD-S), sense of security (Sense of Security in Care-SEC-P) and health related quality of life (The health related quality of life aspects-EQ5D and Kansas City Cardiomyopathy Questionnaire-KCCQ). In addition patients answered questions regarding, background, access, the use and cost of healthcare. Clinical data was extracted from electronic patient records.

Results: 124 participated, mean age was 73 (± 14.9) and 69% were males. Most were either in New York Heart Association functional class II (37%) or III (55%). Cost of healthcare had changed for 71% since 2008. Patients reported a mean prevalence of 4.8 (± 2.56) symptoms. Most common was tiredness (82%), shortness of breath (77%) and drowsiness (76%). The mean score of self-care on the EHFScB scale was 29.7 (± 7.9) and HF knowledge was high 11.6 (± 3.07). Patients rated their overall health on average 65 (± 22.8) with the EQ-5D visual analogue scale. The overall summary score and the clinical summary score of KCCQ was 61.3 (± 23.4) and 63.17 (± 23.8) respectively. No difference was found in patient-reported outcomes between those who had and had not experienced changes in their out-of-pocket costs since 2009.

Conclusions: Health status of Icelandic HF patients is similar to other European countries and patients managed their disease well during and after a time of economic crisis. The result give valuable information on directions to take in the development of outpatient services for heart failure patients.

P1485

Ranolazine reduces symptoms and arrhythmia in patients with ischaemic left ventricular dysfunction

G Marazzi¹; G Campolongo¹; R Massaro¹; V Pasceri¹; G M C Giuseppe M C Rosano¹; M Volterrani¹; F Pelliccia¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Background: Ranolazine decreases the frequency of arrhythmias during the acute phases of ischemic heart disease (IHD), but it remains unknown if it has similar effects in the chronic phase of the disease. We performed a prospective, randomized, cross-over pilot trial to test the hypothesis that chronic treatment with ranolazine can reduce the incidence of documented arrhythmias and the related symptoms of palpitation in stable patients with IHD and left ventricular dysfunction.

Methods: We randomized 105 patients with stable IHD, LV function <40% and symptoms of angina and palpitations already on therapy with beta-blockers and/or calcium antagonists to ranolazine (750 mg bid, n = 53) or placebo (n = 52) for 30 days (until T-1). After a wash-out period to avoid any carryover effect, cross-over was performed, and patients were switched to the other drug which was continued for 30 days (until T-2). All patients underwent symptom-limited exercise stress testing and 48-hour ECG Holter monitoring at T1 and T2. During the study period, patients were told to use a OmronN[®] portable ECG monitor HCG-801 device in case of symptoms of palpitations.

Results: Ranolazine reduced the number of anginal episodes more commonly than placebo (5 ± 8 episodes/30 days vs. 21 ± 24 episodes/30 day, $p = 0.001$) and increased exercise durations at 1 mm ST-segment depression (514 ± 211 s vs. 402 ± 287 s, $p = 0.025$) and at onset of angina (614 ± 199 s vs. 519 ± 151 s, $p = 0.007$) at stress testing. These effects were coupled by significant decreases with ranolazine as compared with placebo treatment periods in the occurrence of frequent (> 1,000 beats) supraventricular arrhythmias (33% vs 52%, $p = 0.01$) and complex ventricular arrhythmias (17% vs 30%, $p = 0.045$). Complete resolution of symptoms of palpitations was significantly more common with ranolazine than placebo (31/53 vs 16/52 patients, $p = 0.008$). Also, portable ECG recordings

showed that arrhythmias were less common during ranolazine vs. placebo, with significant decreases in number (7 ± 10 episodes/30 days vs. 23 ± 29 episodes/30 day, $p = 0.001$) and duration (10 ± 18 min/30 days vs. 19 ± 21 min/30 day, $p = 0.021$) of symptomatic arrhythmic episodes. No severe side effects were recorded during the trial period.

Conclusion: The antianginal and antiischemic properties of ranolazine are paralleled by significant decreases in the occurrence of both arrhythmias and the related symptoms of palpitations in stable patients with IHD and left ventricular dysfunction.

Pharma AG, Basel, Switzerland; ⁵IMS Health Sweden, Stockholm, Sweden; ⁶IMS

Health Germany, Berlin, Germany; ⁷Uppsala University, Department of Public

Health and Caring Sciences, Uppsala, Sweden

Background: A clear understanding of dosing patterns of heart failure (HF) treatments in newly diagnosed patients will allow healthcare professionals to evaluate the implementation of ESC guidelines (Eur Heart J 2012) in the real world.

Purpose: To compare treatment dosing patterns of patients newly diagnosed with HF (reduced ejection fraction, HF-rEF; left ventricular EF $\leq 50\%$) with ESC guidelines.

Methods: Patients in Sweden, were identified via primary and secondary care electronic medical records. Patients aged ≥ 18 years with a first HF diagnosis from 1 Jan 2010 to 31 Mar 2015 were included. A 9-year look-back period was applied per patient to exclude prevalent cases. Data from patients with confirmed HF-rEF were analysed. A patient's maintenance HF treatment was identified from the Swedish Prescribed Drug Register. Maintenance treatment was assumed to start within 90 days after treatment initiation. A prescribed maintenance treatment dose was defined as the median prescribed maintenance dose by patient and treatment and was estimated based on the assumption that the duration of each dispensation during maintenance was 90 days.

Results: Of 8777 records, 728 patients with HF-rEF were identified (33.1% women; mean [SD] age: 70.8 [14.9] years; mean [SD] body mass index: 26.7 [5.4] kg/m²; mean [SD] Charlson comorbidity index: 1.9 [2.3]). Of the treatments analysed (Table 1), only 1.4% of patients prescribed losartan but 96.8% of those prescribed spironolactone received the recommended dose.

Conclusions: The proportion of patients with HF-rEF achieving ESC-recommended doses for HF treatments varied greatly. Various factors may influence this, such as patient-specific factors, dosing regimen, individual treatment goals and structural reasons in the healthcare system. Evaluation of such factors is needed to ensure that patients receive appropriate doses.

	n(%) receiving $\geq 50\%$	n(%) receiving $\geq 100\%$
enalapril (n = 321)	214(66.7)	135(42.1)

P1487

High-precision ECG in patients after heart transplantation

T Tatiyana Vaikhanskaya¹; AV Frolov¹; TA Trofimova¹; YP Ostrovskiy¹

¹Republican Scientific and Practical Center "Cardiology", Minsk, Belarus

The purpose of research was assessment of parameters of high-precision ECG in patients after heart transplantation and a comparison with this values of control group.

Material and methods: The study included 40 healthy subjects (aged 44.2 ± 15.6) and 39 patients after orthotopic heart transplantation (aged 42.8 ± 11.9); follow-up

28,6±9,43 months after allograft transplantation. Parameters of microvolt T-wave alternation (mTWA), heart rate turbulence (HRT), the intervals QT et JT dispersion and acceleration/deceleration (DC/AC) indexes of heart rate were analyzed. All patients were examined by echocardiography, Holter monitoring ECG and 7-min high-definition ECG (Intecard-7). ECG parameters of patients who had transplanted heart (TH) with no signs of rejection of allograft were compared with the control group (CG) of the healthy subjects.

Results: ECG data of TH pts showed an increase mTWA ($p < 0,005$) and significant ($p < 0,05$) decrease of indexes deceleration (DC 2.0 { 1,0; 4,5} {6,5 vs 10,2; 17,5} ms) and acceleration heart rate (AC {2,0 1,3; 6,5} {6,7 vs 10,2; 17,7 } ms) despite signs of reinnervation TH according to data of the heart rate variability (HRV). Thus, the HRV in the early period (1 to 3 months after TH) demonstrated a total denervation of transplanted heart: SDNN 44.5±13.4ms, SDNNi 12.1±6.55ms, rMSSD 18.6±14.6ms, LF \ HF 0.16±0.18; but after 28,6±9,43 months follow-up HRV parameters (SDNN 64.5±16.9 ms, SDNNi 32.6±9.72 ms, $p=0.000$; rMSSD 27.8±13.4 ms, $p=0.006$; LF \ HF 1.42±0.52, $p=0.000$) were significantly improved showing signs of the emergence of physiological innervation still more dominance of sympathetic reinnervation above the parasympathetic autonomic regulation of rhythm. In the stepwise discriminant analysis were included all ECG parameters (TH and CG) with significant differences $p < 0.05$. As result of the analysis (data are demonstrated table below), significant differences in the comparison groups were revealed: test mTWA (% pathological mTWA: $F=6.3$; $p=0,015$ and the average values of mTWA: $F=22.9$; $p=0,00001$); JT dispersion (JTd: $F=6.4$; $p=0,014$).

Conclusion: The dominant sympathetic reinnervation characterized by sympathetic-vagal imbalance in TH pts also has evidence of myocardial electrical instability is associated with markers of high-precision ECG: mTWA and JT dispersion.

Result of stepwise discriminant analysis

Parameters of high-precision ECG	Wilks' - Lambda	Partial - Lambda	F-remove (1,58)	p-level
Test of mTWA (mean parameter mTWA)	0,896319	0,717207	22,86923	0,000012
Test of mTWA (% percent of pathological mTWA)	0,712681	0,902013	6,30065	0,014881
Interval JT dispersion	0,713871	0,900509	6,40804	0,014093

P1488

Prevalence of cardiovascular risk factors in patients followed in a heart failure clinic

H Henrique Guedes¹; P Silva¹; A Pereira¹; RP Santos¹; L Marques¹; D Seabra¹; A Andrade¹; C Lourenco¹; P Pinto¹

¹Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal

Background: Heart failure (HF) is the end stage of several diseases. Its prevalence and incidence remain high, with high rates of morbidity and mortality. The importance of the cardiovascular risk factors (CVRF) in patients with heart failure is well established, and the monitoring of CVRF essential and part of the treatment, since its presence worsens the prognosis of these patients.

Purpose: To evaluate the prevalence of cardiovascular risk factors in patients followed in Heart Failure Clinic (HFC).

Methods: We included all patients in the HFC from a single center. Patients were admitted in the HFC with a previous diagnosis of HF for at least 6 months or prior hospitalization for acute HF. The CVRF assessed were: arterial hypertension (AHT), dyslipidemia, diabetes mellitus (DM), obesity, smoking and chronic kidney disease (CKD, defined as glomerular filtration rate ≤ 60 mL/min/1.73m²); the presence of cerebrovascular disease (CVD) and excessive alcohol consumption were also evaluated.

Results: Included 306 patients, 25.2% were female, with mean age of 60.99 years. 41.8% have ischemic etiology as the cause of HF. 33.7% have atrial fibrillation. 3.6% do not exhibit any of the evaluated CVRF. AHT is the most prevalent CVRF, being present in 61.1%, followed by dyslipidemia (52.3%), smoking (34.0%), DM (33.7%), CKD (33.3%), excessive alcohol consumption (33.0%), obesity (20.3%) and CVD (9.2%). 85.6% have at least two CVRF. 34.6% of patients simultaneously present the two most significant CVRF (AHT and dyslipidemia), and 78.9% have at least one of these CVRF.

Conclusion: The prevalence of CVRF is high in this population of patients followed in HFC, with AHT and dyslipidemia being the most prevalent.

P1489

Prognostic importance of atrial fibrillation in patients with heart failure

H Henrique Guedes¹; P Silva¹; A Pereira¹; RP Santos¹; L Marques¹; D Seabra¹; A Andrade¹; C Lourenco¹; P Pinto¹

¹Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal

Background: Heart failure (HF) keeps increasing prevalence and incidence, with high mortality rate. Atrial fibrillation (AF) is the most common cardiac arrhythmia in the general population, with an estimated prevalence between 1.5% to 2%, and a prevalence of about 30% in patients (pts) with HF.

Purpose: To evaluate the impact of permanent AF in the prognosis of pts with chronic HF and reduced ejection fraction.

Methods: Retrospective study where were included pts followed in a HF clinic (HFC) from a single center. The pts had reduced ejection fraction and were admitted in the HFC with a previous diagnosis of HF for at least 6 months or had prior hospitalization for acute HF. Pts with follow-up (FU) of less than 12 months were excluded. Pts were divided into 2 groups: with FA (G1) and without AF (G2). The groups were compared as to their clinical and echocardiographic characteristics and the occurrence of significant cardiac events - hospitalization for HF (hHF), hospitalization for acute coronary syndrome (hACS), cardiovascular mortality (CVM), non-cardiovascular mortality cause (nCVM). For statistical analysis we used the SPSS 22.0.

Results: Included 270 pts, mean age 61.2±13.5 years. 74.1% were male. 41.9% had ischemic etiology and 64.4% severe depression of left ventricular systolic function. Average FU time was 35.9±16 months. 91 (33.7%) integrated G1 and 179 (66.3%) G2. In univariate analysis, the pts in G1 were older ($p < 0.001$) and had more chronic renal dysfunction (glomerular filtration rate ≤ 60 mL/min/1.73m²; $p=0.017$). In G2, there were more male pts ($p=0.026$) and a higher incidence of dyslipidemia ($p=0.04$). During the FU, the pts in G1 showed higher CVM ($p < 0.001$) nCVM ($p=0.033$) and hHF ($p < 0.001$); hACS showed no significant differences ($p=0.552$).

Conclusion: In this study in pts with HF, with the exception of ACS, the presence of AF was associated with a greater number of events.

P1490

Serum drug levels as a new diagnostic tool for non-adherence to therapy in chronic heart failure patients

R Pelouch¹; V Vorisek²; V Furmanova²

¹Charles University - Faculty of Medicine Hradec Kralove, University Hospital Hradec Kralove, 1st Department of Internal Medicine - Cardioangiology, Hradec Kralove, Czech Republic; ²Charles University - Faculty of Medicine Hradec Kralove, University Hospital Hradec Kralove, Institute of Clinical Biochemistry and Diagnostics, Hradec Kralove, Czech Republic

Purpose: The aim of the study is to assess the frequency of non-adherence to the recommended therapy in chronic heart failure patients and to evaluate its impact on the disease course

Methods: Stable chronic heart failure patients with established medication were enrolled to the study. They passed three study visits (enrollment (M1), month three (M3) and month nine (M9)) and two-year follow-up. Blood sampling was performed during study visits and serum levels of prescribed medications were used as an indicator of drug adherence. Serum drug levels were evaluated by liquid chromatography and mass spectrometry. The subjects were labeled as non-adherent when the serum level of at least one of the evaluated drugs was below the limit of quantification.

Results: Forty chronic heart failure patients (age 64.4±11.4 years, 23men/17women, LV EF 30.6±10.9%, NYHA class median 2) were prospectively enrolled. On the average 3.9±1,1 (median 4) drugs per blood sample were measured.

All of the evaluated drugs were detected in the sera of 27patients (67.5%), the non-adherence was diagnosed in 13 patients (32.5%).

At the end of two-year follow-up next indicators were compared between adherent and non-adherent group: overall mortality (29.6%vs15.4%, $p=0.35$), heart failure mortality (22.2%vs15.4%, $p=0.63$), need for emergency visit/hospitalization due to worsening heart failure (1event 11.1%vs0%, $p=0.23$, ≥ 2 events 3.7%vs0%, $p=0.52$), gender (men 66.7%vs38.5%, $p=0.10$), NTpro-BNP (327.8±482.2vs112.1±128.7 pmol/l, $p=0.43$), LV EF (30.0±10.9%vs31.9±10.8%, $p=0.62$) and NYHA class (2.4±0.6vs2.4±0.6, $p=0.60$).

Conclusions: Our data suggest that the non-adherence to the recommended therapy may be present in significant part of chronic heart failure patients (32.5% in our study). We assume that the estimation of serum drug levels is an useful diagnostic tool in clinical evaluation in these patients. We did not found any difference between groups of adherent and non-adherent patients during two-year follow-up.

Limitations: The main limitation is the size of the study population

P1491

What diagnostic problems do we have among primary care of the heart disease patients.

A A Andrej Dukat¹; J Gajdosik¹; T Szadocka¹; L Serugova¹; M Zelina¹; P Sabaka¹; F Simko²

¹Comenius University, 2nd.Dept.of Internal Medicine, Bratislava, Slovak Republic;

²Comenius University, 3rd.Dept.of Internal Medicine, Bratislava, Slovak Republic

Background: Slovakia with 5.5 millions of inhabitants belongs to the countries with the highest cardio-vascular mortality in Europe.

Aim of the study was to create the national registry of the heart failure patients from the primary care physicians, internal medicine and cardiologists of the 310 centers in the country.

Patients and methods: 7032 heart failure patients (3281 men-46.4% and 3751 women-53.3%) were followed up during one year (2014-2015). Demography (\pm SD): height:167.8 \pm 8.8cm, weight:83.5 \pm 15.7kg, waist: 98.3 \pm 14.7cm, BMI:29.5 \pm 5.4cm², BPs:137.8 \pm 17.0mmHg, BpD:81.5 \pm 10.2mmHg in NYHA class II: 3819, III: 2260, I:696, IV:109pts. Ischaemic etiology was in 52.8%, hypertension 33.7%, cardiomyopathy 5.2, valvular disease in 4.2% of pts.

Results: Incremental trend between NYHA class and NT-proBNP levels (\pm SD ng/l) was seen: NYHA I:587.1 \pm 1650.2, II:919.99 \pm 1410.82, III:1658.71 \pm 2250.16, IV:2729.84 \pm 3309.73. ECG sinus rhythm was in 76.5% pts, non-sinus in 20%, pacemaker 4.2% and atrial fibrillation in 25.2%, AV blocks 5.8%, BBB in 21.4%, ischemia at rest in 64.2%. X-ray increased CTI was in 58.9% and lung congestion in 21.3% of the followed. Echocardiographic normal LVEF was in 23.5%, between 0.55-0.40 in 41.9%, 0.40 -0.30 in 19.4%, \leq 0.30 in 4.9% and correlated with the severity of the clinical status of pts. None of the followed pts had exercise test ever performed (even not 6min walking test). Despite heart failure diagnosis, 20% of them remained smokers and 13.4% took regular alcohol.

Conclusion: National registry creation of the heart failure patients may improve the follow-up, complex management and improvement of their prognosis.

P1492

The xanthine oxidase activity in patients with congestive heart failure

A V Alexandr Bilchenko¹; MV Kolomiets¹

¹Kharkiv Medical Academy for Postgraduate Education, Internal medicine and Nephrology, Kharkiv, Ukraine

Background: Several data suggest the role of the xanthine oxidase metabolic pathway in the pathophysiology of congestive heart failure (CHF). Changes in xanthine metabolism in patients with concomitant chronic kidney disease (CKD) considered due to impaired renal excretion of uric acid and thus not associated with increased xanthine oxidase activity.

Purpose: The goal of our study was to determine the changes in the activity of xanthine oxidase in patients with congestive heart failure and concomitant chronic kidney disease.

Methods: 112 patients with congestive heart failure NYHA class II-III (51 men and 61 women; mean age 72.5 \pm 8.6 years) were included in the study. 72 patients had concomitant CKD with glomerular filtration rate (GFR) <60 mL/min/1.73 m² (1st group) and 40 without concomitant CKD (2nd group).

Xanthine metabolism was studied by determining serum uric acid level and the xanthine oxidase activity. Xanthine oxidase activity was determined fluorometrically by using standard assay kit.

Results: Serum uric acid level was slightly increased in patients with CHF (7.47 \pm 0.18 mg/dL) and 62.5% (70 of 112) patients had asymptomatic hyperuricemia (defined as serum uric acid level \geq 7.0 mg/dL). Mean xanthine oxidase activity was 6.46 \pm 0.59 mU/mg in patients with CHF. Uric acid level and the xanthine oxidase activity were higher in patients with NYHA class III compare with NYHA class II (mean uric acid level 8.50 \pm 0.39 mg/dL vs 6.88 \pm 0.25mg/dL, respectively; p < 0.01; and mean xanthine oxidase activity 7.22 \pm 1.20 mU/mg vs 5.96 \pm 0.61 mU/mg, respectively, p > 0.05).

It was found insignificant increase of serum uric acid level in patients with concomitant CKD (in the 1st group 7.63 \pm 0.27 mg/dL and the 2nd group 7.46 \pm 0.39 mg/dL, respectively; $=$ 0.73). Xanthine oxidase activity was significantly higher in the 1st group as compared with the 2nd group (7.51 \pm 0.77 vs 4.69 \pm 0.77 mU/mg, respectively; p < 0.05). In a multiple regression model, significant relationship between the xanthine oxidase activity and decrease of GFR was found, independent of serum uric acid level, ejection fraction of left ventricular, NYHA class, age and sex (p < 0.05).

Conclusions: There is a strong relationship between the xanthine oxidase activity and decrease of GFR in patients with congestive heart failure and concomitant CKD. Some studies have shown that an elevation in the enzymatic activity of xanthine oxidase can lead to increases in oxidative stress, endothelial dysfunction, and reduced myocardial function in patients with congestive heart failure.

P1493

Impact of a treatment with L-arginine on clinical and hemodynamic parameters in CHF

YAR Akhmatov¹; TA Abdullaev¹; I A Igor Tsoy¹; YUK Yuldasheva¹; NA Kurbanov¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

Objective: To assess the effect of the combination of L-arginine with basic therapy (BT) on clinical and functional parameters of patients suffering from chronic heart failure (CHF) caused by dilated cardiomyopathy (DCM), and DCM with a primary lesion of right (DKMPpzh).

Material and Methods: The study included 52 patients. All studies were performed: physical examination on a scale SHOKS; biochemical blood tests; ECG; Echocardiography; Test 6-minute walk (TSHH) to measuring the length of distance traveled (DPD). All patients received BT and L-arginine (Tivortin, "Yuri Farm", Ukraine) as a 4.2% solution intravenously with 100 ml of 1 times per day (8-10day) with subsequent transition to oral solution of 5- 10 ml 3 times a day for 4 weeks. Depending on the type of cardiomyopathy patients were divided into 2 groups: 1g. - 22 patients with DKMPpzh; 2g. - 30 patients with dilated cardiomyopathy.

Results: The groups were comparable in age, but in 1g. dominated by females (77,3% vs 30%, respectively, in groups 1 and 2, p < 0,05). The heart rate in the analyzed groups did not differ significantly, but the numbers of blood pressure, both systolic and diastolic blood at baseline were higher in 1g. (p < 0,05). The therapy with L-arginine in combination with the BT changes in the heart rate has not been revealed, however, in both groups there was a slight increase in blood pressure and decrease heart failure functional class, with more pronounced in 1g. BT combination with L-arginine has also contributed to the improvement of the parameters of intracardiac hemodynamics in both groups of patients. In particular, 1g. observed a decrease in the size of the bulk of the right heart, with inotropic myocardial function was characterized by an increase in ejection fraction as the RV and LV. This, in turn, was followed by a decrease in the average level of pulmonary artery pressure (PASP) of 10.7% and a decrease in the number of individuals with the presence of tricuspid regurgitation. During 2g. combination therapy with L-arginine contributed to the increase in LVEF and the normalization of PASP values (all P < 0.05). It should be noted that the combined treatment with L-arginine in WT subjects us patients was not associated with any side effects and, therefore, did not require discontinuation.

Conclusions: CHF due to DCM with a primary lesion of the right ventricle, is more common among women and is characterized by relatively intact heart rate and blood pressure. Use of a 4-week course of L-arginine in the complex treatment of chronic heart failure, regardless of its topographical features, improves parameters of intracardiac hemodynamics and reduction of PASP.

P1494

FEW16 questionnaire as new instrument in patients with heart failure with preserved ejection fraction

D Jahandar Lashki¹; E Elvis Tahirovic¹; T Trippel¹; R Wachter²; G Gelbrich³;

M Halle⁴; B Pieske¹; C Herrmann-Lingen⁵; F Edelmann¹; HD Duengen¹

¹Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany; ³University of Wuerzburg, Institute of Clinical Epidemiology and Biometry, Wuerzburg, Germany; ⁴Technical University of Munich, Center for Sports Medicine, Munich, Germany; ⁵University Medical Center Gottingen (UMG), Department of Psychosomatic Medicine and Psychotherapy, Gottingen, Germany

Introduction: In heart failure, improvement of quality of life (QoL) is a major therapy goal. Physical well-being as important part of QoL has not yet been sufficiently covered by disease-specific instruments. A QoL questionnaire, FEW16 was developed for assessing the subjective physical wellbeing.

Purpose: The aim of this analysis was to validate the FEW16 questionnaire in heart failure patients with preserved ejection fraction (HFpEF) from the Exercise Training in Diastolic Heart Failure (Ex-DHF-P) trial.

Methods: Ex-DHF-P was a prospective, randomized, controlled study, with a goal to determine the effects of physical training on exercise capacity and QoL in patients with diastolic heart failure. 64 HFpEF patients (65 years, 56% female) were randomized to usual care with (n = 44) or without training (n = 20). At baseline and at 3 months, patients were clinically evaluated and QoL (SF36), physical wellbeing (FEW16) and depression (PHQ-D) were assessed.

Results: FEW16s' Cronbachs' Alpha coefficients were 0.85-0.93. The crossvalidity with SF36 and PHQ-D was highly significant but more so for psychological aspects. At baseline, the FEW16 score correlated with age, the subscale Resilience with age and 6 minute walking distance. At follow-up, the FEW16 total and Resilience scores had improved in the training group.

In contrast to the SF36, the FEW16 did not detect differences between the groups in Ex-DHF-P. The FEW16 showed good internal consistency and correlation with the SF36 and PHQ-D. Although it did not reflect significantly different changes between the two groups, its total score and Resilience improved after training.

Conclusions: We consider the FEW16 a questionnaire rather for psychological or general well-being than for physical well-being alone. To measure physical well-being, the SF36 Subscale vitality seemed to be more useful.

P1495

The ACE gene and ejection fraction in the uzbek patients having Q-MI

NB Sayfiddinova¹; BDJ Amirkulov¹; TA Abdullaev¹; SHM Erkaboiev¹; I A Igor Tsoy¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

The aim: Evaluation of the interrelationship between ACE gene with myocardial hypertrophy (MH) of the left ventricle (LV) and ejection fraction (EF) in the patients of Uzbek nationality having Q-wave myocardial infarction (Q-MI).

Materials and methods: there were analyzed data of 46 pts who were males with Q-MI. The mean age of pts was 51.7 ± 9 y. All pts were performed analysis for presence of combination I and D of the ACE gene (I/I, I/D, D/D). Isolation of DNA genome was performed from the peripheral blood with use of kit D1AtomDNAprep 200 (Laboratory Isogen, Russia). PCR reaction was performed with use of the kit for genotyping on the polymorphic marker I/D of gene ACE on the amplifier GeneAmpPCRSystem 9700 (Applied Biosystems, USA). In dependence on the results of analysis the pts were divided into 3 grps: gr I (n = 11), 23%, having combination of alleles I/I, gr II (n = 22) 47.8% with combination I/D, gr III (n = 13) 28.3% with combination D/D. On the 10-14 days of the AMI EchoCG were made in all pts.

Results: The comparative analysis of the data of the EchoCG showed that myocardium mass of the LV, wall thickness of the LV prevailed unreliably in the gr of pts with genotype D/D with the following values: MMLV 292.2 ± 103.6 mg, IVS 1.3 ± 0.3 cm. At the same time in gr I/I the thickness of IVS was reliably less and accounted 1.0 ± 0.3 cm (p 1-3=0.02), and myocardial mass of LV was 239.7 ± 45.3 g. In group I/D these parameters were as follows: 253.4 ± 103.6 mg and 1.04 ± 0.3 cm, respectively (p<0.05). The parameter of the ejection was also the least value in the gr with genotype D/D and accounted $47.5 \pm 10.9\%$, however in grs with genotype I/I and I/D, on the average, was $51.5 \pm 10.25\%$ and $48.9 \pm 11.24\%$ (p1-2 =0.4; p1-3=0.1) respectively. Conclusion. In the Uzbek population among the patient having Q-MI I/D the combination of the alleles of ACE gene occurred mostly frequent. In the carriers of D/D gene combination after AMI there was noted lower ejection fraction of the LV, high parameters of the MMLV, thickness of the IVS, PWLV in comparison with parameters of the pts with genotype I/I and I/D.

P1496

Influenza vaccination reduces relative risk of dementia in patients with heart failure

J-C Ju-Chi Liu¹; L-C Sung¹; W-R Hao¹

¹Shung Ho Hospital, Division of Cardiology, Department of Internal Medicine, New Taipei City, Taiwan ROC

Background: There is evidence that vaccination for influenza may decrease risk of acute cardiovascular event in patient with chronic heart failure (CHF). There is a higher prevalence rate of dementia in patients with CHF due to impaired circulatory status in brain. The purpose of this study was to test the hypothesis that influenza vaccination could reduce occurrence rate of dementia in patients with HF. **METHOD:** Using the Taiwan Longitudinal Health Insurance Database 2001 to 2012 (LHID2001-2012), this cohort study comprised patients (age > 60 years) with a recorded diagnosis of CHF (n = 20509) between January 1, 2001 and December 31, 2012. Each patient was followed-up using entry data until the end of 2012. Cox proportional hazard regressions were used to evaluate the dementia-free survival rates, after adjusting for known confounding factors.

Results: We found that patients with CHF receiving influenza vaccination had a lower risk in dementia development after adjusting for potential confounders [adjusted hazard ratio (HR) 0.65, 95% confidence interval (CI) 0.60-0.71, p < 0.001]. When stratified by patient's age, the adjusted HR for dementia was 0.56 (95% CI, 0.51-0.61, p < 0.001) for vaccinated patients with CHF aged over 70 years, but adjusted HR was 0.74 in the subgroup aged from 60 to 69 years. There was a lower adjusted HR (0.60, 95% CI 0.54-0.68) for dementia in male CHF patient receiving influenza vaccination compared with vaccinated female CHF patient (0.69, 95% CI 0.62-0.76). There was a significant reduction of dementia risk in elderly patient with CHF received more than three times influenza vaccination. (Adjusted HR 0.45, 95% CI 0.40-0.51, P < 0.001)

Conclusions: Our data showed that there was a lower rate of dementia development in elderly patient with CHF receiving influenza vaccination, particular in male, aged over 70 years, and receiving more than three times influenza vaccine injection.

P1497

Long-term results of percutaneous coronary interventions at coronary heart diseases pts with low ejection fraction

HG Fozilov¹; RD Kurbanov¹; TA Abdullayev¹; RSH Beckbulatova¹; I A Igor Tsoy¹; AM Karimov¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

The purpose: to study clinical efficiency of percutaneous coronary interventions and its influence on myocardial contractility at CHD pts with low ejection fraction (EF) of the left ventricle (LV) in the long-term period (24 month) without estimate viability of the myocardium.

Materials and methods: From January, 2013 year to December 2014 year PCI have been executed at 1266 pts with various forms of CHD. At pts CHD with low EF of the LV PCI have been executed at 11.9 % (138) pts. In the research conducted by us it has been included 65 (47.1 %) pts with low fraction of emission LV (less than 45 %) at which it was possible to study the long-term results. Pts of a male have made - 80.0 % (52), and female - 20.0 % (13). The age of pts fluctuated from 39 till 76 years, and has on the average made 59.5 ± 8.4 years. From the standard risk factors most often met an arterial hypertension - at 87.7 %, (57) pts, hyperlipidemia - at 90.7 % (59); a diabetes mellitus at 40% (26) pts. The EF LV fluctuated from 27.3 % to 45 %, and has on the average made $38.5 \pm 4.9\%$. In 44.6 % (29) cases PCI have been executed at pts with acute myocardial infarction; in 40 % (26) cases at a stable angina II-IV FC, and in 15.4 % (10) cases at an unstable angina. Three-vascular lesion of a coronary channel took place in 47.7 % (31) cases, two-vascular in 29.2 % (19) and one-vascular lesion in 23.1 % (15) cases. At pts with multivascular lesion (n = 50) in 62 % (30) cases the incomplete functional is executed; in 20 % (11) cases full functional and in 18 % (9) cases full anatomic myocardial revascularization is executed. In total it has been implanted 115 stents (on the average 1.8 stents on one pt) from them of 80 % (92) drug eluting stents; 15.7 % (18) bare metal stents and 4.3 % (5) bioabsorbed vascular skeletons 'ABSORB'.

Results: In our research frequency of angiographic success at implantation stents at pts CHD with low EF LV has made 92.3 % (60), and clinical success at a hospital stage - 85.7 % (59). Frequency of development of complications has made 12.3 % (8) cases; from them dissection a coronary artery has developed in 62.5 % (5) cases; the 'no-reflow' phenomenon has developed in 25 % (2) cases and in 1 case the bleeding from a gastroenteric path took place. Frequency of development myocardial infarction type 4 and a lethal outcome equaled - 0. In the long-term period the EF LV fluctuated from 30 % to 61.5%, and has on the average made $43.5 \pm 6.9\%$ (=0.000). Increase the EF LV was observed at 60 % (39) pts, decrease at 15.4 % (10) pts and at 10.8 (7) pts ejection fraction of LV has not changed. The lethal outcome has developed at 8 (12.3%) pts, operation CABG is executed at 1(1.5%) the pt.

Conclusion: Thus, frequency of clinical success at a hospital stage of supervision has made 85.7% (59) cases. In the long-term period authentic increase of an average index of EF LV to $43.5 \pm 6.9\%$ was marked at initial $38.5 \pm 4.9\%$ (=0.000).

Chronic heart failure and anxiety and depression disorders

SA Matskevich¹; ES Atroschenko¹

¹Scientific and Practical Center "Cardiology", Minsk, Belarus

Objective: to define the presence and severity of anxiety and depression disorders and assess the impact on life quality in patients with chronic heart failure (CHF).

Materials and methods: A total of 130 individuals with CHF NYHA functional class (FC) II, III with previous Q-wave myocardial infarction (MI), mean-age $60.66 \pm .64$ y.o. Mean left ventricular ejection fraction was $50.1 \pm 5.78\%$. Signs of CHF FC II were seen in 58,5% subjects, FC III in 41,5% subjects. All patients had general physical examination. Medical treatment included beta-blocking agents, ACE-inhibitors or angiotensin receptor blockers, aspirin, statins, and diuretics. Assessment of the presence and severity of anxiety and depression disorders was made using Hospital Anxiety and Depression Scale (HADS), and life quality (LQ) was assessed Minnesota Questionnaire (MLHFQ).

Results: As per HADS, anxiety and depression disorders were shown in 46,9% subjects. Signs of isolated depression was defined in 22,3% cases, and anxiety was defined in 24,6% cases. The LQ values in patients with co-disorders were 1,5 times worse compared to patients with normal psychoemotional state. A correlation between LQ and depression severity (r=0,45, <0,001) was shown, as well as between LQ and anxiety severity (r=0,48, <0,001), as well as depression and anxiety (r=0,51, <0,001). It was obvious that 10,8% subjects suffered from depression and anxiety, and LQ in this group was 1.6 times worse compared to subjects without depression and anxiety. In group of subjects with CHF FC II, depression and anxiety disorders were defined in 30,3% subjects, and 9,2% subjects had both depression and anxiety, and signs of isolated depression and anxiety were defined in 4% and 26,3% cases, respectively. In CHF FC III, depression and anxiety was seen in 70,4 % subjects, and signs of isolated depression and anxiety were seen in 48,2% and 22,2% cases, respectively. This group showed a correlation between LQ and depression severity (r=0,48, <0,001), LQ and anxiety severity (r=0,57, <0,001). The

severity of anxiety and depression in patients with CHF FC III exceeds normal limits based on HADS values (1.4 and 1.7 times, respectively). 11.1% subjects showed signs of both anxiety and depression, and LQ in this group was worse compared to isolated anxiety and depression (<0.01). Conclusion. Thus, our study has defined the detection frequency of anxiety and depression in subjects with CHF to be 46.9%. Life quality in subjects with CHF is significantly impaired in the presence of anxiety and/or depression, and when the combination of anxiety and depression is present, this impairment is more prominent. Increased severity of HF FC is combined with the increased number of subjects with depression and anxiety disorders, and in CHF FC III depression prevails while in CHF FC II it is anxiety.

P1499

Features of clinical manifestations in obese patients with heart failure with preserved ejection fraction and obstructive sleep apnea

A Kuchmin¹; AA Kazachenko¹; IV Makarova¹; AN Kulikov¹; DA Galaktionov¹; KB Evsukov¹

¹Military Medical Academy, St. Petersburg, Russian Federation

Purpose: To assess clinical manifestations of obstructive sleep apnea (OSA) in patients with chronic heart failure (CHF) and preserved ejection fraction (EF).

Methods: The study included patients with clinical manifestations of CHF with preserved ejection fraction of left ventricle ($EF > 50\%$). Cause of CHF was stable ischaemic heart disease and essential hypertension. Disturbance of breathing during sleep assessed according to respiratory monitoring with the calculation of the index of apnea / hypopnea (IAH). Patients were underwent echocardiography investigations with estimation of left ventricular contractility, dimensions of heart chambers.

Results: We examined 60 patients (23 women and 37 men), mean age 67 ± 9 years, BMI - 32.6 ± 5.3 kg/m² with CHF with preserved ejection fraction of left ventricle. 42 (70 %) patients had CHF NYHA class II, 18 (30%) patients - CHF NYHA class III. OSA was revealed in 49 (81.7%) patients. The most frequent clinical manifestations of heart failure were dyspnoea (100%), peripheral edema of the lower extremities (55%). According to degrees of severity OSA the patients were distributed as follows: OSA mild degree ($5 < IAH > 15$) - 19 (38.8%), moderate OSA ($15 < IAH > 30$) 12 (24.5%) and severe OSA ($IAH > 30$) - 18 (36.7%) patients. The analysis of clinical manifestations showed that symptoms of CHF were directly dependent on the severity of OSA. There were no statistically significant differences in echocardiographic parameters between groups of patients with and without OSA, but in patients with OSA right ventricular sizes were slightly larger. It was found that the degree of functional classes of congestive heart failure depended on the severity of IAH. $IAH < 5\%$ were observed only in patients with heart failure functional class 2 (11 patients (26.2%)); $IAH 5-15$ were revealed in 17 (41.1%) patients with CHF NYHA class II; $IAH 15-30$ were detected in 5 (27.8%) patients with CHF NYHA class III; clinical signs of right heart failure occurred in 9 (29%) patients with OSA mild and moderate degrees. $IAH > 30$ was observed in 11 (61.1%) patients with CHF NYHA class III; peripheral edema and enlarged liver were found in 16 (89%) patients with severe OSA.

Conclusions: Our study demonstrated features of clinical manifestations in patients with heart failure with preserved ejection fraction of left ventricle and obstructive sleep apnea. The presence of severe OSA ($IAH > 30$) in patients with chronic heart failure are often accompanied with clinical signs of right heart failure (peripheral edema of the lower limbs, enlarged liver). The most prominent clinical manifestations (higher functional class) of CHF observed in patients with severe OSA. Thus, the presence of breathing disorders during sleep in patients with heart failure with preserved ejection fraction can be considered as a possible risk factor for the progression of chronic heart failure and determines the features of its clinical manifestations.

Heart failure in nonagenarian

H Antunes¹; J Gil¹; L Abreu¹; B Marmelo¹; M Correia¹; C Cabral¹; O Santos¹

¹Hospital Sao Teotónio, Cardiology, Viseu, Portugal

Background: Heart failure (HF) is a common disease with an increasing incidence due to the aging population. Older age groups are not clearly characterized.

Purpose: To characterize the nonagenarian HF patients and compare them with the younger age groups.

Methods: We retrospectively evaluated all hospitalizations for HF in the cardiology service of a single center over a period of six years. Only the first episode of each patient was included. The patients were divided in two groups according to the age: Group 1 (≥ 90 years) and group 2 (< 90 years).

It was evaluated the days of hospitalization, history of acute myocardial infarction, cerebrovascular accident or atrial fibrillation (AF). It was also assessed the etiology of HF, the need of aminergic support, the value of BNP, ejection fraction (EF), complications during hospitalization and in-hospital mortality.

Results: During the reporting period, there were 1006 patients who met the inclusion criteria, 936 patients in Group 1 and 70 patients in Group 2. In group 1, a predominance of males (52.1%), 76.15 ± 9.65 years and mean duration of hospitalization 8.75 ± 6.51 days, most of them because of chronic decompensated HF (78.9 %). In older age, female predominance (67.1%) with a mean duration of hospitalization 7.30 ± 3.98 days and 75.7% of admissions due to chronic decompensated HF. BNP at admission was about 850 pg/ml in both groups. 73.2% of nonagenarian had $EF \geq 50\%$ ($55.48 \pm 15.56\%$) while in the other group only 51.8% ($48.76 \pm 16.29\%$) had preserved EF. The most common complication in both groups was the acute kidney injury (18.0% in group 1 and 24.3% in Group 2), and in-hospital mortality was 6.4% in group 1 and 12.9% in nonagenarian.

Conclusion: As expected, mortality was higher in nonagenarian patients, however, this study showed that the duration of hospitalization in these patients was lower than in the younger age groups and the complications during hospitalization were not significantly different in the two groups. It was found that nonagenarian have predominantly HF with preserved EF. This population continues to require better characterization with additional studies.

Females in the polish population of heart failure pilot survey: the clinical characteristics, pharmacotherapy and outcomes in the one-year follow-up.

K Bury¹; A Furman-Niedziejko¹; G Opolski²; L Polonski³; P Ponikowski⁴; J Drozd⁵; P Rozentryt³; M Zembala³; M Broncel⁶; J Nessler¹

¹Institute of Cardiology, Jagiellonian University, John Paul II Hospital, Depart. of Coronary Disease, Krakow, Poland; ²1st Department of Cardiology, Warsaw Medical University, Warsaw, Poland; ³Silesian Center for Heart Diseases, Zabrze, Poland; ⁴Department of Heart Diseases, Medical University, Military Hospital, Wroclaw, Poland; ⁵Medical University of Lodz, Department of Cardiology, Lodz, Poland; ⁶Department of Internal Diseases and Clinical Pharmacology, Medical University of Lodz, Lodz, Poland

Background: In the Heart Failure Pilot Survey (The ESC-HF Pilot) clinical and epidemiological data of 5118 subjects was collected. Females have not always been fully represented in clinical trials. Gender-related differences in heart failure patients are still unclear. Aim of study: The aim of study was to describe female population included in the Polish Population of Heart Failure Pilot Survey: the clinical presentation, pharmacotherapy and clinical outcomes in the one-year follow-up.

Methods: The ESC-HF Pilot study was a prospective, multicentre, observational survey conducted in 136 cardiology centres in 12 European countries, including Poland in the years 2009-2011. In this research the following data were analysed: demographics, presence of cardiovascular risk factors, etiology of heart failure, biochemical, echocardiographic and electrocardiographic parameters, pharmacological treatment and outcomes in patients enrolled in Poland to the Heart Failure Pilot Survey (892 patients).

Results: The study population consist of 33.6% females. Female patients compared to male patients with HF characterized by: older age 70.8 ± 12.4 vs. 63.8 ± 13.1 ($p < 0.05$), higher systolic blood pressure 136.3 mmHg ± 30.8 vs. 130.6 mmHg ± 23.2 ($p < 0.05$), higher left ventricular ejection fraction $47.4\% \pm 13.2$ vs. $39.0\% \pm 13.6$ ($p < 0.05$), higher NYHA functional class 2.9 vs. 2.7 ($p < 0.05$), higher level of BNP 1826.9 pg/ml, vs. 1183.2 pg/ml ($p < 0.05$), longer QTC 401.9 ms ± 38.7 vs. 389.7 ms ± 45.8 ($p < 0.05$). Significantly more often in women than in men occurred hypertension ($p < 0.05$), thyroid dysfunction ($p < 0.05$) and depression ($p < 0.05$). Females were longer hospitalized in ICCU 4.1 days vs. 2.8 days ($p < 0.05$). Females compared to males were more often treated by ARB and CCB, but less frequently by ACEI, BB and Eplerenone. There were no significant differences in the rate of deaths in the in the one-year follow-up between female patients and male patients (99 [11%] subjects died).

Conclusions: 1. The results of ESC-HF Pilot Survey from Polish Centers showed significant gender-related differences in clinical presentation and pharmacological treatment of heart failure. 2. The clinical outcomes were similar in female patients and male patients with heart failure in the one-year follow-up in spite of differences in clinical characteristics and pharmacotherapy.

P1502

Assessment of the dynamics of silent ischemia on the effects of heart rate reducing drugs in patients with ischemic heart disease and diabetes in an actual ambulatory practice.

IV Fomin¹; IV Fomin¹; F Y Valikulova¹; F Y Valikulova¹; A R Vaysberg¹; A R Vaysberg¹; E V Gurvich¹; E V Gurvich¹

¹Nizhny Novgorod State Medical Academy, Internal Diseases, Nizhny Novgorod, Russian Federation

Purpose: To determine the dynamics of silent ischemia and the duration of its single episode in patients with ischemic heart disease (IHD) and diabetes mellitus (DM) on the effects of the prolonged use of drugs that lower heart rate in an ambulatory practice.

Material and methods: Dispensary group of patients, DM 713 people, including patients with CHD and DM. The dynamics of silent ischemia were analyzed according to Holter monitoring (HM) in the first 14 days and on the eighth visit post 184 days of therapy, where episodes of silent ischemia (ESI) were determined by the intensity of horizontal displacement of ST segment more than 2.0 mm in terms of time in minutes (min) and related physical activity (PA).

Results: Using "closed envelopes," or double blind method, two groups were created (Group I and Group II), each group consisting of 40 people. In Group I, were titrated beta-blockers (BAB) (metoprolol tartrate) until reaching the optimal dose. In Group I, in addition to standard therapy patients also received ivabradine with titration from 10 mg per day (58.3%) to 15 mg per day (41.7%) in the second and third visit in order to achieve a significant decrease in heart rate (HR) frequency. Groups were similar in gender, age, initial heart rate, blood pressure, IHD and DM duration. Provision of standard therapy in both groups had no significant differences in the frequency of BAB, ACE inhibitors, diuretics, calcium antagonists, and aspirin. All patients in the two groups took hypoglycemic pills. In Group I, 20.7% of patients and in Group II, 28% of the patients received statins. According to HM ECG, on the day 14, the number of ESI accompanied by physical activity in Group I is 3.06 ± 2.0 and Group II 4.6 ± 2.7. These findings indicate that the number of occurred episodes in Group II is 1.6 times higher than in Group I (p = 0.06). After 184 days, there is a decrease in number of ESI in Group I (2.7 ± 3.0, p = 0.64) and in Group II, (0.7 ± 0.77, p < 0.0001). Duration (D) of one (O) ESI with heightened physical activity in Group I is 3.0 ± 3.2 min, and in Group II, it is 3.5 ± 2.1 min (p = 0.29). After 184 days DOESI in Group I is 1.95 ± 1.4 min, (p = 0.14) and in DOESI in Group II 1.6 ± 1.9 min, (p = 0.01). The results indicate a decrease in DOESI for both groups; specifically 54% in Group II and 35% decrease in Group I.

Conclusion: Long term use of ivabradine and beta-blockers in patients with ischemic heart disease and diabetes leads to a significant reduction in the frequency and duration of episodes of silent ischemia in real ambulatory practice.

P1503

Does elevated right atrial pressure predict post heart transplant outcomes?

A Aggeliki Gkouziouta¹; G Karavoulas¹; E Bousoulas¹; D Miliopoulos¹; A Tsipis¹; M Spartalis¹; PH Cockinos¹; S Adamopoulos¹

¹Onassis Cardiac Surgery Center, Athens, Greece

Purpose: Orthotopic heart transplantation (OHT) is the definitive treatment for end stage heart failure. Patient selection is key in improving post OHT outcomes. Pre-operative right ventricular dysfunction is associated with worse outcomes after mechanical circulatory support but its effect on post OHT outcomes has been a matter of discussion in the literature. Right atrial (RA) pressure is commonly used as a surrogate for RV function. We compared post OHT outcomes in patients with and without preoperative elevated RA pressure.

Methods: An analysis of 135 patients who underwent isolated OHT at our institution from January 1993–October 2015 was performed. Groups were divided based on preoperative RA pressure. Baseline characteristics and post OHT outcomes (post OHT length of stay; 30 day, 1 year and 3 year survival and clinically significant rejection in the 1st year) were compared. Results: Pre OHT characteristics were similar between the 2 groups except for a difference in age and PVR. Post heart transplant survival was worse in the group with pre transplant RA pressure > 15mmHg. Conclusion: Pre-operative elevated RA pressure was associated with a worse short and intermediate term (1 and 3 year) survival after OHT. There was no difference in post transplant rejection in the first year. Possible factors for poor survival include underestimation of pulmonary hypertension or organ dysfunction. RA pressures are readily available and may allow for a more accurate prediction of post OHT outcomes.

Elevated heart rate is associated with cardiac denervation and neurohormonal activation in patients with heart failure: data from a randomised clinical trial comparing ivabradine versus pyridostigmine

The study was supported by Foundation for Research Support of the State of Rio de Janeiro (FAPERJ)

H Humberto Villacorta¹; AS Villacorta¹; BC Precht¹; P Porto¹; CR Alves¹; MCSSS Muradas¹; JAC Teixeira¹; JS Souza¹; CT Mesquita¹; ACL Nobrega¹

¹Fluminense Federal University, Rio de Janeiro, Brazil

Background: In the SHIFT Study, heart rate (HR) reduction with ivabradine was associated with improved survival and reduction in hospitalisations. Pyridostigmine is a cholinergic agonist that has been shown to enhance vagal tone both in normal and HF patients.

Purpose: We sought to assess the relationship of baseline HR with clinical, neurohormonal and cardiac sympathetic activity in 16 patients included in a clinical trial comparing ivabradine versus pyridostigmine.

Methods: Patients with chronic heart failure (HF) who were in sinus rhythm with resting HR > 70 bpm despite optimal medical treatment were included in a randomized, double-blind study comparing ivabradine versus pyridostigmine. This report refers to baseline data from the 16 initial patients. Baseline HR (before randomisation to one of the drugs) was assessed and patients were classified into two groups, below or above mean HR. The two groups were compared regarding clinical characteristics, biomarkers, ejection fraction, functional capacity, and cardiac sympathetic activity as assessed by 123-iodine-metaiodobenzylguanidine (MIBG) myocardial scintigraphy.

Results: Mean HR was 83.5 ± 11.5 bpm (range 72 to 104). All patients were on carvedilol (daily dose was 50 mg in 14 patients and 25 mg in 2 patients). Seven (43.7%) patients were above mean HR. These patients had a trend for worse NYHA functional class (class III and IV 57.1% vs 11.1%, p = 0.10), a lower 6-min walk distance (292.3 ± 93 vs 465.2 ± 97.1, p = 0.0029), higher values of N-Terminal-proBNP (median 708.4 vs 76.1 pg/mL, p = 0.035) and lower late heart/mediastine rate, indicating cardiac denervation (1.48 ± 0.12 vs 1.74 ± 0.09, p = 0.006). No difference was observed regarding peripheral edema (0% vs 33%, p = 0.21) nor total body water estimation as assessed by bioelectrical impedance vector analysis (BIVA) (hydration index 73.6 ± 0.05% vs 75.8 ± 3.75%, p = 0.28).

Conclusion: Elevated baseline HR in patients with HF under optimal medical treatment was associated with worse functional capacity, neurohormonal activation and cardiac denervation but not with congestion.

Profile changes of heart transplant recipient in an argentinean single centre

R R Favaloro¹; M Margarita Peradejordi Lastra¹; L E Favaloro¹; M F Renedo¹; A Guazzone¹; RD Ratto¹; L M Martinez¹; S Moscoloni¹; D O Absi¹; AM Bertolotti¹

¹University Hospital Favaloro Foundation, Intrathoracic Transplantation and Heart Failure Division, Ciudad Autónoma de Buenos Aires, Argentina

Introduction: Advances in the treatment of advanced heart failure, considering mechanical circulatory support devices, have conditioned the survival rates and characteristics of patients (p) included in the heart transplant (HTx) waiting list. Objective To analyze the HTx recipients (R) characteristics in an Argentinean Centre.

Material and Methods: A retrospective analysis was performed on 465 HTx R. The population was divided into 2 groups by era: group 1 (G1), 181 p who underwent HTx between February/1993 and December/2003, and Group 2 (G2), 286 p, between January/2004 and December/2015. We analyzed the clinical and demographic variables at HTx. Continuous variables were expressed as mean and standard deviation or median and interquartile, and categorical variables as absolute values and percentages. Kaplan Meier survival analysis and Log Rank test were performed. Results We classified the different clinical status into p on mechanical circulatory and/or respiratory support 65 p (36%) vs. 128 p (45%) (p 0.04); on IV inotropes, 23 p (12%) vs. 86 p (30%) (p 0.001) and at home with oral medication while on the waiting list 94 p (52%) vs. 72 p (25%) (p 0.001). Overall in hospital mortality was G1, 22 p (13%) vs. G2, 35 p (12%) (p 0.4). Survival at 1.5 and 10 years in both groups was 79% vs. 80%; 63% vs. 68%; 47% vs. 65% (p 0.04) respectively (see Figure 1) Conclusion We found a higher risk profile in G2 due to older age, female gender, severe PH, Chagas disease and mechanical circulatory support requirement, though it did not present a significant impact on mortality.

Table 1

VARIABLES	G1	G 2	p
Age (years)	49 ± 13	50 ± 13	0.02
Age > 65 years	8% (15p)	9% (25p)	0.02
Gender (male)	82%	74%	0.02
Cardiomyopathy	24% (47 p)	32% (90 p)	0.04
Coronary Artery Disease	65% (117 p)	34% (99 p)	0.0001
Chagas Disease	2.8% (5 p)	9% (8 p)	0.006
Renal Failure (Cr > 1.5 mg/dl)	18% (34p)	20% (58p)	0.13
BMI > 30	5% (9p)	14% (41p)	0.04
BMI < 18	3% (6p)	2% (5p)	0.04
Pulmonary Hypertension (PH)(TPG > 12/ > 2.5 Woods)	35% (65 p)	57% (164 p)	0.001

Heterogeneity of readmission rate and in-hospital mortality of patients with heart failure based on the volume of patients at each hospital: analysis of administrative data of a nationwide population

V Bertomeu¹; R Bover²; C Fernandez³; J Elola⁴; A Esteban⁵; I Vilacosta²; JL Bernal⁶; JV Segura⁷; C Macaya²

¹University Hospital San Juan de Alicante, Cardiology, Alicante, Spain; ²Hospital Clinic San Carlos, Department of Cardiology, Madrid, Spain; ³Hospital Clinic San Carlos, Preventive Medicine, Madrid, Spain; ⁴Hospital Clinic San Carlos, Foundation Institute for Healthcare Improvement, Madrid, Spain; ⁵Hospital Clinic San Carlos, Instituto de Investigación Sanitaria San Carlos, Madrid, Spain; ⁶University Hospital 12 de Octubre, Control Management Service, Madrid, Spain; ⁷IUI Operative Research Center, Miguel Hernández University, This author is partially supported by Ministerio de Economía y Competitividad of Spain (Grant N°. MT, Alicante, Spain

Introduction: It is well known that heart failure (HF) is a disease with high morbidity and mortality. We present, for the first time, the influence of the volume of hospital patients in HF in-hospital mortality and readmission rate at 1 year in a whole country (Spain, 46.77 millions population).

Methods: All the discharges from Spanish hospitals corresponding to 2012-2013 with a primary diagnosis of HF, according to the ICD-9-CM classification, were analyzed. High-volume hospitals were considered those with HF hospitalizations ≥ 340 per year, and the low-volume <340 . Crude and adjusted in-hospital mortality and rate of readmissions at 1 year were analyzed.

Results: 400,861 hospital admissions were recorded; 77,652 of them had HF as primary diagnosis. The mean age of the patients was 79.2 ± 9.9 years, with 50% of patients 81 years or more. In-hospital mortality was statistically significantly lower in the high-volume centers compared to low-volume, both the crude rate (8.6% vs. 10.3% in the first hospitalization, and 13.9% vs. 15.8% at 1 year, $p < 0.001$) and the adjusted rate (RAMER) (9% vs. 9.9%; $p = 0.006$). Similarly, readmission rate was statistically significantly lower in the high-volume centers compared to low-volume at 1 year (31.2% vs. 28.1%; $p < 0.001$), also adjusted rates (RARER) (32.2 % vs. 30%; $p < 0.001$), with no significant difference in readmissions at 1 month (10.1% vs. 9.5%; $p = 0.1$). Figure 1 shows the scatter plots between hospital volume and both adjusted rates (RAMER and RARER).

Conclusions: According to our results, the volume of patients treated for HF in a hospital affects their prognosis. Thus, lower hospital volume of patients involves greater heterogeneity in in-hospital mortality and readmission rates in HF patients.

Heart failure in nonagenarians. Clinical profile and prognostic factors of short-term mortality and readmission

M Ciudad¹; R Costa¹; E Emilia Roy¹; A Bautista¹; E Diaz De Mayorga¹; P Carles¹; C Rodriguez¹; P Gil¹

¹University Hospital De La Princesa, Servicio de Medicina Interna, Madrid, Spain

Introduction: Lack of information exists about the clinical characteristics and prognosis of very old patients with heart failure (HF). Better knowledge of this population may help to design appropriate follow-up protocols and treatments.

Purpose: To describe clinical profile and prognosis of nonagenarians hospitalized by decompensated HF. **Methods.** Descriptive retrospective study that included nonagenarian patients admitted to a university hospital with HF as main diagnosis, during an eight-month period. Clinical, analytical and echocardiographic variables were included, as well as treatment. We analysed in-hospital mortality, 30-day mortality and readmissions.

Results: Of all HF admissions, 31% (76 patients) were nonagenarians, with a mean age of 93.4 years and frequent comorbidities: hypertension (92%), chronic kidney disease (45%) and atrial fibrillation (67%) but only 17% with diabetes mellitus. In-hospital mortality rate was 14.5% (11 patients) and 10 patients died later on the next month after discharge, meaning that cumulative mortality at 30 days was 27.6%. HF was the cause of death in 71% of the cases. Readmission rate was 21.5% in the first 30 days, 40% because of HF. Renal function parameters (urea, creatinine and glomerular filtration rate) correlated with in-hospital mortality and readmission. High NT-proBNP levels at discharge or lack of NT-proBNP variation during admission were both 30-day mortality and readmission predictors. There was a tendency to increase HF related drugs prescription at discharge.

Conclusions: Very old patients have high mortality rate in the first month after HF hospitalization, mainly related to HF. Renal function parameters and NT-proBNP levels are useful to identify high-risk patients for death or readmission at 30 days.

ADVANCED HEART FAILURE

P1508

Dealings perception of gravity of complex patients in heart failure

L Baumworcel¹; MW Montera¹; ET Mesquita¹¹Hospital Pro Cardíaco, Centro de Insuficiência Cardíaca, Rio de Janeiro, Brazil

Heart failure is the final pathway of the majority of heart disease. These patients progress for years with various comorbidities and often become frail patients. Upon reaching the stage as D of the disease when no longer have other forms of treatment to improve the quality of life we find a challenge to communication in connection with the patient and family. Understand this perception of care varies with each patient and family, and often these patients hospitalized and has not yet been discussed with family issues related to palliative care. Such that discuss end of life care in Latin culture can bring a negative perception of service quality if not done properly. Thinking in these respects, one heart failure clinic of a city Hospital created a discussion protocol with families in formal meetings in a reception room to the family. This meeting is invited to be present the patient family or the responsible and every physician involved in the case. The purpose of this meeting is to take all the doubts that the family can have with time and without any external interruption. After all the discussion, all the presents sign a book with the summary of the meeting pledging to return the assembled front of any new doubt or drastic change with the patient. The experience of this group with this protocol already covers 38 severe patients using artificial mechanical support or cardiogenic shock. There were no more complaints or negative perceptual signals from families independent of the treatment outcome of these critically ill patients. This result shows that the realizing formal meetings improve the family patient perception and the aggregate value of this treatment chain.

P1509

Lost of chance for enzymatic treatment of a family with Fabry disease and severe right heart failure.

N N Nora Nabila Ali Tatar-Chentir¹; BT Boumediene¹; HB Haddak¹¹University Hospital Centre Mustapha, Algiers, Algeria

Purpose: Anderson-Fabry disease is a rare genetic lysosomal storage disease, inherited in an X-linked manner. The rarity of Fabry disease to many clinicians sometimes leads to misdiagnoses. Little is known from biventricular hypertrophy in this context. The aim of our study is to describe cardiac complications for the mother and three of her sons.

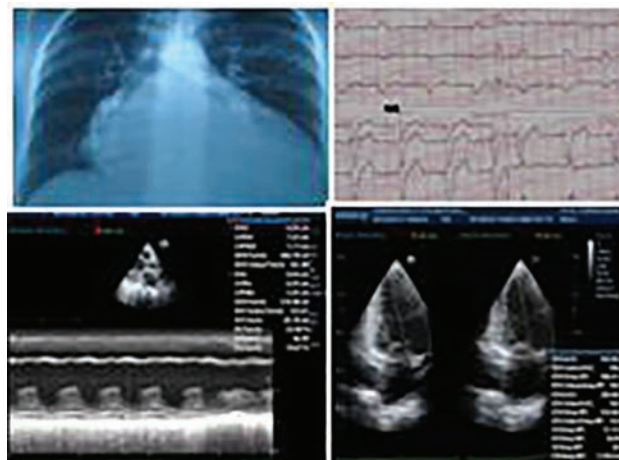

Methods: Medical histories, Clinical features, chest radiography, electrocardiograms (ECG) and echocardiography data of the mother and three of her sons were assessed.

Results: On the five brothers one of them presented a sudden death several years ago. Two brothers respectively 27 and 30 years old were hospitalized in our unit, for severe right heart failure with hepatomegaly leg edemas and abundance of ascites. In addition, one of the brothers had a history of syncope preceded by palpitations. Corneal opacities were reported in the two brothers. Major cardiomegaly in the two brothers with pleural effusion in one of them, persistent atrial fibrillation (AF) and repolarization abnormalities on ECG in the two brothers. In the same way, on echocardiography in the two brothers, we observed ectatic right atria with indexed volume around 300ml/m², area around 100 cm², dense spontaneous contrast grade IV of Fatkins, severe tricuspid regurgitation. Presence of atria septal aneurysm towards the left atrium. Presence of left and right ventricular hypertrophy with preserved left ventricular function and elevated left ventricular filling, severely depressed right systolic function and severe depression parameters of diastolic function.

The mother 56 years old and her fourth son, 24 years old, referred in our outpatient unit were in New York Heart Association class 3 with the same echocardiography findings.

A medical treatment including angiotensin converting enzyme inhibitors (ACE), loop diuretic, aldosterone antagonist and vitamine K antagonist therapy was prescribed without significant improvement in symptoms and echocardiographic parameters over 1 month.

Conclusion: Imaging of the myocardium has been explored as a non-invasive way of early screening and diagnosing patients. Correct diagnosis is of vital importance because the condition is potentially reversible with treatment by enzyme replacement therapy in the early stages of the disease that isn't the case of this family screened at the terminal stage with severe cardiac Fabry Disease.

Preterminal HF in Fabry Disease

P1510

Risk factors of early allograft vasculopathy in patients after heart transplantation

A K Alena Kurlianskaya¹; T A Trofimova¹; V I Stelmashok¹; O L Polonetsky¹; A Y Ostrovsky¹; T L Denisevich¹; Y P Ostrovsky¹¹Research & Practical Centre "Cardiology", Minsk, Belarus

Aim: observe the risk factors of early cardiac allograft vasculopathy (CAV) in patients after heart transplantation.

Methods: 127 patients after heart transplantation were recruited. After 24 ± 3 post-transplant months, coronary angiography and intravascular ultrasonography were done. To determine risk factors of early CAV on the stage when the lesion of coronary arteries is not advanced and angiography lacks the sensitivity, another statistical method using "Classification of the entire coronary tree" (CCT) was performed.

Results and conclusion: According to CA no significant coronary artery luminal narrowing was detected. IVUS results revealed various severity of the coronary arteries impairment in 58 (75%) pts. The high probability of significant changes in the coronary tree (IVUS) has been detected in pts after HT, who initially had degree of histocompatibility in HLA system less than 62.5% and tacrolimus after 3 months ≥ 10,4 ng/ml. Mild lesions in the coronary tree in early period after HT were associated with: 1. hypertension, BMI ≥ 33,5 kg/m², triglyceride ≥ 2,67 mmol/L after 6 months HT; 2. examination after 12 months showed low HDL < 1.06 mmol/L in combination with high LDL ≥ 2,22 mmol/L; tacrolimus ≥ 7,65 ng/ml in combination with increased CRP ≥ 4,47 mg/l. Risk factors identified by the analysis of "CCT" were divided into two groups: immunological (histocompatibility in HLA-system, myeloperoxidase) and non-immunological (metabolic syndrome signs), analyzed in subgroups of patients treated with different immunosuppressive agents. The subgroups with Everolimus (1) or without Everolimus (2) treatment were comparable in the relative percentage of pts with risk factors of early lesions in coronary arteries, according to "CCT" analysis. In 2 group percentage of pts with signs of metabolic syndrome was 41.7%, in 1 group - 58.8% (p = 0.218). Percentage of pts with immunological factors in 2 group 58.3%, in 1 group - 41.2% (p = 0.220). However, among 1 group pts immunosuppressive agent unlike 2 group, cases with progression of lesion in the coronary tree were not detected (follow-up IVUS data). In 2 group progression of CAV was indicated in 21.7% of pts with signs of metabolic syndrome, and in 10% of cases with immunological risk factors.

Is there a heart rate paradox in heart transplantation?

U Umut Kocabas¹; E Kaya¹; S Ertugay²; P Ozturk²; C Engin²; S Nalbantgil¹; M Zoghi¹; T Yagdi²; M Ozbaran²¹Ege University, Department of Cardiology, Izmir, Turkey; ²Ege University, Department of Cardiovascular Surgery, Izmir, Turkey

Introduction: Elevated heart rate (HR) is associated with adverse cardiovascular outcomes in patients with heart failure. After heart transplantation (HTx), cardiac denervation has a variable effect on HR. However, impact of HR after HTx over prognosis is still unclear. In this study, we aimed to evaluate the prognostic impact of HR in HTx patients.

Methods: We studied 140 consecutive HTx patients' data retrospectively (78.6% male, mean age: 39 ± 14). Patients were divided into two groups according to first-month resting HR after HTx: group 1, HR ≤ 80 bpm (mean 76.2 ± 6.7) and group

2, HR>80 bpm (mean 103.9 ± 12.9). Rejection and all-cause mortality rates were compared between groups.

Results: Thirty patients were included in group 1 and 110 patients in group 2. No significant differences were detected between groups when compared according to demographic data, risk factors, NYHA and etiology of heart failure. The most common reasons for morbidity and mortality after HTx such as right ventricular failure, infection, cerebrovascular accident, arrhythmia and rejection were similar between groups (Table). Long-term (>1 year) mortality rate was 50% in group 1 and 28.2% in group 2 ($p = 0.03$).

Conclusion: Although HR did not affect the rate of rejection in heart transplant patients, all-cause long-term mortality tended to be higher among patients with lower HR.

Table: The comparison of group 1 and group 2.

	HR<80 bpm (n=30, 21.4%)	HR>80 bpm (n=110, 78.6%)	P value
Demographic data and clinical parameters before HTx			
Age (yr)	36.5±5.6	40.9±14.2	0.12
Sex (male, %)	80	78.2	0.97
Etiology (Dilated CMR, %)	40	52.7	0.57
NYHA (Class III, %)	55	62	0.24
Atrial fibrillation (%)	15	19	0.12
LVF (%)	24±10	22±8	0.14
Complications after HTx			
Right ventricular failure (%)	26.7	18.3	0.31
Infection (%)	53.3	48.6	0.68
Cerebrovascular accident (%)	6.7	4.6	0.64
Arrhythmia (%)	23.3	18.3	0.60
Rejection and all-cause mortality rates			
Rejection (%)	55.6	55.2	0.98
One-year mortality (%)	23.3	30	0.06

Prognostic implication of biomarkers ST2, NT-proBNP, Galectin-3 during long-term observation in patients with advanced heart failure

A K Alena Kurlianskaya¹; M G Kaliadka¹; T L Denisevich¹; Y P Ostrovsky¹

¹Research & Practical Centre "Cardiology", Minsk, Belarus

Aim: To reveal predictors of adverse cardiac events in pts with different functional class (FC) of severity by NYHA after acute decompensated heart failure (HF).

Methods: The study involved pts with HF: I-II FC – 70 pts, III-IV FC – 68 pts. We performed biochemical blood analysis: NT-proBNP, ST2, Galectin-3, Cardiac troponin-I. The clinical course was evaluated on the start and within 6 months of observation. Adverse cardiac events - death, cardiac transplantation, emergency hospitalization with decompensation. By applying the statistical module "Classification Trees" we identified predictors of adverse cardiac events (ACE) in pts with CF of different FC.

Results and conclusions: Within 6 months 18.8 % of patients with HF developed ACE, precisely I-II FC – 11.4% of cases, III-IV FC – 26.5% of cases.

Classification Trees (CT) were built to minimize the errors of false classification. We used dimensional branching algorithm by the method of CART (Classification And Regression Trees). Importance (rank) of the selected predictors was scored (maximum rank - 100 points). As a result, there were received 3 statistically significant decision trees. The predictors revealed basing on the CT analysis were presented in table 1.

I-II FC of HF pts - the predictors of unfavorable course included of NT-proBNP (rank-78) considering end-diastolic volume of the left ventricle (EDV) (rank - 100).

III-IV FC of HF pts - 2 statistically significant CT. The first decision tree included the following predictors of unfavorable cause of the disease: concentration of ST-2 (rank - 87) and myocardial mass index of the left ventricle (MMI LV) (rank - 100).

The second CT for III-IV FC of HF showed the highest classification accuracy (100%) and was based on the sequential analysis of the following laboratory parameters: Galectin (rank-60), of NT-proBNP (rank-72) and atherogenic factor value (rank-100).

The predictors of unfavorable course

FC CHF	Predictors	favorable outcome*	unfavorable outcome*	Classification accuracy
I-II	NT-proBNP≥4683 pg/ml	100%	78.0%	96.4%
I-II	NT-proBNP<4683 pg/ml and EDV≥411 ml	100%	78.0%	96.4%
III-IV	ST-2≥53 pg/ml	96.5%	100%	97.3%
III-IV	ST-2<53 pg/ml and MMI LV≥262	96.5%	100%	97.3%
III-IV	Galectin≥16 ng/ml and NT-proBNP≥1587 pg/ml	100%	100%	100%
III-IV	Galectin<16.2 ng/ml and atherogenic factor≥5.5	100%	100%	100%

Tissue doppler derived right ventricular isovolumic contraction velocity predicts prognosis in advanced heart failure patients with dilated cardiomyopathy

T Kawata¹; M Daimon¹; K Kimura¹; T Nakao¹; M Hirokawa¹; M Watanabe¹; Y Yatommi¹; I Komuro¹

¹University of Tokyo Hospital, Department of Cardiology, Tokyo, Japan

Background: Right ventricular (RV) function has gained attention recently as a prognostic predictor even in patients who have left-sided heart failure. In routine echocardiographic practice, RV longitudinal parameters such as tricuspid annular plane systolic excursion (TAPSE) and tissue Doppler derived systolic tricuspid annular motion velocity (S') are useful because those are easily obtained and have high reproducibility. Tissue Doppler derived tricuspid isovolumic peak contraction velocity (IVCv) is also easily obtained same as S', relatively afterload-independent longitudinal parameter, and has been reported as a prognostic predictor in patients with pulmonary hypertension. However, IVCv for predicting prognosis in advanced heart failure has been unclarified.

Purpose: To test the hypothesis that IVCv predicts prognosis in advanced heart failure patients with dilated cardiomyopathy.

Methods: We enrolled 60 dilated cardiomyopathy patients with left ventricular ejection fraction <35% who were admitted to our hospital for evaluation or treatment of heart failure. All patients underwent coronary angiography and myocardial biopsy. TAPSE, S' and IVCv were obtained for RV systolic parameters. Primary cardiac events were defined as left ventricular assist device implantation or cardiac death within one year after echocardiography.

Results: All patients were classified as New York Heart Association class III or IV. Thirty-four events occurred (4 deaths, 30 left ventricular assist devices). Univariate analysis showed that age, systolic blood pressure, plasma brain natriuretic peptide level, left atrial volume index, left ventricular end-systolic volume index, transmural E/A ratio, E-wave deceleration time, tricuspid regurgitation velocity and IVCv were predictors of outcome, whereas TAPSE and S' were not. Multivariate stepwise analysis revealed that systolic blood pressure ($p < 0.01$) and IVCv ($p < 0.05$) were independent predictors of events. From the receiver-operating characteristics curve, cut-off value of IVCv to predict outcome was 6.5 cm/sec (area under the curve = 0.70). Kaplan-Meier analysis showed that one-year event rate was significantly higher (log-rank, $p < 0.01$) in patients with IVCv < 6.5 cm/sec than in those with IVCv ≥ 6.5 cm/sec.

Conclusion: IVCv, an easy, noninvasive and reproducible parameter derived by tissue Doppler, is an independent predictor of one year events in advanced heart failure patients with dilated cardiomyopathy.

P1514

Ventricular assist device in pediatric patients

R Rita Gravino¹; G Limongelli¹; A Petraio²; M Verrengia¹; A Rea¹; G Salerno¹; D Masarone¹; C Maiello²; MG Russo³; G Pacileo¹

¹Heart Failure Unit, AO dei Colli-Monaldi Hospital, Department of Cardiology, Second University of Naples, Naples, Italy; ²Cardiac Transplantation Unit, AO dei Colli-Monaldi Hospital, Naples, Italy; ³Pediatric Cardiology Unit, AO dei Colli-Monaldi Hospital, Department of Cardiology, Second University of Naples, Naples, Italy

Introduction: Berlin Heart EXCOR Pediatric ventricular assist device (VAD) is currently used as mechanical circulatory support device for adolescents, infants and small children with advanced heart failure.

Purpose: To report the preliminary experience of a third level centre of Pediatric Cardiology and Cardiac Surgery with VAD

Methods: Between April 2009 and January 2016, 10 children (6 male and 4 female) followed in our Department of Pediatric Cardiology underwent Berlin Heart EXCOR pediatric VAD implantation at the Cardiac Surgery Division of our Hospital. Two cycles of i.v. inotropic therapy were undertaken before implantation (dobutamine and levosimendan), and all the patients underwent imaging evaluation (including cardiac MRI in 3 patients) and cardiac catheterization.

Results: The median age at implant was 8,8 years (2 to 15 years), the mean weight was 36,6 Kg (10 Kg to 65 Kg), and the median support time was 127 days (5-459 days). The diagnosis was myocarditis in 6 patients, a case of idiopathic dilated cardiomyopathy, a case chemotherapy-induced cardiomyopathy and a single case of heart failure secondary to valve disease. Four patients received a BIVAD and 6 patients a LVAD. Three patients underwent cardiac Magnetic Resonance Imaging (MRI), showing diffuse subepicardial enhancement without signs of intracellular and interstitial edema, capillary leakage and hyperemia. Endomyocardial biopsy and viral genome PCR were performed in all patients at VAD implantation. Diffuse fibrotic replacement without signs of active inflammation were evidenced in all the patients, and only in one case a viral etiology (CMV) was revealed. Out of the 10 paediatric patients, 7 were bridged to heart transplantation, 2 died on support, and 1 is still waiting for heart transplantation. After heart transplant, an Extra Corporeal Membrane Oxygenation (ECMO) was needed in 3 patients, 3 patients had chest wound infection and one had hyperacute rejection and bleeding problems. Patients

receiving biventricular support had a more favorable clinical course compared with children implanted with left ventricular assist device.

Conclusions: In agreement with literature, our experience confirmed that Berlin Heart EXCOR pediatric VAD could provide satisfactory and safe circulatory support for children with end-stage heart diseases. Timing of device implantation and the careful choice between univentricular/biventricular support represent important prognostic factors in patients with end stage disease.

Management of end-stage heart failure patients with or without ventricular assist device: an observational comparison of clinical and economic outcomes

NA Aissaoui¹; MM Morshuis²; HM Maoulida³; JES Salem⁴; GL Lebreton⁴; BD Diebold¹; JG Gummert²; IDZ Durand-Zaleski³; PL Leprince⁴; JYF Fagon¹

¹AP-HP - European Hospital Georges Pompidou, Paris, France; ²Heart and Diabetes Center NRW, Cardiac surgery, Bad Oeynhausen, Germany; ³Mondor Hospital, Epidémiologie clinique, évaluation économique et populations vulnérables, UMRS 1123, Unité de Recher, Paris, France; ⁴AP-HP - Hospital Pitie-Salpetriere, Paris, France

Background: Heart transplantation (HT) and ventricular assist devices (VAD) for the management of end-stage heart failure have not been thoroughly compared. We compare the outcomes and use of resources with these 2 strategies in 2 European countries.

Methods: We studied 83 patients (pts) managed by VAD in first intention in Germany (groupI) and 141 managed with HT in first intention, in France (groupII). The primary endpoint was 2-year survival. KM analyses were performed after the application of propensity score weights, to mitigate the effects of non-random group assignment. The secondary endpoints were resource utilisation and costs. Subgroup analyses were performed.

Results: GroupI was more hemodynamically compromised, and 28% underwent HT versus 55% in groupII ($P < 0.001$) after a longer median wait ($P < 0.001$). Table 1. The adjusted probability of survival (APS) was 49% in groupI versus 67% in groupII ($P < 0.001$). The mean cumulated 2-year costs were € 281,361 ± 156,223 in groupI, and € 47,638 ± 35,061 in groupII ($P < 0.0001$). Among HT patients, the APS in groupI versus groupII was 84% versus 73%, respectively (ns), though, in the subgroups treated with inotropes, was 84% in groupI versus 66% in groupII ($P = 0.01$).

Conclusions: HT after VAD therapy yielded results similar to HT non-preceded by VAD, and better results in pts treated with inotropes at the inclusion time. The group I strategy was more expensive.

P1516

Optimizing outcomes after heart transplantation in patients with cardiac amyloidosis - a single center analysis of 43 patients in 2 eras

MM Michael Kreusser¹; AV Kristen¹; P Blum¹; R Tschierschke¹; SO Schoenland²; U Hegenbart²; A Ruhparwar³; HA Katus¹; PW Raake¹

¹University Hospital of Heidelberg, Department of Cardiology, Heidelberg, Germany; ²University Hospital of Heidelberg, Heidelberg, Germany; ³University Hospital of Heidelberg, Cardiac Surgery, Heidelberg, Germany

Introduction: The prognosis of symptomatic cardiac amyloidosis - either of light chain (AL) or transthyretin (ATTR) type - is poor due to limited causative treatment options. Heart transplantation (HTX) might enable causative therapy and ultimately improve prognosis. However, previous reports suggested unfavorable survival after HTX in this population compared to HTX recipients with other indications as ischemic or dilative heart disease.

Methods and results: Forty-three patients with cardiac amyloidosis (AL n=29; ATTR n=14) underwent HTX at the University of Heidelberg Amyloidosis Centre between 2001 to 2015 and were analyzed retrospectively. In all patients with cardiac amyloidosis an exceptional high-urgency (HU) status was requested at Eurotransplant due to extremely poor prognosis. We analyzed the patients in two separate eras: 2001 to 2007 (era 1) and 2008 to 2015 (era 2). The time point separating these two eras was selected because it followed the initial publication of selection criteria for patients with AL amyloidosis undergoing HTX and autologous stem-cell transplantation (ASCT), and because it coincided with more restricted selection of patients as well as significant advances in chemotherapy of AL amyloidosis. Patients were subjected to continuous follow up after HTX in our outpatient clinic and a Kaplan-Meier survival analysis was performed. Both groups (era 1 and 2) were compared to all other patients, who received HTX because of other indications than amyloidosis and who were listed at Eurotransplant in HU status (n=178). Patient characterization did not reveal significant differences in era 1 compared to era 2 except a lower number of organs affected by amyloidosis (1.8 ± 0.2 vs. 1.3 ± 0.1 ; $p < 0.05$) in era 2 (2008-2015), reflecting a more restrictive patient selection in this era. However, while patients in era 1 (2001 to 2007) showed impaired survival after HTX compared to the control HU group. Interestingly, in era 2 the survival of amyloidosis patients measured up to the survival of the other HU HTX patients and was significantly improved compared to era 1 amyloidosis HTX patients.

Conclusions: HTX in advanced cardiac amyloidosis - either of AL or ATTR type - is a promising approach to allow causative treatment and finally improve poor survival of cardiac amyloidosis patients. Our data demonstrates that HU HTX - for AL combined with subsequent stem cell therapy - offers a successful treatment option to improve the poor outcome of this population. Furthermore, the data demonstrates that outcome of patients improved in era 2 (2008-2015) compared to era 1 (2001-2007). This era effect appears to be related to patient selection restricted to patients with sole cardiac involvement. Our data demonstrates that HTX in advanced cardiac amyloidosis should be restricted to highly selected patients in specialized centres.

ATRIAL FIBRILLATION

P1517

Atrial fibrillation and heart failure - experience of one hospital center

A-M Vintila¹; C Stefan²; C Tudorica³; D Isacoff³

¹University of Medicine and Pharmacy Carol Davila, Coltea Clinical Hospital, Internal Medicine Department, Bucharest, Romania; ²Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania; ³Coltea Clinical Hospital, Bucharest, Romania

Background: Atrial fibrillation is a condition frequently associated to heart failure. It is responsible for acute decompensation of heart failure and for thromboembolic complications. Despite good guidelines, therapeutic decision is frequently difficult because of the hemorrhagic risk.

Purpose: We present the experience of one hospital center regarding patients with atrial fibrillation with/out heart failure.

Methods: We studied a group of patients with atrial fibrillation consecutively admitted to our hospital center during a 6-month period. The evaluation consisted in case history and clinical examination, lab tests and transthoracic echocardiography.

Results: The study group consisted in 217 patients, aged 74 ± 9 years, of whom 76% with permanent atrial fibrillation. The prevalence of major cardiovascular risk factors was as follows: arterial hypertension - 80%, dyslipidemia - 43%, obesity - 28%, diabetes mellitus - 34%, smoking - 22%. Thyroid disease was associated in 25% of cases. Heart failure was diagnosed in 86% of patients, with NYHA class III and IV in 75% of cases. Values of NT-proBNP were high irrespective of the presence or absence of heart failure. Higher levels were encountered in permanent versus paroxysmal atrial fibrillation ($p < 0.01$). CHA2DS2-Vasc score had values equal or greater than 2 in 97% of patients, with 68% of patients having values between 4 and 6. Two thirds of patients had HAS-BLED score of at least 3. Anticoagulants were prescribed in 68% of patients (acenocumarol - 46%, NOAC - 22%). 24% of patients were given single antiplatelet therapy, 2% were given dual antiplatelet therapy, whereas no antithrombotic therapy was given in 6% of patients, half of them having CHA2DS2-Vasc scores 0 or 1. 10% of patients experienced hemorrhagic events, with no major hemorrhage encountered. There were no thromboembolic events during the index hospitalization. Echocardiographic evaluation showed preserved left ventricular ejection fraction in 53% of cases, mitral regurgitation in 60%, tricuspid regurgitation in 46% and aortic regurgitation in 24% of cases. All patients survived the index hospitalization. There was a net improvement of NYHA functional class from admission to discharge in patients with heart failure ($p < 0.01$).

Conclusions: Heart failure complicates a great proportion of atrial fibrillation cases requiring hospitalization. NT-proBNP level may not be useful for the diagnosis of heart failure in the setting of atrial fibrillation. Anticoagulant therapy should be given to patients with high thromboembolic risk even in the presence of high hemorrhagic risk.

P1518

Recurrent atrial fibrillation in patients with diastolic heart failure, effects of metoprolol and diltiazem on arterial stiffness

IM Irina Balabanenko¹; AA Shavarov¹; GK Kiyakbaev¹; VS Moiseev¹

¹ Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Diastolic heart failure (DHF) is accompanied by increased arterial wall stiffness, as well as long-standing hypertension and atrial fibrillation (AF). From the epidemiological point of view these conditions are closely related. Beta-blockers have lower efficacy in strokes prevention comparing to renin-angiotensin-aldosterone system blockers and amlodipine due to their less reduction of central blood pressure and pulse pressure. There is no data regarding effects of diltiazem on arterial stiffness in DHF patients with AF.

Aim: the purpose of this study was to compare parameters of arterial stiffness in AF patients with DHF under metoprolol (M) and diltiazem (D) treatment.

Methods: The study included 55 patients (40% men) aged 66 (62; 73) years with mild-to-moderate AH, one year anamnesis of recurrent AF and DHF. Clinical characteristics of M group patients (n=31) and D group patients (n=24) were similar. All patients were performed applanation tonometry before and 3 months after treatment.

Results: All baseline hemodynamic parameters were similar in both groups. There was significant reduction of heart rate (HR) in both groups [by 15 bpm in M group, $p < 0,001$ and by 11 bpm in D group, $p < 0,001$] and SBP [by 18 mm Hg in M group, $p < 0,005$ and by 15 mm Hg in D group, $p=0,03$], but changes in cSBP were significant only in D group ($p=0,03$). DBP and cDBP decreased significantly in M group by 4 mm Hg in both cases ($p=0,03$). Prolongation of ED was observed in both groups, but changes reached significance only in M group (+35 ms, $p < 0,001$). There were no difference in medians of Alx-HR75, but analysis of Δ Alx-HR75 showed opposite changes [+11% in M group and -5% in D group, $p=0,003$]. Both drugs showed PWVf reduction [from 9,3 (7,5; 12,4) to 7,7 (6,5; 10) m/s in M group, $p=0,03$] and [9,4 (7,1; 10,5) to 9,2 (7,8; 11) m/s in D group, $p=0,02$]. However during follow-up period AF recurrence was similar in both groups: 18 (58%) in M group and 18 (75%) pts in D group ($p=0,31$).

Conclusion: Both metoprolol and diltiazem significantly decreased HR, brachial and central BP. Three months follow-up resulted in a significant reduction in arterial stiffness, determined by PWVf. Despite the favorable effect of diltiazem on the pulse wave contour by reducing Alx-HR75, no difference was observed in frequency of AF recurrence in metoprolol and diltiazem groups.

P1519

Management of antithrombotic therapy in atrial fibrillation of patients with aortic stenosis undergoing transcatheter aortic valve implantation.

E Munoz-Garcia¹; M Lopez-Garrido²; M Munoz-Garcia³; AJ Antonio Jesus Munoz Garcia²; V Becerra-Munoz²; AJ Dominguez-Franco²; JM Garcia-Pinilla²; JM Hernandez-Garcia²; JJ Gomez-Doblas²; E De Teresa-Galvan²

¹Department of Cardiology, Malaga, Spain; ²University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain; ³Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain

Background: Many cardiac patients undergoing transcatheter aortic valve implantation (TAVI) required combined antithrombotic therapy consisting of an anticoagulant and inhibition of platelet function, due to atrial fibrillation. Currently the optimal combination of anticoagulants and anti-platelet therapy is unknown, but it is well established that the combination increased bleeding rates. The aim of this study was to analyze prevalence ischaemic and bleeding events in patients with atrial fibrillation undergoing TAVI in according to management of antithrombotic therapy

Methods: A total of 131 consecutive patients with aortic stenosis and atrial fibrillation undergoing TAVI were evaluated, between April 2008 and December 2014.

Results: The patients were characterized by had a HAS-BLED score 2.35 ± 0.5 , CHADS2 3.4 ± 1.07 and CHAD2-Vasc score 5.13 ± 1.3 . Six patients (4.8%) were treated in monotherapy with an oral anticoagulant, 4 (3.2%) triple antithrombotic therapy, dual antiplatelet in 42 patients (33.9%) and 72 patients (58.1%) with oral anticoagulant and a thienopyridine. We found differences in mortality in according to antithrombotic therapy: 16.7% vs. 0% vs. 35.7% vs. 13.9%, $p=0.023$, respectively, [OR=0.628 (95% CI 0.417-0.946), $p=0.026$]. There were no differences in events 0% vs. 0% vs. 19% vs. 6.9%, $p=0.172$, [OR=0.693 (95% CI 0.407-1.181), $p=0.178$]. Of patients treated with oral anticoagulant, 17 received non VKA oral anti-coagulant (NOACs). In patients were treated with an oral anticoagulant, there were differences in events but not in mortality in according to AVK vs. NOACs 2.8% vs. 33.3%, OR=17.5 (95% CI 2.98-102), $p=0.001$ and 11.1% vs. 20%, OR=2 (95% CI 0.463-8.639), $p=0.346$.

Conclusions: in this study seems to suggest that treatment with vitamin K antagonist and thienopyridine seems to be the safest therapy after TAVI.

P1520

Heart failure and atrial fibrillation, a tricky par or not so

L Luis Abreu¹; H Antunes¹; B Marmelo¹; JG Pereira¹; A Delgado¹; D Moreira¹; E Correia¹; JC Cabral¹; JO Santos¹

¹Hospital Sao Teotonio, Cardiologia, Viseu, Portugal

Introduction: The presence of atrial fibrillation (AF) is common in patients admitted for heart failure (HF), and may even be its decompensation cause. The prognostic impact of HF in patients with AF is well defined, but the opposite relationship remains controversial.

Purpose: To evaluate the prognosis impact of AF presence in patients admitted for HF.

Methods: We evaluated all hospitalizations for HF in a cardiology unit, for a six years period. Only the first episode of each patient was included. Were divided them into 2 groups: AF group: patient with history of or AF at admission; SR group: patients without AF. In-hospital mortality (IHM) and one year follow-up was used as end-points. Further sub-analysis of in-hospital mortality according to ejection fraction (EF) and admission BNP was carried out.

Results: We evaluated 969 admissions, corresponding same number of patients, mean age 77.2 \pm 10.1 years, 51.0% male. The overall results and the sub-analysis are presented in table.

Conclusion: In this population we did not evidence any immediate nor follow-up prognosis impact of the AF diagnosis in patients admitted for HF. There was even a trend to lower mortality in patients with AF, but those had a theoretically less severe HF. This can translate a lower admission threshold for patients with AF and HF. Given this possible selection bias, it will be difficult to confirm or refute any relationship between FA and the prognosis of patients with HF.

Comparison between SR group and AF group

	SR Group	AF Group	
Males	51,1%	51,0%	p=n.s.
Mean age	76,9 y	77,7 y	p=n.s.
EF	47%	51%	p=0,01

¹John Paul II Hospital, Department of Coronary Disease and Heart Failure, Krakow, Poland

Background: Patients with atrial fibrillation (AF) and acute coronary syndrome (ACS) constitute a high-risk population, especially in patients with systolic heart failure. However, the impact of new onset AF on patients with ACS and mild left ventricle (LV) systolic dysfunction remains unclear.

Aim: This study was conducted to estimate clinical significance, in-hospital and long-term mortality in patients with acute coronary syndrome, new onset AF and mild LV systolic dysfunction.

Methods: We conducted the cohort study, which included consecutive 237 patients with ACS and mild LV systolic dysfunction (EF 41-54%) diagnosed according to the ESC guidelines, hospitalized in the Department of Coronary Heart Disease and Heart Failure in Cracow between January 2008 and June 2010. The exclusion criteria were: valvular heart disease, pericarditis, permanent AF, active thyroid disease and cancer. We divided patients into two groups: 1st group – 36 pts with new onset AF during ACS (15 M, mean age $73.7 \pm 9,1$) and 2nd group – 201 pts without new onset AF during ACS (141 M, mean age $63,3 \pm 11,1$). After the follow-up of 43-73 months we

contacted with 29 (80,5%) pts from 1st group and 157 (78,1%) pts from the 2nd group.

Results: In contrary to the pts without AF, pts with new onset AF were characterized by: older age (73.7 vs. 63.3 yrs., $p < 0.001$), women prevalence (58.3 vs. 29.9 %; $p < 0.001$) and higher heart rate at admission to the hospital (117 vs. 77/min.; $p < 0.001$). During hospitalization in these pts more often were observed renal dysfunction (47 vs. 21 %; $p < 0.001$), in angiography left main coronary disease (17.1 vs. 6.5 %; $p < 0.001$) and in echocardiography LV diastolic dysfunction (93.5 vs. 70.7 %; $p < 0.001$). What is more, in these patients were also significant higher rate of cardiac arrest during hospitalization (16.7 vs. 0.5 %; $p < 0.001$) and in-hospital mortality rate (2.8 vs. 0.0 %; $p = 0.017$). Follow up revealed higher reoccurrence of atrial fibrillation in the AF group (38 vs. 13%, $p = 0.002$) and all-cause mortality rate (22.5 vs. 0.7 %, $p = 0.007$). Stroke-related mortality rate was 3.7 vs. 0.6 % ($p = 0.157$) and cardiovascular-disease related mortality was 3.7 vs. 3.2% ($p = 0.893$).

Conclusions: Renal dysfunction, left main coronary disease and left ventricle diastolic dysfunction are comorbidities observed during hospitalization in patient with new onset AF, acute coronary syndrome and mild LV systolic dysfunction. This study revealed that in these patients were also higher in-hospital and long-term mortality.

P1522

The impact of heart failure and left ventricular dysfunction in predicting stroke and thromboembolism in non valvular atrial fibrillation patients treated with direct oral anticoagulants

F Francesco Adamo¹; R Di Pietro¹; N Salvi¹; A Fusto¹; P Scarparo¹; M Mancone¹; F Ferrante¹; F Fedele¹

¹Sapienza University of Rome, Department of Cardiov. & Respiratory Sciences, Nephrology & Geriatrics, Rome, Italy

Background: The CHA2DS2-VASc score does not always accurately assess the thromboembolic risk of the patient suffering from Non Valvular Atrial Fibrillation (NVAF) and, thus, it would be useful to have additional parameters to stratify it. The presence of Heart Failure (HF) has been proposed as a risk factor for stroke and is included in CHA2DS2-VASc score.

Purpose: Our objective was to assess the effect of HF and left ventricular dysfunction on the endpoint of stroke or systemic embolism in NVAF patients treated with direct oral anticoagulants.

Methods: In a hospital-based population of 169 patients with NVAF treated with DOACs (90 with dabigatran, 65 with apixaban and 14 with rivaroxaban at recommended dose), we evaluated the following variables: CHA2DS2-VASc, presence of HF clinically assessed, left ventricle end-diastolic diameter (LVEDD) and left ventricle ejection fraction (LVEF) both assessed by echocardiography and 1-year incidence of ischemic stroke, TIA or systemic embolism. For statistical analysis we used Spearman's correlation test and point-biserial correlation test.

Results: Among 169 patients, the mean age was 74.2 ± 9.9 years and 96 were males. Mean CHA2DS2-VASc was 3.8 ± 1.7 ; 48 patients (28.4 %) had heart failure. Echocardiographic parameters were: LVEDD 50.9 ± 7.3 mm, LVEF 47.9 ± 10.3 %. After 1 year of follow up, 3 patients (1.77 %) had ischemic stroke, TIA or systemic embolism. All 3 patients had HF. A significant correlation between CHA2DS2-VASc and LVEF ($r = -0.215$; $p < 0.01$) was observed; no statistically significant correlation between CHA2DS2-VASc and LVEDD was detected. No significant correlation was found between CHA2DS2-VASc and 1-year incidence of ischemic stroke, TIA or systemic embolism. However, significant correlations between presence of HF, LVEDD, LVEF and 1-year incidence of ischemic stroke, TIA or systemic embolism were observed (respectively $\rho = 0.25$ and $p < 0.01$, $\rho = 0.22$ and $p = 0.01$, $\rho = -0.24$ and $p < 0.01$).

Conclusion: The presence of heart failure and echocardiographic data such as left ventricle ejection fraction and left ventricle end diastolic diameter can be useful parameters, in addition to CHA2DS2-VASc score, in thromboembolic risk stratification for the management of therapy with DOACs in patients with NVAF, particularly in CHA2DS2-VASc 1 patients affected by isolated heart failure, in which the indication for anticoagulation is debated. Further studies, with larger number of patients, will be needed.

P1523

SAME-TT2r2 score and quality of anticoagulation in a cohort of elderly heart failure patients with non valvular atrial fibrillation

J A Jose Satue¹; J Marrero Frances¹; A San Martin Prado¹; A Perez Martin¹; S Gonzalo Pascua¹; JC Belinchon Paraiso¹; M Duarte Millan¹

¹University Hospital of Fuenlabrada, Fuenlabrada, Spain

Background/Objectives: SAME-TT2R2 score (Sex female, Age < 60, Medical History more than 2 comorbidities, Treatment interacting, Tobacco use x2 and Race non white x2) has been proposed as a practical tool based on clinical and demographic criteria, to determine prospectively the patients with Non Valvular Atrial Fibrillation (AF) that will do well or not on Antivitamin K (AVK) treatment. The aim of this pilot study is to determine if this score is useful in our elderly patients with Heart Failure and Non Valvular Atrial Fibrillation

Patients and methods: We included prospectively outpatients seen from may 2014 to may 2015, in our Heart Failure Management Unit, with a diagnostic of Non Valvular Atrial Fibrillation (excluding those with prosthetic or significant valvulopathy). Data were recruited prospectively from laboratory and electronic records, and follow up was done in outpatient clinic and by telephone for a minimum of three months, and a maximum of 9. Charlson, CHADS-VASc, HAS-BLED and SAME-TT2R2 scores were done at inclusion. Time in therapeutic range (TTR) was analysed by Rosendaal method.

Results: 60 consecutive patients were included. 55 completed minimum follow up, and 46 (76%) reached maximum follow-up. Mean follow up was 279 days, with a range of 112-334. 2 patients died in follow-up. In 5 cases data were not accessible, and one patient stopped anticoagulation because of major hemorrhage. In all patients antithrombotic K used was acenocumarol. Mean age was 80'9 (57-90), and 38 (63%) were women. Mean Charlson Score was 2'83 (rank 1-5), mean CHADS2-VASc score was 5.48 (range 2-7), and mean HAS-BLED was 3.67 (range 2-6). 34 patients (61%) were below 65% of Time in Therapeutic Range (TTR) measured by Rosendaal method (rank 14-88%). Mean SAME-TT2R2 was 2.08, (rank 1 - 5). 42 patients (76%), had a SAME-TT2R2 over 2 points, and 13 (24%) patients had a SAME-TTR score of 1 point. Patients with a SAME-TT2R2 score of 1 are slightly younger (78.5 vs 81'6 years, $p = 0'14$), with lower CHADS2-VASc and HAS-BLED scores (5 vs 5'6, and 3'2 vs 3'8, $p = 0'11$ and 0'08 respectively, ns), and 53% of them were on adequate TTR > 65%, with a mean time in Therapeutic range of 63,8% ; patients with a SAME-TT2R2 score over 2 points, were slightly older, had higher CHADS2-VASc and HAS-BLED scores and only 33% of them were > 65% of TTR ($p = 0.18$), with a mean TTR of 60'07%. 61,8% of women were < 65% of TTR, in contrast with 38,2% of men ($p = 0.08$)

Conclusions: as described, it is difficult to achieve an adequate TTR > 65% in elderly patients with Non Valvular Atrial Fibrillation and Heart Failure, even in low SAME-TT2R2 scores, and it has to be carefully monitored. Two thirds of elderly patients with SAME-TT2R2 score over 1 point (which are usually older women and have higher CHADS-VASc, and HAS BLED scores) will not reach a correct target of TTR > 65% on AVK, so we must consider the use of Direct Oral Anticoagulants specially in this patients.

P1524

Comparing prognostic role of atrial fibrillation in predominantly HF elderly patients with HFrEF and HFpEF in community setting.

A Iorio¹; M Senni¹; R Rossini¹; L Vitali Serdoz²; A Gavazzi¹; C Mazzone³; G Barbat²; C Concetta Di Nora²; G Sinagra²; A Di Lenarda³

¹Ospedale Papa Giovanni XXIII, Bergamo, Italy; ²University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ³Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy

Background: Information on comparative prognostic impact of atrial fibrillation (AF) in patients with HFpEF compared with HFrEF is still controversial.

Objectives: To compare prognostic contributor of AF according to CHADS-VASc and comorbidity burden in EF-HF phenotypes (LVEF < 50% - HFrEF, LVEF $\geq 50\%$ - HFpEF) in a community-based population.

Methods: From October 2009 to December 2013 we studied all consecutive ambulatory patients with HF whose ejection fraction had been assessed. Clinical variables were derived from the E-data chart for Outpatient Clinic collected in a regional Data Warehouse.

Results: The study population comprised 2314 HF patients (mean age 78 ± 8 , 57% men). Of these: 941 (41 %) patients with LVEF < 50% were identified as HFrEF; 1373 (59%) patients as HFpEF. The high mean age, comorbidity rates (mean 3.2 ± 2.5) and CHA2DS2-VASc (4.1 ± 1.2) were similar between EF-HF phenotypes. In overall population, there was a high prevalence of chronic AF (55%). At a follow-up of 28 ± 14 months, 472 (20%) patients died. AF was associated with higher mortality rates (HR 1.7 [IC 1.2-1.9]; $p = 0.001$), HF hospitalization (HR 1.4 [IC 1.3-1.7]; $p < 0.001$) and all-cause hospitalization (HR 1.9 [IC 1.3-2.6]; $p < 0.001$), contributing to a higher hazard of mortality and morbidity in HFpEF vs HFrEF ($p = 0.001$ for interaction test). After adjustment for all univariable predictors, including CHA2DS2-VASc and comorbidity burden, AF remained independently associated with high mortality and morbidity.

Conclusion: In real-world HF population, AF contributed significantly to worse outcome in overall population irrespective CHADS-VASc and comorbidity with higher prognostic impact in patients with HFpEF compared to HFrEF. These observations suggest that in community-based HF population aggressive management of AF may have a great impact in patients with HFpEF.

Restoration of sinus rhythm in patients with acute heart failure and atrial fibrillation

SR So-Ryoung Lee¹; SE Lee¹; HS Lee¹; HJ Cho¹; HY Lee¹; SH Baek²; ES Jeon³; MC Cho⁴; BH Oh¹

¹Seoul National University Hospital, Department of Internal Medicine, Division of Cardiology, Seoul, Korea Republic of; ²Seoul St. Mary's Hospital, Cardiovascular

Center and Cardiology Division, Seoul, Korea Republic of; ³Samsung Medical Center, Department of Internal Medicine, Sungkyunkwan University College of Medicine, Seoul, Korea Republic of; ⁴Chungbuk National University Hospital, Department of Internal Medicine, Cheongju, Korea Republic of

Background: Atrial fibrillation (AF) is frequent in acute heart failure (AHF) and associated with poor outcome among patients with AHF. However, little is known about restoration of sinus rhythm in patients with AHF and AF.

Methods: From the Korean Acute Heart Failure (KorAHF) registry, a prospective multicenter cohort for consecutive patients who were admitted for AHF, those with AF during hospitalization and available electrocardiogram at discharge were extracted.

Results: Among 1,420 patients who had AF during AHF hospitalization, 368 (18.5%) patients were restored sinus rhythm at discharge. Sinus rhythm was spontaneously restored in 126 (34.2%) of 368 patients, 196 (53.3%) patients underwent the pharmacological conversion, and 46 (12.5%) underwent the electrical conversion. Among three groups, Electrical conversion group showed lower systolic blood pressure and higher heart rate than spontaneous and pharmacologic conversion group at admission. Otherwise, there was no significant difference by method for the restoration of sinus rhythm. Patients with sinus rhythm at discharge (SC group) were more likely to be newly developed AF during hospitalization than patients with AF at discharge (AF group) (72.5% vs. 35.2%, $p < 0.001$). A history of heart failure was more common in AF group (46.4% vs. 31.8%, $p < 0.001$). The etiology of AHF was different between two groups. Ischemic cardiomyopathy was more common in SC group than in AF group (41.8% vs. 19.8%, $p < 0.001$). The proportion of HF with reduced ejection fraction (EF) versus preserved EF was not significantly different between two groups. The mean left atrial (LA) diameter was greater in AF group than in SC group (52.3 ± 8.5 vs. 45.9 ± 8.9 mm, $p < 0.001$). In multivariate logistic regression, sinus conversion during hospitalization was associated with new-onset AF (OR 2.41, 95% CI 1.63-3.57, $p < 0.001$), ischemic etiology (OR 1.61, 95% CI 1.22-2.13, $p = 0.001$), and LA diameter (OR 0.927, 95% CI 0.91-0.94, $p < 0.001$). Area under the curve of LA diameter for predicting sinus rhythm restoration was 0.702 (95% CI 0.670-0.734, $p < 0.001$) and baseline LA diameter 48.25mm showed optimal predictive value.

Conclusion: The restoration of sinus rhythm in patients with AHF and AF was associated with new-onset AF, ischemic cardiomyopathy and smaller LA size. Further investigation will be needed to establish the strategy of restoration of sinus rhythm in AF patients with AHF.

P1526

Presence of atrial fibrillation worsens prognosis in patients with myocardial infarction.

B F Bruno Filipe Lourenco Marmelo¹; J Gil¹; L. Abreu¹; H. Antunes¹; L. Goncalves¹; A. Delgado¹; D. Moreira¹; PC Ferreira¹; J. Cabral¹; J. Oliveira Santos¹

¹Hospital Sao Teotonio, Viseu, Portugal

Background: Atrial fibrillation (AF) is the most common sustained arrhythmia as is an independent risk factor for myocardial infarction (MI). Some studies associated AF to worse prognosis in patients with MI.

Aim: This study aims to understand the impact of AF in the prognosis of patients with MI.

Methods: Selected patients admitted with MI in a coronary unit from 2007 to 2014. Collected clinical, analytical, echocardiographic and angiographic data. The patients were divided in two groups according to the presence of AF. A one year follow up was performed. Statistical analysis in SPSS 20.

Results: In the sample ($n = 1500$) 70,1% were males. The mean age was $69,1 \pm 12,9$ years and higher in the AF group (67,6 vs 77,3 years, $p < 0,001$). The patient with STEMI were 43,4% and the patient with NSTEMI were 56,6. The AF was associated with lower systolic (141,4 vs 132,7mmHg, $p < 0,001$) and diastolic (82,7 vs 76,7mmHg, $p < 0,001$) pressure and higher Killip class at admission (1,33 vs 1,76, $p < 0,001$) and maximum Killip class (1,62 vs 2,32, $p < 0,001$).

Blood analysis showed increased levels of creatinine (1,27 vs 1,37mg/dL, $p = 0,009$) and C-reactive protein (2,12 vs 3,46mg/dL, $p < 0,001$) in patients with AF as well as lower haemoglobin (14,1 vs 13,4g/L, $p < 0,001$). Although there was no difference in the troponin between the groups, the patients with AF had higher BNP levels (812,9 vs 401,9pg/mL, $p < 0,001$). The ejection fraction was lower in patients with AF (54,95% vs 50,91%, $p = 0,005$). There was no difference in angiographic parameters ($p = 0,07$). AF led to longer hospitalization (7,06 vs 9,20 days, $p < 0,001$) increase risk of complications (29,8% vs 39,2%, $p = 0,008$), and increased mortality during hospitalization (6,7% vs 11,4%, $p = 0,022$). AF worsen prognosis after discharge with higher cardiovascular event rate (27,8% vs 42,9%, $p < 0,001$), stroke rate (0,9% vs 4,2%, $p = 0,001$) and higher mortality (2,8% vs 11,8%, $p < 0,001$).

Conclusions: This study showed that previous AF significantly worsen prognosis in patients with STEMI, increasing the risk of heart failure, complications and death during hospitalization, as well as stroke, cardiovascular event or death during the follow up.

Pseudo-coronary scenario of inflammatory viral cardiomyopathy

A Gombozhapova¹; YU Rogovskaya²; T Ryabova¹; E Kruchinkina¹; K Gunderina¹; R Batalov¹; V Ryabov³

¹Research Institute for ?ardiology, Emergency cardiology department, Tomsk, Russian Federation; ²Tomsk State University, Translational laboratory of cellular and molecular medicine, Tomsk, Russian Federation; ³Siberian State Medical University, Tomsk, Russian Federation

Cardiomyopathy is one of the most severe and complicated cardiovascular diseases which leads to development of acute and chronic heart failure. The progress in molecular biochemistry and genetics allows to significant enhancement of its diagnostics. New data has confirmed that cardiomyopathies represent a complex nosological structure. The establishment of diagnosis demands a close attention of clinicians and necessity to go beyond the usual diagnostics schemes.

The purpose of the article is to show a clinical case of pseudo-coronary scenario of inflammatory viral cardiomyopathy. We described the unexpected case of a 50-year-old woman, with medical history of ischemic heart disease, who was admitted to the intensive care unit complaining of chest pain, dyspnea and fatigue. Clinically, we saw signs of pulmonary edema, atrial fibrillation with left bundle branch block, impairment of left ventricular function with progressive increase of myocardial necrosis biomarkers. Clinical findings were evaluated as acute coronary syndrome. The patient underwent to percutaneous coronary angiography which had showed absence of coronary atherosclerosis. Following verification of diagnosis was accomplished using routine, as well as modern imaging technologies, including cardiac magnetic resonance imaging, 2D-speckle tracking echocardiography, endomyocardial biopsy with immunohistochemical analysis. As a result, the diagnosis of inflammatory viral dilated cardiomyopathy was established.

Our clinical case example shows that in spite of the experience, in routine practice the diagnostics of cardiomyopathy is still a difficult and time-consuming task and its success depends on the specialists' coordinated work. Non-invasive heart imaging, such as echocardiography and magnetic resonance image retain their value in routine clinical practice. The implementation of endomyocardial biopsy significantly expands our ability to detect inflammatory cardiomyopathy, and immunohistochemical analysis allows us not only to identify and characterize the cells of the inflammatory infiltrate, but also to identify a number of infectious agents, particularly - viruses. In this clinical case example we want to attract attention to the fact that the establishment of diagnosis and therapy prescription of such complex group of diseases demands all our accumulated knowledge, available resources of diagnostics and treatment, as well as adjustment of patients to treatment compliance and the follow-up importance.

P1528

Increased mortality is associated with proof of perforin-positive cardiac cell infiltration and male gender in a large cohort of patients with inflammatory cardiomyopathy

F Felicitas Escher¹; U. Kuehl¹; D. Lassner²; B. Pieske¹; WC. Poller³; C. Tschöpe¹; HP. Schultheiss²

¹Charité - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany; ³Charité - Campus Benjamin Franklin, Berlin, Germany

Aims: We analysed possible influence of perforin-dependent infiltration upon long-term mortality in patients with inflammatory cardiomyopathy (CMi).

Background: We previously demonstrated that left ventricular function deteriorates and progresses to substantial cardiac dysfunction in patients with perforin-positive myocardial cell infiltration.

Methods and Results: Between 2003 and 2013, 2389 consecutive patients with clinically suspected CMi who underwent endomyocardial biopsy (EMB) were enrolled. EMBs were performed at first admission after exclusion of ischemic of valvular heart disease, and CMi was confirmed in 1717 patients. Follow-up was up to 10.0 years (mean 17.8 ± 25.4 months) and information on vital status was obtained from official resident data files. Multivariable statistical analysis was conducted for all CMi patients regarding significant predictors of all-cause mortality or need for heart transplantation (HTX). Multiple Cox regression analysis revealed perforin above the calculated cut off point of $2.9/\text{mm}^2$ as a strong predictor of impaired survival with hazard ratio (HR) of 1.881, 95% confidence interval (CI) 1.177-3.008, $p = 0.008$, independent of LV function and other myocardial inflammation markers (CD3, Mac-1, LFA-1, HLA-1, and ICAM-1). Unexpectedly, male sex emerged as another strong adverse predictor of survival in CMi (HR 1.863, CI 1.096-3.168, $p = 0.022$). Whereas LVEF course is adversely affected by myocardial perforin, multivariate analysis indicates that LVEF explains only part of the observed overall mortality.

Conclusion: Perforin-positive cardiac cell infiltration and male gender are interacting adverse predictors of long term-mortality in CMi, independent of LV function and other myocardial inflammation markers. Furthermore, exact quantification of immune cells is necessary to assess the prognosis.

P1529**Predictor of stress induced cardiomyopathy in critically ill pneumonia patients.**SK Sung Kee Ryu¹; HK Min¹; JY Park¹; SH Kim¹; JW Choi¹; YS Byun²¹Eulji University, Seoul Eulji Hospital, Seoul, Korea Republic of; ²Inje University, Sanggye Paik Hospital, Seoul, Korea Republic of

Introduction: Stress induced cardiomyopathy (SIC) is caused by stressful situation such as not only emotional but also serious medical illness. SIC sometimes occurs after pneumonia and it worsens the prognosis of pneumonia, but the predictor of SIC after pneumonia is unknown.

Method and Result: We selected consecutive 13 patients with SIC after pneumonia and age and sex matched 38 patients who received ICU care with pneumonia without SIC from 2013. Mean age was 72.3 ± 12.3 and 72.4 ± 14.2 years in each SIC and non-SIC group ($p = 0.971$). There were no significant between-group differences in the rates of male, diabetes, hypertension, stroke, and cancer. There was no significant difference in WBC count between 2 groups. Troponin T was significantly higher. (0.48 ± 0.47 vs. 0.05 ± 0.03 ng/ml, $p = 0.011$) Serum sodium level was higher in SIC (140.9 ± 6.8 vs. 135.7 ± 5.2 mEq/L, $p < 0.01$) but both were in normal ranges. Hemoglobin and Hematocrit level were significantly lower in SIC group (10.7 ± 1.2 vs. 11.8 ± 2.2 g/dl, 31.8 ± 3.8 vs. $35.0 \pm 6.5\%$ all $p < 0.05$).

Conclusion: In critically ill pneumonia patients anemia might be a risk factor or predictor for progression to SIC. Other cardiovascular risk factor and history of stroke or cancer did not affect the rate of SIC from pneumonia.

P1530**Heart failure is the most frequent complication in a portuguese population of left ventricular non-compaction cardiomyopathy - a multicenter study**

Bial, Medinfa, MSD, Trigenius

K Kevin Domingues¹; D Moreira²; M Oliveira³; C Gomes⁴; L Teles⁵; B Picarra⁶; R Faria⁷; P Magalhaes⁸; R Santos⁹; N Marques¹⁰

¹Hospital of Santarem, Cardiology, Santarem, Portugal; ²Hospital Sao Teotonio, Viseu, Portugal; ³Alto Ave Hospital Center, Guimaraes, Portugal; ⁴Hospital Garcia de Orta, Almada, Portugal; ⁵University Hospitals of Coimbra, Coimbra, Portugal; ⁶Hospital Espirito Santo de Evora, Evora, Portugal; ⁷Centro Hospitalar do Médio Ave, Vila nova de Famalicão, Portugal; ⁸Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁹Hospital Centre do Tamega e Sousa, Penafiel, Portugal; ¹⁰Faro Hospital, Faro, Portugal

Introduction: Left ventricular non-compaction cardiomyopathy (LVNC) has great morphologic variability, and its clinical features and prognosis are also variable. It is known that it may lead to left ventricular (LV) systolic dysfunction. Previous studies show that heart failure is one of the main clinical manifestations of LVNC, along with embolic events and arrhythmias. However, natural history of LVNC is not clearly established and current knowledge come from small series.

Aim: To characterize a Portuguese population of patients with LVNC and to determine the prognosis in the medium term follow-up.

Methods: Portuguese multicenter study involving 11 hospital centers and including all patients diagnosed with LVNC. We evaluated the clinical, electrocardiographic, echocardiographic and cardiac MRI data. We evaluated the prognosis in terms of heart failure, embolic events, arrhythmias and death.

Results: We included 86 patients with LVNC, 57% males, with mean age 51 ± 19 years. Symptoms were present at diagnosis in 61.6% of patients, and dyspnea (37.2%) and palpitations (30.2%) were the most common symptoms. The most frequent initial clinical presentation was heart failure (30.2%), followed by arrhythmia (15.1%) and embolic events (8.1%). Only 2.3% had episodes of syncope prior to diagnosis. Diagnosis was established by echocardiogram in 80.2% of patients. The average LV ejection fraction was $48 \pm 16\%$, with 25% of the patients having an ejection fraction $< 35\%$. There were criteria for diastolic dysfunction in 49% of the patients, with grade I in 39.9%, grade II in 33.3% and grade III in 27.8%. The average LV end-diastolic diameter was 56mm, with 25% having a diameter > 60 mm. Most patients were in sinus rhythm (89%). A history of atrial fibrillation was present on 11.9% of the patients, supraventricular tachycardia in 15.3% and non-sustained ventricular tachycardia in 22% of the cases. Family history of LVNC was identified in 8.1% of cases.

In the medium term (mean follow up of 3.4 years), patients with LVNC presented heart failure in 30%, arrhythmia in 14%, embolic events in 6% and death in 4.7% of cases.

Conclusions: In this Portuguese population of patients with LVNC, heart failure was present in about one third of the cases and was the most frequent clinical complication in the medium term follow up. The presence of systolic and diastolic dysfunction and LV dilation was frequent in these patients.

P1531**Analysis of death dynamics in patients with peripartum cardiomyopathy**TA Abdullayev¹; ST Mirzarakhimova¹; NA Kurbanov¹; I A Igor Tsoy¹; SHSH Davirova¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

Objective: Analysis of the dynamics of deaths in patients with peripartum cardiomyopathy (PCM) with long-term of observation.

Material and Methods: We observed 50 patients suffering from PCM, aged from 20 to 41 years (mean age 28.2 ± 0.8 years). The study of the dynamics of the disease lasted from 3 to 175 months (mean 67.4 ± 5.4 months). Complex examination included an electrocardiogram, HMECG, echocardiogram, and 6-minute walking test definition of functional class (FC) of heart failure (HF) by NYHA. Repeated contact with patients or relatives held each year.

Results of the study. Depending on the outcome of the disease retrospectively, all patients were divided into 2 groups. The first group comprised 17 patients with PCM who died in the period from 3 to 131 months of observation (36.6 ± 7.2 months.). The second group consisted of 33 patients who survived during the 31 to 175 months (average 83.1 ± 5.7 months; $p < 0.001$) surveillance. The study of the dynamics of the disease found that in a group of survivors of the 12-month standard therapy of CHF were complete recovery of left ventricular function (LVEF increase of more than 55%) was noted in 19 (38%) cases. As noted above, the cumulative mortality at 67.4 ± 5.4 months was 34% ($n = 17$). This death in the first year follow-up was 8% ($n = 4$), (3 deaths due to progression of heart failure, one case developed pulmonary embolism). During the second year of follow another 3 patients died (in one case, death occurred suddenly, in 2 cases - the progression of heart failure). As a result, the cumulative mortality was 14% ($n = 7$). During the third year of follow marked another 4 deaths due to progression of heart failure (22%). On 4 and 5 years of observations recorded 2 cases of deaths and then another 2 cases from PCM, respectively, due to the growth of HF (30%). Subsequently, in 2 cases death was observed due to the SD (34%). It should be noted that the four (8%) of the patients survived for more than 10 years, 12 (24%) - from 7 to 9 years, 11 (22%) - from 5 to 6 and 8 (16%) - survived for more than 4 years.

Conclusions: Thus, analysis of the dynamics of mortality in patients with peripartum cardiomyopathy showed that the maximum adverse outcomes (30%) observed in the first 5 years of observation, with the leading cause of death (26%) had progressive heart failure. At the same time against the background of optimal drug therapy, patients' life prognosis with PCM favorable, and in 38% cases, accompanied by a complete recovery of left ventricular function.

P1532**Predictors of cardiogenic shock in Takotsubo Cardiomyopathy_a portuguese multicenter study**M Oliveira¹; P Azevedo²; K Domingues³; C Lourenco⁴; AR Almeida⁵; S Leao⁶; L Reis⁴; B Marmelo⁷; B Picarra⁸; O Azevedo¹

¹Hospital Senhora da Oliveira, Cardiology, Guimarães, Portugal; ²Faro Hospital, Faro, Portugal; ³Hospital of Santarem, Santarem, Portugal; ⁴General Hospital, University Hospitals of Coimbra, Cardiology, Coimbra, Portugal; ⁵Hospital Garcia de Orta, Almada, Portugal; ⁶Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁷Hospital Sao Teotonio, Viseu, Portugal; ⁸Hospital Espirito Santo de Evora, Evora, Portugal

Introduction: Takotsubo cardiomyopathy (TC) is characterized by a transient left ventricular (LV) dysfunction that may lead to cardiogenic shock. Cardiogenic shock is one of the most prevalent and serious acute complications of TC. Little is known about the predictors of cardiogenic shock in TC.

Aim: To identify predictors of cardiogenic shock in patients with TC.

Methods: A Portuguese multicenter study involving 10 hospital centers and including all patients diagnosed with TC in the last 10 years. We evaluated demographic, clinical, electrocardiographic and echocardiographic data. We determined the factors that were associated with the occurrence of cardiogenic shock and then conducted multivariate analysis to establish the independent predictors of cardiogenic shock in patients with TC.

Results: We included 192 patients with TC. During the hospital stay (7.1 ± 6.2 days), cardiogenic shock occurred in 7.8% of patients. Other complications: heart failure (24%), atrial fibrillation (8.9%), acute pulmonary edema (4.2%), complete AV block (2.6%), ventricular tachycardia (VT) (2.1%), LV thrombus (1.6%), stroke / AIT (1.6%), and death (2.1%). In patients with TC, the factors associated with the occurrence of cardiogenic shock were the history of heart failure (14.3% vs 1.4%, $p = 0.004$), chronic renal failure (23.1% vs 6.4%, $p = 0.033$), the clinical presentation with dyspnea (53.8% vs 25.3%, $p = 0.027$), bifascicular block in ECG (6.7% vs 0.6%, $p = 0.025$), the in-hospital occurrence of complete AV block (13.3% vs 1.7%, $p = 0.007$). In the multivariate analysis, history of heart failure ($p = 0.037$), chronic renal failure ($p = 0.006$), the clinical presentation with dyspnea ($p = 0.036$), the in-hospital occurrence of complete AV block ($p = 0.001$) were identified as independent predictors of the occurrence of cardiogenic shock during hospitalization of patients with TC.

Conclusion: In this Portuguese multicenter study an history of heart failure, chronic renal failure, the clinical presentation with dyspnea and the in-hospital occurrence of complete AV block were identified as independent predictors of cardiogenic shock in patients with TC.

Predictors of heart failure on takotsubo cardiomyopathy - a portuguese multicenter study

H Hugo Antunes¹; O Azevedo²; K Domingues³; C Lourenco⁴; AR Almeida⁵; R Pontes⁶; B Picarra⁷; P Magalhaes⁸; L Reis⁹; N Marques⁹

¹Hospital Sao Teotónio, Cardiology, Viseu, Portugal; ²Alto Ave Hospital Center, Guimaraes, Portugal; ³Hospital de Santarem, Santarem, Portugal; ⁴University Hospitals of Coimbra, Coimbra, Portugal; ⁵Hospital Garcia de Orta, Almada, Portugal; ⁶Hospital Centre do Tamega e Sousa, Penafiel, Portugal; ⁷Hospital Espírito Santo de Evora, Evora, Portugal; ⁸Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁹Faro Hospital, Faro, Portugal

Introduction: Takotsubo cardiomyopathy (TC) is characterized by a transient left ventricular (LV) dysfunction that may lead to the development of heart failure. Little is known about the predictors of heart failure in TC.

Aim: To identify predictors of heart failure in patients with TC.

Methods: A Portuguese multicenter study involving 10 hospital centers and including all patients diagnosed with TC in the last 10 years. We evaluated demographic, clinical, electrocardiographic and echocardiographic data. We determined the factors that were associated with the development of heart failure and then conducted a multivariate analysis to establish the independent predictors of heart failure in patients with TC.

Results: We included 192 patients with TC. During the hospital stay (7.1 ± 6.2 days), cardiogenic shock occurred in 7.8% of patients. Other complications: heart failure (24%), atrial fibrillation (8.9%), acute pulmonary edema (4.2%), complete AV block (2.6%), ventricular tachycardia (VT) (2.1%), LV thrombus (1.6%), Stroke / AIT (1.6%), and death (2.1%). In patients with TC, the factors associated with the development of heart failure were the history of heart failure (10.8% vs 0%, $p < 0.001$), chronic renal failure (21.6% vs 3.4%, $p < 0.001$), the clinical presentation with dyspnea (59.5% vs 16.5%, $p < 0.001$), complete AV block (8.7% vs 0.7%, $p = 0.003$) and worse LV ejection fraction ($37.0 \pm 11\%$ vs $45.7 \pm 9\%$, $p < 0.001$). In the multivariate analysis, chronic renal failure ($p = 0.012$), the clinical presentation with dyspnea ($p = 0.002$), complete AV block ($p = 0.028$) and worse LV ejection fraction ($p = 0.003$) were identified as independent predictors of the heart failure during hospitalization of patients with TC.

Conclusion: TC has a high rate of in-hospital heart failure. Chronic renal failure, the clinical presentation with dyspnea, complete AV block and worse LV ejection fraction were identified as independent predictors of the heart failure during hospitalization of patients with TC.

P1534

Heart failure during hospitalization is associated with takotsubo cardiomyopathy recurrence at follow-up: a portuguese multicenter study

R A Rui Alexandre Pontes Dos Santos¹; D Bento²; M Oliveira³; K Domingues⁴; H Antunes⁵; S Leao⁶; AR Almeida⁷; L Reis⁸; B Picarra⁹; E Correia⁹

¹Hospital Centre do Tamega e Sousa, Penafiel, Portugal; ²Faro Hospital, Faro, Portugal; ³Alto Ave Hospital Center, Guimaraes, Portugal; ⁴Hospital de Santarem, Santarem, Portugal; ⁵Hospital Sao Teotónio, Viseu, Portugal; ⁶Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁷Hospital Garcia de Orta, Almada, Portugal; ⁸University Hospitals of Coimbra, Coimbra, Portugal; ⁹Hospital Espírito Santo de Evora, Evora, Portugal

Introduction: Takotsubo cardiomyopathy (TC) is characterized by a transient left ventricular (LV) dysfunction. Recurrence of TC has been described in several studies, but the risk factors associated with the recurrence of TC are still unknown.

Aim: To identify the risk factors for recurrence of TC and specifically to determine if the occurrence of in-hospital heart failure (HF) is associated with recurrence of TC.

Methods: A Portuguese multicenter study involving 10 hospital centers and including all patients diagnosed with TC in the last 10 years. We evaluated demographic, clinical, electrocardiographic and echocardiographic data. We determined the risk factors for recurrence of TC by univariate analysis.

Results: We included 192 patients with TC with a mean follow up of 45 ± 32 months. Recurrence of TC was diagnosed in 4.7% of cases. The following factors were associated with recurrence of TC: chronic renal failure (33.3% vs 6.8%, $p = 0.018$), the presence of ST-segment depression in the initial ECG (22.2% vs 4.9%, $p = 0.029$) and the occurrence of HF during hospitalization (54.4% vs 23.0%, $p = 0.040$).

Conclusion: Chronic renal failure, ST-segment depression in the initial ECG and occurrence of HF during hospitalization were associated with recurrence of TC.

P1535

Predictors of heart failure in left ventricular non-compaction cardiomyopathy - a portuguese multicenter study

PM Pedro Azevedo¹; B Marmelo²; C Gomes³; K Domingues⁴; L Reis⁵; B Picarra⁶; P Magalhaes⁷; R Faria⁸; R Santos⁹; O Azevedo¹⁰

¹Faro Hospital, Cardiology, Faro, Portugal; ²Hospital Sao Teotónio, Cardiology, Viseu, Portugal; ³Hospital Garcia de Orta, Cardiology, Almada, Portugal; ⁴Hospital

of Santarem, Cardiology, Santarem, Portugal; ⁵Hospital Center of Coimbra - Covões, Cardiology, Coimbra, Portugal; ⁶Hospital Espírito Santo de Evora, Cardiology, Evora, Portugal; ⁷Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal; ⁸Alto Ave Hospital Center, Cardiology, Guimaraes, Portugal; ⁹Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal; ¹⁰Hospital Guimaraes, Cardiology, Guimaraes, Portugal

Introduction: Left ventricular non-compaction cardiomyopathy (LVNC) may lead to the development of heart failure. Little is known about the predictors of heart failure in LVNC.

Purpose: To identify predictors of heart failure in patients with LVNC.

Methods: A Portuguese multicenter study involving 10 hospital centers and including all patients diagnosed with LVNC. We evaluated demographic, clinical, electrocardiographic, echocardiographic and cardiac magnetic resonance data. We determined the factors that were associated with the development of heart failure and then conducted a multivariate analysis to establish the independent predictors of heart failure in patients with LVNC.

Results: We included 86 patients with LVNC. Heart failure was present in 30.2% of patients. In patients with LVNC, the factors associated with the development of heart failure were older age (60 ± 18 vs 48 ± 18 years, $p = 0.004$), presence of symptoms on diagnosis (84.6% vs 31.7%, $p < 0.001$), higher LV end-diastolic diameter (61 ± 7 mm vs 53 ± 8 mm, $p < 0.001$), lower LV ejection fraction ($37 \pm 12\%$ vs $54 \pm 16\%$, $p < 0.001$), diastolic dysfunction (78.6% vs 34.5%, $p = 0.007$), mitral valve regurgitation (53.8% vs 21.7%, $p = 0.003$), late gadolinium enhancement in cardiac magnetic resonance (36.4% vs 11.9%, $p = 0.021$), left bundle branch block (24.0% vs 3.3%, $p = 0.003$) and bifascicular block (8% vs 0%, $p = 0.027$).

Patients with LVNC and heart failure have higher frequency of ventricular tachycardia in 24h-Holter (43.8% vs 14%, $p = 0.014$) and there was only one sudden death in the 3.4 years of follow up.

In the multivariate analysis we could not identify any independent predictors of heart failure in LVNC patients.

Conclusion: Heart failure is a common complication of LVNC. The presence of heart failure in patients with LVNC was associated with older age, the presence of symptoms on diagnosis, higher LV end-diastolic diameter, lower LV ejection fraction, diastolic dysfunction, mitral valve regurgitation, late gadolinium enhancement in cardiac magnetic resonance and left bundle branch block or bifascicular block in ECG. Patients with LVNC and heart failure had a higher frequency of ventricular tachycardia and sudden death in the follow-up.

P1536

Myotonic dystrophy - must we bother for the heart?

M Gospodinova¹; T Chamova²; S Sarafov²; I Tournev³; S Denchev¹

¹Medical Institute of Ministry of Interior, Clinic of Cardiology, Sofia, Bulgaria;

²University Alexandrovska Hospital, Clinic of Neurology, Sofia, Bulgaria; ³University Alexandrovska Hospital, New Bulgarian University, Clinic of Neurology, Department of cognitive science and psychology, Sofia, Bulgaria

Background: Myotonic dystrophy is the most common hereditary neuro-muscular disorder. Cardiac involvement may also be present.

Purpose: The purpose was to look for the presence, type and frequency of cardiac involvement in patients with Myotonic dystrophy type 1.

Patients and methods: We evaluated 37 patients (22 women) at mean age 38.4 ± 13.4 years. A clinical exam, ECG, Holter ECG and transthoracic echocardiography were performed.

Results

Rhythm and conduction disturbances were found in 59.5% of the patients. Most common findings were A-V block 1st degree in six patients (16.2%), wide QRS complex (> 100 ms) in 18 patients (48.6%) – LBBB in 3 patients, RBBB in 5 and impaired intraventricular conduction in 10 patients. In one patient with A-V block 3rd degree permanent pace maker was implanted. Atrial fibrillation was registered in 2 patients. In four (10.8%) patients repolarization abnormalities were registered. The other findings were left ventricular systolic dysfunction in 3 patients (8.1%) and in 11 (29.7%) – diastolic dysfunction. Right ventricular abnormalities were not detected.

Conclusion: The most common findings were rhythm and conduction disturbances. Heart failure symptoms were not present despite the presence of myocardial dysfunction. Cardiologist must be aware of the cardiac manifestations of the disease in order to follow and treat the patients properly.

P1537

Genotype-phenotype correlation in cardiac mutated transthyretin amyloidosis (m-ATTR)

S Perlini¹; L Obici²; R Mussinelli¹; F Salinaro¹; T Perrone¹; F Cappelli³; F Peretto³; P Milani²; G Palladini²; G Merlini²

¹Dept. Internal Medicine, University of Pavia, Amyloidosis Research and Treatment Center, IRCCS S.Matteo, Pavia, Italy; ²Amyloidosis Research and Treatment Center, Pavia, Italy; ³Careggi University Hospital (AOU), Regional Amyloid Center, Heart and Vessels Department, Florence, Italy

Background: Despite a remarkably similar echocardiographic (or MRI) presentation, the prevalence of some findings such as low peripheral ECG voltages or the extent of serum cardiac biomarker increase, as well as overall prognosis, are quite different when comparing light-chain (AL) vs. mutated transthyretin (m-ATTR) cardiac amyloidosis, overall survival being much worse in cardiac AL. However, since cardiac m-ATTR may be caused by at least 100 different TTR mutations, potential genotype-phenotype correlations should be taken into consideration in order to properly compare these two different aetiologies of cardiac amyloidosis.

Objective and Methods: Genotype-phenotype correlations were evaluated by comparing NT-proBNP release and systo-diastolic function in 173 cardiac AL and 102 cardiac m-ATTR patients at diagnosis. Patients with renal dysfunction (MDRD-estimated glomerular filtration rate < 60 mg/dl) were excluded. Survival was assessed over a median follow-up of 38.9 months (range, 19-75 months).

Results: Despite lower left ventricular mass index (LVMI, an index of the extent of cardiac amyloid deposition) [174(138-195) vs. 196(156-145) g/m², median(IQ range), $p < 0.001$], cardiac AL was characterised by a 6-fold higher serum NT-proBNP level [5931(2330-11957) vs. 994(564-2328) pg/ml, $p < 0.001$], associated with a more severe extent of diastolic dysfunction [(E/E' ratio: 10.1 (6.7-13.7) vs. 8.4 (6.0-11.2), $p < 0.02$] and comparable systolic function and global longitudinal strain. When subdividing cardiac m-ATTR patients according to the different genotypes, serum NT-proBNP levels were remarkably different among the 23 observed TTR mutations. When compared with LVMI-matched cardiac AL patients, Ile68Leu and Val122Ile patients ($n = 13$ and $n = 6$, respectively) had superimposable NT-proBNP levels [4795(1821-8889) pg/ml, $p = ns$ vs. AL] associated with a comparable extent of systolic and diastolic dysfunction. In contrast, NT-proBNP levels were remarkably lower in Val30Met and Glu89Gln ($n = 28$ and $n = 20$) patients [718(446-1287) pg/ml, $p < 0.01$ vs. AL], who had higher midwall fractional shortening, longitudinal systolic shortening and global strain, associated with lower E/E' ratio, compatible with a much more preserved systolic and diastolic function. Prognosis was remarkably different, Val30Met and Glu89Gln patients having a much better survival than AL, Ile68Leu and Val122Ile patients ($p < 0.01$).

Conclusions: In cardiac m-ATTR, the extent of NT-proBNP release is critically dependent on the TTR-related amyloid type, Ile68Leu and Val122Ile being remarkably more toxic than Val30Met and Glu89Gln mutations at comparable extent of amyloid deposition. Such a higher toxicity also translates into a worse prognosis, survival in Ile68Leu and Val122Ile mutations being comparable with cardiac AL amyloidosis.

P1538

Influence of triggering events on the clinical course of takotsubo cardiomyopathy

B Schneider¹; A Athanasiadis²; J Schwab³; U Gottwald⁴; W Toepel⁵; T Mueller-Honold⁶; R Schoeller⁷; U Sechtem²

¹Sana Kliniken, Luebeck, Germany; ²Robert-Bosch-Krankenhaus, Stuttgart, Germany; ³Klinikum Nuernberg, Nuernberg, Germany; ⁴Allgemeines Krankenhaus, Celle, Germany; ⁵Klinikum Idar-Oberstein, Idar-Oberstein, Germany; ⁶Klinikum Augsburg, Augsburg, Germany; ⁷DRK Kliniken Berlin-Westend, Berlin, Germany

Purpose: Tako-tsubo cardiomyopathy (TTC) is frequently preceded by emotional or physical stress. In a large registry, this study evaluated the influence of triggering events on the manifestation and the clinical course of TTC.

Methods: From 37 heart centres, 324 pts (296f, 28m, age 68 ± 12) were included in a registry according to the following criteria: 1) acute chest symptoms, 2) ischemic ECG changes, 3) reversible LV akinesia not corresponding to a single coronary artery territory, 4) absence of coronary artery stenoses >50%. All pts were asked if a stressful event preceded TTC onset.

Results: A trigger event was identified in 77%. Emotional stress was reported by 117 (36%) and physical stress by 104 pts (31%). A combination of both stress modalities felt to be equal was reported by 29 pts (9%). In 74 pts (23%) no trigger could be identified. The four groups were compared by analysis of variance.

Age was similar in all groups. Physical stress was more frequent in males (57% vs 30%, $p = 0.005$) whereas emotional stress or no identifiable trigger were more prevalent in women. Pts with emotional stress as compared with physical, both or no stress more frequently complained about angina (94% vs 57% vs 59% vs 64%, $p < 0.0001$) and less frequently about dyspnea (3% vs 24% vs 34% vs 15%, $p < 0.0001$). There was a trend towards a longer prehospital delay with emotional than with physical stress (8.9 ± 7.4 vs 6.9 ± 7.3 hours, $p = 0.05$). Heart rate after symptom onset was lower with emotional than with physical stress (81 ± 18 vs 93 ± 26 /min, $p = 0.007$). The QTc interval was longer in emotional stress as compared to pts without a triggering event (513 ± 61 vs 486 ± 59 ms, $p = 0.03$). Other ECG parameters, cardiac markers, LV ejection fraction and complications in the clinical course were similar in all groups.

Since pulmonary disease often is the physical trigger for TTC, a pre-medication with betamimetics was more frequently seen in pts with physical stress (18%) or both stress modalities (31%) than in pts with emotional (2%) or no stress (0%), $p < 0.0001$. During the acute phase pts without a trigger more frequently required catecholamines (12% vs 0% vs 6% vs 5%, $p = 0.009$) or intraaortic balloon pumping (4% vs 0%, $p = 0.03$) than pts with stressful events.

Conclusion: Pts with emotional stress triggering TTC frequently complain about angina, have a longer prehospital delay and a lower heart rate. Due to pulmonary disease pts with physical or both stress forms more frequently have dyspnea and a pre-treatment with betamimetics which may play a pathophysiologic role in TTC. Pts without a trigger have a more severe clinical course.

P1539

Effects of hypoxic adaptation on the endothelial dysfunction in the ischemic cardiomyopathy patients

T Tatsiana Dubovik¹; LV Rachok¹

¹Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

THE PURPOSE of this research was to estimate the influence of normobaric intermittent hypoxia adaptation (NIHA) on the endothelium functional (EF) state in the ICMP patients.

Materials and Methods: We studied 50 ICMP patients (57.01 ± 1.38 years) with depressed left ventricle (LV) systolic function less than 35% and CHF class II-IV NYHA treated with the 10-days NIHA course against CHF drug management with no significant differences. EF state was assessed by endothelium-dependent flow-mediated vasodilation (FMD) as measured by using ultrasonography of the brachial artery with reactive hyperemia test. We also analysed the changes of the biochemical ETd markers levels, such as endothelin-1 (ET-1, pg/ml), tumor necrosis factor- α (TNF- α , ng/ml), homocysteine (HCY, μ mol/l), brain natriuretic peptide (BNP, pg/ml).

Results: The initial CHF severity was determined by depressed LV contractile function against maladaptive LV remodeling, multiple myocardial perfusion defects and the presence of ETd with the high level of the biochemical ETd and CHF markers. We marked the reduction of endothelium-dependent vasodilation. After the 10-days NIHA course we revealed significant changes in the EF state. The number of the patients with normal endothelium-dependent FMD increased from 28,57% to 60% ($p < 0,05$) and the number of vasoconstrictor reactions decreased from 29% to 6%. We noted the increase in the endothelium-dependent FMD from $4,09 \pm 1,49$ to $9,42 \pm 1,11$ ($p < 0,05$). The concentration of ET-1 after NIHA decreased from $2,04 \pm 0,23$ to $1,03 \pm 0,14$ ($p < 0,05$), TNF- α from $19,59 \pm 2,67$ to $10,43 \pm 3,28$ ($p < 0,05$), HCY – from $15,46 \pm 0,90$ to $11,77 \pm 0,73$ ($p < 0,05$). The EF state improvement reflected on the clinical CHF course. The BNP concentration decreased from $612,20 \pm 136,19$ to $399,79 \pm 139,16$ ($p < 0,05$).

Conclusion: The use of NIHA helps to improve the EF state and provides a more favorable course of the main pathological process in the ICMP patients with CHF thus allowed to assume a more adequate protection from early cardiovascular events.

Clinical outcome of peripartum cardiomyopathy-a study in a tertiary cardiac hospital

N Fatema¹; SF Ahmed¹; C Ahmed¹; A Habib¹; F Rahman¹; A Ahsan¹;

S Banerjee¹; A Siddique¹; H Hoque¹; N Akhter²

¹Bangabandhu Sheikh Mujib Medical University, Cardiology, Dhaka, Bangladesh;

²Bangabandhu Sheikh Mujib Medical University (BSMMU), Gynae and Obstetrics, Dhaka, Bangladesh

Background: Peripartum cardiomyopathy is an idiopathic serious heart failure of last month of pregnancy or the first 5 months of puerperium in absence of any determinable heart disease. Echocardiographic criteria was added with the definition later which include left ventricular ejection fraction < 0.45 or M-mode fractional shortening <30% (or both) and end-diastolic dimension > 2.7cm/m². The incidence is high in developing country than others. Patients deteriorate very rapid but there is also probability of spontaneous recovery. Risk factors include multiparity, advanced maternal age, multiple pregnancies, pre-eclampsia, chronic hypertension, smoking, alcoholism and malnutrition. Conventional heart failure therapies-diuretic, Selective Beta-blocker (BB), Angiotensin converting enzyme inhibitor (ACEI) or Angiotensin receptor blocker (ARB) and anticoagulant are the treatment of choice.

Purpose: To study the clinical profile, to analysis of pregnancy outcomes of the cardiomyopathy pregnant women, treatment protocol and follow up after treatment and prognosis.

Methods: 72 patients admitted with peripartum cardiomyopathy from July 2009 to June 2014 in a tertiary cardiac hospital of a developing country, were considered for this retrospective study by inclusion and exclusion criteria. They have treated with diuretic, BB, ACEI or ARB, vitamin B complex and anticoagulant who had thromboembolic manifestation. Patients were regularly followed up clinically and by electrocardiogram and colour doppler echocardiography.

Results: Primiparous are 28 (39%) of the total study population. 52 patients (72%) were clinically improved and 34 (48%) the left ventricular functional status returned to normal with the treatment. 12 cases (15%) developed persistent cardiomyopathy that is persistent left ventricular dysfunction beyond six months of presentation. 10 women (14%) presented with thromboembolic events and anticoagulant were prescribed for life long for secondary prevention. Maternal mortality was 8(13%). Among

all live births, 4 had intra uterine growth retardation and another 3 had died during the neonatal period.

Conclusion: The patients of peripartum cardiomyopathy were improved symptomatically and prognosis was good with the treatment of diuretic, selective BB, ACEI or ARB and vitamin B complex. Regular clinical follow up with echocardiography and monitoring of INR are advised if the patients on anticoagulant to reduce the morbidity and mortality. Further study is needed whether Vitamin B complex may has any role to improve the prognosis of peripartum cardiomyopathy.

Peripartum cardiomyopathy: case series and follow up, a single center experience

R Albannay¹; A Aysha Husain¹; W Alhayki¹; F Almoosa¹

¹Salmaniya Medical Complex, Cardiology Unit, Internal Medicine Department, Manama, Bahrain

Background and aim: Peripartum cardiomyopathy (PPCM) is a pregnancy related myocardial dysfunction characterized by the development of heart failure without underlying cause. It has been associated with considerable morbidity and mortality but full recovery is a possibility. Our aim is to study women admitted with PPCM to our hospital and follow their outcomes.

Methods: We prospectively collected demographic, clinical, echocardiographical and basic biochemical data for women admitted with PPCM for period of January 2010 till December 2015. PPCM was diagnosed if heart failure confined to time of last month of pregnancy and 5 months after delivery without defined cause. Follow up data for recovery of myocardium and future pregnancies were documented.

Results: We included 15 women with PPCM confirmed diagnosis. Mean age was 29 ± 6.6 year. 53% has pregnancy induced hypertension, 47% had pre-eclampsia and 53% were multigravida women. Breast-feeding was documented in 47% of women. Left ventricular ejection fraction was 28.7 ± 6.3 at time of diagnosis. There was no maternal mortality. B blockers and RAAS inhibitors are the main stay of treatment. 10 women showed complete recovery of their myocardial function, 3 of them had reconceived with no documented relapse of PPCM. 2 underwent dobutamine stress echo before re-conception.

Conclusion: PPCM is uncommon in our society. Recovery is anticipated with comprehensive anti-failure medications. Normal stress echocardiogram seems to be a favorable prognostic marker for future pregnancies.

Baseline data	Value
Age (mean ± SD)	29 ± 6.6
Hypertension diagnosed in pregnancy % (n)	53 (8)
Pre-eclampsia % (n)	47 (7)
Multi-gravida % (n)	53 (8)
Systolic blood pressure (mean ± SD)	140.4 ± 23.6
Diastolic blood pressure (mean ± SD)	91.8 ± 18.2
Heart rate (mean ± SD)	133.7 ± 19.4
QRS duration (mean ± SD)	77.1 ± 8.1
Left ventricular dimension in diastole (mean ± SD)	55.6 ± 5.8
Left ventricular dimension in systole (mean ± SD)	47.2 ± 7.9
Ejection fraction (mean ± SD)	28.7 ± 6.3
Hemoglobin (mean ± SD)	11.4 ± 1.9
Troponin (mean ± SD)	0.7 ± 2.1

Baseline data for 15 women with PPCM at diagnosis.

Medications used for treatment of PPCM

P1542

Comparative analysis of left ventricular systolic function in females with peripartum cardiomyopathy and idiopathic cardiomyopathy.

A Amam Chinyere Mbakwem¹; C E Amadi¹; E Mbey²; C Oyiriaru²

¹University of Lagos, Lagos, Nigeria; ²Lagos University Teaching Hospital, Lagos, Nigeria

Purpose: Peripartum cardiomyopathy, PPCM, has been defined as an idiopathic cardiomyopathy presenting with heart failure secondary to left ventricular (LV) systolic dysfunction towards the end of pregnancy or in the months following delivery. It is a diagnosis of exclusion when no other cause of heart failure is found. The LV may not be dilated but the ejection fraction is nearly always reduced below 45%. Recent observations from the USA suggests that the genetic basis of PPCM and idiopathic dilated cardiomyopathy, DCM, may be similar and that recovery and outcome of subsequent pregnancies may not be as bad as earlier observed.

We therefore decided to compare the ventricular function and some ECG parameters of the PPCM in our cohort and females with idiopathic dilated cardiomyopathy.

Methods: PPCM and female patients with DCM who presented in acutely decompensated heart failure evaluated. Demographic, clinical parameters were obtained and ECG and echocardiographic evaluation was carried out.

Results: There were 31 patients with PPCM and 17 females with IDCM. The PPCM patients were younger, 31.71 ± 6.16 Vs 48.58 ± 18.49, p 0.002. There was no difference in the BMI and NYHA class, p, 0.94 and 0.74 respectively. The heart rate, SBP and DBP were also similar, p, 0.23, 0.59 and 0.99. The PPCM patients had significantly lower ejection fraction than the IDCM patients, 25.70 ± 10.44 Vs 37.12 ± 9.10%, p = 0.002. The LVDD was lower in the PPCM with a trend, 6.38 ± 0.76 Vs 5.87 ± 0.95cm, p = 0.07 but the systolic dimensions and wall thickness were similar in both groups.

Conclusion: We conclude that there may be more severe LV systolic dysfunction in patients with PPCM than IDCM despite being younger and this would portend a worse outcome.

P1543

Dobutamine Stress echocardiography for predicting LV reverse-remodeling in idiopathic dilated cardiomyopathy

BS Byungsu Yoo¹; JY Kim¹; JW Son¹; JH Yoon¹; MC Cho²; HM Choi¹

¹Wonju College of Medicine, Yonsei University, Division of Cardiology, Department of Internal Medicine, Wonju, Korea Republic of; ²Chungbuk National University Hospital, Cheongju, Korea Republic of

Background: The identification of contractile reserve during pharmacologic stress echocardiography may be helpful for predicting contractility recovery in idiopathic dilated cardiomyopathy (DCM). The purpose of the present study was to assess for prediction of reversible LV systolic function in patients with idiopathic DCM.

Method: We prospectively included hospitalized patients with newly diagnosis of DCM from Mar. 2012 to May. 2014. We exclude patients with AF, LBBB, significant CAD, previous beta blocker treatment, high basal heart rate >100 bpm/min and uncontrolled hypertension. Thirty-three patients (were male, aged 54 ± 12 years) with DCM underwent baseline echocardiography and stress echocardiography. The dobutamine infusion was terminated at the maximal dose (40 γ·kg·min) or if the maximal heart rate was achieved. Changes of LVEF, E/e' and wall motion score index in response to dobutamine infusion (ΔLVEF-dobutamine) were measured. Cardiovascular magnetic resonance (CMR) was used to assess late gadolinium enhancement (LGE)-extent. LV reverse remodeling (RR) was defined as an increase of LV ejection-fraction ≥ 10 units combined with LV end-diastolic volume decrease ≥ 10% at follow-up echocardiography.

Results: Thirty-three patients (42 % male, aged 62 ± 14 years) with DCM were included. The majority of patients were in functional NYHA class II-III (76.3%). Baseline EF was 31 ± 5% by Teich method, 30 ± 3% by Simpson's method and 28 ± 10% by CMR. After dobutamine infusion, change of HR and EF was 26 ± 22 bpm/min and 5 ± 5%. In CMR, LGE was noted in 33 % of patients (6 of 18 patients). 18 patients were follow-up (mean 10 ± 4 months) and 3 patients were died. LV RR was 27.3 % of all patients (50% of 18 patients). In multivariate analysis of LVR, change of LVEF (>5%, 0.042) and LGE by CMR (0.026) was significant predictor of LVR.

Conclusion: Dobutamine Stress echocardiography and CMR was useful to predict LV reverse-remodeling in idiopathic dilated cardiomyopathy. Large number of study patient and further long-term data was needed.

P1544

The evolution of the phenotype in a family with a missense mutation of the Lamin A/C (LMNA) gene with an initially isolated cardiac involvement: a 17 years observation.

N Sanna¹; D Pasqualucci¹; M Corda¹; P Orru¹; G Giardina¹; S Cossa²;

G Matta²; F Muscas¹; M Maurizio Porcu¹

¹G. Brotzu Hospital, Department of Cardiology, Cagliari, Italy; ²G. Brotzu Hospital, Department of Imaging, Cagliari, Italy

Introduction: Lamins A and C are components of the nuclear envelope transcribed by the LMNA gene, encoded on chromosome 1q21.2–q21.3. The mutations of this gene may cause different phenotypic expressions. The long-term evolution of the phenotype in families with a prevalent cardiac involvement at the baseline evaluation is not yet completely defined.

Purpose: The aim of this observation is to describe the 17 years follow up of a family with a missense mutation in the exon 1 (c.178 C/G, p.Arg 60 Gly) of the LMNA gene, with a baseline isolated cardiac phenotype.

Methods and results: Full clinical and laboratory details are available from the 3rd generation (fig.1). Pts. III2, III3 and III6 showed an identical initial phenotype at the age of 37, 38 and 28, respectively, characterized by a dilated cardiomyopathy and A-V conduction defects. All of them underwent heart transplantation and pt. III2 died soon after from postoperative complications. Pt. III7 developed 3rd degree A-V block treated with a pacemaker, but did not show any systolic dysfunction and died from unknown cause at the age of 57. Several years after the first observation, pts. III3, III6 and III7 showed a progressive severe lipodystrophy with a dramatic subcutaneous fat reduction. Pts. III3 and III6 developed also a clinically relevant peripheral neuropathy at the age of 45 and 39, respectively. Pt. III3 died at the age of 50 from allograft vasculopathy and cachexia. Pts. IV2, IV4 and IV5, all with positive genotype, did not manifest any phenotypic expression at their first evaluation in the childhood. However, a reduction of subcutaneous fat was evident since they were twenties. Pts. IV4 and IV5 presented soon after a mild reduction of the EF. Second degree AV block Mobitz 2 was detected in pt. IV4, while the cardiac MRI of pt. IV5 at the age of 28 was consistent with several areas of intramyocardial delayed enhancement. Conclusion. This long-term observation shows an evolving complex phenotype in a family with heterozygous mutation for the LMNA gene and initially isolated cardiac expression. A strict evaluation of the individuals with a positive genotype allows to detect the age of onset, the characteristics and the evolution of the overlapping phenotypic expressions.

P1545 Surgical ventricular reconstruction in cases of ischemic dilative cardiomyopathy: outcome at 13 years in 61 patients

no funds

A Olaru¹; F Pirro¹; M Meli¹; D Trevisan¹; V Smorto¹; G Stefanelli¹

¹hesperia hospital, cardiology and cardiac surgery, modena, Italy

Objective: Aim of the study was to analyze the long term results (13 years) after left ventricular restoration (SVR) in cases of dilated ischemic cardiomyopathy.

Methods: Between March 2003 and September, 2014, 61 patients affected by ischemic dilated cardiomyopathy received a SVR at our unit, along with surgical myocardial revascularization. The STICH trial criteria have been used as indication to SVR. The patients underwent SVR using a typical DOR operation, or, more recently adopting a different surgical technique, with the aim of reshaping the left ventricle also at the dilated equatorial level. A reduction of left ventricular end systolic volume greater than 50% was obtained in all cases.

Results: Total early-in-hospital mortality was 3,4%, (0% in the last 31 cases). Reduction of LVED diameter, improvement of EF and NYHA class after surgery and at last follow-up were statistically significant ($p < 0,05$). Residual mitral incompetence. at discharge was absent in 34 patients (59,6%), moderate in 2 (3,5%), mild in the remaining. Late mortality was 44% (25 pts) (mean follow up time: 7,6 yrs), with a cardiac mortality of 20%. Freedom from rehospitalization for heart failure was 87% for the entire group of patients.

Conclusions: Patients affected by ischemic dilative cardiomyopathy, in our experience, have a satisfactory short and intermediate-time outcome after SVR, particularly if accomplished by using a surgical protocol addressing both the volume and the shape of the left ventricle.

Change of EsLvv and Ejection Fraction

Echo Findings (n = 61)	Total	Surg 1 (n = 30)	Surg 2 (n = 31)	P value
ESLvv (ml)	- 49,7%			
Preintervention	173,2 ± 48,1	173,4 ± 57,2	173,1 ± 40,5	n.s
Discharge	86,0 ± 31,0	109,0 ± 72,9	72,9 ± 18,1	n.s
Follow-up	121,9 ± 63,1	131,9 ± 31,1	117,2 ± 74,0	n.s
EF (%)				
Preintervention	29,1 ± 9,5	29,1 ± 10,0	29,1 ± 9,2	n.s
Discharge	37,4 ± 8,1	36,8 ± 8,2	38,1 ± 8,1	n.s
Follow-up	35,1 ± 10,8	34,1 ± 7,0	35,7 ± 12,6	n.s

Reduction of left ventricular end-systolic volume was 50% or more in all cases, with no difference in the two groups of patients

modified surgical technique

Phenotype of dilated cardiomyopathy with Lamine gene single nucleotide polymorphisms

T Tatiyana Kurushko¹; TG Vaikhanskaya¹; LN Siivitskaya²; NG Danilenko²; OG Davydenko²; AG Mrochek¹

¹Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus;

²National Academy of Science, Institute of Genetics and Cytology, National Academy of Sciences, Minsk, Belarus

The objective of this study was to assess genotype-phenotype correlations in patient with dilated cardiomyopathy (DCM) due single nucleotide polymorphisms (SNPs) in lamine (LMNA) gene.

Methods: We examined 129 patients with DCM (18 family) who had a primary manifestation of conduction or arrhythmic disturbances before dilated phenotype (aged $44,7 \pm 11,9$; 69% male, NYHA $2,6 \pm 0,9$; LVEF $25,9 \pm 9,92\%$). Exons (12) in the functional regions and the adjacent part of introns of the LMNA gene were amplified with polymerase chain reactions (PCR) and the PCR products were sequenced. Genetic testing, echocardiographic and electrocardiographic/24h-Holter ECG data including QTc dispersion, heart rate turbulence (HRT), microvolt T-wave alternans (mTWA), age, gender, NYHA, 6-MWT, serum BNP and CPK levels were analyzed.

Results: Disease-causing (according to Jpred3) missens-mutation in LMNA gene was found in 3 DCM patients: 190P, 520A, r528A. The largest three SNPs were identified numerically. The first is c.1908C>T (H566H, rs4641) which was located at exon 10 of LMNA gene. It was found in 25 (19,4%) DCM cases (TT and TC genotypes). According to NCBI, this SNP does not alter the primary sequence of the protein lamin as it determines synonymous codon for histidine at position 566. But positive correlation was revealed between rs4641 (C>T) SNP and non-sustained ventricular tachycardia (Spearman $k = 0,57$; $p = 0,009$, mTWA ($k = 0,61$; $p = 0,0007$). The second was c.1489-41C>T (rs553016) which located intron between 8 and 9 exons of LMNA gene. It was found in 18 (14%) DCM pts. The third was c.861C>T (A287A, rs538089) which was located at exon 5 of LMNA gene. It was found in 16 (12,4%) DCM cases. No association between last listed LMNA gene SNPs (rs553016, rs538089) and phenotype correlation was found in DCM patients. Such as T1908C selectively splicing transcripts decide lamin A/C relatively content, which may affect the relative content of mRNA and protein production, thus affecting the gene function. However the mechanism of T861C and T1489-41C in DCM is still unclear.

Conclusions: One-third of the DCM Belarus pts with primary manifestation of conduction or arrhythmic disturbances are carriers of the mutation\SNPs in LMNA gene. Thus, the SNPs of LMNA gene mentioned above are subject associated with DCM and require a detailed genetic analysis.

P1547

Does pulmonary hypertension impact clinical outcome or mortality in dilated cardiomyopathy patients?M Mohammad El Tahlawi¹; M Radwan²; M Abdelsamie¹; M Wafaie¹¹Zagazig University Hospitals, Cardiology, Zagazig, Egypt; ²National Heart Institute, Cardiology, Cairo, Egypt**Background:** Elevated pulmonary arterial pressure has been established as a predictor of mortality and morbidity in patients with heart failure.**Aim:** This study aims to evaluate the impact of pulmonary hypertension (PHT) on the short term outcome of patients with DCM.**Patients and methods:** This study included all patients who were admitted to our center's CCU with DCM between January 2014 and July 2014. Patients were divided into 2 groups: Group I: Dilated cardiomyopathy with PHT (PHT group). Group II: Dilated cardiomyopathy without PHT (Non PHT group). All patients were subjected to clinical examination, resting 12 lead ECG done on admission, trans thoracic echocardiography, and laboratory analysis including liver function and serum creatinine. Follow up: All patients were followed up for 6 months as regard physical examination, ECG, labs investigation (liver function, serum creatinine) and echocardiography. End Point: mortality.**Results:** The study involved 50 patients with DCM; 25 patients with PHT and 25 without PHT. There was a significant difference between both group regarding mortality. The incidence of mortality in DCM with PHT group was (44%) vs 12% in Non PHT group ($P < 0.05$). There was significant difference between both groups regarding clinical signs of heart failure especially basal crepitations and lower limb edema ($P < 0.05$). This difference disappeared 6 months later. There was also significant difference between both groups regarding ejection fraction and fraction shortening at the beginning of admission and six months later ($p < 0.05$). There was no significant difference between both groups regarding serum creatinine at the beginning of the admission. However, This difference became significant 6 months later ($p < 0.05$) with more renal impairment occurred more in PHT group.**Conclusion** The presence of PHT is associated with worse clinical scenario and outcome in patients with DCM. The incidence of cardiac death in DCM patients increased with the presence of PHT. DCM patients with PHT need close and more frequent follow up.

Figure (1) Percentage difference between group (I PHT) versus group (II Non PHT) in relation to mortality. $P < 0.05$

P1548

Comparative analysis of intracardiac hemodynamic parameters estimated by using echocardiography and rheocardiography in hypertrophic cardiomyopathy patients with heart failure with preserved ejectionV Y Vera Kaplunova¹; GA Shakaryants¹; MV Kozhevnikova¹; AI Malakhov¹; NV Khabarova¹; EV Privalova¹; YUN Belenkov¹¹I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation**Purpose:** to assess the association between parameters of intracardiac hemodynamic measured by echocardiography (ECO) and rheocardiography (RCG) in hypertrophic cardiomyopathy (HCM) patients with heart failure with preserved ejection fraction (HF/pEF).**Methods:** 40 patients (21 men, 19 women) with HF/pEF included in the study. 47,5% ($n = 19$) of patients had a progressive course (PC) of the disease and 52,5% ($n = 21$) - stable course (SC). Diastolic function was estimated by ECO and RCG. RCG is the electrical impedance method which was performed on RheoCardioMonitor system. The frequency of the probe current is 100 kHz with an amplitude of 3 mA. We evaluated intracardiac hemodynamic parameters by ECO (ejection fraction (EF), E/A, end-diastolic volume (EDV), end-diastolic size (EDS), end-systolic size (ESS),

end-systolic volume (ESV), left atrium (LA), systolic output (SO)) and specific rheocardiography parameters (ejection fraction - 1 (EF1), cardiac output (CO), cardiac index (CI), ejection velocity (EV), system vascular resistance (SVR), end-diastolic pressure in left ventricle (EDP), end-diastolic volume (EDV)).

Results: The largest value of E/A was observed in patients with PC ($E/A = 1.044$, $p = 0.074$). There was no difference of ejection fraction (EF) levels measured by ECO 60.52 ± 6.25 and RCG 60.07 ± 10.1 ($p < 0.074$). EF was correlated with EV ($r = 0.3904$; $p = 0.0128$). There were significant differences in EDP between SC (19.6 ± 1.99) and PC (12.06 ± 3.08) groups ($p = 0.032$). The positive correlation were revealed in EDP and PSO ($r = 0.4170$; $p = 0.0074$). The negative correlation was identified between EDP and EDS ($r = -0.40$; $p = 0.0025$), EDP and SO ($r = -0.52$; $p = 0.0034$).**Conclusion:** 1. Intracardiac hemodynamic parameters estimated by using ECO and RCG in HCM patients with HF/pEF were comparable. 2. It was found that the increase of EDP measured by RCG correlate with decrease of EDS and SO measured by ECO. 3. The most severe diastolic dysfunction revealed in progressive course of HCM. 4. The increase of EDP is more common for patients with progressive course of HCM.

P1549

Clinical risk factors of new onset atrial fibrillation in patient with hypertrophic cardiomyopathy.J-H Jung-Hyun Choi¹; BW Kim¹; JH Choi¹; TJ Hong¹¹Busan National University Hospital, Busan, Korea Republic of**Backgrounds:** Atrial fibrillation (AF) is common clinical manifestation of HCM patients. Prevalence of AF in HCM patients is known to approximately 20%. There are limited data available to predictive factor of AF in patient of HCM. The aim of this study is to investigate of clinical risk factor of AF in HCM patients.**Methods:** This study is retrospective observational study. We investigated the HCM patients who performed echocardiography and had sinus rhythm at presentation ($n = 40$) from 2011 to 2015 in a national university hospital. We divided into two groups according to newly developed AF during follow up period (AF group: $n = 40$) and maintained sinus rhythm (Sinus group: $n = 360$). AF was defined by electrocardiogram and Holter monitoring at index visit. We compared clinical characteristics and conventional echocardiographic parameter and atrial electromechanical delays. AEMD was defined as the time interval between the onset of ECG P wave and the initial (AEMDi) or peak a' wave (AEMDp) on the medial mitral annular tissue Doppler velocity curve (TDI) or PW Doppler at the mitral valve inflow level. Results Compared to sinus rhythm group, new onset AF group had more complained dyspnea. Compared to sinus group, new onset AF group has higher conventional echocardiographic parameter including RVSP (36.58 ± 14.89 vs 31.00 ± 7.99 , $p = 0.001$, LAVI (59.01 ± 24.09 vs 43.58 ± 16.37 , $p < 0.001$, Mitral E velocity (77.03 ± 27.78 vs 61.74 ± 17.56 , $p < 0.001$) and AEMDi (72.07 ± 15.90 vs 63.08 ± 15.43 , $p = 0.004$), AEMDp (152.41 ± 27.59 vs 141.98 ± 15.43 , $p = 0.022$) by PW Doppler. After using multivariate logistic regression, we found that LAVI (OR=1.028 [1.006-1.051], $p = 0.012$), AEMDi by PW Doppler (1.029 [1.000-1.059], $p = 0.049$) are independent predictive factors of new onset AF in HCM patients. Conclusion This observational study shows AEMDi by PW Doppler may have an additional predictive value to LAVI of new onset AF in HCM patients

P1550

Effects of alcohol septal ablation on markers of inflammation and signal peptides in patients with obstructive hypertrophic cardiomyopathyF Pelliccia¹; C Cianfrocca²; L Gatta³; V Pasceri²; A Auriti²; C Pristipino²; G M C Giuseppe M C Rosano³¹Umberto I Polyclinic of Rome, Rome, Italy; ²San Filippo Neri Hospital, Rome, Italy;³San Raffaele Pisana Hospital IRCCS, Rome, Italy**Introduction:** Alcohol septal ablation (ASA) has become a diffuse therapeutic approach in hypertrophic cardiomyopathy (HC) leading to reduced obstruction, relief of symptoms, and improvement in global LV function. It remains unknown, however, if ASA exerts favorable effects on markers of inflammation and signal peptides. Accordingly, we prospectively assessed whether changes in biochemical indexes occur after ASA in HC.**Methods:** We studied 10 patients (6 women, 66 ± 13 years) with obstructive HC who underwent ASA. Before ASA and 6 months later, erythrocyte sedimentation rate (ESR), high-sensitivity C-reactive protein (hsCRP), nuclear factor-kappa B (NF-kB), interleukin (IL)-6, tumor necrosis factor-alpha (TNF-alpha), and the glycoprotein carbohydrate antigen 125 (CA125) were evaluated in all patients. Measurements were done according to standard techniques. NFkB was quantified by a sensitive multi-well colorimetric assay for active NF-kB.**Results:** ASA was successful in all patients, with NYHA functional class decreasing from 3.5 ± 1.1 to 1.6 ± 1.0 and LV outflow tract gradient reducing from 101 ± 45 to 18 ± 12 mm Hg. Procedural complications included only the need of permanent pace-maker in 3 patients. Over follow-up, no death occurred and obstruction recurred in 1 patient who underwent myectomy. Hematologic evaluation at 6-month follow-up did not show any significant change in ESR (from 15 ± 3 to 12 ± 5 mm/h,

$p < 0.05$), hsCRP (from 3.2 ± 2.1 to 2.9 ± 2.0 mg/l, $p < 0.05$), and IL-6 from 4.2 ± 3.1 to 4.0 ± 2.7 pg/ml, $p < 0.05$). Conversely, there was evidence of significant decreases in NF- κ B (from 10.5 ± 6.5 to 4.1 ± 3.9 ng/ μ g cell protein, $p < 0.05$), TNF (from 3.5 ± 2.9 to 1.1 ± 1.9 pg/ml, $p < 0.05$), and CA125 (from 13.4 ± 9.8 to 7.9 ± 8.9 U/ml, $p < 0.05$).

Conclusions: Signal peptides, but not markers of inflammation, decrease significantly after ASA in patients with obstructive HC. These findings suggest that symptomatic and functional improvement after the procedure can be ascribed, at least partly, to favourable changes that occur in some biochemical indexes.

P1551

Hypertrophic cardiomyopathy: an experience in southeastern Sweden

A Kissopoulou¹; C Gunnarsson²

¹Ryhov County Hospital, Department of Cardiology, Jönköping, Sweden;

²Linköping University Hospital, Department of Cardiology/Cardiogenetics, Linköping, Sweden

Background: Hypertrophic cardiomyopathy (HCM) is the most common cause of sudden unexpected death in young athletes and the second most common inherited cardiovascular disease marked by genetic and phenotypic heterogeneity.

Purpose: The aim of this study is to identify the genetic and phenotypic aspects of the disease in southeastern Swedish population.

Methods: In this retrospective descriptive study 50 unrelated adult patients with the clinical diagnosis of HCM according to the diagnostic criteria of international guidelines followed between 2010 and 2015 at a County Hospital in the southeast region in Sweden were included, using a checklist of parameters. Next generation sequencing was used to analyze the 16 genes of the Cardiomyopathy Gene panel.

Results: The mean age of the patients at diagnosis was 47 ± 16.8 . Most patients were male (64%). 64% had symptoms according to NYHA II class. 4% had as initial presentation sudden cardiac death. Arrhythmias, such as Atrial Fibrillation was identified at 32% of patients and ventricular Tachycardia at 34% during Holter monitoring. 38% had a family history of sudden cardiac death (SCD). At ECHO-graphic findings 14% had a maximal wall thickness-MLWT > 30 mm, 32% had Left Ventricular Outflow Tract Velocities- LVOT > 4 m/s at rest, 16% had EF $< 50\%$, 40% had systolic anterior motion-SAM. Regarding their treatment, 12% had undergone an alcohol septal ablation, 20% had a pacemaker and 24% had an Implantable Cardioverter Defibrillator (ICD). Of the 50 HCM patients 35, (70%) had undergone genetic testing. 2 denied to genetic testing. 23% had MYBPC3 genetic variants -1 of unknown significance VUS, 14% had MYH7 pathogenic genetic variants, and 34% had no detected pathogenic variants. 17% of patients are still waiting for the result. In one patient presented with sudden cardiac death (SCD) a disease-causing genetic variant in TNNT2 gene was identified. Those with MYH7 genetic variants were younger and there were 2 individuals with pathogenic MYH7 variants and SCD. 34% of their first degree relatives were offered a genetic testing whereas 58% of their first degree relatives were regularly followed-up with ECHO, Holter, and exercise test according to guidelines. Conclusion This study represents one of the first comprehensive attempts to characterize the genotypes and phenotypes related to HCM in southeastern Sweden. Furthermore this project highlights that HCM patients and their family members can successfully be diagnosed, treated, risk stratified and provided with genetic testing and counselling at a County Hospital in Sweden.

Carotid involvement in patients with non-ischemic heart failure

A Stan¹; I V Sirbu²; P Kelemen¹; S Pogacean¹

¹County Emergency Hospital of Targu Mures, Department of Internal Medicine II, Targu Mures, Romania; ²Institute of Cardiovascular Diseases of Targu Mures, Targu Mures, Romania

Background: Carotid involvement represents an asymptomatic condition which can lead to life-threatening complications including stroke and cardiac ischemia, when the stenosis becomes significant. Heart failure patients have already an elevated morbidity and mortality risk, therefore carotid ultrasound screening can be a useful tool to detect and manage existing alterations.

Purpose: To identify carotid changes in patients with established non-ischemic heart failure.

Methods: We included in our study 30 patients (12 male, 18 female), mean age 57.96 years, previously diagnosed with non-ischemic heart failure and asymptomatic from carotid standpoint (no stroke or transient ischemic attack in the last 6 months), admitted to our Internal Medicine Department. We performed carotid ultrasound, measuring intima-media wall thickness and assessing the degree of stenosis. We considered incipient changes for intima-media thickness > 1 mm and significant stenosis for values $> 60\%$.

Results: The majority of the patients (50%) had incipient changes, followed by non-significant stenosis (33,33%), no changes (10%) and significant stenosis

(6,66%). We could observe this pattern in the female (61,11%) and diastolic dysfunction (69,23%) subgroups. In our other subgroups we observed a different pattern, with the predominance of non-significant stenosis: men (41,66%), systolic dysfunction (44,44%) and combined systolic and diastolic dysfunction (50%).

Conclusions: Heart failure patients are likely to have some form of carotid involvement. We often focus on the coronary changes in these patients and overlook the asymptomatic carotid counterpart. Even if the alterations are only subtle, they can progress in time and lead to debilitating or fatal consequences if they go unnoticed. Carotid ultrasound screening is a non-invasive and cost-effective way to prevent these horrendous complications from happening.

P1553

Influence of diabetes mellitus and renal failure in the short-term mortality in patients hospitalized for heart failure.

JR Beramendi Calero¹; I Irene Rilo Miranda¹; S Garcia Gutierrez²; A Anton Ladislao²; L Quintas Ovejero³; C Goena Vives³; I Villanueva Benito¹; I Solla Ruiz¹; A Izaguirre Yarza¹; F De La Cuesta Arzamendi¹

¹Hospital Donostia, San Sebastian, Spain; ²Hospital Galdakao-Usansolo, Bilbao, Spain; ³Hospital Comarcal de Mendara, Cardiology, Mendara, Spain

Purpose: Assess whether the presence of diabetes mellitus, renal failure ($Cr > 1.5$ mg / dl) or both comorbidities increase mortality at 3 months in patients hospitalized for heart failure.

Methods: Observational prospective cohort study including a total of 1824 patients presenting to emergency departments in acute decompensated heart failure (acute decompensated heart failure and chronic heart failure). Sociodemographic features, cardiovascular risk factors, comorbidities, history of heart disease (ischemic cardiomyopathy, valvular, arrhythmia) and analytical and echocardiographic data were collected during emergency episode and hospital admission. Outcome variables were considered short-term mortality and readmissions in 3 months. Multivariate regression model was performed on the dependent variable mortality at three months after being hospitalized for the index episode.

Results: Of 609 diabetic patients died 71 (11.66%) and of 1215 non diabetic patients 154 died (12.67%), $p = 0.53$. Of the 366 patients with renal insufficiency died 81 (22.13%) and of 1403 patients without kidney failure died 140 (9.98%), $p < 0.0001$. Of the 139 patients with diabetes and kidney failure died 27 (19, 42%) while of the 1630 without both comorbidities died 194 (11.90%), $p = 0.01$ However, when performing the multivariate analysis of mortality at 3 months diabetes presents OR (CI 95%) 0.646 (0.370 to 1.129) $p = 0.12$ sample OR Kidney failure (CI 95%) 3.115 (1.846 to 5.256) $p < 0.0001$ and diabetes and kidney failure associated OR (CI 95%) 1,746 (0.783 to 3.891) $p = 0.17$

Conclusions: 1. In our study, kidney failure has shown to be an independent factor of increased short-term mortality in patients hospitalized for heart failure. 2. Diabetes mellitus, in our study, is not associated with increased mortality to 3 months in this patient group

P1554

Left ventricular diastolic function in hypertensive patients with heart failure and preserved ejection fraction combined with rheumatoid arthritis

L Livia Popescu¹; H Balan¹

¹University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

Background: In a world that is aging and in which hypertension have an increasing prevalence, the proportion of patients with heart failure with preserved ejection fraction (HFpEF) is growing. HFpEF is an important cause of disability and hospitalization. There is strong evidence that rheumatoid arthritis (RA) affects the heart muscle and contributes to heart insufficiency. Left ventricular diastolic function is first impaired in both clinical entities. It would be useful to know the contribution of hypertension and RA in left ventricular diastolic function impairment and which is worse.

Purpose: The aim of our study was to assess the left ventricular diastolic function in patients with hypertension and hypertension combined with mild/moderate RA, both with preserved ejection fraction ($FE \geq 45\%$), admitted in an Internal Medicine Department.

Methods: The study included 23 patients with hypertension, with mean age 54 ± 10 years, and 19 patients with hypertension and RA, mean age 53 ± 9 years. All patients were women and had preserved ejection fraction ($FE \geq 45\%$). Patients with diabetes, significant heart valve dysfunctions, ischemic heart disease and any unstable systemic disease were excluded. The main duration of hypertension was 8.5 ± 5 years, and the mean duration of RA was 5.6 ± 4 years. Transthoracic echocardiography was performed in all patients, including pulse Doppler transmitral flow. Diastolic left ventricular function was assessed by the following Doppler parameters: early (E) and late (A) peak velocities, E/A ratio, isovolumic relaxation time (IVRT), and deceleration time of E velocity (DT). Results There were significant differences between patients with hypertension and those with hypertension and RA. E/A ratio was 1.2 ± 0.4 in hypertensive versus 0.8 ± 0.2 in hypertensives with RA ($p < 0.01$). IVRT was 93.2 ± 20.1 ms in hypertensive patients versus 109.6 ± 25.8 ms in patients

with hypertension combined with RA ($p < 0.01$). As regarding DT, hypertensives had 190 ± 68.3 ms and patients with hypertension and RA 262.5 ± 110.5 ms ($p < 0.01$). The remaining left ventricular parameters and systolic function did not differ between the two groups.

Conclusions: Hypertensive patients with heart failure with preserved ejection fraction combined with rheumatoid arthritis had a more severe impairment of left ventricular diastolic function than patients only hypertensive. It seems that RA worsens the prognosis of patients and may require additional therapeutic strategies.

P1555

Incidence and predictors of long-term of acute kidney injury after transcatheter aortic valve implantation

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; JM Garcia-Pinilla³; AJ Dominguez-Franco³; MF Jimenez-Navarro³; JH Alonso-Briaies³; JJ Gomez-Doblas³; JM Hernandez-Garcia³; E De Teresa-Galvan³

Acute Kidney Injury (AKI) after cardiac surgery is associated with increased mortality, but very few data exist on the occurrence of AKI associated with Transcatheter Aortic Valve Implantation (TAVI). The aim of this study was to determine the incidence and prognosis of AKI after percutaneous treatment in patients with aortic stenosis.

Methods: Between April-2008 and December 2015, 492 patients with severe aortic stenosis were treated with the CoreValve prosthesis. The AKI was defined according to the Valve Academic Research Consortium criteria, as the absolute increase in serum creatinine ≥ 0.3 mg/dl at 72 hours after percutaneous procedure. We excluded patients died during procedure.

Results: the incidence of AKI was 16.5% and none required renal replacement therapy. After implantation there was a slight improvement in renal function, baseline serum creatinine decreased from 1.27 ± 0.4 mg/dl to 1.17 ± 0.4 mg/dl, $p = 0.001$. In patients with AKI, the mortality at 30 days was 69.2% compared to 15.1% of patients without AKI, OR=12.7 (95% CI 3.85-42.4), $p = 0.001$ and late mortality after a mean of 34.3 ± 23 months was 20% in those patients with AKI compared to 14% without AKI, $p = 0.098$. In the multivariable analysis AKI was an independent predictor of cumulative total mortality HR 1.93 (95% CI 1.23-3.01), $p = 0.006$.

Conclusions: the incidence of AKI was associated with increase early mortality and also was a predictor of worse outcomes in the long-term follow-up

P1556

The length of hospital stay in heart failure patients - how to know when to let go

S Petrovic-Nagorni¹; S Ciric-Zdravkovic¹; D Dragana Stanojevic¹

¹Clinic for Cardiovascular Diseases, Nis, Serbia

Background: Substantial decreases in heart failure (HF) hospital stay rates over time are consistent with reports from most European countries and North America. Prolonged hospitalization carries a risk for HF patients such as hospital-acquired infections, deep vein thrombosis, pulmonary embolism, depression, deconditioning of the body and for many other social, economic and medical problems.

Purpose: The aim of our study was to assess the average length of hospital stay in patients with acutely decompensated HF and the factors associated with the increased length of hospital stay

Results: During 3 months we included in our study 201 consecutive patients with acute HF; average age was 71.55 ± 10.35 years and 60.7% were male. The average duration of HF was 1.69 ± 1.13 years. The average length of hospital stay was 2.43 ± 1.89 days. In 29.9% of patients, the cause of HF was coronary artery disease, in 27.9% dilated cardiomyopathy, in 23.9% arterial hypertension and in 18.4% it was a valvular disease. At admission, 55 patients (27.4%) had New York Heart Association (NYHA) class II, NYHA class III had 108 patients (53.7%) while 38 patients (18.9%) had NYHA class IV. Hospital duration was not significantly longer in patients with higher NYHA class. Patients with NYHA class II were hospitalized 4.62 ± 2.1 days, those with NYHA class III: 4.99 ± 2.2 days and with NYHA IV: 4.53 ± 2.25 days. Also left ventricle ejection fraction (LVEF: $37.4 \pm 13.7\%$) did not correlate with the length of hospital stay. Patients with HF and preserved ejection fraction had longer hospital stay compared to those with reduced ejection fraction, but not significantly (5.15 ± 2.31 vs. 4.6 ± 2.08 days). A number of comorbidities, however, was associated with the average duration of hospitalization ($p = 0.012$). Patients without co-morbidities (1.5%) had the shortest hospital stay (2 days) while those with 6 comorbidities (1.5%) were 6.67 ± 2.0 days in the hospital.

Conclusions: The average stay in hospital in our HF patients was not associated with the NYHA class at the admission or with LVEF. However, the presence of comorbidities increased the length of hospital stay. This could be the consequence of lack of the interdisciplinary corroboration between health professionals with different medical specialties. The awareness of the presence of co-morbidities and the need

for multidisciplinary approach should take the high ground regarding the fragile heart failure patients.

P1557

Effects of neuropeptide Y on coronary artery vasomotor tone

G M C Giuseppe M C Rosano¹; D Tousoulis²; E Mcfadden³; C Vitale¹; JC Kaski³
¹San Raffaele Pisana Hospital IRCCS, Rome, Italy; ²Hippokraton General Hospital, Athens, Greece; ³St Georges Medical School, London, United Kingdom

Background: Patients with microvascular angina usually have a reduced coronary blood flow reserve. Neuropeptide Y (NPY) is a potent endogenous vasoconstrictor involved in modulation of coronary vasomotor tone and may play a role in microvascular angina. Methods. We compared the effects of NPY ($0.2-1.0$ pmol/kg, intracoronary) on the vasomotor response of proximal and distal segments of the coronary arteries in 7 patients with microvascular angina and left ventricular dysfunction (MALVD), 9 with chronic stable angina, and 9 control individuals. The coronary response to the administration of ergonovine was also assessed in 9 other patients with microvascular angina and normal LV function. Computerized coronary artery diameter measurements were carried out before (baseline) and after the administration of the vasoactive agents.

Results: Mean baseline coronary lumen diameters were similar in control, MALVD, and coronary artery disease patients. NPY constricted proximal coronary segments by $8 \pm 2\%$, $5 \pm 2\%$ and $6 \pm 3\%$ and distal segments by $14 \pm 2\%$, $11 \pm 2\%$ and $10 \pm 2\%$ in control, MALD, and coronary artery disease patients, respectively ($p = NS$ between groups). In patients with microvascular angina, ergonovine constricted proximal coronary segments by $7 \pm 1.5\%$ and distal segments by $12.5 \pm 3\%$ ($p = NS$ vs. NPY). During NPY administration four MALVD patients developed chest pain, ST segment depression, and a marked lengthening of the contrast medium run off, in the absence of epicardial coronary artery spasm. Control individuals and coronary artery disease patients did not experience chest pain, ST segment shifts, or lengthening of the run off during NPY administration. Ergonovine administration caused chest pain and lengthening of the contrast run-off, in the absence of epicardial coronary artery spasm, in one patient with microvascular angina and normal LV function.

Conclusions: Exogenous NPY causes mild epicardial coronary artery constriction which is similar in patients with non-cardiac chest pain, MALVD and coronary artery disease. Myocardial ischemia and marked lengthening of the contrast run off in response to NPY occurred in MALVD patients but not in control or coronary artery disease patients. An abnormal constrictor response to NPY at the microcirculation level could be the mechanism underlying the ischemic manifestations observed in patients with microvascular angina with LV dysfunction.

P1558

Acute kidney injury is associated with cardiohepatic syndrome in patients with decompensated heart failure

A Soloveva¹; S Villevalde¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Liver and kidney dysfunction is frequently encountered in heart failure and related to worse prognosis. Over the last several years interdependent feedback mechanisms involving the heart, kidney and liver have been discussed. The aim of the study was to assess the prevalence of acute kidney injury (AKI) and abnormal liver function tests (LFTs) and their interrelations in acute decompensated heart failure (ADHF).

Methods: In 322 patients with ADHF (190 male, 69.5 ± 10.7 years ($M \pm SD$), arterial hypertension 87%, myocardial infarction 56.5%, atrial fibrillation 65.5%, diabetes mellitus 41.6%, known chronic kidney disease 39.1%, chronic anemia 29.2%, ejection fraction (EF) $37.6 \pm 12.6\%$, EF $<35\%$ 39.1%) alanine transaminase (ALT), aspartate transaminase (AST), direct and total bilirubin (DB and TB), alkaline phosphatase (AP), gamma-glutamyl transpeptidase (GGT) and international normalized ratio (INR) were measured on admission. LFTs were considered abnormal when levels exceeded local upper normal limit. Patients on warfarin were excluded from INR analysis. AKI was diagnosed based on KDIGO 2012 Guidelines. Mann-Whitney test and multivariate logistic regression analysis were performed, $p < 0.05$ was considered statistically significant.

Results: Abnormal LFTs occurred in 274 (85.1%) patients. Increase of transaminases were detected in 68 (21.1%) patients (alone ALT/ alone AST/ both TA in 35.3, 26.5, 38.2% respectively), DB and/or TB in 264 (82%) patients (alone DB/ alone TB/ DB and TB - in 28, 0.8, 71.2% respectively), AP in 90 (27.9%) and GGT in 102 (31.7%) patients. Community-acquired AKI (CA-AKI) was diagnosed in 60 (18.6%) patients. Patients with versus without CA-AKI had higher levels of ALT (60 ± 88 vs 29 ± 26 U/L, $p < 0.05$), AST (52 ± 45 vs 31 ± 16 U/L, $p < 0.001$), TB (29 ± 13 vs 25 ± 15 μ mol/L, $p < 0.01$), DB (12 ± 7 vs 9 ± 7 μ mol/L, $p < 0.001$), GGT (157 ± 117 vs 102 ± 68 U/L, $p < 0.001$), AP (124 ± 74 vs 112 ± 88 U/L, $p < 0.05$), INR (1.49 ± 0.42 vs 1.29 ± 0.23 , $p < 0.01$). Patients with vs without AKI had higher prevalence of increase of ALT (30 vs 12.3%, $p < 0.001$), AST (33.3 vs 9.2%, $p < 0.001$), TB (73.3 vs 56.2%, $p < 0.05$) and INR (60.8% vs 43.8%, $p < 0.05$). AKI was predictor for increase of ALT

(odds ratio (OR) 3.1, 95% confidence interval (CI) 1.6-5.9), AST (OR 4.9, CI 2.5-9.7), TB (OR 2.1, CI 1.2-4.0) and INR (OR 2.0, CI 1.0-3.9).

Conclusions: Abnormal LFTs occurred in 85.1%, CA-AKI - in 18.6% of patients admitted with ADHF. Patients with versus without AKI had higher prevalence of abnormal LFTs. In patients with ADHF increase of transaminases, total bilirubin and INR can directly contribute to AKI and vice versa.

P1559

Predictors of late mortality after transcatheter aortic valve implantation in patients with severe aortic stenosis with the corevalve prosthesis

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; A Ruiz-Salas³; AJ Dominguez-Franco³; JM Garcia-Pinilla³; JJ Gomez-Doblas³; MF Jimenez-Navarro³; JM Hernandez-Garcia³; E De Teresa-Galvan³
¹Department of Cardiology, Malaga, Spain; ²Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background: Transcatheter Aortic Valve Implantation (TAVI) has become an alternative to surgical treatment in patients with severe aortic stenosis and high surgical risk, however, is limited about long-term outcomes. The purpose of the present study was to analyze the survival and the factors predicting mortality after TAVI with the CoreValve prosthesis.

Methods: From April 2008 to December 2015, the CoreValve prosthesis was implanted in 500 patients with symptomatic severe aortic stenosis with deemed high risk.

Results: The mean age and the logistic EuroSCORE were 79.1 ± 7 years and $17.4 \pm 11\%$, respectively. The implantation success rate was 99.8%. In-hospital mortality was 3.6%. The late mortality (beyond 30 days) was 19.2%. Survival at 1, 2, 3, 4, 5 and 6- years were 89.7%, 84.7%, 80.5%, 72.6, 63.02% and 40.76 % respectively, after a mean follow-up of 30.5 ± 20 months. The predictors of cumulative mortality were: Charlson index [HR 1.19 (95% CI 1.05-1.34), $p = 0.006$], coronary artery disease [HR 1.97 (95% CI 1.15-3.36), $p = 0.012$], extracardiac arteriopathy [HR 1.96 (95% CI 1.07-3.59), $p = 0.029$] and need of pacemaker after TAVI [HR 1.95 (95% CI 1.132-3.36), $p = 0.016$] and protective factors were a preserved left ventricular ejection fraction [HR 0.278 (95% CI 0.109-0.717) $p = 0.008$]

Conclusions: Survival during follow-up depends on the associated comorbidities and the complications of procedure

P1560

Total bilirubin increase is associated with congestion and hypoperfusion in acute decompensated heart failure

A Anzhela Soloveva¹; S Villevalde¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Elevated total bilirubin (TB) is frequently reported in patients with heart failure and associated with worse prognosis. It is presumed that TB increase is related with predominantly right-heart dysfunction and congestion. We aimed to characterize TB increase in patients with acute decompensated heart failure (ADHF), as it is commonly encountered yet poorly defined.

Methods: In 322 patients with ADHF (190 male, 69.5 ± 10.7 years ($M \pm SD$), arterial hypertension 87%, myocardial infarction 56.5%, atrial fibrillation 65.5%, diabetes mellitus 41.6%, known chronic kidney disease 39.1%, chronic anaemia 29.2%, ejection fraction (EF) $37.6 \pm 12.6\%$, EF $< 35\%$ 39.1%) TB was measured on admission. TB increase was considered when serum level exceeded $21 \mu\text{mol/l}$ (local upper normal limit). Mann-Whitney test and multivariate logistic regression analysis were performed. $P < 0.05$ was considered statistically significant.

Results: Increase of TB occurred in 232 (72%) patients. Mean value of TB was $26.3 \pm 14.5 \mu\text{mol/l}$. Patients with versus without TB increase had higher levels of NT-proBNP (9510 ± 8046 vs 6102 ± 5607 pg/ml, $p < 0.01$), higher right ventricular diameter (36 ± 7 vs 32 ± 7 mm, $p < 0.001$), left ventricular end-diastolic volume (LV EDV) (59 ± 9 vs 55 ± 8 mm, $p < 0.001$), pulmonary artery pressure (47 ± 18 vs 59 ± 18 mm Hg, $p < 0.001$), heart rate (103 ± 29 vs 97 ± 29 , $p < 0.05$), lower LV ejection fraction (36 ± 13 vs $40 \pm 11\%$, $p < 0.01$), systolic blood pressure (134 ± 19 vs 142 ± 17 mm Hg, $p < 0.001$) and pulse pressure (52 ± 16 vs 59 ± 13 mm Hg, $p < 0.001$), higher prevalence of severe mitral regurgitation (47 vs 36% , $p < 0.05$) and tricuspid regurgitation (72 vs 21% , $p < 0.001$). TB increase was associated with signs of right-heart dysfunction/ congestion: jugular venous distension (44 vs 35% , $p < 0.05$), dilated inferior vena cava (77 vs 49% , $p < 0.001$) and portal vein (49 vs 26% , $p < 0.05$), echo-hydropericardium (30 vs 17% , $p < 0.01$), hydrothorax (48 vs 32% , $p < 0.01$), ascites (51 vs 21% , $p < 0.001$), hepatomegaly (79 vs 58% , $p < 0.001$) and with signs of left-heart dysfunction/ hypoperfusion - EF $< 35\%$ (50 vs 24% , $p < 0.001$) and SBP < 110 mm Hg on admission (14 vs 2% , $p < 0.001$).

Conclusions: TB increase occurred in 72% of patients with ADHF. The TB increase was associated with signs of right- and left-heart dysfunction.

P1561

We can predict the improvement of cheyne-stokes respiration with central sleep apnea in hospitalized heart failure patients

Y Nishihata¹; Y Takata²; A Yamashina²; N Komiya¹

¹St. Luke's International Hospital, Department of Cardiology, Tokyo, Japan; ²Tokyo Medical University, Tokyo, Japan

Purpose: Cheyne-Stokes respiration with central sleep apnea (CSR-CSA) has been recognized as a prognostic factor in heart failure (HF) patients. Some studies reported that an optimal medical treatment (OMT) for HF including β -blockers suppressed CSR-CSA and also those treatments bring improvement of left ventricular (LV) ejection fraction (EF). However, we often find residual CSR-CSA despite the OMT. We conducted this study to evaluate the predictors for the improvement of CSR-CSA in hospitalized patients due to acute HF.

Methods: We studied hospitalized patients due to acute HF, and enrolled 25 HF patients with CSR-CSA (apnea-hypopnea index [AHI] ≥ 15 /h and central apnea index [CAI] ≥ 5 /h) evaluated by a fully-attended polysomnography just before discharge. After 3 months of the OMT, the sleep study, the echocardiography and blood test were performed again for all patients.

Results: Patient's characteristics at discharge were as listed: mean age, 62 years old; body mass index (BMI), 26.5; brain natriuretic peptide, 364 pg/ml; mean LV end-diastolic dimension, 62 mm; mean LVEF, 31%. On the whole, the OMT decreased AHI (46.6 ± 18.3 /h to 34.8 ± 6.9 /h, $p = 0.05$), CAI (16.3 ± 13.1 /h to 7.8 ± 13.1 /h, $p < 0.05$), and also obstructive apnea index (13.2 ± 15.8 /h to 7.9 ± 7.5 /h, $p < 0.05$). In 17 patients, CSR-CSA vanished accompanied by significant improvement of plasma BNP levels and LVEF after 3 months. By univariate analyses, BMI and relative wall thickness (RWT) at discharge were related to the improvement of CSR-CSA, but plasma BNP level, LVEF, LV mass index, severity of sleep apnea, and dose of β -blockers at discharge were not related to the improvement of CSR-CSA. Multivariate analysis revealed that BMI (odds ratio [OR], 1.68; 95% confidence interval [CI], 1.04 to 3.59; $p < 0.05$) and RWT (OR, 1.35; 95%CI, 1.08 to 2.15; $p < 0.01$) were independent determinants of the improvement of CSR-CSA accompanied by improvement of LVEF.

Conclusion: In hospitalized HF patients, greater BMI and RWT were the clinical predictors for the improvement of CSR-CSA accompanied by improvement of LVEF.

Determinants for the improvement of CSR-CSA (univariate and multivariate analyses)

	univariate analyses			multivariate analysis		
	OR	95% CI	p value	OR	95% CI	p value
age, yr	0.93	0.84 - 1.00	0.05			
BMI, kg/m ²	1.54	1.12 - 2.43	< 0.01	1.68	1.04 - 3.59	< 0.05
BNP, per 100 pg/ml	0.75	0.51 - 1.00	0.053

Echocardiographic variations in pulmonary pressure, vascular resistances and biventricular hemodynamics during different phases of Cheyne-Stokes respiration in heart failure patients

A Alberto Giannoni¹; V Raglianti¹; E Pisanis¹; C Taddei¹; A Aimò²; C Borrelli²; A Valleggi¹; G Vergaro¹; C Passino²; M Emdin²

¹G. Monasterio Foundation, Pisa, Italy; ²High School Sant'Anna, Pisa, Italy

Background and aim: Cheyne-Stokes respiration (CSR) frequently occurs in patients with heart failure (HF), where not only has it proarrhythmic effects, but it also fosters negative hemodynamic consequences. We aim to study the echocardiographic changes associated with ventilatory instability in a group of HF patients with 24-hour CSR.

Methods: 7 HF patients (age 69 ± 11 years, left ventricular ejection fraction $23.5 \pm 6.5\%$) underwent 24-hour cardiorespiratory screening for CSR and simultaneous echocardiographic and respiratory monitoring, via inductance plethysmography.

Results: All patients had 24-hour CSR (diurnal apnea-ipopnea index AHI 28 ± 16 , nocturnal AHI 33 ± 10 events/hour). During CSR we found an increase in both systolic pulmonary artery pressure (sPAP) from hyperventilation to apnea ($H 39.3 \pm 11.1$ versus $A 45.7 \pm 14.9$ mmHg, $p = 0.018$). The same was found for pulmonary vascular resistances (PVR: $H 3.7 \pm 1.8$ versus $A 4.5 \pm 2.2$ wood units, $p = 0.046$). The increase in sPAP and PVR, was even higher comparing mid-hyperventilation with end-apnea (sPAP: 38.7 ± 11.8 versus 47.5 ± 15.3 mmHg, $p = 0.017$; RVP:

3.6 ± 1.7 versus 4.7 ± 2.3 wood units, $p=0.028$), as predictable from O_2/CO_2 and chemoreflex kinetics. This was paralleled by a slight reduction in tricuspid annular plane systolic excursion from early-hyperpnea to late-apnea, (14.6 ± 3.4 versus 13.1 ± 2.8 mm, $p=0.028$), likely due to right ventricular afterload increase, and by mitral E velocity reduction from late-hyperpnea to late-apnea (105.8 ± 27.9 versus 97.6 ± 24.5 cm/s, $p=0.046$), likely due to left ventricular preload decrease.

Conclusions: In HF patients CSR, likely via recurrent hypoxia and hypercapnia cycles and chemoreflex mediated adrenergic discharge, may cause pulmonary vasoconstriction and an increase in pulmonary arterial pressure, with undesirable consequent changes in right and left ventricular preload-afterload (figure 1).

Medical University, Department of Cardiology and Hematology, Fukushima, Japan;

⁴Kyoto University, Department of Respiratory Care and Sleep Control Medicine,

Kyoto, Japan; ⁵Kyushu University Hospital, Sleep Apnea Center, Fukuoka, Japan;

⁶Jichi Medical University Saitama Medical Center, Department of Cardiovascular Medicine, Saitama, Japan

Background: Patients with heart failure (HF) frequently have sleep apnea (SA) and presence of SA is associated with poor clinical outcomes in patients with HF. Thus, assessment of SA is important for risk stratified care management of HF patients. However, polysomnography (PSG), the gold standard technique for the assessment of SA, remains costly, labor intensive, limited access especially for HF patients. Therefore, portable sleep study devices have been developed in order to increase accessibility and reduce costs of diagnosing and treating SA. One such device includes peripheral arterial tonometry (PAT) -based portable device. Although meta-analysis indicated that apnea-hypopnea index (AHI) determined by PAT device correlated significantly with those determined by PSG in the general population, there are no specific data regarding accuracy of AHI determined by the PAT device in patients with HF.

Purpose: The purpose of this study was to compare the AHI determined by the PAT device with the AHI derived from the PSG in patients with HF.

Methods: Patients undergoing overnight PSG in 5 centers, Juntendo University Hospital, Tokyo Medical University Hospital, Fukushima Medical University Hospital, University Hospital, University Hospital and Medical Center of the Medical University were enrolled. Overnight PSG was performed according to standard protocol/criteria using electroencephalogram, electrooculogram, submental and anterior tibialis electromyogram, electrocardiogram, airflow, chest and abdominal wall motion, body position and arterial oxygen saturation. PAT device was attached in addition to the full PSG set-up. All PSG recordings were sent to the core laboratory and scored centrally by one experienced registered PSG technician who was blinded to the results of PAT device. All PAT device recordings were also sent to the core laboratory but scored using automatic algorithm. The AHI derived from the PSG (AHI-PSG) and the AHI determined by PAT device (AHI-PAT) were obtained. The correlation between AHI-PSG and AHI-PAT and agreement of them were assessed separately in patients with and without HF.

Results: Overall, 120 patients including 91 without and 29 with HF were analyzed. Compared with patients without HF, those with HF were more likely to have diabetes (34% versus 16%, $P=0.046$) and coronary artery disease (41% versus 13%, $P=0.002$) and predominant central sleep apnea (59% versus 16%, $P<0.001$) despite similar AHI-PSG. There were strong correlations between AHI-PSG and AHI-PAT in both patients with and without HF ($r=0.80$, $P<0.001$ for those with HF and $r=0.87$, $P<0.001$ for those without HF). In addition, there was no interaction between presence or absence of HF and AHI-relationships ($P=0.643$).

Conclusion: AHI-PAT positively and strongly correlated with AHI-PSG. Strengthened by the blinded design, PAT device can be an important alternative to PSG for evaluating SA even in patients with HF.

P1564

Hematocrit as a marker of short-term mortality and length of stay in hospitalised patients with congestive cardiac failure

M Mohammad Alkhalil¹; A Kearney¹

¹Mater Hospital, Belfast, United Kingdom

Background: OPTIMIZE-HF has identified predictors of in-hospital mortality but did not include markers of intravascular fluid status such as hematocrit (HCT). Get With the Guidelines study has concluded that stratifying patients for length of stay (LOS) is limited for heart failure.

Purpose: We sought to establish whether hematocrit would prove to be a useful predictor for short term mortality and length of stay in hospitalised patients with congestive cardiac failure (CCF).

Methods: A retrospective analysis of all consecutive patients who were admitted with diagnosis of CCF between September 2012 and August 2013. Patients were included using hospital coding database and only included if the primary diagnosis was CCF. Patients were divided into two groups: low HCT (<36% in females & <38% in males) and normal HCT. Statistical analysis was performed using SPSS 22.0.

Results: Total of 121 patients were identified with 79 patients met inclusion criteria. Of these, 45 (57%) had low HCT. Mean age was 77 ± 9 , 57% females with median LOS of 7 days. There was no difference between low & normal HCT groups in terms of gender, co-morbidities, or ejection fraction. Normal HCT patients were younger with better renal functions, while low HCT group had longer LOS (16 versus 8 days, $p=0.01$) and higher mortality (23% versus 6%, $p=0.028$). There was a significant association between baseline HCT and LOS (Spearman $r=-0.4$, $P=0.0003$). ROC area under the curve was 0.7 ($p=0.02$) for HCT cut off of 36%. HCT was significant predictor of LOS on univariate (OR 0.87 CI 0.79-0.96, $p=0.007$) but not on multivariate regression analysis (OR 0.93 CI 0.62-1.39, $p=0.73$). Kaplan-Meier curves at eight weeks showed statistical significance (Log Rank $p=0.028$) between low & normal HCT groups.

Conclusion: HCT is a useful marker to predict LOS and short-term mortality for hospitalised patients with CCF. HCT is available to all patients with no extra costs for this beneficial test.

P1565

Iron status in patients with chronic heart failure in an asian cohort

GSK Lau¹; SH Ng¹; WH Han¹; NOEL Thomas Ross¹; MR Yusoff¹; YY Ngau¹

¹Hospital Kuala Lumpur, General Medicine, Kuala Lumpur, Malaysia

Iron deficiency is a common comorbidity in chronic heart failure which has unfavourable clinical and prognostic consequence. Studies regarding iron status in an Asian population has been sparse. The objective of this study was to look at iron status in patients with chronic heart failure in an Asian cohort and to look at its association with short term outcomes in patients with chronic heart failure.

Method: We enrolled 74 consecutive patients who attended the heart failure clinics in a General Hospital. Full iron studies were obtained from blood sample. Results - Total of 74 patients were recruited, sixty percent ($n=44$) were male. Mean haemoglobin 13.1 g/dl (SD ± 0.2), TSAT was 23% (SD ± 13), ferritin was 206 microgram/L (SD ± 23), TIBC was 57 micromol/L (SD ± 1.7) and iron was 13.6 micromol/L (SD ± 0.8). TSAT distribution among NYHA I, II and III were

26.3%(SD+/-15.1), 29.4%(SD+/-13.9), 21.6%(SD+/- 9.8) and haemoglobin distribution among NYHA I,II,III were 13.3g/dl(SD+/-2.1), 13.2g/dl (SD+/-2.1) and 12.7 g/dl(SD+/-2.0) respectively (P = not significant). Survival rate at 6 months was 93%(n = 69). Haemoglobin (P=0.02) and serum ferritin(P=0.034) was associated with increase mortality whilst TSAT levels, serum iron and TIBC was not significantly associated with mortality at 6 months.

Conclusions: - In an Asian cohort patients with chronic heart failure, presence of anemia had an unfavourable outcome. Ferritin levels is also associated with mortality most likely due to underlying inflammatory process.

Left ventricular ejection fraction recovery associated to myocardial iron repletion in patients with heart failure treated with intravenous iron

A Anna Mollar Fernandez¹; JV Monmeneu¹; MP Lopez-Lereu¹; E Nunez¹; G Minana¹; V Bodi¹; E Santas¹; S Garcia-Blas¹; J Aguero¹; J Nunez¹

¹University Hospital Clinic of Valencia, Cardiology, Valencia, Spain

Purpose: In patients with heart failure with reduced ejection fraction (HFrEF), treatment with intravenous iron has shown to improve symptoms, functional capacity, and quality of life regardless of anemic status. Some authors have speculated myocardial iron repletion may explain, at least in part, this beneficial effects. Cardiac magnetic resonance (CMR) T2* sequence is a well-considered technique for assessing myocardial iron content. Thereby, we aimed to evaluate whether T2* sequence changes ($\Delta T2^*$) after intravenous iron administration in HFrEF patients with iron deficiency (ID) and whether such changes correlate with simultaneous changes in left ventricular ejection function (LVEF).

Methods: We enrolled 8 patients with HFrEF, NYHA class \geq II and ID. All patients received a dose of 1000 mg of ferric carboxymaltose (FCM). CMR and blood laboratory tests were performed baseline and 43 days (IQR=35-48) after FCM administration. A partial correlation analysis and a quantile regression analysis ($q=0.5$) were performed.

Results: After intravenous administration of FCM, NYHA class improved in 50% of patients. T2* decreased from a median of 39.5 (35.9-48) to 32 msec (32-34.5), $p=0.012$. The median of LVEF showed a borderline increase [40 (36-44.5) to 48.5% (38.5-53) $p=0.091$]. In a bivariate correlational analysis, $\Delta T2^*$ was highly correlated with changes in LVEF ($\Delta LVEF$) ($r=-0.747$, $p=0.033$). After controlling for anemia at baseline, the association between $\Delta T2^*$ with $\Delta LVEF$ persisted ($r[\text{partial}]=-0.865$, $R2[\text{partial}]=0.748$, $p=0.012$). Likewise, in a quantile regression, per decrease in 1 unit of $\Delta T2^*$ there was an associated increase in the median of LVEF by a factor of 0.81 ($p=0.007$) having the sample adjusted by anemia (Figure).

Conclusion: In a small group of patients with HFrEF and ID, myocardial iron repletion, as assessed by CMR, was associated to positive changes in LVEF.

Relationship between $\Delta T2^*$ sequence and $\Delta LVEF$

Improvement of parameters of heart failure after intravenous iron therapy in patients with defibrillator.

A Amalio Ruiz Salas¹; N Gonzalez-Cruces¹; A Robles-Mezcua¹; L Morcillo-Hidalgo¹; J Robledo-Carmona¹; JJ Gomez-Doblas¹; J Alzueta¹; E De Teresa¹; JM Garcia-Pinilla¹

¹University Hospital Virgen de la Victoria, Arrhythmias, Malaga, Spain

Purpose: Iron deficiency (ID) is one of the main comorbidities seen in patients with advanced heart failure (HF) and can worsen the prognosis of the disease. Many studies have demonstrated that ID can worsen functional class, myocardial contractility, renal function, quality of life and prognosis in patients with heart failure. The aim of our study was to analyze the early clinical response based on HF parameters of the defibrillators (ICDs), after the administration of intravenous ferric carboxymaltose (FCM) in patients with chronic HF, systolic dysfunction and deficient iron stores.

METHODS

This was an observational, retrospective cohort study, which included 35 patients with HF and ID. Absolute ID was defined as ferritin < 100 μ g/L, functional ID was defined as ferritin 100-299 μ g/L and transferrin saturation (TSAT) < 20%. ID was calculated using the simplified Ganzoni formula. The parameters obtained by ICDs were the average daily activity, nocturnal heart rate, average daily ventricular premature beats, unsustained ventricular tachycardia, sustained ventricular tachycardia and the necessity of appropriate therapies. These data were compared at the time of iron administration and three months

RESULTS

Mean age was 61.2 ± 13.3 years, and patients were predominantly male (68.6%). All had EF < 35%; 13 were ischemic. 21 patients had ICDs and 13 CRT-D. After three months of treatment, patients had clinical improvement based on an increased daily activity and reducing the number of premature ventricular contractions and night heart rate (Table 1).

Conclusions: Intravenous iron therapy improved functional status stage of patients with HF and ID based on objective parameters of ICDs

Table 1

Parameters	Before FCM	3 months post FCM	p
Daily activity, hour/day	2.49 ± 1.67	2.87 ± 1.69	< 0.001
PVC/hour	153.13 ± 237.03	93.25 ± 142.25	< 0.01
2-4 PVC/hour	48.94 ± 77.54	35.38 ± 72.79	< 0.001
> 4 PVC/hour	7.28 ± 35.06	0.21 ± 0.79	0.24
Average night ventricular rate, bpm	70.63 ± 12.37	67.68 ± 10.49	< 0.001

Iron deficiency and functional capacity in patients with advanced heart failure with preserved ejection fraction

P Palau Sampo¹; E Dominguez Mafe²; E Nunez Botero³; R Heredia³; J Gonzalez²; L Lopez⁴; JM Ramon³; E Santas³; J Sanchis³; J Nunez Villota³

¹Hospital de La Plana. Universitat Jaume I, Cardiology Department, Castellón, Spain; ²Hospital General de Castellón. Universitat Jaume I, Cardiology Department, Castellón, Spain; ³Hospital Clínico Universitario, INCLIVA. Universitat de València, Cardiology Department, Valencia, Spain; ⁴Universitat de València, Facultat de fisioteràpia, Valencia, Spain

Background: Heart failure with preserved ejection fraction (HFpEF) is a highly prevalent syndrome characterized for an elevated morbimortality. Iron deficiency (ID) has emerged as a novel prognostic factor and therapeutic target in patients with heart failure with reduced ejection fraction (HFrEF); however, poor is known about the pathophysiological implications of ID in HFpEF. In this work we sought to evaluate whether standard parameters of ID were related to functional capacity in patients with HFpEF.

Methods: we prospectively studied a cohort of 40 patients with advanced HFpEF (74 years (66-77), 55% female, 50% NYHA III). Maximal functional capacity was evaluated with an incremental and symptom-limited cardiopulmonary exercise testing and was expressed as peak oxygen consumption (peakVO2). ID was defined as: ferritin < 100 mg/L or ferritin 100-300 mg/L with transferrin saturation (TSAT) < 20%.

Results: The median (IQR) peakVO2, hemoglobin (Hb), ferritin and TSAT were 10 ml/min/kg (8.9-12.9), 13 g/dL (11.7-13.8), 94 mg/L (53-220), 19% (15-26), respectively. Anemia and ID were present in 15 (37.5%) and 28 (70%) patients, respectively. In a bivariate setting, log-peakVO2 was negatively correlated with age, NT-proBNP, and E/E' ratio, while positively correlated with Hb, TSAT, estimated glomerular filtration rate (eGFR), tricuspid annular plane systolic excursion and ferritin (Figure 1). In a multivariable setting, age, resting heart rate, NT-proBNP, eGFR, E/E' ratio, Hb, TSAT and serum ferritin were retained as significant predictors for the mean peakVO2 (82.3% of variability).

Conclusion: in patients with advanced HFpEF, standard parameters of ID were related to patient's functional capacity evaluated by peakVO2.

P1569

Nonalcoholic fatty liver disease is associated with higher 1-year all-cause rehospitalization rates in patients admitted for acute heart failure

F Filippo Valbusa¹; D Agnoletti¹; S Bonapace²; C Grillo¹; L Scala¹; A Rossi³; G Targher⁴; G Arcaro¹¹Sacro Cuore - Don Calabria Hospital, Internal Medicine, Negrar-Verona, Italy;²Sacro Cuore - Don Calabria Hospital, Division of Cardiology, Negrar-Verona, Italy;³University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Cardiology, Verona, Italy; ⁴University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Endocrinology, Diabetes and Metabolism, Verona, Italy

Background: Repeat hospitalization due to acute heart failure (HF) is a global public health problem that markedly impacts on health resource use. Non-alcoholic fatty liver disease (NAFLD) is an emerging risk factor for many heart diseases, including HF.

Purpose: We assessed whether NAFLD at hospital admission predicts 1-year re-hospitalization in patients with acute HF.

Methods: We enrolled all patients consecutively admitted for acute HF to our General Medicine Division during 2013 after excluding patients with acute myocardial infarction, severe heart valve diseases, malignancy, known liver diseases and those with volume overload related to extra-cardiac causes. NAFLD was diagnosed by ultrasonography. Primary outcome: 1-year all-cause re-hospitalization rate.

Results: Among the 107 patients enrolled in the study, patients who had been hospitalized during the follow-up period had significantly lower eGFR values and higher serum GGT and AST concentrations, they have a higher prevalence of atrial fibrillation, and were more treated with spironolactone than those not requiring re-hospitalization. At baseline, age, sex distribution, body weight, BMI, heart rate, systolic/diastolic blood pressure, plasma NT-proBNP levels, LV-EF, prior histories of diabetes, COPD, CHD/angina, peripheral artery disease, current use of ACE-inhibitors, sartans, beta-blockers, furosemide and amiodarone did not differ significantly between the two groups of patients. Notably, the prevalence of NAFLD at baseline was markedly higher in patients with re-hospitalization at follow-up (70.7% vs. 31.8%, $P < .001$). Patients with NAFLD at baseline had markedly higher 1-year re-hospitalization rates than those without NAFLD (58% vs. 21% at 1 year; $P < .001$ by the log-rank test) (Figure). Cox regression analysis revealed that NAFLD was associated with a 5- fold increased risk of re-hospitalization (adjusted-hazard ratio 5.56, 95% CI 2.46–12.1, $P < .001$) after adjustment for multiple HF risk factors and potential confounders. In conclusion, NAFLD was independently associated with higher 1-year hospital readmission in patients hospitalized for acute HF.

Multivariable Cox regression models

Cox Hazard Models	Hazard ratio	95% CI	P value
NAFLD (yes vs no) Unadjusted model	3.71	1.88-7.30	< 0.001
Adjusted model 1 (age and sex)	4.83	2.36-10.1	< 0.001
Adjusted model 2 (model 1+eGFR and GGT)	5.38	2.55-11.2	< 0.001
Adjusted model 3 (model 2+NT-proBNP, LV-EF, BMI, Diabetes, history of AF)	5.56	2.46-12.1	< 0.001

Factors independently associated with 1-year all-cause re-hospitalization rate in patients with acute AF at baseline.

P1570

Determining risk of heart failure hospitalization and mortality using routine liver function tests.

JSS Jagdeep Singh Surmukh Singh¹; D Levin¹; CC Lang¹¹University of Dundee, Cardiovascular and Diabetes Medicine, Dundee, United Kingdom

Background: Deranged liver function has been demonstrated in both acute and chronic heart failure (HF) patients, but has always been considered as merely a sequel to HF itself. There has been recent interest in using parameters of liver function as markers of HF severity and prognosis, however the majority of analysis has been limited to patients in clinical trials only. We aimed to use a population-based database of an unselected cohort of HF patients to develop a risk prediction model based on liver function parameters to predict HF hospitalization and all-cause mortality.

Methods: We analyzed data from the BIOSTAT-CHF database which prospectively tracks patients with heart failure from a region in Scotland. Multivariable cox proportional hazard models were used to assess the prognostic impact of liver dysfunction on heart failure outcomes, while controlling for covariates like age, gender, treatment regime, previous history of myocardial infarctions, atrial fibrillation, diabetes, renal disease and CHF duration.

Results: Out of a total 1585 patients with a mean age of 73.6 (+/-10.6) years and mean HF duration 3.49 (+/-4.61) years, there were 401 (25.3%) HF hospitalizations and 329 (20.8%) deaths. Of the 6 liver function parameters, 4 were independent predictors of composite HF hospitalization or death. Per log unit reduction in serum albumin (ALB) showed increased hazards by 1.59 (95% CI 1.29 -1.97, $p < 0.001$). Whereas per log unit increase in total bilirubin(TB), alkaline phosphatase(ALP) and gamma-GT(GGT) were associated with increasing hazards of the composite outcome by 1.63 (95% CI 1.25-2.13, $p < 0.001$), 1.29 (95% CI 1.02-1.62, $p = 0.030$) and 1.49 (95% CI 1.21-1.82, $p < 0.001$) respectively. AST and ALT were not predictors of HF outcomes. We then developed a simplified 4-point risk scoring model using the above parameters which demonstrated increasing HF risk as the score increased, reaching a peak hazard of 5.52 (95% CI 3.48–8.76) in patients with the maximum score of 4 points.

Conclusions: Our findings demonstrate lower ALB, elevated TB, ALP and GGT are independent predictors of HF hospitalization or all-cause mortality among HF patients. Our simplified risk scoring model can be used as an easy-to-use tool to prognosticate HF patients.

P1571

Model for end-stage liver disease excluding normalized ratio (MELD-XI) score as a measure of hepato-renal dysfunction in patients with decompensated heart failure

LM Gomez Madronero¹; LR Moraes¹; CB Terhoch¹; HF Moreira¹; SM Ayub-Ferreira¹; MT Oliveira¹; SG Lage¹; VS Issa¹; EA Bocchi¹¹Heart Institute of the University of Sao Paulo (InCor), heart Failure, Sao Paulo, Brazil

Introduction: The occurrence of hepato-renal dysfunction is important for the selection of patients to procedures such as heart transplant and ventricular assist-devices. We investigated the value of hepato-renal dysfunction in patients with decompensated heart failure.

Methods: We analyzed a cohort of 409 patients admitted for decompensated heart failure in a tertiary hospital dedicated to cardiology from August 2013 through December 2015; MELD-XI at hospital admission was determined in 312 patients

and categorized in quartiles; values were confronted with clinical characteristics and prognosis

Results: Mean age was 55.3 ± 15 years and 254 (62.1%) patients were male; left ventricle ejection fraction was 30 ± 12 ; 102 (24.9%) patients had ischemic heart disease, 97 (23.7%) Chagas' cardiomyopathy, 74 (18.1%) idiopathic dilated cardiomyopathy and 48 (11.7%) hypertensive disease. At admission BNP level was 1486 ± 1297 pg/dL and creatinine 1.96 ± 1.2 mg/dL. During hospital admission 45 (11%) patients were submitted to heart transplant and 128 (31.3%) died. The analysis of MELD-XI quartiles showed that increasing MELD-XI was associated with higher proportion of male patients (44.9% for first quartile, 56.4% for second quartile, 71.8% for third quartile, 71.8% for fourth quartile, $P=0.01$), increasing age (49.6 ± 15.1 years, 55.4 ± 13.8 , 52.7 ± 15.5 , 56.7 ± 12.9 , $P=0.01$), higher proportion of patients with ascites (14.3%, 23.1%, 31.2%, 38.5%, $P=0.036$), higher proportion of patients with peripheral edema (45.5%, 64.1%, 70.1%, 59.7%, $P=0.044$), higher proportion of patients with right ventricular dysfunction (26.9%, 43.6%, 53.8%, 47.4%, $P=0.06$) and higher BNP levels (868 ± 107 pg/dL, 1480 ± 179 , 1201 ± 141 , 1475 ± 178 , $P=0.013$). The rate of heart transplant decreased according to MELD-XI quartile (21.8%, 12.8%, 11.8%, 10.3%) and mortality increased (21.8%, 33.3%, 44.7%, 46.2%, $P=0.021$). When MELD-XI score was analyzed in multivariable logistic regression model that included sodium, hemoglobin, blood pressure and heart rate at admission, BNP and ejection fraction, only blood pressure was associated with mortality (OR 0.977, $P=0.001$).

Conclusion: Hepato-renal dysfunction is frequent in patients with heart failure especially in older male patients with right ventricular dysfunction. However, in the setting of decompensated heart failure, hemodynamic variables remain as more important markers of prognosis than organ damage.

P1572

Brain natriuretic peptide levels and echocardiography data of patients with acute myocardial infarction against the background of non-alcoholic steatohepatitis

M Maryna Filonenko¹; L Zhuravlyova¹

¹Kharkiv National Medical University, Kharkiv Regional Hospital, Kharkiv, Ukraine

Background: Brain natriuretic peptide (BNP) level and echocardiography are the two most informative tests to evaluate the risk of future heart failure development in patients with ST-elevation myocardial infarction (STEMI). The presence of non-alcoholic steatohepatitis (NASH) can influence the prognosis of STEMI. The purpose of this study was to determine BNP levels and the dynamics of functional heart parameters in patients with STEMI accompanied with NASH. Methods. 76 patients with STEMI accompanied with NASH and 31 patients with STEMI without liver pathology were examined. Groups were comparable in age and gender. Cardiac ultrasonography was done to all patients on 3rd and 28th day after AMI. The amount of troponin, creatine phosphokinase, transaminases was determined in blood of all patients. BNP levels were assessed 64 \pm 7 hours after onset of chest symptoms. Also the data of liver ultrasound and liver biopsy were used to confirm the diagnosis of NASH.

Results: Patients with STEMI accompanied with NASH had the following dynamics of functional heart parameters from 3rd to 28th day: left ventricular enddiastolic volume (LVEDV) was slightly decreased (-2.9%; 60.74 ± 4.16 mm), left ventricular endsystolic volume (LVESV) showed a tendency to increase (+14.8%; 54.36 ± 5.13 mm) as well as ejection fraction (EF) +14.6%; $45.39 \pm 2.82\%$. However, the mentioned above changes weren't statistically significant. Patients with STEMI without liver pathology demonstrated significant decrease of LVEDV (-17.2%; 54.08 ± 3.97 mm; $p=0.031$), as well as LVESV (-21.1%; 39.49 ± 3.25 mm; $p=0.042$); EF increased to 28% ($51.93 \pm 2.69\%$; $p=0.007$). The analysis of indexes on 28th day showed increase of EF in both groups (70.36 % and 84.57% of patients respectively, $p=0.048$); decrease of contractile ability determined in 23.6% and 15.13% of patients respectively, $p=0.042$). Patients with STEMI accompanied with NASH demonstrated significantly higher levels of BNP compared to controls (749.25 pg/ml vs 435.18 pg/ml, $p \leq 0.05$). Also, a positive correlation was found between BNP and LVESV ($r=0.358$, $p \leq 0.05$), BNP and peak troponin levels ($r=0.452$, $p \leq 0.05$) in such patients. Conclusion. Patients with STEMI accompanied with NASH had worse dynamics of functional heart parameters than the ones without liver pathology. These included insufficient improvement of left ventricular systolic function and its contractile ability, tendency to enlargement of left ventricular cavity. Together with significantly higher levels of BNP such changes may predict increased probability of the left ventricle dysfunction, heart failure development and poorer prognosis in patients with STEMI accompanied with NASH.

P1573

Urinary levels of new kidney biomarkers and risk of worsening renal function and mortality in patients with acute heart failure.

This work has been supported by a grant from National Centre of Science (Poland) no NN 519 654340/6543/B/T02/2011/4

¹Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland;

²Centre for Heart Disease - Clinical Military Hospital, Wroclaw, Poland; ³Singulex, California Inc. 1701 Harbor Bay Parkway Alameda, CA 94502, United States of America; ⁴Wroclaw Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wroclaw, Poland

Background: Increased urinary levels of cystatin C (uCysC), neutrophil gelatinase-associated lipocalin (uNGAL) and kidney injury molecule 1 (uKIM-1) are proposed as sensitive, early markers of renal tubular injury. We investigated their predictive value for the development of worsening renal function (WRF) and long-term outcomes in patients hospitalized with acute heart failure (AHF).

Methods: Urinary levels of CysC, NGAL, KIM-1 were measured using high sensitive immunoassay based on a single-molecule counting technology (Singulex, US) at baseline, days 1 and 2 in 132 patients with AHF (mean age: 65 ± 13 years, male: 78 %). The concentration of the biomarkers was normalized to the creatinine in urine (ng/gCr for uKIM-1, μ g/gCr for uNGAL and uCysC). WRF was defined as an increase ≥ 0.3 mg/dl in serum creatinine or a decrease $>25\%$ in the glomerular filtration rate from the baseline value during hospital stay.

Results: WRF occurred in 28 (22%) patients and they had significantly higher levels of uNGAL at baseline ($29.7 [10.3-45.7]$ vs. $13.1 [5.9-41.2]$, μ g/gCr), at day 1 ($24.6 [17.2-54.0]$ vs. $14.7 [6.3-31.6]$, μ g/gCr), and day 2 ($29.2 [16.3-114.3]$ vs. $18.7 [6.9-30.5]$, μ g/gCr) (patients with vs without WRF, medians [interquartile range], $p < 0.05$ in all comparisons). There were no differences in uKIM-1 and uCysC between groups. In the multivariable analyses elevated uNGAL at day 1 remained as independent predictor of WRF (1.53 [1.09-2.14], $P=0.012$), with area under curve of 0.71 (0.60-0.82). During 1-year follow-up there were 36 (27%) deaths. WRF was not associated with mortality [$P=0.94$]. After adjustment for other prognostic factors, uNGAL at days 1 and 2 and uCysC at day 1 were independent predictors of mortality with hazard ratios of 1.36, 1.39 and 1.35, respectively ($P < 0.05$ for all).

Conclusions: Elevated uNGAL measured at 24 hours after admission predicts WRF during hospitalization in patients with AHF. Elevated levels of uNGAL and uCysC could be used to identify patients at risk of poor outcome.

P1574

Effect of implementation of algorithm preventing loading in clinical practice before primary percutaneous coronary intervention on contrast-induced acute kidney injury

A Anna Gaskina¹; S Villevalde¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Background: Patients with ST-segment elevation myocardial infarction (STEMI) undergoing primary percutaneous coronary intervention (PCI) are at high risk of contrast-induced acute kidney injury (CI-AKI), a complication that negatively affects outcomes. In primary PCI we have limited time to assess the risk and preventing of CI-AKI. Therefore important to develop and implementation of algorithm preventing.

We performed a single-centre prospective study to determine the effect of implementation of algorithm preventing on the incidence of CI-AKI in patients with STEMI and primary PCI.

Methods: We used of historical control data for assessing of algorithm preventing CI-AKI in routine clinical practice. The study compared two groups of patients with ST-segment elevation myocardial infarction (STEMI) and primary PCI before and after implementation of algorithm preventing CI-AKI. In 1 Group - control group ($n=33$) we used the routine prophylaxis CI-AKI: in patients with eGFR <60 ml/min/1.73m² received intravenous hydration of 0.9% saline solution of sodium chloride (NaCl) at a rate of 1.0-1.5 ml/kg/h before the PCI. In 2 group - prevent group ($n=33$) we prevented CI-AKI according to the algorithm: patients with eGFR <60 ml/min/1.73m² and/or with Mehran risk score ≥ 11 received intravenous fluid administration hydration of 0.9% NaCl and N-Acetylcysteine (NAC): 0.9% NaCl \times 500-1000 ml before PCI and 1 ml/kg/h post contrast administration with NAC 300 mg before PCI and 900 mg after PCI. Both groups were comparable in age (63 ± 11 and 62 ± 12 years), comorbidity (hypertension 89 and 85%, chronic kidney disease 14 and 15%, diabetes mellitus 19 and 17%) and received therapy. CI-AKI was defined using 2012 KDIGO Guidelines. Isoosmolar contrast media iohexanol (Visipaque-320) or low-osmolar contrast media iohexol (Omnipaque-350) were used. Transradial access for PCI was used in 98% of patients. Mann-Whitney test and multivariate logistic regression analysis were performed. $P < 0.05$ was considered statistically significant.

Results: The incidence of CI-AKI in intervention group was significantly lower than in the control group (20 and 11%, $p < 0.05$).

Conclusion: Implementation of algorithm preventing of contrast-induced acute kidney injury significantly reduced the risk of CI-AKI in clinical practice in patient with STEMI and primary PCI.

P1575

To assess effect of ultrafiltration by peritoneal route on echocardiographic parameters in refractory congestive heart failure by two dimensional echo and tissue doppler imaging

P Praveen Pawal¹; S Hedau²; P K Raju¹; R Chakravarthi²

¹CARE Hospitals, cardiology, Hyderabad, India; ²CARE Hospitals, nephrology, Hyderabad, India

Background: - Ultrafiltration by peritoneal route is an effective alternative to conventional diuretic treatment for refractory heart failure. There are no direct studies demonstrating effect on Echocardiographic parameters.

Purpose: - 1. To assess the effect of ultrafiltration on echocardiographic parameters and TDI at baseline and three month post ultrafiltration 2. To determine the therapeutic role of ultrafiltration in improving patient clinical status; this is assessed by New York Heart Association (NYHA) functional class, Change in number of days of hospitalization 6 minute walk test.

Methods: The study population includes both outpatient who attended Heart failure clinic as well as inpatients admitted for heart failure. It was a non randomised observational study. The baseline data was collected at start and then after three months of ultrafiltration therapy. The collected data was entered and analyzed using Microsoft office window excel 2007 and SPSS version 16 (SPSS 16.0 for Windows, release 16.0.0. Chicago: SPSS Inc). We considered the association or difference to be significant when the p value was less than 0.05.

Results: 19 patients of refractory heart failure of various etiologies were recruited in the study. Out of 19 patients 16 were alive and undergoing CAPD at 3months. 19 study subjects were studied. EF (Ejection fraction) before the treatment was (35.4±6.6) which improved to (43.1±13.8) (P<0.01). RAVI (Right atrial volume index) before the treatment was (31.8±14.3) and improved to (28.3±14.9) (P=0.016). IVC diameter before the treatment was (2.27±0.44) at 3 months (1.8±0.68). PASP (Pulmonary artery systolic pressure) was compared before the treatment was 50.7±14.4 to post CAPD decreased (38.1±15.6)(P<0.01). There was significant decrease in duration of hospitalisation from (17.5±8.3) to (1.7±3.4) (p<0.0001). NYHA class III & IV significantly improved to NYHA class I & II pre 19 (100%) and post 3 (17.6%) ultrafiltration (p<0.0001). There was highly significant increase in the duration of 6 minutes' walk test pre 58.52±47.6 and post 176.4±80.7 (p<0.0001) after ultrafiltration. Conclusion - Ultrafiltration was safe and associated with significant improvement in echocardiographic parameter. LV systolic function (ejection fraction) was improved; also there was reduction in LV dimension and volumes. We found ultrafiltration was associated with a substantial improvement in NYHA functional class, physical performance (6MWT), and with significant reduction rehospitalization days.

P1576

Biochemical determinants of worsening renal function after diuretic therapy for heart failure patients

H Hajime Kataoka¹

¹Nishida Hospital, Oita, Japan

Background Diuretic therapy for worsening heart failure (HF) frequently leads to deterioration of renal function. How changes in serum substance(s) are associated with changes in renal function after diuretic therapy in HF patients, however, is unknown.

Purpose: We tested our hypothesis that changes in serum solute(s)/albumin are associated with the changes in the serum creatinine (SCr) level after diuretic therapy.

Methods: Data from 47 patients (32% men; 78.2±9.7 years) with mild-to-moderate HF that experienced a worsening episode of HF defined by ≥2 HF signs were analyzed. Each patient underwent conventional diuretic therapy and returned to stable HF status after therapy. Blood tests included measurement of hemoglobin (Hb), hematocrit (Ht), serum albumin, solutes, and serum b-type natriuretic peptide. The relative change in the plasma volume (%PV) from worsening HF to recovery was estimated as follows: 100 x {Hb (worse) x [1-Ht (recovery)]/[Hb (recovery) x [1-Ht (worse)]]-100.

Results: Among a total of 47 worsening HF events, the incidence of an increase and decrease in SCr was 40 (85%) and 7 (15%), respectively, after decongestive therapy. Changes in SCr negatively correlated with changes in sodium (Na) (r=-0.453, P=0.0014) and chloride (Cl) (r=-0.534, P=0.0001), and positively correlated with changes in BUN (r=0.621, P<0.0001), although changes in SCr did not correlate with changes in body weight (r=0.149, P=0.317) or %PV (r=-0.09, P=0.559). When divided into two groups by the median SCr, the group with increased SCr [SCr≥0.12mg/dL (range 0.12 to 1.31); n=24] exhibited a greater decrease in serum Na (-4.29±4.39 vs -1.39±3.93mEq, P=0.02) and Cl (-7.3±5.05 vs -1.4±3.44mEq, P<0.0001) after decongestive therapy compared with the group without increased SCr [SCr (range -0.66 to 0.1)<0.12mg/dL; n=23], whereas the decrease in body weight and log BNP did not differ between the two groups. Multivariate logistic regression analysis demonstrated an independent association between the increase in SCr and the decrease in serum Na (OR: 0.145, 95% CI: 0.023-0.883, P=0.036) and Cl (OR: 0.134, 95% CI: 0.02-0.919, P=0.04) after decongestive therapy.

Conclusions: Deterioration of renal function defined by an increase in SCr after

decongestive therapy in worsening HF patients is associated with a decrease in the serum Na and Cl concentrations. Preservation of these solutes might be crucial toward maintaining renal function in patients under diuretic therapy for worsening HF.

P1577

Association between galectin-3 and worsening renal function

M Leone¹; C Rizzo¹; MS Lattarulo¹; F Monitillo¹; P Terlizze¹; D Grande¹; F Di Serio²; M Iacoviello³

¹University of Bari, School of Cardiology, Bari, Italy; ²Polyclinic Hospital of Bari, Clinical Pathology Unit, Bari, Italy; ³Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

Background and aim of the study: Galectin-3 (Gal-3) is a biomarker reflecting inflammation status and fibrosis which has been demonstrated to be related to both chronic heart failure (CHF) and renal dysfunction. The aim of this study was to evaluate the association between Gal-3 serum levels and worsening renal function (WRF) in a group of CHF outpatients.

Methods: We enrolled 171 outpatients (81% males, 64±13 years, NYHA class 2.4±0.6, left ventricular ejection fraction, LVEF, 33±8%, GFR EPI 74±26 ml/min*1.73 m²) with CHF (ESC criteria) due to left ventricular systolic dysfunction, in stable clinical conditions (>1 month) and in conventional therapy. All patients underwent a clinical evaluation, a routine chemistry and an echocardiogram. WRF was defined as an increase in serum creatinine of ≥0.3 mg/dl associated with a change >25% or a decrease in GFR>20% at 1 year follow-up.

Results: During follow-up, WRF was observed in 21 patients (12%). At baseline patients with WRF, when compared with those without WRF, showed significantly lower mean GFR values (63±27 vs. 73±25 ml/min*1.73 m², respectively; p: 0.03), but these differences further increased at 1 year (41±19 vs. 74±24 ml/min*1.73 m², respectively; at ANCOVA analysis p<0.001).

Patients with WRF, when compared to patients without, showed also significantly higher serum levels of Gal-3 (21.2±11.8 vs 15.1±5.5 pg/ml; p<0.001). At univariate logistic regression analysis Galectin 3 was associated with WRF occurrence (OR: 1.10; 95%CI: 1.04-1.17; p: 0.002) and this association remained significant (OR: 1.09; 95%CI: 1.01-1.19; p:0.038) after correction for the others univariate predictors, i.e. baseline GFR EPI, baseline central venous pressure >5 mm Hg and baseline logarithm of NT-proBNP.

At ROC curve analysis (AUC 0.65; 95% CI: 0.51-0.79) the best cut-off was 16.1 (with a sensitivity of 64% and a specificity of 64%). Panel A of the figure shows changes in creatinine serum levels according to this cut-off value of Gal-3. Patients with high Gal-3 showed greater baseline values, which further and significantly increased at one year (p<0.01 at ANCOVA analysis). Panel B shows the percentage of patients with one year occurrence of WRF according to Gal-3 cut-off.

In conclusion, our findings demonstrate the independent association between Gal-3 and worsening renal function in CHF outpatients. These results can be explained by the fact that Gal-3 reflects the pathophysiological status underlying both cardiac and renal dysfunction, thus strengthening the potential clinical usefulness of this biomarker in predicting the progression of cardiorenal syndrome in heart failure patients.

Markers of renal dysfunction in chronic heart failure

SA Matskevich¹; ES Atroschenko¹; OA Barbuk¹; MI Belskaya¹

¹Scientific and Practical Center "Cardiology", Minsk, Belarus

Introduction: Kidneys are one of the most critical target organs in individuals with chronic heart failure (CHF). As CHF progresses, a significant number of patients develop renal dysfunction achieving a degree of chronic renal dysfunction.

Objective: to define and assess markers of renal dysfunction in chronic heart failure (CHF).

Materials and methods: A total of 132 subjects (mean-age 60,75±7,31 y.o.) with CHF NYHA functional class II, III with previous Q-wave myocardial infarction (MI) were assessed. Myocardial infarction was not older than 4,06±3,27 years. Mean

left ventricular ejection fraction (LVEF) was $50.2 \pm 7.68\%$. Patients with renal impairments and/or endocrine pathology were excluded from the study. Medical treatment: beta-blocking agents, ACE-inhibitors or angiotensin receptor blockers, aspirin, statins, and diuretics. All patients had general physical examination. Echocardiography was performed using Vivid-7 (GE, USA-Belgium) device with a sensor of 3.5 MHz. Biochemistry was obtained using Olympus analyzer: the level of cystatin was detected using Randox kits with the application of Olympus analyzer (normal between 0.57 and 1.05 mg/l), creatinine concentration was obtained using Beckman kits (normal 44.0–110.0 $\mu\text{mol/l}$). Glomerular filtration rate (GFR) by cystatin level based on the formula: $\text{GFR (ml/min/1.73m}^2\text{)} = -4.32 + 80.35/\text{cystatin}$. Urine microalbuminuria (MAU) was assessed using Olympus analyzer, microalbumin OSR 6167, urine alpha-microglobulin-1 (1) was obtained using direct enzyme-linked immunosorbent assay using monoclonal antibody pairs EIA-1 (normal not exceeding 10 mg/l).

Results: Urine, blood glucose, and enzyme levels were normal in all the subjects. Mean values of creatinine (99.80 ± 11.67 $\mu\text{mol/l}$) and cystatin (0.93 ± 0.09 mg/l) in the above-mentioned group were normal. However, higher creatinine was shown in 21.9% subjects, and higher cystatin was seen in 28% subjects. Mean GFR by creatinine and cystatin was below normal and accounted for 83.72 ± 12.78 and 85.65 ± 11.87 ml/min/1.73m^2 , respectively. Decreased GFR (from mild to moderate) defined by cystatin was seen in 62.1% subjects. Thus, most of the CHF subjects had evidence of chronic renal dysfunction. Moderately decreased GFR (by cystatin) was shown in 8.3% subjects. These patients had lesions of target organs with no clinical signs. Higher levels of 1 (14.4% subjects) and MAU (12.9% subjects) were also present. A correlation between cystatin and 1 was defined ($r=0.50$, $p<0.001$), as well as a negative correlation between LVEF and cystatin C ($r=-0.54$, $p<0.001$). Conclusion: Thus, most of the subjects with CHF had signs of renal dysfunction with no clinical manifestations. It is obvious that cystatin, microalbuminuria and alpha-1-microglobulin may be considered as early markers of renal dysfunction in GFR that are associated with the development of systolic heart failure.

P1579

Renal resistance index and microalbuminuria as multiparametric approach to assess renal function in heart failure: prognostic aspects

M Leone¹; A Doronzo²; V Paradies³; F Monitillo¹; C Rizzo¹; MS Lattarulo¹; D Grande¹; P Terlizze¹; MM Ciccone⁴; M Iacoviello⁴

¹University of Bari, School of Cardiology, Bari, Italy; ²F. Ferrari Hospital Center, Cardiology Unit, Casarano, Italy; ³Anthea Hospital, Cardiology Unit, Bari, Italy;

⁴Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

Background: In order to better evaluate renal function in chronic heart failure (CHF) patients, it has been suggested that microalbuminuria and the evaluation of renal blood flow, by renal resistance index (RRI), can integrate information obtained by glomerular filtration rate (GFR). The aim of the study was to evaluate the prognostic relevance of a multiparametric approach for the assessment of renal function in a group of CHF outpatients.

Methods: We enrolled 253 outpatients (81% males, 64 ± 13 years, NYHA class 2.3 ± 0.6 , left ventricular ejection fraction, LVEF $33 \pm 10\%$, GFR EPI 69 ± 27 ml/min/1.73 m^2) with CHF (ESC criteria) due to left ventricular systolic dysfunction, in stable clinical conditions (> 1 month) and in conventional therapy. In all patients, on the basis of pulsed Doppler peak systolic velocity and end diastolic velocity of segmental renal artery, RRI was calculated. Microalbuminuria was defined as the urinary albumin/creatinine ratio (UACR) of 30 to 299 mg/g. Patients with macroalbuminuria were excluded from the analysis. Creatinine serum levels were used to estimate GFR by EPI formula. During follow-up heart failure progression was defined as the occurrence of hospitalization and/or heart transplantation and/or death due to worsening of heart failure.

Results: During a mean follow-up of 19 ± 7 months, in 56 patients heart failure progression occurred. At Cox univariate regression analysis a GFR < 60 (HR 2.19; 95%CI: 1.25–3.81; $p=0.006$; C index 0.59), an RRI ≥ 75 (HR 3.83; 95%CI: 2.04–7.22; $p<0.001$; C index 0.65) and microalbuminuria (HR: 3.81; 95%CI: 2.18–6.67; $p<0.001$; C index 0.66) were all associated to heart failure progression. However, in a multivariate analysis including the three parameters only RRI > 75 (HR: 2.99; 95%CI: 1.54–5.83; $p=0.001$) and microalbuminuria (HR: 2.99; 1.66–5.36; $p<0.001$), but not GFR < 60 (HR: 1.15; 95%CI: 0.63–2.09; $p=0.65$) remained significantly associated to events.

When a score was computed, on the basis of the presence or not of a high RRI and of microalbuminuria, it was obtained a new parameter associated to events at univariate (HR 3.09; 2.10–4.56; $p<0.001$; C-index: 0.71) as well as at multivariate Cox regression analysis (HR: 1.14%CI: 54–1.72; $p<0.001$) after correction for age, NYHA class, LVEF and NT-proBNP. Moreover, the new parameter showed a significant incremental value when added to the multivariate model (free net reclassification index $p<0.001$). Figure shows Kaplan Meier curves of the three groups according to RRI ≥ 75 and/or microalbuminuria.

Conclusions: The combination of RRI and microalbuminuria allows to obtain an evaluation of renal function with a greater value in predicting heart failure progression. This can be explained by the fact that these parameters are more able to reflect the different pathophysiological mechanisms leading to the progression of heart failure and cardiorenal syndrome.

Cardiorenal relations in patients with prosthetic valve IE

EO Kotova¹; T S Getiya²; PV Lazarev¹; AS Pisaryuk¹; JL Karaulova¹; GK Kiyakbayev¹; V L Filatov²; V S Moiseev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation;

²M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Purpose: To study the features of heart failure and kidney injury in patients with prosthetic valve (PV) infective endocarditis (IE).

Material and methods: 80 patients (50 men) with IE (Duke 2015) were included, of which 16 (12.8%) patients have PVIE (group 1) and 64 (51.2%) have native valve IE (group 2). We evaluated the anamnesis, echocardiogram, renal function (GFR, proteinuria, microscopic hematuria, serum Cystatin C, urinary KIM-1), heart failure (NYHA) rates and NT-proBNP levels, acute kidney injury (AKI, KDIGO 2012) and mortality rates. Early AKI was defined as AKI at the moment of hospital admission, AKI developed during hospitalization was considered as late AKI.

Results: The median age in the group 1 was 64 [58–67], in group 2 — 63 [54–69] years, $p>0.05$. Groups did not differ by age, gender and comorbidity. Subacute IE prevailed in both groups [11 (68.8%) vs. 34 (53.1%), $p>0.05$], left ventricular EF mainly was preserved [53.8 ± 8.7 (39–69) vs. 55.6 ± 8.4 (28–72), $p>0.05$]. In the group of PVIE condition was significantly more often associated with medical interventions [8 (50.0%) vs. 21 (32.8%), $p<0.05$] and characterized by multivalve involvement [7 (43.8%) vs. 4 (6.3%), $p<0.05$]. Heart failure was more severe in group 1 than in group 2 and more frequently presented by NYHA FC III/IV HF [13 (81.3%) vs. 33 (51.6%), $p<0.05$]; NT-proBNP median values were 3792 [649–4570] pg/ml vs. 1603 [584–4068] pg/ml, respectively, $p<0.05$. Median GFR in group 1 was 41 [31–53] ml/min , in the group 2 — 55 [39–85] ml/min , $p<0.05$. AKI occurred more often in group 1: in 11 (68.8%) vs. 30 (49.6%) patients, $p<0.05$. The same was true for early [3 (18.8%) vs. 6 (9.4%), $p<0.05$] and late AKI [8 (50.0%) vs. 24 (36.5%), $p<0.05$]. Groups did not differ by incidence of urine laboratory changes [13 (81.3%) vs. 49 (76.6%), $p>0.05$]. In group 1 there were higher values of serum Cystatin C — 3.5 [3.0–4.8] vs. 2.0 [1.6–2.2] pg/ml ($p<0.05$), KIM-1 in urine — 2.8 [2.5–3.3] vs. 1.6 [1.5–1.7] ng/ml ($p<0.05$). In the group of PVIE prevailed *Enterococcus* spp. (n=6) and *Staphylococcus* spp. (n=4) presented by *Staphylococcus epidermidis* and *Staphylococcus haemolyticus*. Mortality rates were similar in both groups [5 (31.3%) and 20 (31.3%), $p>0.05$], but surgical treatment was performed more often in group 1 [6 (37.5%) vs. 4 (6.3%), $p<0.05$]. Conclusion. Prosthetic valve IE has stronger connection to medical interventions, is often associated with *Enterococcus* spp. and *Staphylococcus* spp. and characterized by more severe heart failure and higher frequency of AKI, higher NT-proBNP, Cystatin C and KIM-1 values.

Uncovering heart failure in stable chronic obstructive pulmonary disease

A Milovanec¹; S Puskar¹; J Matijasevic¹; M Vukoja¹; J Dejanovic²; V Kuruc¹; V Kolarov¹

¹Institut of Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia; ²Institute of Cardiovascular Diseases of Vojvodina, Sremska Kamenica, Serbia

Background: Heart failure (HF) is one of the major causes of death in chronic obstructive pulmonary disease (COPD) patients. Despite the fact, HF remains to be underrecognized and undertreated in COPD patients as clinical symptoms of both diseases frequently overlap and echocardiography is not routinely performed in COPD patients.

Purpose: The aim of our study was to assess the prevalence of HF in stable COPD patients.

Methods: The prospective cohort study included 120 patients with previously diagnosed COPD. In all patients spirometry and transthoracic echocardiography were performed. Patients were divided into four stages of COPD according to Global Initiative for Chronic Obstructive Lung Disease (GOLD) criteria.

Results: The overall HF prevalence was 28.3%:40% in GOLD stage IV, 30% in stage III, 26.7% in stage II and 16.7% in stage I. The prevalence of HF with preserved EF was 23.3%:16.7% in GOLD stage I, 26.7% in stage II, 23.3% in stage III and 26.7% in stage IV. The HF with reduced EF <45% was diagnosed in 6.7% of cases and was present only in severe stages of COPD (6.7% in stage III and 20% in stage IV).

Conclusion: The high prevalence of unrecognized HF highlights the need for echocardiography in COPD patients, especially in advanced COPD stages.

P1582

Small airways obstruction better predicts mortality risk than central airways obstruction in patients with stable heart failure and reduced ejection fraction

Grants from the German Ministry of Education and Research (BMBF), Berlin, Germany [BMBF 01GL0304, BMBF 01GI0205, BMBF 01EO1004, BMBF 01EO1504]

S Brenner¹; M Christa¹; D Berliner²; G Ertl¹; M Held³; A Marx¹; CE Angermann¹; S Stork¹; FH Rutten⁴; G Guder¹

¹University of Würzburg, Department of Internal Medicine I / Comprehensive Heart Failure Center, Würzburg, Germany; ²Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany; ³Medical Mission Clinic, Department of Internal Medicine, Würzburg, Germany; ⁴Julius Health Center - Julius Gezondheidscentra, Department of General Practice, Utrecht, Netherlands

Background: Impairment of pulmonary function increases symptom burden and mortality risk in heart failure (HF). Previous studies focused on the prognosis of a reduction in forced expiratory volume in the first second (FEV1), that is, central airways obstruction. By contrast, the prognostic effect of small airways obstruction as measured by the limitation of mid-expiratory flow (MEF) has not been investigated. We compared the prevalence and prognostic utility of central and small airways obstruction in patients with HF and reduced ejection fraction (HFrEF).

Methods: Spirometry was performed six months after hospitalization for cardiac decompensation in patients with HFrEF at discharge (left ventricular EF ≤40%). We measured the ratio of FEV1 and forced vital capacity (FVC) and the MEF at 50% of FVC. The cut-offs defining central and small airways obstruction were <0.7 for FEV1/FVC and <60% of predicted value for MEF, respectively.

Results: We included 585 patients (mean age 65 ± 12 years, 75% male). 359 (61%) patients had no expiratory flow limitation, 88 (15%) had a FEV1/FVC <0.70 (all of those subjects also showed a MEF reduction), and 138 (24%) patients exhibited only a reduced MEF. During the follow-up period of twelve months, 42 patients (7.2%) died. Figure 1 shows Kaplan-Meier plot of patients with i) no, ii) central, and iii) small airways obstruction. In univariable Cox regression, MEF <60% and FEV1/FVC <0.7 were associated with increased all-cause mortality risk (hazard ratios [95% confidence intervals]: 2.65 [1.42-4.94], p = 0.002, and 2.04 [1.02-5.05], p = 0.043, respectively). In a bivariable model including both parameters, only MEF <60% remained associated with increased mortality risk (2.51 [1.24-5.08], p = 0.010), but not FEV1/FVC <0.7.

Conclusions: Expiratory flow reduction in small airways is more common than central airways obstruction in HFrEF and seems a better predictor of increased risk of death as central airflow limitation.

Kaplan-Meier survival plot

P1583

Prolonged use (18 months) of tiotropium and indacaterol in patient with chronic heart failure due to coronary artery disease combined with chronic obstructive pulmonary disease

V Evdokimov¹; A Evdokimova¹; E Kovalenko¹; K Tebloev¹

¹State University of Medicine & Dentistry, Moscow, Russian Federation

Purpose: to compare clinical efficacy and safety of tiotropium and indacaterol prolonged (18 months) administration in patient with chronic heart failure (CHF) due to coronary artery disease (CAD) combined with chronic obstructive pulmonary disease (COPD).

Methods: after enrollment in this trial 81 patients (58 men and 23 women), aged 66.5 ± 4.3 years, with CHF classes II to III (New York Heart Association) combined with moderate to severe COPD (GOLD-2013) and with initial ejection fraction of the left ventricle (LVEF) less than 45%, were randomized to three groups - tiotropium (18 µg daily, n = 29), indacaterol (150 µg daily, n = 27) and tiotropium+indacaterol group (18/150 µg daily, n = 25). Patients of all groups received the complex CHF treatment comprising diuretics, nebivolol, losartan, cardiac glycosides (subject to indications) and basic COPD therapy (inhalation corticosteroids). Echocardiography, exercise tolerance (6-min walk distance), 24-hour electrocardiography and blood pressure monitoring were assessed at baseline and every 6 months of treatment, respiratory function test was assessed at baseline, after 1 month and every 6 months. The quality of life was evaluated by MYHFG, SGRQ and mMRC.

Results: after 18 months of therapy the improvement of clinical condition and quality of life were marked in all groups. In 1st, 2nd and 3rd group LVEF was increased by 4.2%, 5.0% and 8.8%, pulmonary hypertension decreased by 7.4%, 10.8% and 14.5%, episodes of silent myocardial ischemia decreased by 15.3%, 16% and 21.4%, respectively. Towards the end of the observation period, in all groups there was a confident and authentic increase of forced expiratory volume during 1st second (FEV1) which made 6.6%, 7.7%, and 12.1% accordingly. 6-min walk distance increased by 19.1%, 21.6% and 30.2% accordingly. Patients showed statistically significant and clinically meaningful reduction of SGRQ score (19.4%, 18.1%, 23.7%) and MYHFG score (14.2%, 13.8%, 21.9%), significant improvements in mMRC dyspnea grade (23.1%, 22.2%, 27.5% respectively). All treatments were well tolerated.

Conclusions: the tiotropium and indacaterol inclusion in the structure of complex therapy in patients with CHF combined with COPD raises efficiency of treatment, improves quality of life, basic parameters of central hemodynamics and pulmonary function. Efficacy of long-acting inhaled anticholinergic agent (tiotropium) and long-acting β-agonist (indacaterol) in patient with CHF due to CAD combined with COPD are similar. Combination of these drugs significantly enhances the positive effects of the prolonged therapy.

P1584

Right heart failure as a risk factor for exacerbation in patients with chronic obstructive pulmonary disease

B Santellano-Juarez B¹; A Orea-Tejeda¹; R Zenteno-Hernandez R²; D Gonzalez-Islas D¹; C Cintora-Martinez C¹; R Sanchez-Santillan R¹; J Pineda-Juarez J¹; V Pelaez-Hernandez V¹; R Pablo-Santiago R¹; R Sansores H²

¹Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Clinic, Mexico City, Mexico; ²Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Tabaquism and EPOC Investigation Department, Mexico City, Mexico

Background: Patients with Chronic Obstructive Pulmonary Disease (COPD) exacerbations have progressive and widespread vascular disease and not just respiratory. Heart Failure (HF) is common in patients with COPD, with a prevalence of 10-40%, and is implicated in a considerable number of exacerbations, morbi-mortality and hospitalization. It is estimated that the prevalence of HF undiagnosed in patients presented at emergency services is 20.9%. However it is unknown the role of Right Heart Failure (RHF) on exacerbations in patients with COPD.

Aim: Determine whether the RHF is an independent risk factor for COPD exacerbation.

Materials and Methods: A retrospective cohort study was performed in patients diagnosed with COPD from the Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas" between 2009 - 2015. COPD was diagnosed based on FEV1 / FVC <0.7. Patients with bronchial hyperreactivity or asthma attack were excluded. X2 and independent t-test were performed in order to contrast the differences between the groups with and without exacerbation. Multiple regression analysis was made in order to assess the risk of exacerbations in patients with ICD adjusting for confounding variables.

Results: Were studied 250 patients diagnosed with COPD, age mean 72.22 ± 10 years, 48% were men, from them 105 (42%) presented exacerbations. The differences between subjects with or without exacerbations were: RHF (63.9% vs. 58.8%, p = 0.66), PAH (7.6% vs. 1.6%, p = 0.04), pneumonia (24.2% vs. 51.4%, p = 0.001) thyroid disease (1.1% vs. 10%, p = 0.01). No differences in sex, age, GOLD, diabetes, HAS, dyslipidemia, cancer, diastolic or systolic HF between the two groups

were observed. Adjusting for age, sex, hemoglobin, hematocrit, leukocytes, pneumonia, asthma, hypertension, diabetes, systolic or diastolic HF, patients with Right HF have 5.78 (HR: 5.78; 95% CI 1.13 - 29.49) times the risk of developing COPD exacerbation.

Conclusion: In COPD patients, RHF is an independent risk factor for exacerbations develop, consequently its diagnosis and treatment are essential to prevent complications and / or hospitalizations.

P1585

Trastuzumab-induced cardiomyopathy: a retrospective observational study assessing the prevalence, characteristics and outcomes over 3 years. a single center experience in the eastern province of Saudi

MM Alqaseer¹; H Soudi¹; S Alghamdi¹; A Alalawi¹; KH Herzallah¹; AO Alomar¹; B Alrashidi¹; MA Shaheen¹; M Kharasani¹; B Mushannen¹

¹ King Fahad Specialist Hospital, Cardiology Department, Dammam, Saudi Arabia

Background: The field of cardio-oncology is rapidly growing. Treatment-related cardiotoxicity has been of a significant concern in the management of breast cancer patients. There are well-established reports on the cardiotoxic effects of anthracyclines and trastuzumab in breast cancer. However, there is scarce data to describe its prevalence in the Eastern Province of Saudi Arabia.

Purpose: To better understand the prevalence of trastuzumab-induced cardiomyopathy in our population and the characteristics of the patients that develop this complication along with reversibility of specific type of cardiomyopathy.

Methods: A retrospective observational study was conducted to looking at consecutive patients that received trastuzumab from January 1st, 2012 up to September 30th, 2015 in a single tertiary oncology center in the Eastern province of Saudi Arabia. The patients' baseline characteristics were obtained from chart review and a detailed review of serial echocardiographic studies was gathered. Those with reduction of Ejection Fraction (EF), defined as an EF of less than or equal to 50%, were identified and a careful review of their medications and cardiac biomarkers was done. Serial measurements of EF for those who experienced a decline in EF were captured to assess the percentage of myocardial recovery.

Results: A total of 302 patients received trastuzumab in the pre-specified time period in our center. Out of the 302 patients, 71 patients developed trastuzumab induced cardiomyopathy as defined earlier. This constitutes 23.5% of the population studied. Out of those affected, the mean age was 48.3 ± 10.9 years. 46.4% were hypertensive and 18.30% were diabetic. Out of the 71 patients who developed cardiotoxicity, 55 recovered leaving 22.5% of the population with residual LV dysfunction. However only two patients had persistently significant LV dysfunction defined as an EF of <45%. From the 71 patients with trastuzumab induced cardiomyopathy, 23.4% were initiated on ACE-I/ARB and 20.59% were instituted on beta blockers. As for the biomarkers, BNP was requested in 7 cases and Troponin was requested in 11 cases. Out of all requested troponins, only one patient had a value above the 99th centile. As for the BNP, 11 were above elevated, defined as a value greater than or equal to 100 — . g of those elevated BNP's correlate to those cases with persistent LV dysfunction.

Conclusion: The prevalence of Herceptin induced cardiotoxicity in our population was 23.5% over 3 years. Almost half of these patients were hypertensive and 18.3% were diabetic. 74.3% of these patients recovered, but only 2.8% had significant residual LV dysfunction. Elevation in BNP closely correlated to persistent LV dysfunction. Given the data listed above, we have initiated a pathway by which the population at risk of cardiotoxicity are identified and initiated on an ACE I/ARB at the time of, or even prior to, starting trastuzumab.

Factors associated with cancer chemotherapy-induced cardiomyopathy: a cumulative case-control study

RC Rod Castro¹; AID Dy¹

¹ St. Luke's Medical Center, Dr. HB Calleja Heart and Vascular Institute, Quezon City, Philippines

Objective: To determine the factors associated with the occurrence of cancer chemotherapy-induced cardiomyopathy. Design: Retrospective study. Setting: Pay and charity patients of our Medical Center in Philippines. Patients/Participants: All newly diagnosed cancer patients who underwent chemotherapy, 18 years old and above seen from January 2009 to December 2014. Patients who had cardiomyopathy prior to study period or who have had cardiomyopathy prior to study period or who have had cardiomyopathy prior to having cancer; pregnant patients and patients who were diagnosed with coronary artery disease by coronary angiogram were excluded.

Results: Among the risk factors studied (age, gender, body surface area, type of cancer, stage of cancer, left ventricular ejection fraction before chemotherapy and presence or absence of comorbidity), gender is the only significant risk factor associated with cancer chemotherapy-induced cardiomyopathy with an odds ratio of 10.6 (95% CI 3.07, 36.65) with a p value of 0.00001, which is statistically significant. Thus, male is 10.6 times more likely to develop cardiomyopathy compared to female.

Conclusion: Gender is significantly associated with the occurrence of cancer chemotherapy-induced cardiomyopathy. Specifically, males are 110.6 times more likely to develop cardiomyopathy than females.

VALVULAR HEART DISEASE(DIAGNOSIS, MANAGEMENT AND INTERVENTIONAL THERAPIES)

Permanent pacemaker implantation after a new fully repositionable device for trans-catheter aortic valve implantation; impact on left ventricular function and myocardial deformation.

F Irazusta Cordoba¹; R Moreno Gomez¹; T Lopez Fernandez¹; D Gemma¹; M D'angelo¹; V Rial Baston¹; P Meras Colunga¹; O Gonzalez Fernandez¹; SO Rosillo Rodriguez¹; JL Lopez-Sendon¹

¹ University Hospital La Paz, Cardiology, Madrid, Spain

Background: Fully repositionable trans-catheter aortic valve devices (TAVI) facilitate precise positioning and minimise paravalvular regurgitation. However, the occurrence of some periprocedural complications remains a concern, and the need for permanent pacemaker implantation (PPI) after the procedure is frequent. Very few data exist on the clinical, myocardial deformation and left ventricular ejection fraction impact of PPI after second-generation TAVI procedure.

Methods: A total of 20 consecutive patients with symptomatic severe aortic stenosis undergoing TAVI with fully repositionable devices were included.

Results: Mean age was 80.6 years, 65% were female and 70% were New York Heart Association functional class III/IV. Eight patients (45%) required a PPI within the first 30 days after TAVI. The average hospital stay for TAVI procedure was 9 days, with no differences between the PPI and no PPI groups ($p=0.3$). After a mean follow-up of 12 months, a total of 3 patients (15%) either had died or required a rehospitalization for heart failure, with no differences between the PPI and no PPI groups (8.3% versus 25%; Fisher's exact: 1.045; $P=0.31$). Left ventricular ejection fraction decreased slightly in the overall population at 12-month follow-up (from $60.29 \pm 10.9\%$ to $57.57 \pm 11\%$). But a small improvement in myocardial deformation by global longitudinal strain (GLS) was observed over time by mean (from $-16.05 \pm 4.1\%$ to $-16.53 \pm 4.8\%$), with no differences between PPI and no PPI groups (-15.02% versus -18.42% ; T-student: -1.15 ; $P=0.28$).

Conclusions: PPI after a new fully repositionable device for trans-catheter aortic valve implantation remains a frequent complication, but it was not associated with any increase in cardiovascular death or rehospitalization for heart failure after a follow-up of 12 months. Indeed, myocardial deformation by GLS increased in the overall population over time.

P1588

The effects of TAVI on arterial stiffness and ventricular-arterial coupling

E Edoardo Sciatti¹; E Vizzardi¹; I Bonadei¹; F Platto¹; M Metra¹

¹ University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy

Background: transcatheter aortic valve implantation (TAVI) is a percutaneous intervention for patients affected by severe aortic stenosis not suitable for cardiac surgery, typically the eldest. The ageing process itself is responsible of vascular and ventricular stiffening. Arterial stiffness and ventricular-arterial coupling (VAC) are independent prognostic factors in patients suffering from heart failure (HF).

Purpose: we aimed at evaluating arterial stiffness and VAC before and early after TAVI.

Methods: 20 patients scheduled for TAVI were enrolled. Within 3 day before and at least 3 day after the procedure they underwent radial artery applanation tonometry to evaluate central blood pressures and augmentation index (AIx@75), and transthoracic echocardiography to calculate the aortic elastance (Ea), the end-systolic left ventricular elastance (Ees) and their ratio, namely VAC.

Results: mean age was 82 ± 8 years. 12 (60.0%) were male. Functional aortic valve area was 0.7 ± 0.2 cm², peak gradient 82 ± 26 mmHg and mean gradient 49 ± 17 mmHg. Hemodynamic parameters are reported in Table 1. After TAVI there was a great improvement in AIx@75. Moreover, a tendency to amelioration was found for central blood pressures, stroke volume, Ea, Ees and VAC, without statistical significance.

Conclusion: TAVI is associated with an early improvement in arterial stiffness and a tendency to better central hemodynamics and VAC. Considering the prognostic role of these factors in patients with HF, TAVI is of growing importance under different points of view.

Table 1

Variable	Before TAVI	After TAVI	p
Aortic SBP (mmHg)	117 ± 20	113 ± 19	0.4
Aortic DBP (mmHg)	71 ± 12	66 ± 10	0.1
Aortic MAP (mmHg)	88 ± 14	89 ± 12	0.1
Aortic PP (mmHg)	46 ± 15	47 ± 13	0.8
Alx@75 (%)	33 ± 16	23 ± 12	0.005
Stroke volume (mL)	76 ± 21	85 ± 30	0.2
Ea (mmHg/mL)	1.6 ± 0.6	1.5 ± 0.5	0.5
Ees (mmHg/mL)	1.8 ± 0.9	1.9 ± 0.8	0.8
VAC	1.0 ± 0.4	0.9 ± 0.3	0.3

SBP=systolic blood pressure; DBP=diastolic blood pressure; MAP=mean arterial pressure; PP=pulse pressure; Alx@75 augmentation index corrected for 75 bpm; Ea=aortic elastance; Ees=end-systolic left ventricular elastance; VAC=ventricular-arterial coupling

Mitral regurgitation severity correlates with symptoms and extent of left atrial dysfunction: effect of mitral valve repair

M Lisi¹; M Cameli¹; C Di Tommaso¹; F D'ascenzi¹; M Focardi¹; M Maccherini²; M Chiavarelli²; P Linqvist³; S Mondillo¹; M Henein³

¹Department of Cardiovascular Disease, University of Siena, Siena, Italy; ²Division of Cardiac Surgery, University of Siena, Italy, Siena, Italy; ³Heart Centre & Department of Public Health & Clinical Medicine, Umea University, Umea, Sweden

Background: Severe mitral regurgitation (MR) causes left ventricular (LV) and left atrial (LA) volume overload, and atrial fibrillation (AF). The aim of the study was to assess the relationship between MR severity, symptoms and LA structure and function, and their response to mitral valve repair (MVR).

Methods and Results: Global peak atrial longitudinal strain (PALS) was evaluated in 37 patients with severe symptomatic MR and preserved LVEF (60 ± 4.6%) before and 3 months after MVR and was compared with values from 30 age- and gender-matched controls. Before surgery, compared with controls, global PALS was reduced and indexed LA volume was increased (p < 0.0001 for both) and fell after MVR (p = 0.001 and p = 0.05, respectively). After surgery, LVEF and longitudinal strain (LS) reduced (p = 0.05 and p < 0.001, respectively) and LV mass (LVM) regressed (p < 0.0001). Before surgery, LA volume correlated modestly with end-diastolic volume (R = 0.51; p = 0.01); effective regurgitant orifice area (EROA) correlated strongly with PALS (R = -0.69; p < 0.001) and modestly with LVLS (R = 0.54; p = 0.01); and NYHA class correlated strongly with PALS (R = -0.69; p < 0.001) and EROA (R = 0.60; p < 0.001), modestly with LA volume (R = 0.51; p = 0.04), but not with LVLS (R = 0.23; p = ns). LA volume was the strongest predictor of global PALS reduction (p < 0.001) and indexed LVM of LA volume reduction (p < 0.001) after MVR while global PALS was the main predictor of post-operative AF (p < 0.001).

Conclusions: In patients with severe MR, symptoms correlate with EROA as does LA PALS, which itself predicts the occurrence of post-operative AF and is determined by LA volume.

P1590

Adverse events in operated and non-operated patients with severe aortic valve stenosis

J M Bye¹; M Hansen¹; A Auensen¹; A H Hussain¹; K I Pettersen¹; L L Gullestad¹

¹University of Oslo, Faculty of Medicine, Department of Cardiology, Oslo, Norway

Background/Introduction: Aortic valve replacement (AVR) in patients with severe aortic valve stenosis (SAVS) provides considerable improvement of survival and quality of life. Postoperative adverse events are not negligible, but little is known about the total burden when compared with patients refused for AVR. Purpose To report adverse clinical events one year following AVR and one year after refusal for AVR, in patients with SAVS. Methods Of 480 patients with SAVS evaluated for AVR, 389 underwent operation (OP) and 91 were declined operation (NON-OP). Mean (SD) age was 74 (10) and 81 (9) years, and percentage women was 41 and 52 for OP- and NON-OP respectively. Counting one year from the operation day, or time of evaluation for non-operated patients, all available medical records were reviewed. The outcomes of interest were predefined as clinically relevant. Results See table Conclusion This study demonstrate a significant number of adverse events among OP patients, but not being operated for SAVS is associated with significantly more myocardial infarctions, new hospital admissions as well as significantly increased one-year mortality. These results advocate AVR in patients with SAVS.

Frequencies of adverse clinical events

	OP, n = 389	NON-OP, n = 91	p-value
	During postoperative stay	One year	One year
One-year mortality, n (%)	-	22 (6)	17 (19) < 0.01

Low cardiac output syndrome after aortic valve replacement in 2045 elderly patients

WP Mistiaen¹; I Deblier²; P Van Cauwelaert²; K Dossche²; P Muylaert²; A Vanermen²

¹Artesis-Plantijn University College, Health and Social Care, Antwerp, Belgium;

²ZNA Middelheim Hospital, Cardiovascular surgery, Antwerp, Belgium

Background: Low cardiac output syndrome (LCOS) is one of the most lethal hospital complications after aortic valve replacement. If modifiable predictors can be identified, postoperative outcome might improve.

Purpose: Identification of modifiable predictors for LCOS. Methods A retrospective file study of 2045 patients was performed, in whom a diseased aortic valve was replaced by a bioprosthesis. Of these, 1124 were males and 513 were over 80. The mean age was 76 ± 6 years. Concomitant CABG was performed in 1243 patients. For 36 preoperative and 10 operative variables, a chi-square test was performed to examine their effects on LCOS. The significant variables were entered in a stepwise logistic regression, to identify the independent predictors. Results LCOS was diagnosed in 110 patients, which was fatal in 51% of the cases. Need for urgent valve replacement is the most dominant predictor. LCOS is also associated with a prolonged stay in the intensive care unit (p < 0.001), pulmonary complications (p < 0.001), increased need for transfusion (p = 0.007), ventricular arrhythmias (p = 0.012) and delirium (p = 0.015). Conclusion Need for urgent valve replacement is the most dominant modifiable predictor for postoperative LCOS. This points to an exhaustion of compensatory mechanism of the left ventricle to maintain an adequate circulation. This could be prevented by removing timely the pressure burden of the stenotic valve. Once symptoms develop, surgery should not be delayed. Except for the choice for a Carpentier-Edwards pericardial valve, there are no other modifiable predictors.

P1592

Magnesium orotate improves health-related quality of life after surgical valve replacement

IR Ilshat Gaisin¹; AS Gazimzyanova²; VM Abseeva²; EA Chernikh²; LV Richkova²; AA Galimova²; MA Voronova²; ER Sabirzyanova²

¹State Medical Academy, Izhevsk, Russian Federation; ²Clinical Diagnostic Centre of the Udmurt Republic, Izhevsk, Russian Federation

Purpose: Successful surgical intervention in valvular heart disease has been shown to prolong and improve quality of life. We aimed to evaluate postoperative

health-related quality of life (HRQoL) in patients following metabolic magnesium orotate therapy.

Methods: 100 patients (aged 56.2 ± 3.5 years, 62 males, 35% concomitant SCAD) 2–4 weeks after surgical aortic (n=58) and mitral (n=42) valve replacement by mechanical prostheses were randomized 1:1 to receive either conventional therapy (vitamin K antagonists, ACEIs/ARBs, beta-blockers, diuretics, MRAs, statins and digoxin) or magnesium orotate (500 mg t.i.d.) added to standard treatment. HRQoL was assessed at baseline and 12 months using the Short Form (SF-36 v.1) Health Survey.

Results: There were no significant differences between magnesium orotate and control groups at baseline. Patients reported poor postoperative HRQoL. In both groups, SF-36 scores substantially rose after follow-up. Magnesium orotate patients had significant higher improvements in HRQoL over time compared to controls. One patient died in the control group ($p = 0.63$).

Conclusions: Mechanical valves patients commonly suffer from severe HRQoL impairment. Long-term magnesium orotate, added to conventional treatment, greatly improves HRQoL. The results provide support for nonsteroidal anabolic magnesium orotate as an additional therapy for patients with heart valve prostheses.

Health-related quality of life				
SF-36 scales	Baseline mean scores (SE)	1-year % change from baseline		
Control (n = 50)	Magnesium orotate (n = 50)	Control (n = 49)	Magnesium orotate (n = 50)

Improvement of left ventricular function beyond ejection fraction in patients undergoing percutaneous mitral valve repair

O M Galuszka¹; S Rutschow¹; M Gross¹; U Landmesser¹; M Kasner¹

¹Charité - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany

Aims: Long-standing mitral regurgitation (MR) causes chronic volume-overload leading to left ventricular (LV) enlargement and remodeling. The objective of this study was to investigate the effect of LV remodeling on LV function after percutaneous mitral valve repair (PMVR).

Methods and Results: 66 heart failure patients with moderate-to-severe MR undergoing PMVR underwent speckle-tracking echocardiography (STE) at baseline and at six-months follow-up. Despite no notable improvement in LV ejection fraction (LVEF; $43.3 \pm 14.6\%$ vs. $44.5 \pm 14.9\%$, $p = 0.163$) study patients provided an increase in effective forward stroke volume (SV) determined by means of PW Doppler in left ventricular outflow tract (63.4 ± 37.1 ml vs. 76.2 ± 35.1 ml, $p < 0.001$) implying an improvement of global cardiac performance.

In our study we differentiated 35 patients with LV remodeling and 31 patients without (LVN). LVN patients showed preserved LV function with higher baseline LVEF ($50.9 \pm 12.2\%$ vs. $35.2 \pm 12.7\%$, $p < 0.001$) and LV global longitudinal strain (GLS)

than LVR patients ($-13.8 \pm 3.5\%$ vs. $-9.9 \pm 4.5\%$, $p < 0.001$) indicating better myocardial contractility. Most importantly, we noted a salient amelioration in GLS following PMVR in LVN patients ($-13.8 \pm 3.5\%$ vs. $-16.3 \pm 3.8\%$, $p < 0.001$) whereas no improvement was observed in LVR group ($-9.9 \pm 4.5\%$ vs. $-9.9 \pm 5.1\%$, $p = 0.936$).

Conclusion: In patients with chronic MR PMVR results in increased SV, which remains undetected by means of conventional echocardiographic parameters. STE describes significant reverse remodeling in patients undergoing PMVR demonstrating that patients with preserved LV geometry show notable improvement in terms of LV contractile function.

P1594

Influence of atrial fibrillation on heart remodelling and severity of heart failure at patients with mitral valve disease

A Andrey Zhadan¹; O Romanenko²; E Zedginidze¹; V Tseluyko¹

¹Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine; ²City Clinical Hospital #8, Kharkiv, Ukraine

Purpose: To evaluate the influence of atrial fibrillation on heart remodelling at patients with mitral valve disease after valve replacement. **Methods:** 95 patients (mean (SD) age 57.4 ± 9.6 years) with mitral valve disease (isolated mitral stenosis (MS) – 40 patients, isolated mitral regurgitation (MR) – 48 patients, combined valve lesion – 7 patients) who underwent mitral valve replacement. Atrial fibrillation (AF) before valve replacement has 65 patients (permanent – 39 patients, paroxysmal and persistent – 26 patients). Before and 12 months after valve replacement patients underwent transthoracic echocardiography and 6-minute walk test (MWT). **Results:** At baseline the size of the left atrium was greater in patients with AF 57.6 ± 6.4 mm and 49.2 ± 5.3 mm, respectively. At 12 months after surgery in patients with atrial fibrillation there was a significant ($p < 0.05$) decrease in the size of the left atrium from 49.2 ± 5.3 mm to 41.4 ± 4.1 mm. In patients with AF, such changes were not observed. Also in the second group there was a significant ($p < 0.05$) decrease in the size of the left ventricle (LVESD and LVEDD). In the first group these parameters also were unchanged. At month 12 it was significant improving ($p < 0.05$) in 6-minute walk test distance in both groups: from 186.6 ± 89 m to 339 ± 80 m at patients with AF and from 227.5 ± 74 m to 457 ± 91 m at patients without AF.

Conclusions: The absence of atrial fibrillation positively affects on parameters of cardiac remodeling at patients with mitral valve disease 12 months after valve replacement. The presence of AF in patients with mitral valvular disease does not significantly affect the positive dynamics of the 6-minute test 12 months after valve replacement.

Table 1

	1 groupe (with AF)		2 groupe (without AF)	
	Pre-operative	12 month	Pre-operative	12 month
LA (mm)	57,6 ± 6,4	51,5 ± 4,9	49,2 ± 5,3*	41,4 ± 4,1*
LVESD (mm)	36,3 ± 6,1	37,1 ± 5,4	40,5 ± 5,8*	32,6 ± 4,9*

Is there any difference in interplay between kidney and heart after TAVR or SAVR?

M Marta Zaleska-Kociecka¹; A Skrobisz¹; I Wojtkowska¹; M Grabowski²; M Dabrowski³; K Kusmierski⁴; J Imieli⁵; J Stepinska¹

¹National Institute of Cardiology, Intensive Cardiac Therapy Clinic, Warsaw, Poland;

²National Institute of Cardiology, Department of Acquired Cardiac Defects, Warsaw, Poland;

³National Institute of Cardiology, Department of Interventional Cardiology and Angiology, Warsaw, Poland;

⁴National Institute of Cardiology, Department of Cardiosurgery and Transplantation, Warsaw, Poland;

⁵Miedzyleski Specialist Hospital, 1st Department of Internal Medicine and Nephrology, Warsaw, Poland

Background: Data on acute and chronic cardio-renal syndromes in patients undergoing aortic valve replacement are scarce.

Purpose: To compare influence of AKI on 6-month cardiac and kidney performance in the elderly with severe aortic stenosis (AS) undergoing surgical or transcatheter aortic valve replacement (SAVR or TAVR). **Methods:** Eighty over 70-year-old consecutive patients with severe symptomatic AS undergoing SAVR (n=40) or TAVR (n=40) were enrolled in prospective, observational single-centre study. Thirty-five patients in each group attended 6-month follow-up visit. AKI was defined based on VARC-2 criteria.

Results: AKI was more prevalent after SAVR compared to TAVR (72.5% vs 47.5%; $p=0.022$) despite higher baseline eGFR ($p=0.01$), younger age ($p<0.001$) and lower logistic EuroSCORE ($p=0.001$). Baseline NTproBNP levels and left ejection fraction (LVEF) were similar between the groups but NYHA class was lower in TAVR ($p=0.004$). To assess the influence of AKI occurrence patients were divided into 4 subgroups: SAVR/AKI SAVR/nonAKI TAVR/AKI TAVR/nonAKI. Baseline LVEF, NTproBNP levels and NYHA class were comparable between AKI and nonAKI subgroups in both SAVR and TAVR. eGFR was lower in AKI subgroups compared to correspondent nonAKI ones. After procedure NTproBNP increased ($p=0.042$) only in SAVR/AKI patients. Thus, at discharge median NTproBNP values were higher in SAVR/AKI compared to SAVR/nonAKI patients ($p=0.003$; Figure 1B). At the follow-up SAVR/AKI patients improved NYHA class ($p<0.001$) and reduced NTproBNP (both $p<0.012$), however median NTproBNP levels remained higher in SAVR/AKI vs SAVR/nonAKI ($p=0.006$; Figure 1B), along with tendency for higher median NYHA class (1 IQ 0 vs 1 IQR 1; $p=0.056$). Neither NYHA class nor NTproBNP values were affected by AKI in TAVR (Figure 1A). NYHA class improved in both TAVR subgroups (both $p<0.002$). AKI occurrence did not lead to significant reduction of eGFR in neither group (Figure 1A and 1B).

Conclusions: AKI affected NTproBNP levels only after SAVR. The effect persisted for 6 months. AKI occurrence did not alter chronic kidney function in neither therapeutic group.

Figure 1. Comparison of NTproBNP and eGFR changes between AKI and nonAKI patients after (A) TAVR and (B) SAVR.

P1596

Calcium-phosphate metabolism disturbances and quality of life in patients with significant mitral regurgitation.

O Olga Mozenska¹; A Segiet²; D Rabczenko³; DA Kosior¹

¹Clinical Hospital of the Ministry of Internal Affairs, Cardiology and Hypertension, Warsaw, Poland; ²Medical University of Warsaw, 1st Medical Faculty, Warsaw, Poland; ³National Institute of Public Health - National Institute of Hygiene, Warsaw, Poland

Purpose: There are several factors connected with quality of life (QL) in patients with valvular heart disease (VHD). Though new ones are still researched. In recent years trials indicated vitamin D (25(OH)D3) and other calcium-phosphate (Ca-P) metabolism parameters and its disturbances as potential new factors influencing QL. Taking under consideration frequency of Ca-P metabolism disturbances and frequency of VHD in general and cardiovascular population we assessed the extent of Ca-P metabolism disturbances in this population and their influence on QL.

Methods: 99 consecutive patients hospitalized in our Department 07-09.2013 were included in the study. Inclusion criteria were: age>18, significant mitral regurgitation (MR) assessed with TTE (vena contracta>3mm, effective orifice area>0.2 cm², MR volume>30ml/s). EQ-5D, SF-36 and MacNew QL Questionnaires (MNQLQ) were used to assess health-related QL (HRQL). Results We included 39 patients with severe and 60 with moderate MR (39.9% and 60.6% accordingly, average (avg) age 73.2yrs, 33.3% female). There were no significant differences in anthropometric measures between 2 studied groups. Avg serum Ca level corrected by albumins was 3.2mmol/L in both groups, avg serum Ca ionized level

corrected by pH was 1.06mmol/L in severe MR group and 1.05mmol/L in moderate MR group, avg serum P level was 3.6mmol/L and 3.4mmol/L in severe MR and in moderate MR group accordingly ($p=0.055$), avg 25(OH)D3 level was 17.7ng/ml in severe MR group and 14.9ng/ml in moderate MR group. Additionally avg daily urinary P excretion was 37.2g/24 hours and 29.08g/24 hours in moderate and in severe MR group respectively and avg PTH level was 72.04pg/ml and 71.8pg/ml accordingly. We ascertained presence of Ca-P metabolism disturbances in population with significant MR, but with no significant differences in groups divided according to MR severity. There was significant negative correlation between parathormone (PTH) level and HRQL in 3 domains assessed with MNQLQ ($(\rho)=(-0.242);(-0.243)$ and (-0.255) , $p=0.018$; 0.018 and 0.013 for Global, Physical and Social domains respectively). Additionally we found significant correlation between the presence of abnormal PTH level itself and scores gained in 3 HRQL domains assessed with MNQLQ (4.34 ± 1.26 and 3.76 ± 1.30 , $p=0.031$; 4.17 ± 1.44 and 3.49 ± 1.38 , $p=0.027$; 4.48 ± 1.44 and 3.81 ± 1.39 , $p=0.019$ for Global, Physical and Social domains respectively).

Conclusions: There are significant Ca-P disturbances in population with significant MR. Those disturbances result in significantly worse QL. Further studies are needed to assess importance of those findings.

P1597

Could one-year effect of cardiac resynchronization therapy on hemodynamic parameters evaluated by impedance cardiography be predicted?

M Michal Orszulak¹; A Filipceki¹; K Mizia-Stec¹

¹7th Public Hospital of the Silesian Medical University, I Departement of Cardiology, Katowice, Poland

Background: Impedance cardiography (ICG) is a plethysmography technique for non-invasive measurement of hemodynamic parameters.

Purpose: the aim was to find out if ICG can be an useful in assessment of cardiac resynchronization therapy (CRT) efficacy.

Methods: A single-center, prospective study included 26 patients with chronic HF (92.3% male, 65.5 ± 9.4 years, 42.3% NYHA class II, 57.7% NYHA class III, 15.4% with atrial fibrillation, 61.5%, ischemic etiology of HF) qualified to CRT implantation. In all patients CRT were optimized in periprocedural period. ICG was performed twice: one day before CRT implantation (before CRT) and 9-12 months post-implantation (after CRT).

Results: There was a significant improvement in some hemodynamic parameters in patients after CRT implantation (Table). In 8 patients (30.8%) a significant increase (defined as more than one standard deviation change) in stroke volume was observed. In 16 patients (61.5%), the changes were not significant and only 2 patients had deterioration of hemodynamic parameters (fall over one standard deviation in SV). Efficacy of treatment (defined as no heart failure worsening measured by ICG) was observed in 24 patients (92.3%). No significant differences in baseline demographics, clinical and echocardiographic parameters were found between 8 responders in comparison with the remaining 18 patients.

Conclusion: One-year efficacy of CRT in patients with heart failure can be demonstrated by ICG. No baseline demographics, clinical or echocardiographical data were able to predict the one-year response.

Hemodynamic parameter	before CRT	after CRT	p
Heart rate (HR) / bpm	$65 \pm 7,1$	$63,4 \pm 8$	$p=ns$
Stroke volume (SV) / ml	$66,6 \pm 10,3$	$76,2 \pm 18,7$	0,029
Cardiac output (CO) / l/min	$4,3 \pm 0,7$	$4,8 \pm 1,1$	0,056
Cardiac index (CI) / l/min/ m ²	$2,2 \pm 0,4$	$2,4 \pm 0,6$	0,074
Left Ventricular Ejection Time (LVET) /ms	$276,2 \pm 55,9$	$304 \pm 63,9$	0,028
Systemic vascular resistance (SVR) / dyn·s/cm ⁵	$1552,8 \pm 235,3$	1631 ± 407	$p=ns$
Systemic vascular resistance index (SVRI) / dyn·s/cm ⁵ / m ²	$3103,8 \pm 541,1$	$3249,9 \pm 802,2$	$p=ns$

FDA expedited access pathway enables staged approval opportunity for baroreflex activation therapy for heart failure with reduced ejection fraction: the BeAT-HF trial

This study is funded by CVRx, Inc., Minneapolis, Minnesota, USA.

WT Abraham¹; J Lindendorf²; EG Lovett³; F Weaver⁴; FA Zannad⁵; MR Zile⁶

¹The Ohio State University, Division of Cardiovascular Medicine, Columbus, United States of America; ²Vanderbilt University, Division of Cardiovascular Medicine, Nashville, United States of America; ³CVRx, Inc., Department of Research, Minneapolis, United States of America; ⁴University of Southern California, Division of Vascular Surgery and Endovascular Therapy, Keck School of Medicine, Los Angeles, United States of America; ⁵University Hospital of Nancy, Department of Cardiovascular Disease, Nancy, France; ⁶Medical University of South Carolina, Division of Cardiology, Charleston, United States of America

Background: Baroreflex activation therapy (BAT) improves quality of life, functional status, exercise capacity and biomarkers in patients with heart failure with reduced ejection fraction (HFrEF). Phase II randomized, controlled results also indicate BAT may reduce HF hospitalization. While these findings secured European regulatory approval, in the United States it is commonly necessary to improve outcomes. This may not only increase time to approval but also pre-market costs of clinical development to >100 million Euros. Thus, FDA initiated a program to accelerate approval of novel therapies targeting an unmet need for life-threatening conditions, the Expedited Access Pathway (EAP). The EAP allows initial approval using surrogate and intermediate endpoints with post-approval demonstration of improved outcomes. Motivated by strong Phase II results, coupled with the unmet need, FDA worked with the sponsor and clinical steering committee to design a trial within the EAP.

Purpose: To describe BeAT-HF, a 2-phase, prospective, randomized trial of BAT in HFrEF.

Methods: The overall objective of BeAT-HF is to demonstrate that BAT reduces HF hospitalization and cardiovascular mortality. At least 480 HFrEF patients will be randomized to guideline-directed medical therapy (GDMT) or BAT+GDMT. The first study phase includes the initial 264 patients followed for 6 months. Improved 6-minute hall walk distance, quality of life from the Minnesota Living with HF Questionnaire and NT-proBNP will suffice for pre-market approval submission if the probability of meeting the outcomes endpoint is trending positive, with an associated indication for HFrEF symptom relief. At the end of the first phase, accrued events will be analyzed to determine if sample size adjustment is required. Following enrollment completion events will be monitored until the outcomes endpoint is determined. Improved outcomes will result in a supplemental indication for the general treatment of HFrEF with commensurate labeling. The adaptive design is guided by a Bayesian approach with the final sample size determined by predictive probability with observed effect sizes at pre-specified interim analyses.

Conclusion: Based on favorable Phase II results of BAT in HFrEF and the unmet need of the population, a unique collaboration with FDA, taking advantage of the Expedited Access Pathway and using an innovative adaptive trial design has produced the BeAT-HF trial for possible US regulatory approval. The trial allows for staged approval of BAT, first for symptom relief and later for outcomes improvement. Enrollment is to begin early in 2016.

A local network for refractory cardiogenic shock

C Carlotta Sorini Dini¹; C Lazzeri¹; M Chiostrì¹; P Bernardo¹; A Sorì¹; F Cappelli¹; PL Stefano¹; S Valente¹

¹Careggi University Hospital (AOU), Florence, Italy

Background: Veno-Arterial Membrane Oxygenation (VA-ECMO) represents a therapeutic option in patients with refractory cardiogenic shock (RCS).

Purpose: Only a restricted number of centers have technical capabilities for implanting VA-ECMO and for management of this support, so it is necessary to create a local network for patients with RCS. We report on the initial experience of our ECMO referral center for patients with RCS. **Methods:** We analyzed our ECMO data registry for RCS, particularly we considered 9 patients with RCS treated with VA-ECMO, consecutively transferred by peripheral hospitals to our Intensive Cardiac Care Unit (ICCU). A multidisciplinary team assessed indications and the suitable setting of ECMO implantation.

Results: In our population (6 male, median age 54.7 years) the most frequent etiology of RCS was acute coronary syndrome (55.5%). 4 patients (44.4%) implanted VA-ECMO in the peripheral centers and after on-site stabilization, they were transferred to our hospital with no adverse events (median distance 38 Km). Other 5 patients were directly transferred to our ICCU and there treated with VA-ECMO. All 9 patients survived at discharge, their length of stay in ICCU median was 19 days. After discharge 7 patients showed a complete recovery, one patient underwent to cardiac transplantation (CT) effectively, one patient died while waiting for CT because of cerebral haemorrhage. The survival rate after 30 days was 88.9% and all survival showed a good neurological outcome (cerebral performance category scale 1-2).

Conclusions: In our series, the survival rate of RCS patients supported by VA-ECMO is high (100% during ICCU, 88.9% after 30 days) and the neurological outcome is good. Our data support that a network for RCS is needed to transfer safely patients in well-experienced center.

Sex	Age	Etiology	Site ECMO implantation	Length of ECMO (days)	ICCU LOS (days)	Evolution

Long-term survival and predictors of mortality in patients supported with a left ventricular assist device as destination therapy

CJ Kapelios¹; I Tachliabouris¹; E Vlaras¹; M Tsamatsoulis²; K Malliaras¹; S Theodoropoulos³; C Charitos²; J John Nanas³

¹University of Athens, School of Medicine, 3rd Cardiology Dept., Athens, Greece;

²Evangelismos Hospital, Athens, Greece; ³University of Athens, Athens, Greece

Background: Left ventricular assist devices (LVADs) represent an established therapeutic option for patients with end-stage heart failure (HF). Due to the paucity of cardiac allografts, LVADs are increasingly used as destination therapy.

Purpose: To study the long-term outcome and identify predictors of mortality in patients who underwent implantation of a continuous flow LVAD as destination therapy in a single, tertiary teaching hospital.

Methods: All patients who underwent implantation of a continuous flow LVAD with the indication of destination therapy during the period 1/2006-12/2015 were included in the analysis. We recorded the baseline characteristics and the long-term outcome, and performed univariate analysis to identify predictors of 1-year mortality.

Results: Thirty four patients (mean age 53±11 years) underwent implantation of a continuous flow LVAD as destination therapy during this period. Twelve percent of the patients were female; 59% suffered from ischemic cardiomyopathy. Mean values of New York Heart Association class, left ventricular ejection fraction (LVEF), cardiac index and BNP were 3.9±0.5, 23.2±5.7%, 1.9±0.5 L/min/m² and 1494±1319pg/ml. Only 32.5% and 14.7% of the patients tolerated administration of a b-blocker and an ACE inhibitor/ARB prior to implantation, while mean daily dose of furosemide was 554±404mg. Predicted 1-year survival based on the Seattle Heart Failure Model was 40%.

Peri-operative mortality was 8.8%. Survival rates at 1, 3 and 5 years were 81.3%, 44% and 29.2%, respectively. The longest observed survival exceeds 8.5 years from LVAD implantation. In univariate analysis, the baseline characteristics that correlated with 1-year mortality were female sex (HR: 7.1, p=0.025), non-ischemic cardiomyopathy (HR: 8.5, p=0.05), INTERMACS profile (HR: 0.28, p=0.032), LVEF (HR: 1.17, p=0.043) and systolic arterial pressure (HR: 0.79, p=0.04).

Conclusion: The implantation of a continuous flow LVAD impressively increases the survival of patients with end-stage HF. Identification of factors that affect the long-term outcome of these patients will enable selection of the most suitable candidates for chronic mechanical support.

P1601

Single center long term results of mechanical circulatory support in the Netherlands

SEA Felix¹; FZ Ramjankhan²; F De Heer²; MP Buijsrogge²; WJL Suyker²; N Hulstijn²; C Klopping¹; JH Kirkels¹; N De Jonge¹

¹University Medical Center Utrecht, Cardiology, Utrecht, Netherlands; ²University Medical Center Utrecht, Cardiothoracic surgery, Utrecht, Netherlands

Background: Prevalence of heart failure (HF) increases. Despite improvement in medical therapy it has a poor prognosis (1 year mortality 26% in patients aged ≤ 75 years). In end-stage HF refractory to medical therapy mechanical circulatory support (MCS) improves survival and quality of life. Nowadays, continuous-flow left

ventricular assist devices (cf-LVADs) are most often implanted. In The Netherlands, duration on MCS has increased because of an increasing waiting list for heart transplantation due to lack of donor hearts. Consequently, experience is built on longer term support. We present the long term results from our hospital.

Purpose: To provide insight in long term mechanical circulatory support.

Methods: Of all patients (pts) who received MCS between March 2006 and January 2016, data were prospectively collected in a central database, including baseline clinical characteristics as well as complications defined according to INTERMACS. Data were extracted for statistical analysis.

Results: 203 cf-LVADs were implanted in our hospital. 67 pts were transplanted and 7 pts explanted. Actuarial survival at 5 years is 68% (figure 1). Death was most often caused by neurological complications and sepsis. Gastro-intestinal bleeding and intracerebral complications (hemorrhage and stroke) both occurred 0.15 times per patient year. Twenty-seven replacements were performed, most often due to pump thrombosis or technical defects.

Conclusion: MCS in patients with end-stage HF has a 5-year survival of 68%. It is a promising therapy that might be a good alternative for heart transplantation in selected patients. However, further optimization of the therapy as well as management of long term complications is required.

Evolution of mitral regurgitation in Berlin Heart EXCOR LVAD patients less than 10kg

A Arianna Di Molfetta¹; R Adorisio¹; R Iacobelli¹; G Pontrelli¹; A Toscano¹; F Gandolfo¹; S Filippelli¹; A Amodeo¹

¹Bambino Gesù Childrens Hospital, Pediatric Cardiology and Cardiac Surgery, Rome, Italy

Background: Left ventricular assist device (LVAD) is an important treatment option for bridging pediatric patients to heart transplant. LVAD allows left ventricular (LV) unloading with an improvement in mitral regurgitation (MR). However, a significant MR may persist in some patients with LVAD.

Purpose: The aim of this work is to evaluate the evolution of mitral regurgitation in pediatric patients less than 10Kg undergoing LVAD implantation.

Methods: Echocardiographic data of 15 pediatric patients less than 10Kg undergoing Berlin Heart EXCOR LVAD implantation were retrospectively collected before implantation and one, three and six months after LVAD to assess LV unloading and MR evolution.

Results: HF etiology was idiopathic dilated cardiomyopathy (79%) and non compacted LV myocardium (21%). Mean time of LVAD staying was 115.45 ± 84.33 days. The incidence of MR was in 8 patients at the baseline and 4 patients at the three and six months follow up. At the univariate analysis of patients with and without significant MR at the implantation, age, mitral valve annulus, left atrial size and vena contracta were predictive for residual significant MR after LVAD implantation. LV unloading provided by the LVAD was more evident till the first month follow-up and decreased at the three and six months follow up. Nine patients (60%) were successfully transplanted, two (13%) are still on LVAD and four (26%) died for major complication.

Conclusion: MR persistence is a possible complication also in pediatric LVAD recipient. The possibility of concomitant valve surgery is controversial, especially in low weight children. A patient-tailored LVAD setting optimization could potentially improve the haemodynamic benefits of LVAD and, in particular, LV unloading and MR.

Parameters	Baseline	1 month	3 months	6 months
Weight (Kg)	6.0 ± 1.9	6.5 ± 1.9	7.4 ± 2.0	7.9 ± 1.9

Soluble ST2 levels in end-stage heart failure and during LVAD support

CCS Tseng¹; MMH Huibers¹; LH Gaykema¹; SAJ Chamuleau¹; N De Jonge¹

¹University Medical Center Utrecht, Cardiology, Utrecht, Netherlands

Background: The interleukin 33 (IL-33)/suppressor of tumorigenicity 2 (ST2) pathway might play an important role in the progression of heart failure (HF) and is related to cardiac fibrosis. Although the exact source of the ST2 protein is not clarified, increased serum levels (sST2) are associated with adverse outcome in HF. In this study sST2 measurements were performed sequentially in patients with end-stage heart failure, before and after LVAD support. Furthermore we analyzed whether sST2 levels during HF were related to clinical parameters. Method: Serial serum measurements of sST2 were performed in EDTA plasma prior to LVAD and 1, 3 and 6 months after LVAD-implantation in 38 patients, using the high-sensitive Presage ST2 assay. Several clinical factors were analyzed for their relation with sST2 levels.

Results: sST2 levels were significantly elevated in end-stage HF just before LVAD implantation (74.2 ng/ml (IQR $54.7 - 116.9$; normal < 30 ng/ml) and decreased substantially during LVAD support, to 29.5 ng/ml (IQR $24.7 - 46.6$) ($p < 0.001$), normalizing in most patients. This normalization was complete at 3 months post-LVAD. The variation in sST2 levels at baseline could not be correlated to any of the clinical factors tested (gender, HF etiology, duration of HF, right ventricular function and renal function).

Conclusion: LVAD support results in a significant drop in sST2 levels with normalization within 3 months post implantation. This suggests that even in patients with end-stage HF, sST2 may be used as a biomarker to monitor therapy. The great variance in sST2 levels at baseline cannot be explained by differences in gender, HF etiology or duration, right ventricular function and renal function.

Figure 1. Boxplot showing median sST2 levels during LVAD support with IQR (25-75%), $p < 0.05$ was considered significant.

P1606

Hemodynamics during ramp testing predicts functional capacity in patients supported with continuous-flow left ventricular assist devices (CF-LVADs).

The Danish Heart Foundation.

M Holme Jung¹; F Gustafsson¹; B Houston²; SD Russell²

¹Rigshospitalet - Copenhagen University Hospital, Heart Centre, Copenhagen, Denmark; ²Johns Hopkins Hospital, Department of Cardiology, Baltimore, United States of America

Background and Purpose: Ramp studies- measuring changes in cardiac parameters as a function of serial pump speed modulations - are increasingly being used as an indicator of device function in CF-LVAD patients. The ability to predict functional status, quality of life (QOL) and survival from ramp studies, however, remains unexplored.

Method: Hemodynamic changes as a function of serial pump speed increase (Δ rpm) were measured by right heart catheterization at the time of routine examination. Measures were undertaken at baseline pump speed (Ramp-base) followed by incrementally increasing pump speed steps until reaching maximal pump speed (Ramp-high). Ramp-high was decided bedside based upon left ventricular dimensions and/or septal shift. Finally pump speed was decreased to a minimum of support or to the point of aortic valve opening (Ramp-low). Subsequently functional capacity, QOL and survival were assessed. Results Eighty ramp tests were performed in 44 CF-LVAD patients. Changes in pump speed, cardiac output (CO) and pulmonary capillary wedge pressure (PCWP) are shown in Table 1. Functional status was evaluated in 70% (31/44). Average 6-MWT was 312 ± 220 m, NYHA I-II/III-IV (70/30%) and activity scores Very low-Low/Moderate-Very high (55/45%). Decrease in PCWP per Δ rpm was related to better NYHA classification; NYHA I-II vs III-IV, -0.29 ± 0.15 vs -0.09 ± 0.16 mmHg/rpm*10⁻² ($p = 0.007$) as well as to activity score; Very low-Low vs Moderate-Very-high, -0.16 ± 0.16 vs -0.31 ± 0.16 mmHg/rpm*10⁻² ($p = 0.02$). Changes in CO per Δ rpm was correlated to measures of QOL. Ramp tests did not predict survival. Conclusion Hemodynamic changes during ramp studies are associated with measures of functional capacity and QOL. Hence such tests could potentially identify patients in risk of failure to thrive during CF-LVAD support.

Table 1

	Ramp-low	Ramp-base	Ramp-high	Difference Ramp-low to Ramp-high	Δ Change/ Δ rpm
Pump Speed	8,609 \pm 518	9,605 \pm 362	10,573 \pm 555	1,964 \pm 584 ($p < 0.001$)	NA
CO (l/min)	4.9 \pm 1.2	5.5 \pm 1.2	6.0 \pm 1.4	1.1 \pm 1.0 ($p < 0.001$)	0.6 \pm 0.6 ml/min/rpm
PCWP (mmHg)	14.5 \pm 7.3	10.8 \pm 6.7	8.7 \pm 6.1	-5.8 \pm 6.1 ($p < 0.001$)	-0.28 \pm 0.19 mmHg/rpm*10 ⁻²

Health care utilization, QOL and user satisfaction using the heart failure risk score (HFRS): insights from the TRIAGE-HF Trial

Medtronic

S Zieroth¹; V Sharma²; M Mccann²; J Koehler²; B Tsang³; SA Virani⁴

¹University of Manitoba, Winnipeg, Canada; ²Medtronic, Minneapolis, United States of America; ³Southlake Regional Health Centre, Newmarket, Canada;

⁴University of British Columbia, Vancouver, Canada

Background: TRIAGE-HF was a Canadian prospective observational post-market study to evaluate the performance and usability of the heart failure risk status (HFRS) feature. HFRS integrates device diagnostics to generate a dynamically updated risk status (low, medium or high) which has been previously demonstrated to correlate with 30 day probability of HF hospitalization.

Purpose: During the TRIAGE-HF trial, HFRS was introduced to HF care providers to better understand how HFRS and HF diagnostics were incorporated into "real life" workflow and patient management strategies. Study objectives included measurements of healthcare utilization (HCU), changes in HF related QOL, and user satisfaction.

Methods: TRIAGE-HF enrolled 100 patients with HF and a wireless CRT-D/ICD device followed for 8 months. All-cause HCUs were collected and included HF-related HCUs and HF-related hospitalizations. QOL was measured by MLWHF scores at baseline and study exit and compared using a one-sample t-test. A 9 question user satisfaction survey was completed by clinical care providers at study end.

Results: Patients enrolled were mostly male (78%), with a mean age of 66.9 ± 11 years and NYHA class II/III symptoms (82%). Mean EF was $31.1 \pm 12.3\%$. 83% were on ACE-i/ARB and 95% on a β -blocker. A total of 96 HCUs were reported during the study with an annualized rate of 1.5 HCU/patient/year. 26 HCUs

were HF-related with an annualized rate of 0.4 HCU/patient/year. 13 HCUs were HF-related hospitalizations consistent with an expected rate of 0.2 HF hospitalizations/patient/year. MLWHF scores demonstrated a non-significant trend towards improvement (32.8 ± 21 vs 30.0 ± 21.6 , $p = 0.19$). A total of 91 user surveys were completed mostly by nursing staff (81%). HFRS was reported as easy to interpret by 96%, allowed quick triage of patients (85%) with 37% reporting HFRS led to better patient care. However, satisfaction rate for overall clinical utility of HFRS was in the range of 20 – 40%.

Conclusion: TRIAGE-HF demonstrated no impact on HCU, possibly because the protocol did not mandate clinical actions upon HFRS review. User surveys revealed that HFRS is easy to interpret by nursing staff and it scored well on its ability to triage at-risk patients. This may allow HF clinic staff to reduce the frequency of in person follow up visits. However, the satisfaction rate for overall clinical utility of HFRS was low and may be because device patients are a small subset of the overall HF population and hence the specific value of a device feature may be diluted.

P1608

Patient's satisfaction about remote monitoring system of cardiac implanted electronic devices

A Zanni¹; C Sticozzi¹; A Malagoli¹; L Rossi¹; U Corvi¹; M Piepoli¹; G Villani¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Introduction: Overall satisfaction and acceptance of patients about remote monitoring (RM) of cardiac implanted electronic devices (CIEDs) was assessed in several studies. Currently, no validated questionnaires are available to be applied to RM.

Purpose: To evaluate patient's satisfaction of RM by a self-made questionnaire in our institution.

Methods: We used a self-made questionnaire designed to investigate five different aspects strictly connected to patient's acceptance and satisfaction of RM: 1) the overall satisfaction, 2) the completeness of the information provided by staff, 3) the difficulty of use of the equipment of RM, 4) the psychological impact of RM and 5) the impact on the lifestyle of the patient. All items allowed only one answer choosing among five options.

Results: The questionnaire was given to 207 patients followed by RM. 100% of all the administered questionnaire items were answered. Regarding overall satisfaction, the survey showed that 97% of patients judged very satisfactory the service, and 95% of patients said they received a complete and exhaustive initial training. The 98% of patients had no difficulty in using the equipment. The 90% of patients percent of patients received a sense of security by the transmitter, while only 60% of patients improved their lifestyle.

Conclusions: Patients show high level of satisfaction and acceptance of RM suggesting its proper usefulness in daily practice.

P1609

CHF therapy guided by pulmonary artery pressure monitoring: does baseline right heart catheterization predict outcome?

G Giovanni Perego¹; G Malfatto¹; A Villani¹; FM Brasca¹; R Brambilla¹;

M Oldani¹; E Bressan¹; G Parati²

¹Italian Institute for Auxology IRCCS, Cardiology, Milan, Italy; ²University of Milan-Bicocca, Milan, Italy

Background: Remote monitoring of Pulmonary Artery Pressure (PAP) and haemodynamic guided optimization of therapy are effective in reducing events in Chronic Heart Failure (CHF). The improvement in prognosis is correlated to the decrease of diastolic PAP, with a target of 20 mmHg or less. The purpose of our study was to verify whether any baseline haemodynamic parameter could predict the degree of the maximum PAP reduction obtained by sensor guided therapy. Methods. In 2015 11 CHF patients (Age 71 ± 9 ; EF 27 ± 4 ; NYHA III) underwent pulmonary artery catheterization, haemodynamic study and PAP sensor implant. PAP tracings were transmitted daily. For three months (observation period) CHF specialists were blinded to PAP transmissions (no medical intervention was guided by PAP). Afterwards, therapy was adjusted on PAP, according to CHAMPION study workflow (active phase).

Results: Baseline haemodynamics: Cardiac Index (CI) 2.0 ± 0.57 L²/m²; Systolic PAP(sPAP) 58.6 ± 14.5 mmHg; Diastolic PAP(dPAP) 25.7 ± 6.6 mmHg; Pulmonary Wedge Pressure (PWP) 26.4 ± 6.0 mmHg; TransPulmonary gradient (TPG) calculated as mean PAP-PWP 13.8 ± 3.6 mmHg. During active phase the lowest stable (average of 15 consecutive days) dPAP was 23.1 ± 8.7 mmHg ($p < 0.001$ vs. baseline). Lowest dPAP was significantly correlated with baseline dPAP ($r = 0.869$; $p = 0.001$) and with TPG ($r = 0.712$; $p < 0.01$).

Conclusions: In a population of NYHA class III CHF patients with advanced hemodynamic impairment, sensor guided therapy was associated to significant decrease of dPAP. The lowest dPAP was directly correlated to baseline dPAP, suggesting that the benefit of this approach might be limited in patients with very high baseline filling pressures. Pulmonary vascular disease might be involved in the non reversibility of pulmonary hypertension, as suggested by the correlation of lowest dPAP and

baseline TPG.

P1610

Changes in left ventricular ejection fraction after primary prevention ICD implantation and its correlation with appropriate ICD shocks

Z Majoros¹; B Muk¹; P Bogyi¹; D Vagany¹; M Szabo¹; M Dekany¹; T Borsanyi¹; G Duray¹; RG Kiss¹; N Nyolczas¹

¹Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary

Background: Left ventricular ejection fraction (LVEF) lower than 35% is a key criterion in determining eligibility for implantable cardioverter defibrillator (ICD) for primary prevention (PP) in patients (pts) with chronic systolic heart failure (HFrEF). Although HFrEF pts may experience an improvement in LVEF after PP ICD implantation (particularly after CRT-D implantation), it is unknown whether LVEF improvement affects subsequent risk for sudden cardiac death (SCD).

Aim: The aim of our study was to assess the changes in LVEF after ICD implantation and the implication of this parameter on ICD shocks.

Methods: We analysed the data of 99 HFrEF pts referred for PP ICD implantation between 2010 and 2014 (mean age: 63.4 ± 9.9 years, male: 75.8%, ischaemic: 56.6%, NYHA: 2.4 ± 0.8, LVEF: 26.0 ± 5.8%), who received their devices according to current guidelines (CRT-D: 80 pts, ICD: 19 pts). Every pts got optimal medical therapy at least 3 months before device implantation. The change in LVEF was assessed 6 months after device implantation. The occurrences of ICD shock was observed during the follow-up (mean: 31.5 ± 12.7 months) of the pts.

Results: 6 months after ICD implantation LVEF improved at least 5% in 73 pts (73.7%). 35.4% (35 pts) had an LVEF improvement to above 35%. During follow-up 31 pts died and we observed appropriate ICD shocks in 12 pts and inappropriate ICD shocks in 6 pts. Among pts with LVEF improved above 35% there was no appropriate ICD shocks at all, in contrast with the 12 pts with appropriate ICD shocks observed in the group of pts with LVEF < 35% six months after device implantation (p=0.0072).

Conclusion: Remarkable number of pts has an improvement in LVEF after PP ICD implantation. It seems that the improvement in LVEF reduces the risk of appropriate ICD shocks. To avoid unnecessary implantations we should identify HFrEF pts with baseline LVEF < 35% who benefit most from ICD therapy by determining additional markers predicting the risk of SCD more specifically than LVEF alone.

Cardiac implantable defibrillator in primary prevention: predictors of appropriate therapy

M Marta Braga¹; H Nascimento¹; V Ribeiro¹; F Melao¹; S M Oliveira¹; M Vasconcelos¹; P Dias¹; C Frutuoso¹; M J Maciel¹

¹Sao Joao Hospital, Porto, Portugal

Background: Prophylactic implantable cardiac defibrillator (ICD) therapy (Rx) has been shown to improve survival in some conditions. Finding the predictors of appropriated ICD Rx can be helpful in medical management of patients (pts) with ICD as well as improve pts' selection at first. Our aim was to describe clinical profile of pts with ICD for primary prevention (PP) and to evaluate the predictors of appropriate ICD Rx and the predictors of poor outcome.

Methods: We reviewed the data of ICD implantation from a tertiary centre between June 2012 and December 2014. Of 134 pts, we included 62 pts, who had left ventricular (LV) systolic dysfunction and were referred for ICD implantation for PP. Appropriate ICD Rx was defined as occurrence of ATP or shock triggered by ventricular arrhythmia at first event.

Results: Mean age was 62.5 ± 10.4 years and 83.9% were males. More than 90% pts had at least 1 cardiovascular (CV) risk factor. The diagnosis was dilated cardiomyopathy (DC) in 50%, ischemic cardiomyopathy in 41.9% and valvular heart disease in 6.5% of the cases. The echocardiography (echo) before implantation showed a mean ejection fraction (EF) of 23.2 ± 6.8% and a mean LV end-diastolic dimension of 66.2 ± 10.8 mm. During a mean 20.0 ± 8.2 months of follow-up (FU), 32.3% pts had auricular fibrillation/flutter (AF) and 56.5% had non-sustained ventricular tachycardia (NSVT). Only 13 pts received appropriate ICD Rx (40% ATP alone and 60% ATP followed by shock or shock alone). The main trigger for appropriate ICD Rx was ventricular tachycardia. Appropriate ICD Rx occurred in mean 10.3 ± 6.9 months after implantation. Fifteen pts were admitted for CV causes and 5 pts died during FU. No clinical or echo feature of pts before ICD implantation was associated with appropriate ICD Rx, whereas NSVT was an independent predictor of appropriate ICD Rx (OR 11.4, p=0.02). Alcoholic DC, AF and shock of any cause during FU were associated with admissions for CV causes. Appropriate ICD Rx was associated with admissions as well. In our cohort, only alcoholic DC was predictor of CV death (66.7% vs. 10.2%, p=0.04).

Conclusions: In this study, ICD implantation for PP occurred mainly in male pts. Half of pts had DC. The mean EF was lower than 25% and most pts had LV dilatation. Many pts had NSVT and this was a strong predictor of appropriate ICD Rx. AF and shock of any cause was predictor of hospitalization. Interestingly, alcoholic DC was associated with admissions and CV death.

Gap between guidelines and clinical practice in device implantation in heart failure patients: insights from HEARTS registry

T Aldoheyan¹; A Hersi¹; A Alhammad¹; K Alhabib¹; H Alfaleh¹; W Alhabib¹; D Almuniri¹; J Alaskar¹; H Alfazan¹; M Alweri¹

¹King Khalid University Hospital (KKUH), Riyadh, Saudi Arabia

Background and Objectives: Patterns of implantable cardioverter-defibrillator (ICD) and cardiac resynchronization therapy (CRT) use in patients with Heart Failure (HF) vary by geography, and data from developing countries are limited. Therefore, our aim was to identify the gap in the application of device implantation guidelines for acute on chronic systolic heart failure patients in Saudi Arabia. Design and Setting: We used data from the heart function assessment registry trial in Saudi Arabia (HEARTS) to explore the rate of device implantation. In consecutive cohort admitted in 18 governmental hospitals with heart failure between October 2009 and December 2010.

Results: Of 1664 patients with acute on chronic systolic heart failure enrolled in the HEARTS registry, 227 (13.64%) have undergone a past ICD/CRT, 148 (8.9%) patients with ICD and 79 (4.7%) patients with CRT. 1437 (86.36%) patients did not go through an ICD or a CRT. From 71 VT/VF patients who are required to have an ICD only 10 (14%) patients received an ICD therapy. 223 patients have a left bundle branch block and 35 (15.6%) of those patients received an ICD/CRT device. From 831 patients with LVEF < 30%, 170 (20.5%) went through a past ICD/CRT.

Conclusion: Since a large number of whom required an ICD/CRT did not receive a device, a gap in the application of ICD/CRT devices had been identified. The estimated ICD/CRT implant rate is lower than what has been reported in many developed countries, further studies are required to establish the reason behind this.

Cardiac rehabilitation programs in left ventricular systolic dysfunction: do these programs reduce the number of patients requiring an implantable cardioverter defibrillator?

O Oscar Gonzalez Fernandez¹; P Meras Colunga¹; J Irazusta Cordoba¹; V Rial Baston¹; R Dalmau Gonzalez-Gallarza¹; C Alvarez Ortega¹; R Mori Junco¹; J Caro Codon¹; A Castro Conde¹; JL Lopez Sendon¹

¹University Hospital La Paz, Cardiology, Madrid, Spain

Introduction: Cardiac rehabilitation programs (CRPs) in left ventricular systolic dysfunction (LVSD) patients (p.) provide optimal medical treatment (OMT), close monitoring, exercise and counselling. Implantable cardioverter defibrillators (ICDs) should be considered in symptomatic p. and a left ventricular ejection fraction (LVEF) ≤ 35% despite OMT. CRPs represent a favourable scenario for a suitable stratification and optimal selection of these p.. Our purpose was to describe the population with LVEF ≤ 35% in our program and to analyse predictors for an ICD implantation in these p..

Methods: We made an observational retrospective study including p. with LVSD admitted to a CRP between 2006 and 2015. Physical training, OMT, medical counselling and smoking cessation support, were supplied for 8 to 10 weeks. LVEF was assessed before and after the program using TTE. Functional capacity (FC)

was tested before and after the CRP in accordance with the NYHA Classification, besides a treadmill stress test (TST). Exercise capacity (EC) was reported in METs.

Results: A total of 206 p. were included, mean age 57.6 ± 12.3 years, male 89.8%. Baseline characteristics are shown in graphic 1. The 89.8% of these p. had a recent acute coronary syndrome. After the CRP, an ICD was implanted in 35 p. (17%). Regarding medical therapy, the number of p. receiving B-blockers, ACEi/ARB2, MRAs and ivabradine was higher after the CRP ($p < 0.01$). Not significant differences according to sex, age, cardiovascular risk factors (CVRF) and comorbidities were found among p. requiring or not an ICD. The use of diuretics was superior in p. requiring an ICD before (48.6% vs 20.4%; $p = 0.002$) and after CRP (26.5% vs 12.6%; $p = 0.047$), no differences were found with any other treatment. The NYHA class before the program was I 44.7%, II 48%, III 6.7%, IV 0.6%. After CRP NYHA improved: I 73.2%, II 25.6%, III 1.2% ($p < 0.001$). Referring to TST, medium METs before CRP were 6.2 ± 2.8 and after were 9.8 ± 2.7 . Mean LVEF were 29.5 ± 5.6 before and 41.8 ± 10.3 after. Patients requiring an ICD had both worst functional class before and after CRP ($p = 0.005$, $p = 0.002$; respectively), and lower LVEF before (27.6 ± 6.8 vs 30.5 ± 4.6 ; $p = 0.02$) and after CRP (30.8 ± 7.8 vs 44.8 ± 8.7 ; $p < 0.001$), as well as less METs at the beginning (5.2 ± 2.8 vs 6.6 ± 2.6 ; $p = 0.012$) and the end of the program (8.6 ± 2.9 vs 10 ± 2.7 ; $p = 0.02$). Considering p. with $LVEF \leq 35\%$ and NYHA II-III, differences were found before and after the program (55.3% vs 14.5%; $p < 0.001$), which modifies the indication for an ICD implantation along the CRP.

Conclusions: CRPs are a valuable tool to properly select candidates to an ICD. CRPs improve FC, optimize medical therapy and increase LVEF. No differences in CVRF and comorbidities among p. requiring or not an ICD were found. However, these p. had less LVEF and worst FC and EC at the beginning of the CRP, besides a minor improvement of these parameters within the program. The proportion of p. with ICD indication decreases after the CRP is completed.

CVRF, comorbidities and treatment

Predictive factors of death and appropriate ICD shock in primary prevention: analysis with a competing risk model.

R Roque Arana Granado¹; J Fernandez-Armenta Pastor¹; R Vazquez Garcia¹; M Rodriguez Manero²; J Jimenez Lopez²; L Martinez Sande²; J Benecet Mazuecos⁴; A Fernandez Cisnal⁵

¹University Hospital Puerta del Mar, Cardiology, Cadiz, Spain; ²University of Santiago de Compostela, Santiago de Compostela, Spain; ³Hospital Virgen de la Salud, Toledo, Spain; ⁴Foundation Jimenez Diaz, Madrid, Spain; ⁵University Hospital of Virgen del Rocio, Seville, Spain

Background: The indication of ICD implantation for primary prevention of sudden death could be optimized with a prognostic tool that identifies those patients who will die without an appropriate ICD shock (AIS) and those ones who will have a first AIS. Our purpose is the development of a competing risks predictive model (Fine-Gray) and the evaluation of its predictive accuracy.

Methods: Multicenter national level cohort study of 1171 patients with ICD for primary prevention with this clinical profile: 81 % male, mean age 62 y. (30 % over 70 y), ischemic 55 %, complete revascularization 29 %, LVEF $< 25\%$ 51 %, NYHA 3-4 39 %, serum creatinine > 2 mg/dl 4 %. In univariate study we determined the cumulative incidence function for death without AIS and Pepemori's test. In multivariate analysis we built a Fine-Gray regression model, calculated a risk score of death without AIS and stratified the cohort population by its value. We calculated the predictive accuracy of the model with Harrell's c index. Then we calculated pseudo-values and estimated the potential years of life lost as a function of the selected covariates. We also built a predictive model of first AIS.

Results

The incidence rate of death without AIS was 4.22 /100 person-years (155 p) and first AIS 3.94/100 p-y (145 p). The predictive model of death without AIS included age > 70 y, LVEF $< 25\%$, NYHA 3-4, COPD, serum creatinine > 2 mg/dl, previous admission because of heart failure, malignant neoplasm, dyslipemia, previous implanted pacemaker, male sex, digoxin treatment, ischemic cardiomyopathy and

indication of resynchronization therapy (Harrell's c index 0.76 corrected 0.75 95%CI 0.72-0.80). The model of first AIS included creatinine > 2 mg/dl, arterial hypertension, malignant neoplasm, antidiabetic treatment and complete revascularization (Harrell's c index 0.66 corrected 0.65 95% CI 0.62-0.70).

Conclusions: Mortality without first AIS can be predicted reasonably with a questionnaire of clinical variables. We can establish different groups of risk of death without AIS according to the value of death risk score. The prediction of first appropriate shock is, so far, unreliable.

Death risk score

Ultrasound-guided venous access for PMK and ICD. randomised trial.

M Mattia Liccardo¹; ML Liccardo¹; PN Nocerino¹; AB Borrino¹; CC Carbone¹; EDM Di Meo¹; GS Salzano²

¹Azienda Sanitaria Locale Napoli 3 - Outpatient cardiology, cardiology of the hospital santa maria delle grazie di pozzuoli, napoli, Napoli, Italy; ²BOSTON SCIENTIFIC, MILAN, Italy

In the light of increasingly stringent recommendations of companies of anesthesiology and intensive care units to use approaches vascular eco-guided we wanted to evaluate the safety and efficacy approach to the axillary vein methodically drove to the eco system leads to stimulation and cardiac defibrillation. After disinfection of the skin in the region clavicular and preparation of the sterile field was used a sterile covers for cardiac probe that was previously coated with sterile gel. To improve visualization of the images and reduce the air-skin interface probe cover was used saline. Deliberately not sterile gel was used to reduce the costs of the procedure. The operator right-handed wielding the probe with the left hand and the syringe with the needle with your right hand. It identified the anatomical region extrathoracic axillary vein was pricked after local anesthesia in the area of interest, with Seldinger technique. The progression of the needle was guided by ultrasonography. The puncture was possibly carried out two or three times depending on the type of plant programmed. After a learning period of the echo-guided technique were enrolled 90 patients in which consecutive, randomly 1:1, was chosen the initial approach (echo or subclavian). If in a maximum time of 5 minutes the first approach failed in the cannulation is passed to the second approach. In the learning period of about three months the frequency of failure is lower than 30%. In the period of enlistment randomized, the frequency of success at the first attempt of the approach echo is comparable with that for subclavian (42/45, 93.3% vs. 43/45, 95.6%). Are not reported to the system and major events in the postoperative period. Are registered minor events such as dislodgment during the procedure and / or raising the threshold post-procedure to be comparable in the two groups (Eco: 2.2% vs 6.7% Subclavian). The proposed technique appears to be effective and safe as the classical technique for subclavian, also presents the advantage of being free from risk of pneumothorax and breaking of leads. Ratings on a follow-up in the medium and long term are in place to assess their reliability. Studies with an adequate number of patients would be desirable to confirm our preliminary results.

P1616

The effectiveness of implantable cardioverter-defibrillator in preventing sudden cardiac death in patients with chronic heart failure.

T Talgat Eskarayev¹; BK Iskakova¹; TK Moldabeckov¹; SK Ainamkulov¹; AA Abdulchakov¹

¹JSC "National scientific center of oncology and transplantology", Astana, Kazakhstan

Introduction: Chronic heart failure is one of the leading cause of mortality all over the world. Its optimization and therapy is one of the priority task in cardiology.

Purpose: To analyze the own results of implantable cardioverter-defibrillator in preventing sudden cardiac death (SCD) in patients with chronic heart failure.

Materials and Methods: 47 patients received implantable cardioverter-defibrillator (ICD) from 2010 to 2014. Among them are 27 men (average age 51 ± 3.7 year) and 20 women (average age 49 ± 2.5 year). 32 patients with myocardial infarction, 14 patients with dilated cardiomyopathy and 1 patient with idiopathic ventricular tachycardia also received ICD. 9 patients with CHD had a permanent form of atrial fibrillation, they received a single-chamber implantable cardioverter-defibrillator. Other patients received dual-chamber device. Control inspection, testing and reprogramming was in terms of ICD in 3.6 and 12 months after the initial implantation or after the triggering device. Complications were not during and after operation period. Results Triggering the ICD reported in 11 patients. 5 patients had unmotivated triggering as cardioversion and defibrillation in response to atrial fibrillation with high conduction of impulses to the ventricles. After selection of antiarrhythmic therapy with amiodorane hydrochloride (in 3 patients), digoxinum (in 1 patient), bisoprololum (in 2 patients), and the correction parameters discrimination tachycardia ICD, repeated episodes of unwanted discharges were not observed. The remaining 6 patients had antithetically triggering ICD in one case, and in 5 cases had defibrillation with discharge to 34J.

Conclusions: Implantable cardioverter-defibrillator has been reducing the number of deaths from life-threatening tachycardias in patients with high risk of SCD. Timely correction of the ICD parameters, with additional features of supraventricular tachycardia discrimination, appropriate treatment of the underlying heart disease may reduce the number of unwanted alarms ICD and improve the quality of patients' lives.

P1617

Possibilities of cardiac resynchronization therapy and ablation of the atrioventricular junction in patients with heart failure and atrial fibrillation

T Tatyana Troyanova¹; D Goncharik¹; A Chasnoy¹; Y Persidskikh¹; A Kurlinskaya¹

¹Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Purpose: to explore the effectiveness of cardiac resynchronization therapy (CRT) in combination with ablation of atrioventricular junction (AV-ablation) in patients with chronic heart failure with NYHA functional class III or IV (III-IV FC CHF), ejection fraction (EF) <35%, QRS duration ≥ 120 ms and permanent atrial fibrillation. Methods. The study involved 55 patients who underwent CRT and AV-ablation. Examination was carried out at baseline, in 6 and 12 months after surgery, and included general clinical tests, determination of the level natriuretic peptide (NT-proBNP), myocardial dyssynchrony, transthoracic echocardiography and the 6-minute walk test.

Results: No significant changes in clinical tests were revealed. The level of NT-proBNP decreased from 7954 pg/ml at baseline to 3476 pg/ml by the 6 month and to 1228 pg/ml by the 12 month ($p < 0.05$). In a year after the surgery presystolic aortic delay decreased from 175.6 ± 4.8 ms to 157.8 ± 7.2 ms ($p < 0.05$). Interventricular dyssynchrony reduced from 175.6 ± 4.8 ms to 169.4 ± 5.7 ms after 6 months and to 157.8 ± 7.2 ms after 12 months ($p < 0.05$). Atrioventricular dyssynchrony was not measured. End-diastolic volume (EDV) decreased from 345.2 ± 32.4 ml to 316.5 ± 28.7 ml by the 6 month and to 318.3 ± 34.6 ml by the 12 month ($p < 0.05$). At baseline end-systolic volume (ESV) was 285.4 ± 30.4 ml. After 6 months it was 243.6 ± 28.7 ml, after 12 months it was 235.7 ± 30.2 ml ($p < 0.05$). EF increased from $24.6 \pm 2.5\%$ to $30.1 \pm 2.4\%$ by the 6 month and to $31.2 \pm 1.8\%$ by the 12 month ($p < 0.05$). At baseline mitral regurgitation (MR) was 3.6 ± 1.2 ; after 6 and 12 months it became 3.1 ± 1.3 and 2.7 ± 1.2 ($p < 0.05$). The 6-minute walk test revealed an increase of distance from 152 m to 326.7 m by the 6 month and to 358.4 m by the 12 month, respectively ($p < 0.05$). Conclusion. CRT in combination with AV-conjunction ablation is an effective method of treatment in patients with III-IV FC CHF (NYHA), EF <35%, permanent atrial fibrillation, QRS duration ≥ 120 ms. The treatment resulted in the decrease of NT-proBNP level, ESV, EDV, the degree of MR and the increase of EF, a distance of the 6-minute walk test.

P1618

Unfavourable outcome after the upgrade of an implantable cardioverter defibrillator to cardiac resynchronisation therapy

A Alexandra Kiss¹; G Sandorfi¹; I Edes¹; Z Csaniadi¹; M Clemens¹

¹University of Debrecen, MHSC-Faculty of Medicine, Institute of Cardiology, Debrecen, Hungary

Background: Cardiac resynchronization therapy (CRT) improves survival in selected patients with heart failure (HF). As the potential survival benefit of CRT performed as an upgrade from a previously implanted cardioverter defibrillator (ICD) has not been explored, we evaluated total mortality after CRT upgrade in this context.

Methods and Results: A total of 31 patients (27 male, mean age: 63.7 ± 9.6 years)

with structural heart disease underwent CRT device implantation as an upgrade of a previously implanted single or dual chamber ICD between 2004 and 2015 at our Institute. The indication for ICD implantation was prophylactic based on the MADIT II or SCD-HeFT criteria (in 13 patients) or secondary prevention after a sustained ventricular arrhythmia (in 18 patients). Mean left ventricular ejection fraction (LVEF) was $29.9 \pm 7.8\%$ and mean NYHA status was 2.4 ± 0.8 at the time of ICD implantation. No indication for CRT was present in any of these patients at the time of ICD implantation. CRT upgrade was performed after a mean follow-up of 3.9 ± 2.9 years based on the following indications: widening of the QRS complex (from 108 ± 20 to 158 ± 24 msec.) in 24, decreasing LVEF (from 41.5 ± 2.1 to $26.5 \pm 2.1\%$) in the presence of LBBB in 2, and an increase in the need for right ventricular stimulation (burden > 40%) in 5 patients. A significant reduction in the QRS width after CRT upgrade (from 160.3 ± 26 to 130.3 ± 23 msec., $p < 0.001$), an improvement in NYHA class (from 3.1 ± 0.8 to 2.5 ± 1.0 , $p = 0.16$) and an increase in the mean LVEF (from 27.6 to 33.3% , $p = 0.049$) was observed including 4 patients (13%) who demonstrated an increase in LVEF above 10 % at the 1-year follow-up. 17/31 patients (55%) died during a mean follow-up of 19.0 ± 16.6 months after CRT upgrade (Figure). No statistically significant prognostic factor of survival was found among the patients' baseline data by using the Cox proportional hazard model.

Conclusion: Despite a marked reduction in QRS width and a modest improvement in LV EF, mortality remains high after CRT upgrade in this patient cohort. This would argue for an earlier administration of alternative treatment modalities (assist device, heart transplantation) in HF patients who demonstrate QRS widening, a significant decrease in the LV EF or a need for ventricular stimulation.

Kaplan-Meier survival curve

P1619

The influence of cardiac resynchronization therapy on prognosis and functional status of blood circulatory system at patients with mild chronic heart failure

V A Volha Sujayeva¹; OV Koshlataya¹; DV Romanovsky¹; VM Silchenko¹

¹Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Purpose: to study the influence of cardiac resynchronization therapy (CRT) on tolerance to physical loading (TPL), aerobic capacity and predictors of pure prognosis at patients with the chronic heart failure (CHF) according to spiro Bicycle Ergometry Test (spiroBET).

Methods: We studied 13 patients with CHF NYHA Class II, sinus rhythm, duration of QRS ≥ 130 ms and a dissinhrony according to echocardiography (EchoCG). Implantation of CRT and treatment of CHF were carried out according to ESC Guidelines (2013). TPL was measured in the conditions of spiroBET using Schiller AG AT-104 ErgoSpiro equipment. We used Bruce protocol. Efficiency of CRT was estimated according to EchoCG: increase of ejection fraction $\geq 5\%$ was regarded as "responder" (R); <5% - "non-responder" (NR).

Results: Improvement of myocardial contractility in 12 months after implantation of CRT we found at 8 (62%) from 13 patients, they made R Group, another 5 (38%) made NR Group. The age of patients of R Group and NR Group was similar - 58.6 ± 9.8 and 57.5 ± 8.8 years, respectively (> 0.05). In 12 months after implantation of CRT EF was $38.5 \pm 13.8\%$ in R Group and $21.0 \pm 10.9\%$ - in NR Group, < 0.05 . We also found significant improvement of TPL in R Group in comparison to NR Group - maximal achieved loading was 72.3 ± 24.9 Wt and 33.3 ± 9.1 Wt correspondingly (< 0.05). Improving of myocardial contractility in R Group brought to increase not only TPL but also to augmentation of maximal oxygen consumption in comparison to NR Group - is taped 8.5 ± 4.2 and 7.3 ± 4.9 ml/kg/min., respectively, < 0.05 . Earlier (Sujayeva V.A., 2013) we found that TPL < 50Wt in combination with level <20% from age expected were strong predictors of 1 year mortality in patients with CHF (sensitivity 100%, specificity 82%). The most important result of 12 month CRT was disappearance of above mentioned predictors in patients of R group. It means that implantation of CRT leads not only to improvement of prognosis but also to decrease of requirement of heart transplantation in patients with CHF.

Conclusions: at patients with CHF NYHA Class II efficiency of CRT in 12 months was 62%. In group of responder along with improvement of global myocardial contractility we found increasing TPL, maximal oxygen consumption, improve of prognosis and decrease of requirement of heart transplantation.

Cardiac resynchronization therapy alters serum lipids profile in patients with chronic heart failure - results of the pilot study.

Annual grant for Young Scientists 2014, Club 30-Polish Cardiac Society
M Marta Marcinkiewicz-Siemion¹; K Ptaszynska-Kopczynska¹; M Ciborowski²;
M Jasiewicz¹; A Lisowska¹; A Szpakowicz¹; M Witkowski¹; A Kretowski²;
WJ Musial¹; K Kaminski¹

¹Medical University of Bialystok, Cardiology, Bialystok, Poland; ²Medical University of Bialystok, Clinical Research Centre, Bialystok, Poland

Introduction: Cardiac resynchronization therapy (CRT) leads to reversal of the processes occurring in the course of development of the heart failure. The molecular basis of lack of response to CRT in a group of about 20-30% of chronic HF patients remain unknown.

Aim: The use of metabolomics to identify changes in the blood metabolites profile, occurring as a result of cardiac resynchronization therapy.

Methods and Results: We prospectively studied 15 optimally treated patients with stable chronic HF (M=93%, 63.8 ± 11.7 years, BMI 27.5 ± 2.9 kg/m², 53% ischemic etiology, QRS duration 174.7 ± 24.5 ms, left ventricular ejection fraction-LVEF 19.9 ± 5.5%, NYHA class II/III 27/73%) who had indications for CRT listed in current ESC CHF guidelines. Acute and chronic inflammatory diseases (rheumatoid arthritis, diabetes mellitus, asthma) were excluded. All of the enrolled patients were assessed clinically, biochemically, echocardiographically and functionally on baseline and 6 months after device implantation. Fasting serum samples were collected and fingerprinted by liquid chromatography-mass spectrometry (LC-QTOF-MS). Depending on the data distribution, paired t-test or Wilcoxon signed rank test were used and solely statistically significant metabolites (p < .05) were selected to draw

Conclusions: Identification of significant features was performed based on custom library with accurate mass and retention time of more than 100 metabolites. 66% (n = 10) of enrolled patients responded positively to the CRT. Six months after CRT implantation there were significant reduction in the width of QRS complex (mean 175 vs 147 ms, p = .01), increase in LVEF (20 vs 28%, p = .00) and decrease in LV end-diastolic diameter (LVEDd; 6.98 vs 6.41 cm, p = .00). We observed also higher level of sphingosine-1-phosphate (+30 ± 11%, p = .014), lysophosphatidylethanolamine - LPE 16:0 (+26 ± 8%, p = .021), LPE 18:1 (+32 ± 14%, p = .028), hexadecenoyl carnitine (+72 ± 51%, p = .034) and decrease in hydroxysphingosine (-40 ± 21%, p = .040). Higher baseline level of LPE 18:1 was correlated with lower endsystolic/-diastolic baseline volume of left ventricle (LVEsV, LVEDV; r = -.59; r = -.65, respectively) and lower LVEDd (r = -.61). Those who responded positively to CRT had higher median intensity of LPE 18:1 than those who had no benefits from the therapy (0.78 vs 0.46, p = .02).

Conclusions: Serum metabolites profile changes in the course of CRT especially in terms of lipids (sphingolipids, phospholipids). LPE 18:1 seems to be associated with echocardiographic parameters and positive response to cardiac resynchronization therapy.

P1621

Analysis of strain in CRT patients with mild systolic dysfunction and LBBB: the miracle EF cohort

ES Chung¹; N Patel²; GF Egnaczyk¹; B Volz³; C Linde³

¹The Christ Hospital, Cincinnati, United States of America; ²Medtronic, Minneapolis, United States of America; ³Karolinska Institute, Stockholm, Sweden

Background: MIRACLE EF attempted to test the hypothesis that heart failure (HF) patients with LVEF 36-50% and left bundle branch block (LBBB) might benefit from cardiac resynchronization therapy (CRT). Although the study was halted for lack of enrollment, we analyzed the effect of CRT on global and regional longitudinal strain (GLS).

Methods: Major inclusion criteria were LVEF 36 % to 50%, QRS > 130 ms, and LBBB morphology. Patients were randomized 2:1 to treatment with CRT-P vs. Control (implanted, LV lead turned OFF). Speckle tracking analysis was performed on all patients with matched 6-month studies utilizing commercial software GLS measurements were compared within groups over time with a paired t-test and the change in GLS measurements were compared between groups with a two-sample t-test. Results In the control group there is no discernible change in GLS at 6 months, with a mean GLS of -9.7 at both time points (p = 0.99; n = 3). Latest activated segment was non-anterior in all three patients. In contrast, for the CRT patients, mean GLS improved from -10.7 to -12.5 (p = 0.15; n = 7), though it was not

statistically significant. There was no detectable difference between randomization groups in the change in mean GLS from baseline to six months (p = 0.37; n = 10). Further, those with the greatest improvement in GLS demonstrated latest activation in the non-anterior segments.

Conclusions: In HF patients with moderate systolic dysfunction and LBBB, CRT may improve GLS, most notably in those with non-anterior latest activating segments.

Left ventricular rotational dyssynchrony before cardiac resynchronization therapy: a step forward into ventricular mechanics.

A Alessandro Paoletti Perini¹; S Sacchi¹; P Attana¹; C Votta²; R Bani¹;
P Pieragnoli¹; G Ricciardi¹; I Ricceri¹; L Padeletti²

¹Careggi Hospital, Clinica Medica Department, Florence, Italy; ²University of Florence, Florence, Italy

Background: Systolic Heart Failure (HF) patients show impaired left ventricular (LV) rotation and twist. In patients undergoing Cardiac Resynchronization Therapy (CRT) the significance of pre-implant LV rotational timing between different ventricular regions is unknown.

Purpose: in the present study we aimed at 1) thoroughly evaluating, in healthy subjects and in HF patients with severe systolic dysfunction and prolonged QRS, who were eligible for CRT, the baseline LV rotational mechanics, also assessing rotational timing of each different LV segment, and 2) investigating whether the presence of a specific pattern of rotational dyssynchrony may be associated with echocardiographic response after CRT application.

Methods: By 2-dimensional speckle-tracking echocardiography, baseline peak apical and basal rotation, peak twist, and time-related parameters, such as delays between opposite segments at base and apex, were assessed in 55 CRT patients and 11 healthy subjects.

Results: At 6 months, 30 (54%) patients were echocardiographic responders. LV rotation and twist had no association with response. All time-related parameters were significantly altered in CRT patients, as compared to control group. Maximum basal and apical segments delay, and anteroseptal-posterior (AS-P) delays at base and apex, were longer in responders than in non-responders (p < 0.05 for all), regardless of the presence of left bundle branch block (LBBB) and QRS duration (Figure). At multivariable analysis, apical AS-P delay resulted independently associated with response [OR: 1.022 (1.007-1.038); p = 0.004]. A cut-off value of 97.5 ms for apical AS-P delay predicted response with 96% specificity and 57% sensitivity (AUC = 0.83). Magnitude of LV reverse remodeling was significantly related to apical AS-P delay (p = 0.001).

Conclusion: In HF patients eligible for CRT, LV rotational timing is altered. Dyssynchrony in rotational mechanics shows a specific pattern in responders regardless of the presence of LBBB. Apical anteroseptal-posterior rotational delay is independently associated with LV reverse remodeling.

Apical AS-P delay, QRS and response.

DIURETICS AND FLUID STATUS MANAGEMENT

Heart failure with preserved ejection fraction: does the intra-venous diuretic treatment duration matter?

JM Joana Maria Ribeiro¹; R Teixeira¹; P Dinis¹; L Dias¹; M Madeira¹; L Reis¹; A Siserman¹; L Puga¹; L Goncalves¹

¹Centro Hospitalar e Universitário de Coimbra - Hospital Geral, Serviço de Cardiologia, Coimbra, Portugal

Background: Heart failure with preserved ejection fraction (HFpEF) is a prevalent disease among hospitalized patients. However, its prognosis and optimal medical treatment are still poorly defined.

Purpose: To assess the impact of intravenous (IV) diuretic therapy duration on prognosis in patients with HFpEF.

Methods: We enrolled a total of 317 consecutive admissions due to acute heart failure to either the cardiology ward or the coronary intensive care unit of a single center between January 2012 and December 2013. Of those, 55% were excluded due to reduced ejection fraction (<50%), 9% due to severe valvular heart disease and 12% due to misclassification of the episode (not due to acute heart failure). A total of 34 patients (12.5%) were included. We registered and analyzed the clinical variables as well as short (in-hospital mortality) and long time follow-up (mortality and heart failure [HF] re-admission rate). The mean follow-up time was 25 ± 15 months.

Results: Mean age was 79 ± 9 years, with female gender predominance. Hypertensive cardiopathy was the most common etiologic factor (46%). Atrial fibrillation, ischemic heart disease and moderate valvular disease were present in 71%, 21% and 64% of the patients, respectively. Of note, non-cardiovascular morbidity had a high prevalence. Mean nt-pro-BNP at admission was 7650 ± 8078 pg/dL and mean hospital stay was 8 ± 8 days. In-hospital mortality rate was 14.7%; mortality and HF re-admission rates during follow-up were respectively 37.9% and 55.9%. In-hospital mortality was associated with a longer duration of IV diuretic therapy (13 ± 12 vs 5 ± 4 days, $P < 0.01$). IV diuretic therapy duration of less than three days had a sensitivity of 100% for the outcome of in-hospital survival (area under the curve of 0.74).

Conclusions: Our data showed that patients admitted for HFpEF were older, had an important burden of cardiovascular and non-cardiovascular morbidity and a significant number of events during follow-up. Remarkably, the need for a shorter duration (<3 days) of IV diuretic therapy seemed to be a clinical marker of good prognosis.

P1624

Blood purification in end-stage heart failure: a study in 16 patients

K Kitada Masahiko¹

¹Japan Red Cross Society Wakayama Medical Center, Wakayama, Japan

Background: End-stage heart failure ultimately leads to cardiorenal syndrome, in which control of the patient using pharmacological therapy or a device for cardiac resynchronization therapy (CRT) becomes difficult. For patients with refractory heart failure, fluid removal through hemodialysis (HD) or recently continuous ambulatory peritoneal dialysis (CAPD) may be used. We reviewed the effectiveness of each of these filtration methods in the treatment of end-stage heart failure.

Subjects and Methods: We treated 7 patients with end-stage heart failure with CAPD and 9 patients with HD (Cr=2.8 ± 1.3; Age 71.3 ± 10.8 years; non-ischemia=8/16 patients; ejection fraction (EF) 34.7 ± 15.0%; New York Heart Association [NYHA] 3/4=8/8 patients; device implantation 10/16 patients). We compared the clinical outcomes of these patients. Results At the end of the observation period, 3 out of 7 patients treated with CAPD survived while 2 out of 9 patients treated with HD survived. The mean survival time of the patients treated with CAPD was 204.4 ± 177.4 days while that of those receiving HD treatment was 184.6 ± 243.2 days ($P = 0.6198$). Although there was not a significant difference, the CAPD group had a better outcome. Better outcomes were also observed in the CAPD group with other indexes such as body weight (BW), NYHA, days and number of hospitalizations. For both groups, the prognosis of the patients was poor if they were unable to be discharged from the hospital within 30 days after the introduction of the treatment. Meanwhile, compared to the HD group, the CAPD group had a lower rate for both EF (CAPD 28.3 ± 17.5% vs HD 40.3 ± 13.1%; $P = 0.14$) and systolic blood pressure (SBP) (CAPD 105.9 ± 24.0 mmHg vs HD 120.1 ± 35.6 mmHg; $P = 0.49$) at the time of introduction of the treatment. Although 2 shunt failures were observed for the HD group, no complications were seen for the CAPD group and the treatment was conducted safely.

Conclusions: CAPD not only has a lower risk of complications but also appears to be a better choice compared to HD as a treatment method for end-stage heart failure and cardiorenal syndrome patients with low blood pressure and low heart function.

P1625

What are predictive factors for body weight loss in patients with acute decompensated heart failure added an oral aquaretic, tolvaptan?

T Tomotaka Ando¹; S Hirotani¹; T Mano¹; M Ishihara¹; T Masuyama¹

¹Hyogo College of Medicine, Internal Medicine, Cardiovascular Division, Nishinomiyama, Japan

Background: Tolvaptan is an aquaretic agent and has been used for fluid management in patients with acute decompensated heart failure (ADHF). However, it remains unclear what are predictive factors for body weight (BW) loss following administration of tolvaptan in patients with ADHF.

Purpose: The purpose of this study was to identify predictive factors for BW loss in patients with ADHF treated with tolvaptan.

Methods: This is a single-center, prospective, and observational study. Forty-two consecutive patients with ADHF were enrolled. Tolvaptan was administered at a dose of 15 mg/day for 3 days in addition to standard heart failure medication. Water intake was not restricted during this study. BW was measured before and 3 days after the administration of tolvaptan. Measurement of multiple biomarkers and echocardiographic parameters were performed before the administration of tolvaptan. 72h-Urine volume (UV) was measured. Patients were divided into 2 groups: responders and non-responders. The definition of responders to tolvaptan was based on more than 2% decrease in BW in 3 days.

Results: The decreases in BW were 4.4 ± 1.7% in responders and 0.3 ± 0.5% in non-responders. Total UV tended to be larger in responders compared with non-responder (6125 ± 2097 ml vs. 5131 ± 1998 ml, $p = 0.08$). There were no significant differences in baseline serum and urinary sodium levels, plasma osmolality, and echocardiographic parameters between 2 groups. Estimated glomerular filtration rate (eGFR) was significantly higher in responders than non-responders (56 ± 17 ml/min vs. 41 ± 15 ml/min, $p < 0.05$). There were significant differences in serum potassium and serum glucose levels. Multivariate analysis revealed that eGFR was the independent predictive factor for responders (OR; 0.90, 95% CI; 0.77-1.06, $p < 0.05$). Receiver operating characteristics analysis identified eGFR 43 ml/min/1.73m² as the optimal cut-off point for the prediction of responders (AUC 0.84 with sensitivity of 0.64 and specificity of 0.74).

Conclusion: eGFR before the administration of tolvaptan might be the predictive factor for more than 2% BW loss in patients with ADHF treated with tolvaptan.

P1626

Discontinuation of diuretic therapy is safe in accurately selected patients with chronic heart failure and severely reduced ejection fraction: a prospective cohort study in the outpatients setting

G Romano¹; G Vitale²; V Agnese¹; C Mina¹; G Di Gesaro¹; C Falletta¹; CM Hernandez Baravoglia¹; C Scardulla¹; D Bellavia¹; F Clemenza¹

¹Mediterranean Institute for Transplantation and High Specialization Therapies (IsMeTT), Palermo, Italy; ²Azienda Sanitaria Provinciale Caltanissetta - Ospedale "Sant'Elia", Caltanissetta, Italy

Introduction: long-term diuretic therapy in patients with heart failure with reduced ejection fraction (HFrEF) portends unknown and likely non benign side effects. Our hypothesis is that diuretics can be safely suspended in well selected, asymptomatic patients with chronic HFrEF once adequate neuro-hormonal blockage has been accomplished.

Purpose: To evaluate independent predictors of diuretics withdrawal (DW) in patients with chronic HFrEF from our outpatient's clinic.

Methods: Two hundred and sixteen consecutive patients with HFrEF (left ventricular ejection fraction (LVEF) = $26 \pm 6\%$) were enrolled. Clinical evaluation, N-terminal pro brain natriuretic peptide (NT-proBNP) level as well as standard 2D and Doppler echocardiogram were performed every six months for a median follow-up period of 18 month. Patients for which DW was not recommended based on clinical judgment were included in the Non-Withdrawal (NW) group, N = 169 (78%), while patients where diuretic discontinuation was considered safe were included in the withdrawal (W) group, N = 21 (10%). N = 26 (12%) patients had no diuretics at baseline. Patients with recent (i.e. <30 days) admission for acute HF, recent (< 180 days) myocardial revascularization and/or resynchronization therapy, congenital heart disease or more than mild valve disease were excluded.

Results: Baseline factors positively associated with DW included: younger age (OR 1.05; 95% p = 0.04), NT-proBNP < 550 ng/L, (OR 3.82; p = 0.005). Among echocardiographic parameters, LV end-diastolic diameter < 60 mm (OR 5.34; p = 0.0005), end-diastolic indexed volume (OR 3.25; p = 0.02), left atrial indexed volume ≤ 33 ml/mq (OR 3.53; 95% p = 0.009), tricuspid annular plane systolic excursion (TAPSE) ≥ 20 mm (OR 5.78; p = 0.001) were positively related to DW. Baseline factors negatively associated with DW included: body mass index ≥ 25 (OR 0.25; p = 0.005), arterial hypertension (0.11; p = 0.01), implantable cardioverter defibrillator (ICD) carrier (0.22; p = 0.002), LVEF $\leq 30\%$ (0.33; p = 0.02). According to multivariable logistic analysis TAPSE ≥ 20 mm, and NT-proBNP < 550 ng were the only independent predictors of DW (ROC AUC = 0.76). In the W group no patients required diuretic resumption, no episode acutely decompensated HF and no NT-proBNP modification (p = 0.27) occurred afterwards.

Conclusions: Diuretic therapy can be safely discontinued in patients with chronic HFrEF, in particular when NT-proBNP level is < 550 ng/L and TAPSE is > 20 mm. Further studies enrolling a bigger study sample with extended follow-up are warranted to confirm our preliminary report.

Influence of clinical severity on the association of loop diuretic dose with mortality in patients with heart failure: insights from the unite-hf registry

KF Adams¹; JK Ghali²; IL Pina³; AK Lee¹; RM Oren⁴; CM O'Connor⁵; TA Schwartz¹; JH Patterson¹; AB Vanbake⁶; SH Dunlap⁷

¹University of North Carolina Chapel Hill, Chapel Hill, United States of America; ²Mercer University, Macon, United States of America; ³Albert Einstein College of Medicine, Bronx, United States of America; ⁴Southern Illinois University, Springfield, United States of America; ⁵Inova Heart and Vascular Institute, Falls Church, United States of America; ⁶Medical University of South Carolina, Charleston, United States of America; ⁷University of Cincinnati, Cincinnati, United States of America

Introduction: Higher loop diuretic doses have been associated with increased mortality in patients (Pts) with heart failure (HF) but less is known about the influence of clinical severity on the long term risk of this therapy.

Purpose: To test the influence of clinical severity on the association of loop diuretic dose with mortality in Pts with HF predominately due to systolic dysfunction.

Methods: The relationship between loop diuretic dose, clinical severity and mortality was investigated in the UNITE-HF Registry, a prospective, observational HF study. Total daily doses of loop diuretics at baseline were converted to milligram equivalents of furosemide (Furo mgEq). Clinical severity was categorized by median LVEF ($\geq 28\%$ versus <28%) and NYHA class (1-2 versus 3-4) at baseline. Loop dose (continuous and categorical) and the risk of death during follow-up (relative to Pts not on loop diuretic) was assessed in all Pts and in clinical subgroups. Risk models were adjusted for predictors of mortality.

Results: This cohort (n = 1303) was 37% female, 37% African American, with mean (\pm SD) age of 58 ± 14 years, creatinine 1.43 ± 1.26 and LVEF of 31 ± 15 . Loop diuretics were taken at baseline in 83% of Pts with median dose 40 mgEq/day (lower quartile <25, upper quartile > 120). There were 676 deaths during 6.6 ± 3.7 years of follow-up. Mortality was significantly related to loop diuretic dose (continuous) for all study Pts (adjusted HR 1.06 95% CI 1.05-1.08, p < 0.0001 per 20 mgEq). In Pts with higher LVEF, larger doses of loop diuretic were weakly associated with increased mortality. In contrast, there was a strong association between increasing loop dose and increasing mortality in Pts with lower LVEF. NYHA class did not alter the association of loop diuretic dose with mortality.

Conclusion: Increasing loop diuretic dose was associated with higher mortality in this retrospective observational analysis of Pts with HF. LVEF but not NYHA class influenced the adverse association of increasing loop dose with mortality.

Loop dose and death by clinical severity

Furo mgEq Quartiles	Lower 25%	Mid 50%	Upper 25%

Diuretic resistance and chronic renal disease, how to face it?

R Rocio Eiros¹; N Salterain¹; A Hernandez¹; I Baraibar¹; A De La Fuente¹; M Palacio¹; E Iglesias¹; J Ibero¹; M Jimenez¹; JJ Gavira¹

¹University Clinic of Navarra, Cardiology, Navarra, Spain

Purpose: Diuretic resistance (DR) (defined as reduction of efficacy of loop diuretics seen as weight gain and lower diuresis) is still a challenge in daily clinical practice. The relationship between chronic kidney disease (CKD) (known as MDRD less than 60 mL/min/1.73m²) and DR is a common scenario that limits the treatment, making the use of thiazides controversial. Our aim is to study the utility and safety of the combination of thiazides (HTZ) and amiloride associated with loop diuretics, in patients who developed DR and had CKD. **METHODS** A retrospective study of all patients with DR admitted for DHF treated with the combination of amiloride (5 mg) and HTZ (50 mg) was made. Two groups were created according to their basal glomerular filtration rate [MDRD (mL/min/1.73m²)], (Group A <60 mL/min/1.73m² basal, and group B >60 mL/min/1.73m² basal). Evaluation of sodium, potassium (mEq/L), creatinine (Cr) (mg/dL) and glomerular filtration rate by MDRD in plasma was made at 24 hours and at discharge. The rate of diuresis (mL/h) and weight (kg) was evaluated at 24 and 48 hours after initiating treatment. **RESULTS** Eighty two patients were included (52 male) with a mean age of 74 ± 9 . Ischemic and valvular heart disease were the most prevalent cause of HF (41% vs 26%). Both groups (A and B) had 41 patients. Diuresis increased significantly at 24 hours and 48 hours in both groups (figure 1) which correlated with a corresponding significant weight loss at 24 hours (Group A: 73 ± 19 vs 66 ± 18 and Group B: 71 ± 13 vs 70 ± 14 , p < 0.05). Not statistically significant changes of Cr at 24 hours were found (figure 1) neither of MDRD (figure 1). None of them developed electrolytic disturbances. **DISCUSSION** Our study shows that the combination of loop diuretics, thiazides and potassium sparing diuretics, is an effective and safe treatment for diuretic resistance, regardless CKD, being an option in DR.

Diuresis, Creatinine and MDRD basal/24h

P1629

Mortality and rehospitalization data from diuretic therapy with effective doses of oral torasemide and furosemide in treatment of patients with exacerbation of chronic heart failure (DUEL-CHF) trial

V Mareev¹; Y Mareev²; V A Vygodin³; Y Belenkov⁴

¹M.V. Lomonosov Moscow State University, Faculty of Basic Medicine, Moscow, Russian Federation; ²Royal Brompton & Harefield Hospitals, Imperial College,

London, United Kingdom; ³National Research Center for Preventive Medicine, Moscow, Russian Federation; ⁴I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Torsemide is a loop diuretic that may have a more favorable side-effect profile, particularly with regards to its influence of potassium. There are limited data on its efficacy when compared to furosemide in the management of patients with decompensated chronic heart failure (CHF).

Purpose: to compare efficacy and safety therapy with furosemide and torsemide in patients hospitalized for an acute decompensation of CHF

Methods: Patients with NYHA II-IV CHF, hospitalized for an acute decompensation, were randomly (2:1) assigned to either torsemide (T) 20 mg/day or furosemide (F) 80 mg/day plus to conventional therapy. They were subsequently followed for 180 days. The primary endpoint was time to compensation based on the elimination of symptoms (clinical assessment scale dynamics, VAS dynamics and optimal reduction in body weight). Secondary endpoints included safety, worsening of renal function and number of 30 days rehospitalisation and 180 days mortality and CHF hospitalization. The study was carried out in 30 clinical centers in 23 Russian cities.

Results: 470 pts from 18 to 75 years were included (n = 143, LVEF < 40%, mean 32,6%) and preserved (n = 184, LVEF > 50%, mean 56,9%). T was more effective and 95% vs 86% (p < 0,01) reach optimal elimination of symptoms up to 6 day (vs 10 days with F). Clinically meaningful side effects were much lower in T group 0,3% vs 4,1% (p < 0,001). Worsening of renal function (increased creatinine > 0,3 mg/dl) appears only in 1,2% in T vs 4,2% in F treated patients. After 180 days 13/144 (9%) died in F vs 19/326 (5,8%) T group (p=0,23) and 41/144 (28,5%) was rehospitalised due to worsening of CHF vs 50/326 (15,4%), p=0,0014 in F and T groups, respectively. The risk of combine endpoint was lower in T group (21,2% vs 37,5%, =0,0004)

Conclusion: Non-intensive therapy with oral diuretics is well tolerated and does not cause deterioration of either renal function or electrolyte balance. Compensation was seen without complications in most patients with CHF and with lower rates of readmission. Torsemide had advantages over Furosemide on the time to CHF compensation, a degree of clinical improvement and achievement of complete compensation with a significantly lower rate of adverse events and rehospitalizations.

P1630

Hyponatremia in acute heart failure: relationship with congestion and outcome

G Ruocco¹; PA McCullough²; E Aloia¹; V Palumbo¹; B Franci¹; R Nuti¹; A Palazzuoli¹

¹University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine, Siena, Italy; ²Baylor University Medical Center, Baylor Heart and Vascular Institute, Dallas, United States of America

Background: Hyponatremia is the most common electrolyte disorder in clinical practice in patients submitted to loop diuretic treatment. The prognostic importance of hyponatremia in heart failure (HF) patients is well-recognized. However the clinical determinants of hyponatremia in AHF are not well understood.

Purpose: The aims of this study are: 1- to investigate the link among hyponatremia and congestion in HF patients; 2- to evaluate prognostic influence of hyponatremia considering renal function and diuretics received.

Methods: In this study, we enrolled 164 patients admitted to our department with diagnosis of acute HF (performed by B-type natriuretic peptide [BNP] levels more than 400 pg/ml, echocardiography and chest-ray). We performed a systematic assessment of congestion (pulmonary rales, jugular venous distension, third heart sound, peripheral edema and hepatomegaly: one point for each sign) as well as laboratories (BNP, creatinine, blood urea nitrogen [BUN], sodium, potassium) at admission and at discharge. The mean daily dose of loop diuretic infusion was also calculated. Hyponatremia was defined as admission sodium levels lower than 135 mEq/L. Patients were followed for six months for death or re-hospitalization due to cardiovascular causes.

Results: Of 164 patients, only 151 completed the follow-up. Of these, 36 patients presented with hyponatremia. Univariate predictors included congestion score ≥ 3 points (50 patients) p=0.009, and higher loop diuretic dosage (250 \pm 125 mg vs 125 \pm 50 mg p<0.001). Hyponatremic patients had a higher composite of re-admission or death over 180 days of followup (72% vs 55% p<0.05). Cox regression analysis showed that hyponatremia was significantly related to poor outcome also after adjustment for congestion, CKD, age and other baseline variables (Univariate HR: 1.87 [CI:1.21-2.91]; p=0.005. Multivariable HR: 1.64 [CI: 1.02-2.65]; p=0.04). Kaplan Meier survival plot confirmed these findings (see Figure).

Conclusions: Hyponatremia on admission is associated with greater degrees of pulmonary and systemic congestion and higher diuretic usage after admission. Baseline hyponatremia is an independent predictor of death or hospitalization after discharge after controlling for degree of congestion, renal function, and other baseline variables. Future strategies that specifically address initial hyponatremia upon admission are warranted in attempts to reduce re-admission and death.

P1631

Increase of HF re-admission rate by chronic administration of tolvaptan for the tolvaptan non-responders.

KT Tsukamoto¹; MA Aichi¹; SH Hasegawa¹; MW Watanabe¹; KY Yazaki¹; KM Mizobuchi¹; TS Saitou¹; YA Ajiro¹; FM Mori¹; KI Iwade¹

¹National Hospital Organization Yokohama Medical Center, Yokohama, Japan

Background: Tolvaptan is a novel water diuretic which exerts its diuretic effect via selective vasopressin type-2 receptor inhibition and subsequent renal collecting duct aquaporin-2 suppression. The usefulness of tolvaptan in acute decompensated heart failure (HF) was demonstrated in EVEREST trial, whereas those in chronic HF was unfavorable. However, another report showed the possible usefulness of tolvaptan administration for the chronic HF patients who preserved urine aquaporin-2 synthesis and trafficking. The efficacy of tolvaptan administration for the patients in chronic phase of HF was not fully understood.

Purpose: To investigate the efficacy of tolvaptan administration in chronic HF.

Methods: 67 patients who had acute decompensated HF treated by tolvaptan from April, 2014 through March, 2015 were enrolled in this retrospective observational study. Responder was defined as the patient whose urine volume was increased after tolvaptan administration. We divided the patients into four groups as follows: group A as for the responders who continued tolvaptan administration after discharge (n=25); group B as for the responders who ceased tolvaptan administration after discharge (n=22); group C as for the non-responders who continued tolvaptan administration after discharge (n=12); and group D as for the responders who ceased tolvaptan administration after discharge (n=8). Four groups were compared with regard to all-cause mortality and the rate of HF re-admission during observation period. The deviation among four groups were analyzed by chi-square test. Comparison between groups were analyzed by Fisher's exact test adjusted using Bonferroni method. P<0.05 considered significant. Results There were significant deviation in all-cause mortality (chi-square test, p=0.0476) and HF re-admission rate (chi-square test, p=0.0008) among group A, group B group C, group D (all-cause mortality were 0.0% (0/25), 4.6% (1/22), 25.0% (3/12), 12.5% (1/8); and HF re-admission rate were 20.0% (5/25), 22.7% (5/22), 83.3% (10/12), respectively). The significant difference were found in HF re-admission rate comparing between group A and C (p=0.0042), and group B and C (p=0.0066).

Conclusions: It was demonstrated that non-responder and continuous administration of tolvaptan would be harmful combination with high HF re-admission rate.

Comparison of HF re-admission rate

Ambulatory intravenous diuretic heart failure unit: 18 months experience

A Birchall¹; K Morton¹; M Warriner¹; J Gosai¹; D Rogers¹; NT Lewis¹;
A Abdallah Al-Mohammad¹

¹Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Background: Heart failure (HF) with fluid overload requires intravenous diuretic therapy that may need to be given over a long and costly admissions to hospital. We established an ambulatory intra-venous diuretic therapy unit for heart failure (AID-HF). We present our experience in the last 18 months.

Methods: We replaced 4 beds with chairs in one of the wards, trained the ward nurses in the principles of heart failure management. The patients who were no longer in pulmonary oedema, who were mobile and otherwise ready to return home apart from peripheral oedema with or without ascites were invited to be admitted to AID-HF. Those who consented were admitted daily for intravenous (iv) diuretics given over 2-6 hours/day while monitoring their weight, blood pressure and renal function. The patients were discharged when the oedema became limited to below the knees, and they tolerated the switch to oral diuretics. Care was provided by the HF specialist nurses supported by the ward nurses, the HF cardiologists and a junior doctor in HF. Data are collected on the patients' background, the days of attendance as a marker of hospitalisation days saved, the patients' re-admission to hospital, their chance of re-admission into the service within 1 month.

Results: There were 77 patients admitted to AID-HF unit between June 2014 and December 2015. Of these patients, 61 patients (79%) were 50-80 years of age, and 67 patients (87%) were males. HF with reduced ejection fraction was the diagnosis in 49 patients (64%). All the patients had a degree of pulmonary hypertension and/or right ventricular impairment with or without tricuspid regurgitation. Re-admission to the AID-HF unit affected 25 patients (33%), and 8 patients (10%) had more than one re-admission. In addition, 16 patients (21%) were hospitalised from the AID-HF unit. The mean length of attendance is 11 days with a median of 7 days. In total, the patients attended the AID-HF unit on 888 days which are the total hospital days saved.

Conclusion: Ambulatory intravenous diuretic therapy is feasible in advanced heart failure even in high risk patients and could possibly result in health economic savings.

Assessment of the use of ESC heart failure guideline recommended therapy among patients followed at a heart failure outpatient clinic participating in the ESC Heart Failure long-term Registry

B Muk¹; P Bogyi¹; ZS Majoros¹; T Borsanyi¹; B Ancsin²; B Szabo³; ZS Bari¹;
M Dekany¹; RG Kiss¹; N Nyolczas¹

¹Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary;

²Eastbourne District General Hospital, Cardiology, Eastbourne, United Kingdom;

³Orebro University Hospital, Cardiology Clinic, Orebro, Sweden

Background: In the large randomized, controlled trials which proved the favourable effect of neurohormonal antagonists on the outcome of chronic systolic heart failure (HFrEF), the proportion of patients receiving the target doses (TD) of these drugs reached about 60-70%. Contrary to that, in observational studies, even in the whole cohort of the recently published ESC Heart Failure Long-term (EORP) Registry the proportion of patients receiving TD of these drugs was significantly lower.

Aim: To assess the proportion of patients receiving the ESC guideline recommended treatment in the patient cohort (PC) suffering from HFrEF followed at our heart failure outpatient clinic (HFOC) participating in the EORP Registry.

Patients and methods: We analysed the data of 154 consecutive ambulatory patients with HFrEF followed at our HFOC (LVEF: $34.6 \pm 10.3\%$; NYHA: 1.7 ± 0.8 ; blood pressure: $119.3 \pm 19.2/68.3 \pm 11.1$ mmHg; ischemic etiology: 57.1%; diabetes: 31.8%; hypertension: 68.2%; atrial fibrillation: 32.4%; male: 79.8%; age: 66.7 ± 13.3 years; eGFR: 52.1 ± 22.5 ml/min/1.73m²) at the time of inclusion to the EORP Registry and one year later. The majority of the patients was managed at our HFOC for more than one year before the inclusion.

Results: Treatment at baseline were: ACEi/ARB in 95.4% (at TD: 55.1% of pts of PC), beta-blocker (BB) in 97.4% (at TD – 62.3% of pts) and mineralocorticoid receptor antagonists in 77.2%. Resynchronization therapy (CRT-P/CRT-D) was used in 32.4% and ICD was implanted in 17.5%. Contrary to the whole EORP cohort, our pts were younger, had slightly lower LVEF, better mean NYHA class, and higher percentage of prior coronary artery disease. At one-year follow up the proportion of patients receiving TD of an ACEi/ARB and a BB increased slightly (59.8% and 65.8%, respectively) contrary to the data of the whole EORP registry. In total, 57.1% of pts were suitable for ICD, and 78.4% of them had already undergone the implantation, while 40.2% fulfilled the criteria for CRT-P/CRT-D and 90.3% had already have the device. One-year survival of our ambulatory PC was 90.3%.

Conclusions: Although the worldwide rate of patients receiving the cornerstone

neurohormonal antagonist regime of HFrEF has increased within the last years, the proportion of pts receiving the target doses of these drugs is still moderately low. Follow up of HFrEF patients at a HFOC, and the effort and motivation to optimize the treatment by specialists can make it possible to reach the doses of neurohormonal antagonists that is similar to that were used in the large landmark heart failure trials.

P1634

Long-term follow up of hospitalized patients with systolic heart failure undergoing early treatment with beta-blockers more ivabradine: a randomized study

The authors claim to have received an unconditional grant from Servier
F Francisco Jose Hidalgo Lesmes¹; M Anguita Sanchez¹; JC Castillo Dominguez¹; S Rodriguez Diego¹; L Pardo Gonzalez¹; M Ruiz Ortiz¹; D Mesa Rubio¹; M Delgado Ortega¹

¹University Hospital Reina Sofia, Cardiology, Córdoba, Spain

Background and aims: Heart rate (HR) seems to have prognostic value in patients with heart failure and depressed ejection fraction (HF-dEF) in sinus rhythm. HF guidelines recommend to obtain a HR < 70 bpm, but it is not well known if the way in which this target is reached affects outcomes. The aim of our study was to analyze the effect or early administration of ivabradine added to betablockers (lv+BB) versus only betablockers (BB) on heart rate and outcomes in this kind of patients. Methods.- The effect of two different protocols, lv+BB or only BB during hospitalization, in patients with HF-dEF, sinus rhythm, HR>70bpm and left ventricular ejection fraction (LVEF) < 40% was evaluated in a comparative, randomized study. HR at 28 days after discharge was the primary end-point. HR, LVEF, NYHA class, BNP levels and clinical outcomes at 1 year were also analyzed. In the lv+BB group, ivabradine was started at 24 hours after admission.

Results: Sixty-two consecutive patients who met inclusion criteria were included, 30 in the lv+BB group and 32 in the BB groups. Mean age was 66.2 ± 15.4 bpm in the lv+BB group, and 67.7 ± 12.3 bpm in the BB group ($p=0.68$). The LVEF was $29.8 \pm 7.5\%$ in the lv+BB group and $29.9 \pm 6.1\%$ in BB group ($p=0.6$). Both groups were homogeneous in terms of gender, blood pressure and HR at admission, BNP levels, renal function and drug therapy with diuretics, ACEi or ARA and ARM too. Ivabradine dosage at discharge was 5 mg/12 hours in 18 patients and 7.5 mg/12 hours in 12 patients. Betablockers dosage at discharge and at 1 year follow up was similar in both groups. HR at 28 days after discharge was significantly lower in the lv+BB Group (64.3 ± 7.5 vs 70.3 ± 9.3 bpm; $p=0.01$). HR at 1 year remained lower in the lv+BB group (61.84 ± 5.5 vs 68.47 ± 9.3 bpm; $p=0.01$). LVEF at discharge was similar in both groups (32.9 ± 8.7 vs $31.9 \pm 6.1\%$), but significantly higher at 1 year in the lv+BB group (48.2 ± 17.2 vs $41.8 \pm 10.2\%$; $p=0.002$). There were no differences in BNP levels at 1 year (404 ± 200 vs 368 ± 113 pg/ml; $p=0.9$), as well as the proportion of patients in NYHA class III or IV (16 vs 21.5%). There were no differences in clinical events (re-hospitalizations or death) at 1 year. Mortality was 16.7% in the lv+BB and 12.5% in the BB group. No severe adverse effects related to drugs were noted.

Conclusions:- Co-administration of lv+BB early after admission in patients with HF-dEF, sinus rhythm and HR>70 bpm is feasible, safe and significantly decreases 28 days-HR as compared to only BB. This drug protocol also decreased HR at 1 year and seems to improve systolic function without differences in BB doses.

P1635

Comparison of perindopril-amlodipine and losartan-amlodipine combinations in the management of hypertension in patients with metabolic syndrome

JK Jamol Uzokov¹; AL Alyavi²; BB Karimov¹; IY Ahmedov¹; EJ Rakhmonkulov¹;
GT Sultanova¹; IKH Vakhidova¹

¹Tashkent Medical Academy, Tashkent, Uzbekistan; ²Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan

Background: Metabolic syndrome (MS) is a condition linking insulin resistance, dyslipidemia, hyperglycemia, and hypertension that increases the risk of developing diabetes, cardiovascular disease, and subsequent cardiovascular morbidity and mortality. High blood pressure is considered one of the key features of metabolic syndrome. It is a very prominent feature of the metabolic syndrome, present in up to 85% of patients.

Aim of the study was to compare the efficacy and tolerability of perindopril 4 mg + amlodipine 5 mg combination (P+A) versus losartan 50 mg + amlodipine 5 mg (L+A) combination in patients with MS.

Material and Methods: We investigated 84 hypertensive patients with metabolic syndrome with mild-to-moderate arterial hypertension not adequately controlled by a monotherapy with ACE inhibitors or calcium channel blockers or ARB entered this work, randomized, parallel-group study. After a two week placebo run-in, all patients with sitting diastolic blood pressure (DBP) > 95 mmHg and/or sitting systolic (BP) > 160 mmHg were randomized to receive either P+A (42 patients) or L+A (42 patients) once daily for 12 weeks. Main outcome measure was sitting DBP and SBP values at the end of active treatment. The response rate was defined as the

proportion of patients with either a final sitting DBP < 90 mmHg or decreased by at least 10 mmHg or a sitting SBP < 150 mmHg or decreased by at least 20 mmHg from baseline.

Results: The DBP and SBP values obtained with P+A were, respectively, 1.9 and 2.6 mmHg lower than those obtained with L+A (both $p < 0.002$). The response rate in the L+A group (90.6%) was better than that observed in the P+A group (88.4%, $p = 0.01$). The incidence of adverse events was similar with the 2 treatment groups (14.2% vs. 16.6%, $p < 0.02$).

Conclusions: These data suggest a higher antihypertensive efficacy of the fixed combination L 50 mg + A 5 mg as compared with P 4 mg + A 5 mg. Further investigations are required with a large amount of patients.

P1636

How do we use anticoagulation therapy in the era of novel drugs - results of FIRST II registry

T Novakova¹; L Privarova¹; M Felsoci¹; J Jarkovsky²; J Spinar¹

¹University Hospital Brno, Department of Internal Medicine and Cardiology, Brno, Czech Republic; ²Institute of Biostatistics and Analyses of Masaryk University, Brno, Czech Republic

Background: Patients with need of anticoagulative treatment (ACT) are substantial part of daily clinical practice. Clinical and risk assessment, especially in the era of novel anticoagulative drugs, (NOAC) is yet not well known.

Purpose: To compare patients with indication for ACT, their clinical and pharmacological profile and to assess their risk for bleeding.

Methods: Compared were patients with atrial fibrillation/flutter (group AF, $n = 650$) to patients with valve prosthesis (group P, $n = 14$), acute pulmonary embolism (group PE, $n = 80$) and deep venous thrombosis (group VT, $n = 71$) who were hospitalized at university cardiology centre during the study period of May 2013 to May 2014.

Results: Patients with AF were the oldest (71.4 years), PE population the youngest (65.9, $p = 0.001$). Patients with PE presented with better renal function (estimated creatinine clearance 67.8 vs. 58.3 ml/min in AF group, $p < 0.05$). VT patients had the lowest BMI (27.3 vs. 28.9 in AF population, $p < 0.05$) and higher incidence of myocardial infarction in the history (29.6% vs. 18.8% AF group, $p < 0.05$). AF patients suffered more by hypertension (82.5%), diabetes mellitus (31.5%) and heart failure (30.9%) when compared to PE subgroup (56.3%, 13.8% and 6.3% respectively, $p < 0.05$). NOAC were used more frequently in PE and VT population (25.0 and 19.7% respectively, AF in 15.2%, $p < 0.05$). Warfarin was used dominantly in P and AF indication (85.7 and 70.9% vs. 57.5 and 49.3% in PE and VT group). Rest of the patients used low molecular weight heparin. Patients with AF and in the P group had higher risk of bleeding when assessed by HAS BLEED score (2.2 and 2.1 points vs. 1.6 and 1.8 in PE and VT group, $p < 0.05$).

Conclusion: Patients with AF are older, present with higher incidence of comorbidities (especially hypertension, diabetes, heart failure, renal dysfunction) and have the highest risk of bleeding when ACT is used. Warfarin is used dominantly in AF indication, while NOAC in the indication of PE and VT.

P1637

Cardioprotective effects of long-term high-dose therapy with atorvastatin in patients with STEMI in the prevention of chronic heart failure

V Valentin Oleinikov¹; L Salyamova¹; E Romanovskaya¹; V Galimskaya¹; A Khromova¹

¹Penza State University, Penza, Russian Federation

Objective: to study the dynamics of the characteristics of the global contractility, the structural parameters of the myocardium of the left ventricle (LV) in patients with acute myocardial infarction with ST segment elevation (STEMI) against the backdrop of 24 weeks of treatment with different doses of atorvastatin.

Methods: The study included 46 patients with STEMI, confirmed by the ECG data, level of troponin I, CK-MB. An obligate criterion was the presence of hemodynamically significant stenosis of only one coronary artery based on the results of coronary angiography. Patients were randomized into two groups. The group C (control) included 26 people who received atorvastatin at a dose 20 mg/day. Group A consisted of 20 patients with STEMI, treated with atorvastatin 80 mg/day. Comparison groups were matched by sex, height, BMI, office blood pressure values. Lipid-lowering therapy was started in the first 24-96 hours from the onset of the disease. Initially, at 7-9 day from the beginning of the STEMI and at 24 weeks of treatment all patients underwent echocardiography using ultrasonic device MyLab90 (Esaote, Italy). Computer analysis was performed using the XStrain™ software with evaluation of the following parameters: global longitudinal strain (GLS), circular strain (GCS) and radial strain (GRS). Among the traditional echocardiographic parameters the index of end-diastolic volume (EDV index) and ejection fraction (EF) have been analyzed.

Results: According to the two-dimensional Strain in the group C the baseline value of the global deformation were the following: GLS - $-14.9 \pm 7.6\%$, GCS - -20.2 (12.9; 25.0)%, GRS - 29.7 (25.4; 40.0)%; the follow-up, respectively, $-16.8 \pm 5.9\%$, $-21.1 \pm 7.5\%$ and $32.3 \pm 11.4\%$ ($p > 0.05$). In group A no significant dynamic of global

Strain parameters have been revealed as well. The baseline values of GLS was $-17.2 \pm 5.3\%$, GCS - $-18.3 \pm 8.3\%$, GRS - $37.2 \pm 13.5\%$; after 24 weeks of treatment - $-17.0 \pm 4.9\%$, $-19.7 \pm 5.0\%$ and $34.0 \pm 9.6\%$ ($p > 0.05$). While in the group C an increase of EDV index has been revealed from 47.2 ± 8.2 ml/m² to 58.0 ± 7.9 ml/m² ($p < 0.05$). In patients treated with atorvastatin 80 mg, the dynamic of this parameter was the following: 7-9 hours - 52.0 ± 6.7 ml/m², 24 weeks - 48.0 ± 9.1 ml/m² ($p > 0.05$). Initial values of the EF in the control group were 56.11 ± 11.9 , follow-up - 56.0 ± 9.7 ($p > 0.05$); patient of comparison group - $54.5 \pm 10.0\%$ and $58.6 \pm 8.7\%$, respectively ($p < 0.05$).

Conclusions: The 24-weeks of treatment with different doses of atorvastatin in patients with STEMI was not accompanied by deterioration of the deformation characteristics of the left ventricle. An increase of LV end-diastolic volume in the group treated with 20 mg of atorvastatin has been revealed. High-dose statin therapy was accompanied by a significant increase in LVEF.

P1638

Mineralocorticoid receptor antagonists improve quality of life in patients with systolic heart failure highly treated with neurohormonal inhibitors: a propensity-score matching analysis

DT Farmakis¹; J Parissis¹; A Karavidas²; V Mantzaraki²; A Perpinia²; G Papingiotis¹; V Bistola¹; J Lekakis¹; G Filippatos¹

¹National & Kapodistrian University of Athens, 2nd Dept. of Cardiology, Athens, Greece; ²General Hospital of Athens G. Gennimatas, Department of Cardiology, Athens, Greece

Background: Mineralocorticoid receptor antagonists (MRA) constitute a cornerstone of therapy in patients with heart failure with reduced ejection fraction (HFrEF), as they improve significantly long-term outcome. However, their effect on quality of life (QoL) in the current HFrEF populations who are highly treated with neurohormonal inhibitors has not been clarified.

Purpose: We sought to assess the effects of MRA therapy on QoL along with exercise capacity, neurohormonal activation and central hemodynamics in chronic HFrEF patients highly treated with neurohormonal inhibitors

Methods: We analyzed retrospectively a cohort of 120 stable chronic HFrEF patients (57% male, NYHA class II or III, mean left ventricular ejection fraction, $28 \pm 5\%$). We compared quality of life between patients receiving or not MRA using propensity-score matching. Kansas City Cardiomyopathy Questionnaire (KCCQ) functional and summary scores were used for QoL evaluation. Six-min walked distance (6MWD), B-type natriuretic peptide concentration (BNP) and mitral E/e' ratio were also assessed.

Results: Of 120 patients, 106 (88%) were on MRA therapy. In addition, 114 patients (95%) were receiving angiotensin converting enzyme inhibitors or angiotensin II receptor blockers and 117 (97%) beta-blockers. Therapy with MRA was associated with significantly better KCCQ functional and summary scores [average treatment effect (ATE), 0.16, 95% confidence interval (CI): (0.13, 0.18), $p < 0.001$ and 0.13, 95% CI: (0.11, 0.14), $p < 0.001$, respectively]. In addition, MRA therapy was associated with significantly lower BNP [ATE, -135.46, 95% CI: (-245.61, -25.31), $p = 0.016$] and mitral E/e' ratio [ATE, -3.59, 95% CI: (-4.56, -2.62), $p < 0.001$], but not with significantly longer 6MWD [ATE, 10.43, 95% CI: (-16.20, -37.07), $p = 0.443$].

Conclusion: In chronic HFrEF patients highly treated with neurohormonal inhibitors, MRA was associated with better QoL, along with improved central hemodynamics and neurohormonal activation.

P1639

Ivabradine in the treatment of severe left ventricle systolic dysfunction in very elderly patients

A Alvaro Garcia Ropero¹; M Cortes Garcia¹; ML Martin Mariscal¹; M Lopez Castillo¹; AM Romero Daza¹; JA Palfy¹; M Taibo Urquia¹; J Farre Muncharaz¹

¹Foundation Jimenez Diaz, Cardiology, Madrid, Spain

Introduction: Congestive heart failure (CHF) is a common syndrome, especially in advanced-age patients. Ivabradine has shown to be beneficial in the treatment of CHF with left ventricle systolic dysfunction (LVSD). However, there are still very few available data regarding its usage and efficacy in very elderly patients (PT). Thus, we aim to describe our experience with respect to ivabradine and elderly population.

Methods: Since January 2008 to December 2013 we prospectively collected data (in a single third level hospital) from PT with LVSD (ejection fraction (EF) < 35% and ≥ 75 years of age. We included clinical, electrocardiographic and echocardiographic variables. We performed prospective follow-up with clinical history and phone calls.

Results: We finally included 802 PT. The mean age was 82.03 years ($SD \pm 4.95$) and 66.2% were male. Only 7% of the total population was on Ivabradine (51 PT) with a mean age of 80.13 years ($SD \pm 4.03$) in this subgroup, being 70.6% of them males. 70.6% of them had hypertension, 39.2% diabetes mellitus, 56.9% dyslipidemia, 27.5% chronic renal injury, 31.4% chronic obstructive pulmonary disease (COPD) and 13.7% cerebrovascular disease. The mean EF was 26.9% ($SD \pm 6.4$) with ischemic origin in 76.7% of the total. There were no side effects in this Ivabradine-subgroup. In 2 PT, ivabradine was removed to start in beta-blockers

(BB), not considered initially due to history of asthma in one of them, and intolerance in the other one. Nevertheless, up to 43.1% of the subgroup was receiving both Ivabradine and BB without complications. The main cause of patients who did not receive BB was the presence of COPD. After a mean follow up period of 36.5 months (SD ± 18.06), up to 37.3% of the PT were admitted due to an episode of CHF and up to 39.2% of them died. PT in Ivabradine treatment had a significant reduction in the heart rate as compared with those non receiving Ivabradine (78.8 versus 69.8 bpm, respectively; $p=0.05$) and a significant increase in the mean EF in those receiving Ivabradine during the follow up period (26.9 versus 34%; $p=0.05$). We also detected an improvement in the NYHA functional class in the Ivabradine-subgroup during the follow up (1.8 versus 1.6; $p=0.05$).

Conclusions: Ivabradine might have clinical benefit in very elderly patients with severe left ventricle systolic dysfunction and congestive heart failure. In addition, it has a good profile of tolerance and safety in our population. We suggest that further trials should be performed in this a common specific subgroup of patients.

P1640

The effects of ivabradine on diastolic function in patients with decompensated systolic heart failure

D Darabantiu¹; R Lala¹; A Pop-Moldovan¹; L Pilat¹; RM Christodorescu²

¹Vasile Goldis Western University, Arad, Romania; ²University of Medicine & Pharmacy Victor Babes, Timisoara, Romania

Premises and purpose: In patients with heart failure and reduced ejection fraction (HFrEF) diastolic function also has an important prognostic value. The objective of this study was to assess the influence of ivabradine on diastolic function in patients with decompensated HFrEF.

Material and methods: This prospective study recruited 42 consecutive patients (32 males, 10 females) admitted for decompensated heart failure, with LV systolic dysfunction, sinus rhythm and resting heart rate >70 b/min, treated according to current guidelines in whom ivabradine therapy was initiated (in hospital or in the first week after discharge). Echocardiographic data on systolic and diastolic function (LV ejection fraction, indexed LV endsystolic and enddiastolic volumes – iESV and iEDV, mitral E velocity, E/A ratio, e' velocity, E/e' ratio, E deceleration time, left atrial volume) were measured at baseline and after 6 months of ivabradine therapy.

Statistics: data were expressed as mean \pm standard deviation or percentages, comparisons between baseline and follow-up data were done with Student's paired t test.

Results: Study group consisted of 35 P in whom both baseline and 6 month data were available (1 P died, 3 P did not tolerate ivabradine, 1 P presented atrial fibrillation during follow-up with subsequent interruption of ivabradine, 2 P lost to follow-up). Mean age was 60 ± 12 years, heart failure etiology was ischemic in 19 P (54%), 11 P (31%) had diabetes, 15 P (43%) had left bundle branch block, 7 P (20%) had COPD. Associated heart failure therapy consisted of ACE inhibitors/ARBs in 26 P (74%), betablockers in 33 P (94%), furosemide in 33 P (94%), spironolactone in 29 P (82%). Mean ivabradine dose at 6 months was 10.8 ± 3 mg/day. After 6 months LV ejection fraction increased from 26 ± 8 to $31 \pm 8\%$ ($p=0.007$), LV volumes decreased (iEDV from 93 ± 25 ml/m² to 87 ± 27 ml/m² $p=0.1$, iESV from 69 ± 23 ml/m² to 61 ± 24 ml/m² $p=0.02$). Diastolic parameters under ivabradine therapy showed improvement after 6 months: E velocity decreased from 83 ± 23 cm/s to 77 ± 22 cm/s ($p=0.1$), E/A ratio decreased from 1.9 ± 1.2 to 1.3 ± 1.02 ($p=0.009$), e' velocity increased from 5.5 ± 1.7 cm/s to 7.2 ± 1.6 cm/s ($p=0.0009$), E/e' ratio decreased from 14.7 ± 5 to 11 ± 4 ($p=0.0003$), EDT increased from 165 ± 56 ms to 190 ± 68 ms ($p=0.1$) and left atrial volume decreased from 38.6 ± 13 to 35.4 ± 11 ml/m² ($p=0.2$). Readmissions due to HF aggravation were noted in 5 P (14%).

Conclusions: In patients with decompensated HFrEF, well treated with guideline recommended medical therapy, association of ivabradine, besides the beneficial effects on systolic function, seems to improve also left ventricular diastolic function parameters.

P1641

Risk of heart failure related to non - ergot derived dopaminergic agonists in Parkinson disease. A meta-analysis of randomized controlled trials

C Carmelina Ariano¹; R De Vecchis¹; C Cantatrione¹; D Mazzei¹; C Cioppa¹; A Giasi¹; S Cantatrione¹

¹Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy

Background: Parkinson's disease (PD) is a neurodegenerative disorder caused by the disruption of dopaminergic neurotransmission in the basal ganglia. Levodopa is currently the most effective agent used in the treatment of PD. Even though dopaminergic agonists(DAs) are less effective than levodopa as treatment regimen, they are associated with lower risks of dyskinesia and motor fluctuation. This has caused the wide-scale application of DAs in the early stages of PD in order to postpone the use of levodopa, or as an add-on treatment to reduce levodopa dosages. With regard to the more recently developed non-ergot-derived DAs

such as pramipexole and ropirineol, a number of randomized controlled trials(RCTs) and observational studies have reported a clear, albeit nonsignificant, trend to the increase in the risk of heart failure and cardiovascular events associated with the use of non-ergot DAs, especially in the case of the pramipexole.

Purpose: Thus we decided to carry out a systematic review and meta-analysis of RCTs related to the use of non-ergot DAs in patients with PD. Our primary endpoints were all-cause mortality and cardiovascular events.

Methods: Systematic searches were performed in Pubmed, Embase and Clinical-Trial.gov up to June 2015. Eligibility for inclusion in the meta-analysis was based on the following: RCTs of non-ergot DA use in PD patients, trials exceeding three months in duration, more than ten participants in each arm of the intervention, and the availability of outcome data pertaining to mortality and cardiovascular events. Both fixed and random effects models were used to assess the risk of mortality associated with the use of non-ergot DAs. The effect size was expressed as relative risk (RR) of non-ergot DA versus placebo on overall mortality and cardiovascular events (including any cardiovascular events, major adverse cardiovascular events and heart failure). Results Thirteen trials (5215 PD patients) were comprised in our analyses of mortality rates and 24 RCTs(6734 patients) were considered to evaluate cardiovascular events. Overall, the use of non-ergot DAs was associated with a risk of death lower than that associated with placebo use (RR: 0.53; 95% CI: 0.30-0.96). Moreover, the use of non-ergot DAs was not associated with increased risk of cardiovascular events(RR: 0.87; 95% CI: 0.56- 1.37), including myocardial infarction, stroke, and heart failure.

Conclusions: The use of non-ergot DAs was shown to modestly reduce overall mortality without increasing the risk of cardiovascular events, including heart failure. Further research is warranted to assess the potential risks and benefits concerning therapy with non-ergot DAs by analyzing large population-based data.

P1642

Ivabradine treatment for chronic heart failure in clinical practice is associated with reductions in symptoms and hospitalizations with improved quality of life, independent of beta blocker dose

Study supported by Servier Germany

C Zugck¹; S Stoerk²; G Georg Stoeckl³

¹Joint Practice for Internal Medicine, Steiner Thor, Straubing, Germany;

²Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany; ³Servier Deutschland GmbH, Munich, Germany

Background & Objectives: Ivabradine is recognized in current treatment guidelines of chronic heart failure (CHF). We aimed to evaluate the symptomatic effectiveness, tolerability, effect on quality of life (QoL) of ivabradine in CHF patients treated in clinical practice, with a special focus on hospitalizations over a 12-month period.

Methods: In this non-interventional study heart rate (HR), heart failure symptoms and medication were documented at cardiologist level in outpatients with CHF. The frequency of heart failure hospitalizations during the study period was compared with an internal control period of 12 months prior to study start. Patients with indication for ivabradine treatment were eligible (NYHA class II-IV, sinus rhythm, HR ≥ 75 bpm). Therapy with ivabradine twice daily was initiated for a duration of 12 months, with possibility of dose adjustment. QoL was evaluated by the EQ-5D patient questionnaire. A descriptive statistical analysis was performed, with stratification according to beta blocker (BB) dose categories (i.e., $<50\%$, $50-99\%$ or $\geq 100\%$ of recommended target dose).

Results: A cohort of 767 CHF patients (mean age 65.5 ± 11.4 years, 23% ≥ 75 years; 57% male) was recruited. Median follow-up was 11.9 months. 61% of patients had ischemic etiology of CHF. Hypertension (81%) and dyslipidemia (50%) were the most prevalent comorbidities. Concomitant medication at baseline: 65% BB (Metoprolol 42%, Bisoprolol 41%, Nebivolol 8%, Carvedilol 8%), ACEI/ARB 86%, diuretics 60%, aldosterone antagonists 21%, aspirin 59%, statins 59%.

Follow-up information after 1 year of treatment was available in 90% of all patients. Ivabradine (mean daily dose 11.3 mg) was associated with reduced HR by 14-18 bpm in all three categories of BB dose. The absolute percentage of patients with NYHA III classification was reduced by 25%, 33% and 31% in patients with $<50\%$, $50-99\%$ or $\geq 100\%$ of BB target dose, respectively, whereas the percentages in NYHA class I substantially increased ($p < 0.0001$ for changes).

Compared to the 12 months prior to ivabradine treatment percentages of patients with any hospitalization for heart failure were significantly reduced during the study period in all three BB subgroups: from 19% to 5%, from 31% to 6%, and from 29% to 3%. QoL (EQ-5D score) improved by 20%, 26%, and 19%, respectively ($p < 0.0001$). Mean BB doses remained stable during the trial. Adverse drug reactions, potentially related to ivabradine use, occurred in 3.4% of all patients.

Conclusion: In this cohort of CHF outpatients treated by cardiologists, ivabradine was associated with reductions in heart failure symptom burden and frequency of CHF-related hospitalizations, independent of concomitant BB dose. QoL consistently improved in all BB subgroups. These effects were accompanied by good general tolerability of the drug.

P1643

Diastolic dysfunction in lipotoxic myocardial damage by patients with obesityG Galina Chumakova¹; O Gritzenko²; N Veselovskaya²¹Altay State Medical University, Barnaul, Russian Federation; ²Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation

The risk of lipotoxic myocardial damage is significantly increased in patients with obesity. Visceral obesity is characterized by impaired lipid metabolism, which leads to "overload" cardiomyocytes lipids that contribute to initiation of apoptosis that leads to myocardial fibrosis and heart failure.

Purpose: To identify risk factors for lipotoxic myocardial remodeling and explore features of remodeling heart in patients with obesity.

Materials and

Methods: Was included 48 patients (43.8 ± 5.2) with common obesity. Patients have obesity I-III degree, BMI 33.86 ± 4.23 kg / sq.m. From the study were excluded patients with diabetes, hypertension, coronary heart disease. All patients measured the thickness of epicardial adipose tissue (EAT), end-diastolic and end-systolic volume, size of LA, end-diastolic size of RV, diastolic dysfunction by echocardiography and determined the level of metabolic risk factors and free-fatty acid (FFA). Was allocated 2 groups: Group 1 with obesity and EAT more than 7 mm (26), Group 2 with obesity and EAT less 7mm (22).

Results and discussion: In Group 1 higher level of glucose (4.2 ± 0.2 and 5.7 ± 0.4 mmol/l in group 1 and 2 respectively, $p = 0.004$), level of insulin in group 1 was 7 ± 0.3 mcEd/ml, in group 2 – 16 ± 0.7 mcEd/ml ($p = 0.02$), higher level of unsaturated FFA in group 1 than in group 2 (0.2 ± 0.01 and 0.8 ± 0.1 respectively, $p = 0.003$), level of TG was 0.9 ± 0.1 mmol/l and 1.5 ± 0.2 mmol/l respectively in group 1 and 2 ($p = 0.04$) and level of VLDL was higher in group 1 than in group 2 (2.2 ± 0.2 mmol/l and 3.5 ± 0.3 mmol/l respectively, $p = 0.002$). Evaluation of remodeling of left ventricular was made and it was found that end-diastolic volume and end-systolic volume in group 1 were significantly higher than in group 2 (73.2 ± 4.3 ml and 46.7 ± 3.5 ml respectively $p = 0.02$). In addition, patients in Group 1 with a 7mm EAT has more size of the LA – 44.42 ± 4.89 mm and end-diastolic RV size – 29.41 ± 3.52 mm than patients in Group 2 ($p = 0.001$). In group 1, diastolic dysfunction (DD) type 1 is determined in 28.5% of patients in group 2, 14% of patients.

Conclusion: Obesity significantly increases the risk of myocardial lipotoxic. This risk increases in visceral adiposity patients. Myocardial fibrosis and heart failure are causes lipotoxic myocardial damage. Markers of lipotoxic myocardial damage are increased level of FFA, TG and VLDL.

P1644

Type II diabetes mellitus and its early effects on the heart: an echocardiographic studyR Petroni¹; M Di Mauro¹; V Porretta¹; N Borrelli¹; S Romano¹; M Penco¹¹University of L'Aquila, cardiology, L'Aquila, Italy

Introduction: Diabetes mellitus (DM) is a chronic disease characterized by elevation of blood glucose levels with multi organ damage, steadily increasing and burdened with a high mortality. It was estimated that in 2000 the prevalence of DM was around 2.8 % of the world population and that in 2030 will reach 4.4% with a parallel increase in cardiovascular risk

Purpose: to identify early myocardial changes in order to choose the best treatment and to establish the correct follow-up of these patients

Materials and methods: eighteen consecutive patients suffered from Type II Diabetes Mellitus (mean age 50 ± 4 ; mean BMI 32.7) referred to our center were enrolled. All these patients were submitted to an echocardiographic evaluation. All the obtained data were compared with a population of eighteen patients without Type II Diabetes Mellitus but similar in age and gender. We evaluated both systolic and diastolic parameters (diameter, volumes, functional parameters) for right and left ventricle. Results For right ventricular parameters the following significant differences were observed: Tricuspid Annular Plane Systolic Excursion (TAPSE) was significantly lower in diabetic patients ($p < 0.05$); right ventricular end-systolic and end-diastolic volume and right atrium area were higher in diabetic patients ($p < 0.001$); E/A ratio and deceleration time of E wave (DTE) were altered in diabetic patients ($p < 0.05$) and Doppler tissue imaging-derived peak systolic velocity (S') was lower ($p = 0.002$). For left ventricular parameters the following significant differences were observed: Left ventricular end-systolic volume, end-diastolic volume and left atrium area were significantly higher in diabetes patients ($p < 0.001$). E/A and E/E' ratio were altered in diabetic patients more than in normal patients ($p < 0.001$ and $p = 0.02$), and Doppler tissue imaging-derived peak systolic velocity (S') was lower ($p = 0.001$) in diabetic patients. Conclusion Echocardiographic parameters demonstrate that type II diabetes mellitus leads to a very early damage of the heart muscle. Variation of speed contraction may be the first sign of this damage and changes in intraventricular volumes the consequence. These observations are very important

to establish in which kind of type II diabetic patients we must optimize therapy in order to prevent or slow the progression to a full-blown heart disease.

P1645

The differences between various obesity indices in predicting clinical severity and prognosis of acute myocardial infarctionZ Babic¹; M Marko Mornar Jelavic²; H Pintaric³¹University Hospital "Sestre Milosrdnice", Coronary Care Unit, Zagreb, Croatia;²Health Center Zagreb - East, Center for Internal Medicine and Dialysis, Zagreb, Croatia;³University Hospital "Sestre Milosrdnice", Cardiac Catheterisation Laboratory, Zagreb, Croatia

Introduction: Measurement of anthropometric parameters is a primary method for diagnosing obesity. Central obesity measures are stronger predictors of CVD risk than overall obesity.

Purpose: To investigate the differences between various obesity indices in predicting clinical severity and prognosis of acute ST-elevation myocardial infarction (STEMI).

Methods: We included 250 acute STEMI patients treated with primary percutaneous coronary intervention. They were classified into two groups (with/without obesity, according to obesity indices: overall - body mass index (BMI) vs central - body adiposity index (BAI), conicity index (Cindex), visceral adiposity index (VAI), waist circumference (WC), waist-to-hip (WHR) and waist-to-height ratio (WHtR)) which were analyzed by baseline (medical history and demography), severity (clinical presentation, laboratory, echocardiography, coronary angiography and in-hospital complications) and prognostic parameters (major adverse cardiovascular events (MACE) and sick leave duration (SLD) during 12-month follow up).

Results: Of the total of 250 patients, there were 72 (28.8%) patients with overall obesity. Central obesity has 24 (10.3%), 202 (80.8%), 114 (52.8%), 149 (59.6%), 222 (88.8%) and 81 (32.4%) patients with very high BAI, Cindex $> 1.25/1.18$, $WC \geq 102/88$ cm, $WHR \geq 0.90/0.85$ and $WHtR \geq 63/58$, respectively. Very high BAI (adjusted for BMI < 30.0 kg/m²) increased the risk of dyspnea, Cindex $> 1.25/1.18$ (adjusted for WHtR $\geq 63/58$) of total in-hospital complications, $WHR \geq 0.90/0.85$ of significant proximal/middle coronary segments stenosis and Gensini score ≥ 20 , and $WHtR \geq 63/58$ (adjusted for hyperglycemia) of heart failure ($p < 0.05$). The number of significantly stenosed coronary arteries increased the risk of total MACE ($p < 0.05$).

Conclusions: Several central obesity indices are superior to BMI in predicting acute STEMI severity (clinical presentation, in-hospital complications, severity of coronary disease), while the others (VAI, WC) have no influence on it. They all have no influence on prognosis (MACE and SLD).

P1646

Using the modified seattle angina questionnaire for patients with heart failure and metabolic syndrome after percutaneous intervention for assessment the effectiveness of treatment.NV Chumachenko¹; LS Kholopov¹; VN Bondar¹¹Odessa National Medical University, Odessa, Ukraine

Background: Patients with coronary artery disease and metabolic syndrome (MS) after percutaneous coronary intervention (PCI) for acute coronary syndrome without ST-segment elevation (ACS nST) have a very high risk of the further development of heart failure (HF), due to significant signs of severe microvascular inflammation and endothelial dysfunction. Assessment of subjective condition of the patient is an important diagnostic component for a quick solution of necessity of in-depth examination and treatment strategies correction. The purpose of the work: to evaluate the information content of "Modified Seattle Angina Questionnaire for Patients with MS after PCI" (MSAQ) in the presence of HF.

Methods: 94 patients (M 61, F 33) took part in the research; average age 65.6 ± 6.1 year; all of them either in clinical routine, or in connection with health aggravation. They were clinically tested especially for determination of asymmetric dimethyl-L-arhynyn (ADMA) and N-terminal prohormone of brain natriuretic peptide (NT-proBNP) of plasma. Patients filled in Personal Health Questionnaire Depression Scale (PHQ-8) and MSAQ.

Results: Patients with the results from 81 to 100% of questionnaire MSAQ ($n = 26$) were considered as an effective treatment group I, 61-80% ($n = 49$) - the group II - group of medium effectiveness of treatment and less than 60% ($n = 19$) - the III group of ineffective treatment. The average period after PCI was 15.1 ± 1.2 months and didn't differ between groups. In the group III there has been distinguished a big percent of patients independently visiting hospital on the occasion of health aggravation, 73.5% against 50.0% and 16.7% in group II and I. Verasiously big indices of ADMA were observed in the III group (0.74 ± 0.21 , mmol / L) and the II group (0.65 ± 0.08 , mmol / L) compared with group I (0.61 ± 0.09 mmol / L), ($p < 0.05$); and NT-proBNP: 814.1 ± 71.3 pg / mL, 730.7 ± 65.1 pg / mL, 534.1 ± 52.2 pg / mL, ($p < 0.05$) for III, II and I group, respectively. Patients demonstrated high indices of the left ventricular systolic function (measured by Simpson) in group I (50.1 ± 5.9 , %) and II (49.2 ± 5.24 , %), compared with III group (43.1 ± 3.8 , %), ($p < 0.05$), respectively.

Conclusions: Designed "MSAQ" conveys multicomponent aspects for diagnosing of comorbid patients. It can be useful as an accessible screening method for evaluating the effectiveness of treatment for patients with HF and MS after PCI.

Nutritional assessment and prognosis in hospitalized patients with acute heart failure

R Gonzalez Ferreiro¹; A Alfonso Varela Roman¹; I Gomez Otero¹; P Conde Sabaris²; M Moure Gonzalez¹; A Seoane Blanco¹; S Raposeiras Roubin¹; A Garcia Castelo¹; A Virgos Lamela¹; JR Gonzalez Juanatey¹

¹Clinical University Hospital. Service of Cardiology, Santiago de Compostela, Spain; ²University of Santiago de Compostela, Santiago de Compostela, Spain

Background: Malnutrition is common in hospitalized patients with heart failure (HF) and may predict adverse outcomes. The relationship between nutritional status and outcomes in HF has been only partially studied.

Purpose: Our objective was to measure the relationship between assessment of nutritional status (CONUT method) and long-term prognosis (hospital admission for HF or mortality) in patients hospitalized for acute HF.

Methods: We analyze 145 patients (mean age 69.6 years, 61% men) admitted to a cardiology service for acute HF, 54 with previous HF hospitalization (37%), 112 with hypertension (HTA) (77%); 67 diabetic (DM) (46%); 135 class III or IV NYHA (93%), and 39 ischemic etiology (26.9%), with mean left ventricular ejection fraction (LVEF) 42.7%. Nutritional status was measured with the CONUT method, a validated measure of nutritional status based on laboratory test (albumin; cholesterol; lymphocytes) analysed during hospitalization. Patients were classified as normal, mild, moderate or severely malnourished, and followed prospectively in a HF clinic.

Results: Forty eight patients (33%) have normal nutritional status; 75 mild malnourished (52%); and 22 moderate malnourished (15%). There were no severely malnourished patients. Age, sex, history of HTA or DM, NYHA class, LVEF or ischemic etiology among the 3 groups there were no statistically different. Previous hospitalization for heart failure was more frequent in moderate malnourished patients (55%), than in mild malnourished (45%) and well nourished (17%) patients ($p < 0.01$). After a mean follow-up of 327 days, 19 patients died (13%) and 27 had a HF hospitalization (19%). In well nourished group 9 patients (19%), in mild malnourished group 18 patients (24%) and in moderate malnourished group 11 patients (50%) presented an event (death or HF hospitalization). The analysis by Kaplan-Meier curves and log rank test shows that these differences are statistically significant.

Conclusion: Malnutrition is common in patients hospitalized for HF and determines a poor prognosis especially in its more advanced forms.

Effect of liraglutide on myocardial glucose uptake and blood flow in non-diabetic heart failure patients

The present study was funded by an unrestricted grant from Novo Nordisk A/S
R Roni Nielsen¹; A Jorsal¹; P Iversen²; L Tolbod²; K Bouchelouche²;
J Sorensen²; A Flyvbjerg³; HJ Harms²; HE Botker¹; H Wiggers¹

¹Aarhus University Hospital, Skejby, Department of Cardiology, Aarhus, Denmark;
²Aarhus University Hospital, Department of Nuclear Medicine & PET center, Aarhus, Denmark; ³Aarhus University, Clinical Medicine, Aarhus, Denmark

Introduction: Liraglutide is a glucagon-like peptide-1 (GLP-1) receptor agonist that is used for treatment of type 2 diabetes (T2D) and obesity. Liraglutide may protect the heart against ischemia-reperfusion injury. The effect in chronic heart failure (HF) patients is undetermined. However, animal studies have shown improvement in mitochondrial and vascular function, and an increase in myocardial glucose uptake (MGU) during GLP-1 infusion that may be beneficial in HF. The present study is a sub-study of the LIVE study investigating the effect of liraglutide on left ventricular systolic function in patients with chronic HF.

Purpose: We investigated the effect of liraglutide treatment on MGU and myocardial blood flow (MBF) in non-diabetic patients with HF and reduced ejection fraction (LVEF < 45%) (HFrEF).

Methods: 36 patients with HFrEF (LVEF $33 \pm 8\%$) and no known T2D were enrolled and randomized 1:1 in a double blinded design to receive either 1.8 mg liraglutide or placebo once daily for 24 weeks. Global MBF during rest, myocardial flow reserve (MFR) and MGU were quantified by H₂O-PET and FDG-PET at baseline and follow-up. MGU was measured during an oral glucose tolerance test (OGTT) to reflect daily oral intake in a standardized setup.

Results: Two patients in each group dropped out, and 32 patients completed the study. Compared with placebo, liraglutide treatment reduced HbA1c levels (mean difference between groups: -3 ± 1 mmol/mol, $p = 0.03$) and the 2-hour peak glucose level during OGTT (mean difference between groups: -2.1 ± 0.7 mmol/l, $p = 0.006$). MGU was similar at baseline in the groups (liraglutide: 0.26 ± 0.08 mmol/g/min; placebo: 0.26 ± 0.10 mmol/g/min), and the change between baseline and follow-up did not differ between groups (mean difference between groups: 0.01 ± 0.04 mmol/g/min, $p = 0.69$). MBF (liraglutide: 0.75 ± 0.18 ml/min/g; placebo: 0.78 ± 0.16 ml/min/g, $p = 0.51$) and MFR (liraglutide: 2.70 ± 1.12 ; placebo: 2.48 ± 1.04 , $p = 0.55$) were similar at baseline, and the change during the study did not differ between the groups (MBF mean difference between groups: 0.03 ± 0.06 ml/g/min, $p = 0.60$; MFR mean difference between groups: -0.21 ± 0.29 , $p = 0.48$).

Conclusion: Despite an improvement in HbA1c levels and lowering of glucose levels during an OGTT, the GLP-1 analogue liraglutide does not affect global MGU, MBF or MFR in non-diabetic HF patients. Whether the effect of liraglutide is different in patients with diabetes and HFrEF needs to be investigated.

²Institute of Cardiology, Niska Banja, Serbia; ³Clinical Center, Nis, Serbia

Background/Introduction: Coronary patients with diabetes are at high risk of cardiovascular events. Echocardiographic parameters of left ventricle function and heart rate variability (HRV) are used to identify coronary patients at risk for cardiovascular event or death.

Purpose: The aim of this study was to assess the significance of diabetes mellitus on left ventricular function and heart rate variability in patients with stable angina.

Methods: The study included 135 patients with stable angina, who were in the sinus rhythm without AV blocks or branch blocks (average age 57.4 years) and 35 subjects without cardiovascular disease (average age 51.1 years), that were in the control group. Patients with stable angina were divided into two subgroups: 49 patients were with diabetes mellitus, and 86 were without diabetes. There was no significant difference in age or sex between two subgroups of patients. In all subjects echocardiographic examination and 24-hour ECG recording were performed. From the holter record, the analysis of the heart rate variability was performed by software. Four parameters of the time domain heart rate variability were assessed: SDNN, SDANN, RMS-SD and NN>50ms.

Results: The study has shown that patients with stable angina had significantly lower values of left ventricular ejection fraction (LVEF: 60.2 ± 9.4 vs $70.5 \pm 4.8\%$, $p < 0.001$), and significantly higher values of left ventricular end-systolic diameter (LVESd: 35.2 ± 6.2 vs 30.4 ± 3.5 mm, $p < 0.001$) and left ventricular end-diastolic diameter (LVEDd: 53.4 ± 6.2 vs 50.9 ± 4.2 mm, $p < 0.01$), as well as higher degree of left ventricle diastolic dysfunction, in comparison to the control group ($p < 0.05$ for ratio E/A and $p < 0.02$ for Dt). Patients with stable angina and diabetes had significantly lower values of LVEF (55.1 ± 8.3 vs $63.4 \pm 10.2\%$, $p < 0.001$), and significantly higher values of LVESd (37.8 ± 5.3 vs 33.4 ± 6.0 mm, $p < 0.001$) and LVEDd (55.4 ± 5.3 vs 52.3 ± 5.8 mm, $p < 0.005$), as well as higher degree of left ventricle diastolic dysfunction, in comparison to those without diabetes ($p < 0.01$ for ratio E/A and $p < 0.001$ for Dt). Patients with diabetes also had significantly lower values of followed parameters of HRV (94.5 ± 21.7 vs 118.9 ± 24.9 ms, $p < 0.001$ for SDNN; 85.8 ± 17.3 vs 103.4 ± 20.6 ms, $p < 0.001$ for SDANN; 28.1 ± 9.3 vs 36.5 ± 11.5 ms, $p < 0.001$ for RMS-SD and 5.9 ± 4.7 vs 11.8 ± 9.3 , $p < 0.001$ for NN>50ms) in comparison to those without diabetes.

Conclusions: The study demonstrated that patients with stable angina and without diabetes have better left ventricle systolic and diastolic function and significantly higher values of HRV parameters in comparison to those with diabetes.

Diabetes and treatment as predetermining factors of heart failure in patients with STEMI

A Arkel Duka¹; E Zaimi¹; A Kristo¹; L Kresto¹; I Sharka¹; J Seiti¹; E Tane¹; M Xhafaj¹; E Petrela¹; I Balla¹

¹University Hospital Center Mother Theresa, Cardiology, Tirana, Albania

Background and purpose: Heart Failure (HF) is a major complication in patients with ST-Elevation Myocardial Infarction (STEMI). In outpatients, Diabetes Mellitus (DM) is an independent risk factor, increasing the risk twofold to fivefold for HF development compared to non diabetic patients. In acute coronary syndromes, diabetic patients are more prone to develop HF. Revascularization therapies have changed tremendously the mortality and morbidity in patients with STEMI. Our purpose is to determine the impact of DM and treatment on in-hospital development of HF in patients with STEMI.

Methods: In this study were included 629 patients, admitted in our hospital with STEMI within the first six hours, in the period between September 2012 and November 2015. They were treated with conservative therapy, thrombolysis or with primary percutaneous coronary intervention (PPCI). For all the enrolled patients, data about DM, smoking habit, age, gender, race, hypertension and the type of Myocardial Infarction (MI) were registered, and they were observed during hospitalization regarding HF development. Determination of HF was done with the Framingham criteria.

Results: In total 629 patients were followed up, out of which 194 patients (30.8%) had DM. HF was present in 191 patients (30.3%), 87(45.5%) of which were diabetics. They developed HF 2.6 fold compared to those without diabetes (OD:2.59, CI95%, 1.61-3.39). There was a statistically significant correlation between age and HF (72.04±/-10.93 years old vs. 63.21±/-11.99 years old, $P < 0.001$); also between gender and HF (47.23% females vs. 24.46% males, $P < 0.001$). The patients treated with conservative therapy were 6.8 fold risked to develop HF compared to patients treated with PPCI (OD:6.78, CI95%, 2.78-16.03); while patients treated with thrombolysis were 2.9 fold risked to develop HF compared to those treated with PPCI (OD: 2.89, CI%, 1.83-4.55).

Conclusion: Diabetes Mellitus and conservative treatment are important predetermining factors of in-hospital development of HF in patients with STEMI. Also gender and age were found to be statistically significant risk factors for the occurrence of HF.

Impact of fibrosis extent on left ventricular deformation: application of 3D wall motion tracking technology in hypertrophic cardiomyopathy

A Adriana Pereira¹; N Moreno¹; L Marques¹; R Pontes Dos Santos¹; H Guedes¹; D Seabra¹; J Azevedo¹; P Pinto¹

¹Hospital Centre do Tamega e Sousa, Penafiel, Portugal

Background: Hypertrophic cardiomyopathy is characterized by myocardial hypertrophy, disarray of the muscle fibers and fibrosis. Fibrosis is associated with loss of ventricular function and worse prognosis. The decrease myocardial deformation parameters, namely global longitudinal strain, has been related to the presence and extent of myocardial fibrosis.

Aim: To evaluate the impact of the extent of left ventricular fibrosis (number of segments with fibrosis) in the myocardial deformation parameters in patients with HCM.

Methods: Single-center, retrospective, study including patients with HCM who underwent three-dimensional echocardiography (3D Echo) with 3D Speckle tracking technology and cardiac Magnetic Resonance (MRI). Obtained global myocardial strain values for each component: global longitudinal strain, global circumferential strain, global radial strain and area tracking. Myocardial fibrosis extension was defined according to the number of segments with late enhancement in cardiac MRI. For statistical comparison between groups, patients were divided into 3 groups: no fibrosis (0 segments); mild extensive fibrosis ≤ 2 segments, moderate or very extensive fibrosis ≥ 3 segments affected). Statistical analysis: Spearman correlation coefficient and comparison of means between groups with non-parametric tests; defined statistical significance at $p < 0.05$.

Results: 19 patients were included, mean age 62.4 ± 10.4 years; 52.6% were male. The mean LVEF assessed by 3DEcho was $59.1 \pm 7.3\%$; the mean left ventricular mass was $103.5 \text{ g} / \text{m}^2$ (MRI). From the total patients, 16 had late enhancement cardiac MRI, mean of 3.3 ± 2.8 segments affected by fibrosis. More frequently affected segments were the septal basal segments. There was no statistically significant correlation between the number of segments affected by delayed enhancement and

LVEF ($p = 0.6$) or ventricular mass ($p = 0.56$); and global longitudinal strain values ($r = 0.03$, $p = 0.9$), global circumferential strain ($r = 0.4$; $p = 0.008$), global radial strain ($r = 0.14$, $p = 0.54$) and area tracking ($r = 0.02$; $p = 0.8$). When analyzed groups (no fibrosis vs mild extensive fibrosis vs extensive fibrosis) also statistically significant differences were not found.

Conclusion: In this group of patients with HCM, there was no correlation between the number of segments with evidence of fibrosis and ventricular function and deformation parameters, which may be related to the small sample size. Additional studies are needed, particularly with quantitative evaluation of mass/% of myocardial fibrosis that may have a better correlation with the parameters of ventricular function and overall strain.

P1652

Correlation between wall motion score and global longitudinal strain.

B F Bruno Filipe Lourenco Marmelo¹; J Gil¹; A Delgado¹; L Abreu¹; H Antunes¹; L Goncalves¹; D Moreira¹; PC Ferreira¹; J Cabral¹; J Olivera Santos¹

¹Hospital Sao Teotónio, Viseu, Portugal

Background: Global longitudinal strain (GLS) allows evaluation of the longitudinal function of the left ventricle (LE) and to distinguish the global and regional deformation. On the other hand the wall motion score (WMS) is a visual subjective score of radial contractility. Together they present a more complete evaluation of global and regional function in ischemic patients.

Aim: This study aims to correlate GLS and WMS and to interpret their role in establishing the prognosis in this patients.

Methods: Reviewed echocardiograms performed since February 2013 to July 2014. The exams that allowed performing longitudinal strain with speckle tracking (ST-E) in 3 apical windows (4 chamber, 2 chamber and 3 chamber) were selected. The patients with 3 or more LV segments unable to be analysed by ST-E were excluded. From this selection resulted a sample of 138 patients. A minimum follow up of 365 was performed. As endpoints were selected cardiovascular hospitalization (stroke, heart failure, acute coronary syndrome) and death. Statistical analysis in SPSS 20, using T student test, Spearman correlation and linear regression.

Results: In the sample ($n = 138$) 81.9% were males. The mean age was 64.36 ± 14.37 years, being that 21.0% were older than 80 years and 28.3% were younger than 55 years. The patient with STEMI were 54.7%, the patient with NSTEMI were 41.6% and the patients with unstable angina were 3.7%. The mean ejection fraction was 53.49%, the mean GLS was -13.88 and the mean WMS 1.296. A bivariate correlation was performed between GLS and WMS and showed a strong correlation (Pearson coefficient 0.668, $p < 0.001$; Rsquare 0.449, $p < 0.001$). Linear regression was performed successfully with statistic significance ($p < 0.001$). The GLS and WMS did not correlated with hospitalization or death at 3, 6 e 12 months. Total mortality was different in the follow up according to GLS (alive 14,138, death 11,520, $p = 0.048$), but not to WMS ($p = 0.108$).

Conclusions: This study was able to correlate successfully GLS and WMS, with a strong correlation. The GLS was better predicting death during the follow up of this study.

P1653

Assessment of left ventricular mass in hypertrophic cardiomyopathy by three-dimensional echocardiography

A Adriana Pereira¹; L Marques¹; N Moreno¹; R Pontes Dos Santos¹; H Guedes¹; D Seabra¹; J Azevedo¹; P Pinto¹

¹Hospital Centre do Tamega e Sousa, Penafiel, Portugal

Introduction: Left ventricular (LV) mass is an important prognostic indicator in hypertrophic cardiomyopathy (HCM). Although LV mass can be easily calculated using conventional echocardiography, it is based on geometric assumptions and has inherent limitations in asymmetric left ventricles. Three-dimensional echocardiographic techniques may provide a more accurate evaluation method in this context.

Purpose: Compare three-dimensional echocardiography technique (3DEcho) with two-dimensional echocardiography (2DEcho) in evaluation for left ventricular mass compared to cardiac magnetic resonance imaging (cardiac MRI) in patients with HCM.

Methods: Single-center study, including patients with HCM who underwent 2D, 3D echocardiography and cardiac MRI. For mass calculation the following formulas were used: 2DEcho mass = $0.8 [1.4 (PWV + LVId + SWT) 3 - LVId3] + 0.6$; 3D Echo: mass = $1.5 * \text{Volume myocardial diastolic} \{(\text{myocardial diastolic volume within the epicardial contour}) - (\text{diastolic ventricular volume})\}$. We compared the results of left ventricular mass calculated by Echo 2D and 3D, using as reference values obtained by cardiac MRI. The degree of agreement between methods was assessed using the Bland-Altman analysis.

Results: 20 patients were included in the analysis of left ventricular mass by 2DEcho and MRI; 1 patient excluded from the three-dimensional analysis by poor acoustic window. The mean age was 61.15 ± 11.2 years; 55% were male. The mean left ventricular mass (global and indexed to body surface area) were

lower when measured by MRI (191.7 g , $103.5 \pm 38.3 \text{ g / m}^2$), and the values obtained by 3DEcho (236.6 g , $129.4 \pm 37.0 \text{ g / m}^2$) were most approximate to MRI compared to those obtained by 2DEcho (317 g , $172.1 \pm 42.8 \text{ g / m}^2$). There was no significant difference in mean ventricular mass obtained by MRI and 3DEcho ($p=0.068$). Figure 1 corresponds to the Bland-Altman analysis of agreement between the 2DEcho-MRI and 3DEcho-MRI in assessment of left ventricular mass.

Conclusion: Assessment of left ventricular mass by 3D echocardiography is a practical method and results closer to those obtained by cardiac MRI than 2DEcho in patients with HCM, and thus can provide a more accurate assessment of ventricular mass, especially in cases asymmetric ventricular hypertrophy. The 2D echocardiography tends to overestimate the ventricular mass in these patients.

Echocardiography in dyssynchrony assesment and factors related to its severity

D Dmitry Duplyakov¹; Z Vozhdaeva²; E Sysuenkova²; E Suslina¹; I Fillipova¹
¹Samara Regional Cardiology Dispensary, Samara, Russian Federation; ²VAZ Medical Center, Togliatti, Russian Federation

The role of mechanical dyssynchrony (MD) in the selection of patients suitable for CRT is not well-established and still a matter of debates in current guidelines.

Aim: To compare the value of 2D- and 3D-echo in the diagnosis of intraventricular dyssynchrony (IVD) and to identify factors related to its severity.

Methods: 164 patients (110 men, 54.8 ± 10.1 yrs) with left bundle branch block (LBBB) on the ECG were enrolled into the study. 52 of them (31,7%) had dilated, and 19 (11,6%) ischemic cardiomyopathy; 43 patients (26,2%) had a history of previous myocardial infarction and/or myocardial revascularization; 43 (26,2%) had hypertension as a primary diagnosis, and the remaining 7 (4,2%) had no clinical manifestations of any CVD (idiopathic LBBB). 53 patients had $EF < 30\%$; 70 patients had $EF 31-49\%$; 41 patient had $EF \geq 50\%$. IVD was examined by 2D-, and 3D-echo. The presence of IVD on 2D-echo was demonstrated by the the septal to posterior wall motion delay (SPWMD), obtained from M-mode in the parasternal long axis (SPWMD > 130 ms). 3D-echo: time to minimum systolic volume (Tmsv) and its dispersion (Diff.) for each segment of LV were analyzed. Parameters of IVD were calculated for 5 positions. $Tmsv > 12\%$ was considered as a criterion of IVD.

Results: 2D-echo allowed detecting IVD accurately in only 40% of patients with LBBB, mainly due to the presence of severe wall motion abnormalities (a-, hypo-, dyskinesia), and inability to obtained an adequate echo image. 3D-echo revealed IVD in 87% of the total cohort of patients with LBBB. The incidence of IVD in patients with $EF < 30\%$ was 95.4%, but only 14.8% in patients with $EF > 50\%$. Multiple linear regression analysis was used to identify factors associated with the severity of IVD. Twenty six parameters were analyzed altogether. The severity of TMSV Sel-SD (the maximum value of dyssynchrony between randomly selected segments) was related to the distance of 6-minute walk test ($p=0.006$), and the points score of the the Minnesota questionnaire ($p=0.05$). LVEF was the only predictor of TMSV 16-SD severity (all segments except the apex of LV, $p=0.006$), TMSV 6-SD (dyssynchrony between the basal segments of LV, $p=0.001$), and it showed a tendency for TMSV Sel-SD as well ($p=0.055$).

Conclusions: 3D-echo reveals IVD in 87% of patients with LBBB, with the incidence of 95.4% in patients having $EF < 30\%$. EF value, and signs of CHF determined the severity of IVD.

Utility of myocardial deformation analysis in the heart failure

M Miguel Martinez-Marin¹; C Josa-Laorden¹; J Rubio-Gracia¹; I Lacambra-Blasco¹; M Sanchez-Marteles¹; V Garces-Horna¹; I Torres-Courchoud¹; I Gimenez-Lopez²; JI Perez-Calvo¹; F Roncales G-Blanco¹
¹Clinical University Hospital Lozano Blesa, Zaragoza, Spain; ²Aragones Institute of Health Sciences, Zaragoza, Spain

Introduction: Heart failure (HF) has become one of the most important health problems worldwide. Around 50% of patients with chronic HF have preserved ejection fraction (HFpEF). Current diagnostic criteria lack of accuracy, thus HFpEF is probably overdiagnosed. The aim of this study is to assess the diagnostic and prognostic role of the myocardial deformation analysis (MDA) measured by echocardiography in a group of patients with HFpEF vs. reduced EF (HFrEF).

Material and methods: A cross-sectional and prospective study was performed to evaluate the differential aspects of HFpEF vs. HFrEF with regard to MDA. We included 81 consecutive patients admitted for an acute decompensation of HF. Patients with intraventricular conduction disorders, valvular prostheses or pacemakers were excluded. Patients were followed-up for 180 days.

Results MDA showed statistically significant differences in all its parameter when comparing both populations. The longitudinal deformation of the left ventricle (LV) was higher among HFpEF as compared to HFrEF (-12.79% vs -9.18% ; $p < 0.05$). Strain rate was also higher in HFpEF in its 3 dimensions: longitudinal (-1.46 vs -1.26 ; $p < 0.05$), radial (21.9 vs 17.3 / s, $p < 0.05$) and circumferential (-15.3 vs -10.4 / s, $p < 0.05$). The ability of MDA to discriminate between HFpEF and HFrEF was optimal (ROC curve: 0.808). Strain rate circumferential systolic was a good predictor of cardiac event as well (OR 2.20 (95% CI 1.16 to 4.20; $p=0.02$). It was associated with an increase to suffer from an adverse event during follow-up (ER visits, readmission or death).

Discussion: MDA, measured by 2D-echocardiography, is an emerging technique, with a potential new role in HF diagnosis and prognosis assessment. MDA has an optimal power to discriminate between HFpEF and HFrEF. Hence it may be a new useful tool in the diagnosis of HFpEF, especially in patients with borderline decrease of EF. In our experience MDA has proven to be, as well, good predictor of cardiac events in HF irrespective EF. This is especially important in HFpEF due to the lack of good echocardiographic prognostic markers among such patients.

Conclusions: MDA may help to improve the accuracy of HFpEF diagnosis. In addition functional abnormalities found in main parameters of MDA help identifying a group of patients with higher risk of complications during follow-up. We, thus, suggest including MDA as a routine test in every patient with HF irrespective of EF.

Assessment of right ventricular systolic and diastolic parameters in pulmonary sarcoidosis

E Emrah Ipek¹; S Demirelli¹; E Ermis¹; E Yildirim¹; M Ozturk¹; M Yolcu²; O Araz²; K Kalkan¹

¹Regional Training and Research Hospital, Cardiology, Erzurum, Turkey; ²Arel University Medica Hospital, Cardiology, Istanbul, Turkey; ³Ataturk University, Pulmonology, Erzurum, Turkey

Background: The clinical manifestations of cardiac involvement are seen in about 5% of sarcoidosis patients however the incidence of cardiac involvement is higher in autopsy series. About 14% of patients with pulmonary sarcoidosis (PS) without known cardiac involvement had diastolic dysfunction.

Purpose: Herein we aimed to determine the role of parameters of RV systolic and diastolic function in PS patients without evidence of cardiac symptoms.

Methods: Our study population consisted of 28 patients with grades 1 to 4 PS and 24 healthy subjects. This study was a clinical prospective cohort study.

Results: RVEDA was found to be significantly higher in PS group ($p=0.032$). RVFAC and TAPSE were statistically lower in PS group as compared to the control group ($p < 0.001$). However, PASP was significantly higher in PS group ($p=0.003$). The tricuspid E velocity and E/A ratio were detected to be significantly lower in PS group ($p=0.025$ and 0.009 , respectively), while the tricuspid A velocity and MPI were found to be significantly lower in the control group ($p=0.034$ and 0.007 , respectively).

Conclusions: Early detection of cardiac involvement in PS is crucial because of increased morbidity and risk of sudden cardiac death. RV diastolic Doppler parameters, tissue Doppler MPI, RVFAC and TAPSE are practical and cheap techniques in diagnosis of cardiac involvement in PS.

Interatrial septal tissue doppler time intervals in patients with heart failure

M Mikheil Tsverava¹; D Tsverava²

¹Tbilisi Medical Academy, Tbilisi, Georgia Republic of; ²Khechinashvili University hospital, Tbilisi, Georgia Republic of

The purpose of our research was to study the changes in interatrial septal (IAS) TDI parameters in patients with Heart Failure (HF).

Material and Methods: We studied 45 patients with II-IV NYHA functional class systolic HF (I gr) 90 normal persons (II gr) and 90 patients with Arterial Hypertension and Coronary Artery Disease but without HF (III gr). IAS TDI was registered from apical 4-chamber view. All patients were in sinus rhythm. We measured maximal systolic (s), early diastolic (e) and late diastolic (a) velocities.

Results: There was significant difference in IAS TDI velocity parameters between patients with and without HF. The s velocity was lower in persons with HF (I gr - 5.2 ± 1.8 cm/sec, II gr - 7.0 ± 1.7 cm/sec, III gr - 7.0 ± 1.8 cm/sec). The e (I gr - 4.6 ± 1.6 cm/sec, II gr - 8.7 ± 2.5 cm/sec, III gr - 6.4 ± 2.0 cm/sec) and a velocities (I gr - 6.4 ± 2.4 cm/sec, II gr - 7.4 ± 1.9 cm/sec, III gr - 8.2 ± 2.1 cm/sec) also were lower in persons with HF.

Conclusion: There are prominent changes in IAS TDI velocity parameters in patients with systolic left ventricular HF which were significantly lower in systolic HF group than in persons without HF.

Insights into cardiovascular alterations after pre-eclampsia: a 2D strain echocardiographic study

R Orabona¹; E Edoardo Sciatti²; E Vizzardi²; I Bonadei²; A Valcamonica¹; M Metra²; T Frusca³

¹University of Brescia, Maternal-Fetal Medicine Unit, Department of Obstetrics and Gynecology, Brescia, Italy; ²University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy; ³University of Parma, Department of Obstetrics and Gynecology, Parma, Italy

Background: Pre-eclampsia (PE) is characterized by a subsequent higher cardiovascular (CV) risk. Previous studies demonstrated the persistence of left ventricular (LV) dysfunction after this syndrome.

Purpose: We aimed at evaluating myocardial 2D strain and LV torsional mechanics after pregnancies complicated by early-onset (EO) or late-onset (LO) PE.

Methods: 30 pregnancies complicated by EOPE, 30 with a previous LOPE and 30 controls were retrospectively selected from our electronic database and evaluated by echocardiography 6 months to 4 years after delivery using speckle-tracking imaging. All the study cohort was free from any CV risk factor. Multivariate regression was run to test the association between gestational age (GA) at PE onset and 2D strain parameters.

Results: 2D strain and torsional parameters suggested a subclinical impairment in LV systole in the EOPE group which also showed a slight alteration in right ventricular (RV) function. Multivariate regression confirmed a positive correlation of GA at PE onset and echocardiographic alterations at long term.

Conclusions: Women with a history of EOPE and free from CV risk factors showed a persistent subclinical contractile impairment involving the whole heart, if compared to LOPE and healthy controls. This is responsible of their predisposition to CV diseases and Heart failure.

P1659

Myocardial work efficiency in heart transplanted patients

Health Research Fund of Central Denmark Region and the Danish Heart Association

T S Tor Skibsted Clemmensen¹; H Eiskjaer¹; BB Loegstrup¹; SH Poulsen¹

¹Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark

Aims: Myocardial work efficiency (MWE) is a well established measure of left ventricular function closely linked to the oxidative myocardial metabolism. MWE may be influenced by fibrosis and reduced perfusion. Hence, MWE assessment could provide new insight to the reduced physical capacity seen in heart transplanted (HTx) patients. We sort to evaluate the clinical significance of alterations in MWE during exercise in HTx patients.

Methods: Sixty-four HTx patients underwent comprehensive 2D and 3D echocardiographic assessment of graft function at rest and during symptom-limited, semi-supine exercise test. Cardiac allograft vasculopathy was assessed by 2D quantitative coronary angiography and coronary flow velocity reserve (CFVR) assessment by Doppler echocardiography. We calculated a rejection score based on previous acute cellular rejection episodes. Rate pressure product (RPP) was calculated as mean arterial blood pressure x stroke volume estimated from left ventricular (LV) outflow tract x heart rate. MWE was calculated as RPP / LV mass estimated from 4D full volume echocardiography. Furthermore, we calculated rate systolic pressure product (RSPP) as systolic blood pressure x stroke volume estimated from left ventricular (LV) outflow tract x heart rate.

Results: At rest MWE was 3.0 ± 0.9. We found no relation between MWE at rest and NYHA functional class (r = -0.15, p = 0.23), exercise capacity (r = 0.03, p = 0.80), CFVR (r = 0.09, p = 0.49), severity of CAV (r = -0.10, p = 0.45), or rejection score (r = -0.16, p = 0.20).

At peak exercise MWE was 7.3 ± 2.2. The change in MWE (ΔMWE) correlated significantly with NYHA functional class (r = -0.40, p < 0.01), exercise capacity (r = 0.43, p < 0.01), CFVR (r = 0.35, p < 0.05), and severity of CAV (r = -0.28, p = 0.05). No relation between rejection score and ΔMWE was seen (r = -0.21, p = 0.15).

We found slightly better correlations using MWE based on RSPP: NYHA functional class (r = -0.46, p = 0.001), exercise capacity (r = 0.54, p < 0.0001), CFVR (r = 0.37, p < 0.01), severity of CAV (r = -0.35, p < 0.05). No relation between rejection score and ΔMWE based on systolic blood pressure was seen (r = -0.18, p = 0.21).

Conclusions: MWE during exercise was moderately correlated with NYHA functional class, exercise capacity, and vasculopathy burden, whereas MWE at rest was not. Hence, exercise MWE may provide new insight to the reduced physical capacity seen in HTx patients.

P1660

Reproducibility and value of quantitative computed tomography to diagnose heart failure in patients with non-ST-elevation myocardial infarction

A Andreas Fabricius-Bjerre¹; TJ Kuhl²; P Kumarathurai¹; H Asraf³; KF Kofoed²; OW Nielsen¹

¹Bispebjerg University Hospital, Copenhagen, Denmark; ²Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark; ³Oslo and Akershus University College, Oslo, Norway

Background: Assessing pulmonary congestion from cardiac CT images in patients is poorly investigated. Animal models have showed Quantitative CT (QCT) is correlated to pulmonary congestion and we therefore hypothesized it also has potential to improve a diagnosis of heart failure in patients with non-ST-elevation myocardial infarction (NSTEMI).

Purpose: To test if QCT assessed from cardiac-CT images in patients with NSTEMI can differentiate between patients and without a clinical heart failure (HF).

Methods: Patients were identified from a previously examined cohort of 371 patients with NSTEMI who underwent 64-slice cardiac-CT. Two groups were defined: A HF group defined as Killip class > 1 within 5 days prior to CT, at least 1 significant stenosis on coronary angiogram, and LVEF < 45%. A control group was defined as Killip class 1, no stenosis on angiogram, and LVEF > 55%. Patients with inappropriate image quality, signs of emphysema or pneumonia were excluded.

Results: 25 patients (12 HF, 13 control) were identified from the previously examined cohort of 371 patients. 15 patients fulfilled the criteria for the HF group. 3 were excluded because of incomplete lung delineation, bullae and pneumonia. 30 patients fulfilled the criteria for the control group. 17 were excluded because of incomplete lung delineation ($n=12$), motion artifacts ($n=2$), bullae ($n=2$) and pneumonia ($n=1$). Mean lung density was significantly decreased in the HF group (-732 ± 31 vs -653 ± 48 , $p < 0.0001$). The ROC area under the curve was 0.93 (0.84-1.00). The Intra observer variability and inter observer variability (CV) among examiners was 0.8 % and 0.6 % respectively.

Conclusion: QCT is highly reproducible, objective and accurately discriminates NSTEMI patients with and without overt heart failure.

P1661

Cardiac magnetic resonance: diagnostic and therapeutic impact on suspected acute coronary syndrome with near normal coronary angiography

H Helena Nascimento¹; M Braga¹; SM Oliveira¹; R Rodrigues¹; M Vasconcelos¹; T Pinho¹; AJ Madureira¹; P Dias¹; MJ Maciel¹

¹ Sao Joao Hospital, Porto, Portugal

Background and purpose: A subset of patients with suspected acute coronary syndrome (ACS) undergoing coronary angiography have non-significant coronary stenosis. The clinical guidelines available are not well-defined regarding the diagnosis, therapeutic and outcome in this setting. The goal of this study was to investigate the diagnostic role of cardiac magnetic resonance (CMR) and its implications in defining therapy and prognosis.

Material and methods: This study was based on a retrospective analysis of 109 consecutive patients presenting to a tertiary centre with a clinical diagnosis of ACS and normal or near normal coronary arteries on angiography, in a 7-year period (2007-2014). All patients were referred to CMR, performed in a 3 T scanner. Clinical, radiological and therapeutic data was collected from the electronic clinical process and registered in a uniform base.

Results: Mean age at admission was 52.3 ± 16.9 years and 52.3% were females. At least one known cardiovascular risk factor was identified in 82.6% of the patients, hypertension being the most frequent (45.9%). At presentation, dynamic ST-T segment changes were registered in 37.0% of the cases and mean troponin I was 12.0 ± 36.2 ng/ml. Besides chest pain, fever or other infectious features were referred by 25 of the patients and an emotional stress event was identified in 21 cases. A completely normal coronary angiography was identified in 85.2%. The mean left-ventricular ejection fraction was 50.1% estimated by echocardiography and 56.1% calculated by CMR. CMR was diagnostic in 78.7% of the cases studied. Myocarditis was the most frequent diagnosis (38.9%), followed by stress cardiomyopathy (15.7%) and myocardial infarction with normal coronary arteries (14.8%). Delayed-enhancement and edema were present in 63.0% and 35.2% of the exams, respectively, and correlated significantly with the CMR diagnosis ($p < 0.05$). At discharge, all patients with CMR diagnosis of ACS were on antiplatelet therapy. On the other hand, this therapy was suspended in 47 patients because other diagnosis was established. The CMR diagnosis correlates significantly with antiplatelet suspension at release (67.7% vs 31.3%, $p = 0.008$). During a mean 3-year follow up time, 3 non-cardiac deaths and 6 hospital readmissions for cardiac reasons were registered.

Conclusions: Suspected ACS with non-significant coronary artery disease is a very heterogeneous entity. CMR may contribute to better establish etiologic diagnosis in this setting, helping in adjusting antiplatelet therapy. More studies are needed in order to define the best diagnostic and therapeutic approach.

P1662

Left ventricular diastolic function with cardiac magnetic resonance imaging in systemic sclerosis patients

L Agoston-Coldea¹; Z Marjanovic²; N Kachenoura³; S Lupu⁴; D Farge-Bancel²; E Mousseaux³

¹ "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania, Cluj-Napoca, Romania; ²Department of Internal Medicine and Vascular Disease Unit, Saint-Louis Hospital, Paris, France; ³Department of Cardiovascular Imaging, Hôpital Européen Georges Pompidou, Paris, France; ⁴University of Medicine & Pharmacy, Targu Mures, Romania

Background: Cardiac impairment frequently occurs in systemic sclerosis (SSc) patients and is often clinically silent until the late stages of the disease. The early diagnosis of cardiac involvement by certified non-invasive methods such as cardiac magnetic resonance imaging (CMR) may favor prompt initiation of adequate treatment and consequently improve prognosis. Phase-contrast cardiovascular magnetic resonance (PC-CMR) studies performed on small groups of patients compared to healthy controls suggested the ability of PC-CMR to assess LV diastolic function in agreement with echocardiography.

Purpose: In the present study we sought to assess the ability of PC-CMR to detect sub-clinical left ventricular (LV) diastolic parameters in patients with SSc.

Methods: Thirty-five consecutive SSc patients (48 ± 13.6 years, 22 women) were enrolled in a prospective CMR-based study and compared against thirty-five healthy volunteers with similar demographic characteristics. All subjects underwent standard echocardiographic and CMR examinations to assess LV and RV systolic and diastolic function. Transmitral flows and LV myocardial PC-CMR images were analyzed by an operator blinded to clinical data using Argus Flow. PC-CMR was used to estimate: 1) early trans-mitral and trans-tricuspid (E) and atrial (A) peak filling flow-rates (ml/s) and filling volume (FV), 2) deceleration time (DT), isovolumic relaxation time (IVRT), and 3) early myocardial longitudinal (E') peak velocity.

Results: PC-CMR diastolic parameters were reproducible, as reflected by low coefficients of variation, and were found to be independently associated to LV remodelling, assessed by LV mass to end-diastolic volume ratio and to myocardial wall thickness ($p < 0.01$). Although the LV systolic function was preserved, LV diastolic function parameters were impaired. Reasonable correlations were found between CMR and echocardiography-derived parameters of diastolic dysfunction. Mitral flow velocities (E wave: $r = 0.38$, $p = 0.001$; A wave: $r = 0.32$, $p = 0.006$) and particularly the E/A ratio ($r = 0.61$, $p < 0.0001$) measured by CMR correlated well with the corresponding echocardiography measurements, as did the mean value of lateral mitral annular myocardial velocities (E' wave: $r = 0.59$, $p < 0.001$).

Conclusions: SSc patients without cardiovascular symptoms rarely exhibit LV systolic dysfunction, whereas LV diastolic function impairment occurs frequently. Such parameters, which were shown to be reproducible and consistent, might be useful for a fast and reliable characterization of diastolic function in patients referred for CMR. Early identification of such changes in the asymptomatic stages of the disease by CMR may improve the overall prognosis of SSc patients.

BIOMARKERS

P1663

Biomarkers and drugs prescription before discharge in patients hospitalized with acute heart failure

ER Perna¹; ML Coronel¹; JP Cimbaro Canella¹; SM Macin¹

¹ J.F. Cabral Cardiology Institute, Heart Failure Division, Pulmonary Hypertension Unit, Corrientes, Argentina

Purpose: To evaluate the association between the number of prescribed drugs at discharge with levels of biomarker's panel of myocardial stress and injury, renal dysfunction and fluid overload, at admission and discharge in patients (pt) hospitalized with acute heart failure (AHF).

Methods: Between 01-Feb and 30-Jun 2014, 144 pt hospitalized with AHF were prospectively included. At admission and discharge, serum levels of creatinine, NT-pro brain natriuretic peptide (NT proBNP), high sensitive troponin T (hsTnT), carbohydrate antigen 125 (CA125) and urine levels of neutrophil gelatinase-associated lipocalin (NGAL) were determined. According with the number of drugs with proved benefit in morbidity and mortality in heart failure (betablockers [BB]; angiotensin converting enzyme inhibitors or angiotensin receptor blocker [ACE/ARB] and mineralocorticoid receptor antagonist [MRA]) prescribed before discharge, patients were classified in group 1 (G1: 0-1 drugs); 2 (G2: 2 drugs) or group 3 (G3: 3 drugs) results.

Results: Mean age was 68 ± 13 years, 35% were women and 35% has ischemic aetiology, with mean ejection fraction of $45\% \pm 38$. At discharge, 39 (27.1%) were classified as G1, 53 (36.8%) as G2 and 52 (36.1%) as G3. One-year free rehospitalization for AHF survival was for G1, G2 and G3, 36; 60 and 69%, respectively ($p = 0.003$). The comparison is shown in table 1.

Conclusion: The number of evidence-based drugs used at discharge after AHF hospitalization was associated with the long-term outcome. Patients who receive 0-1 drug at discharge have a worse biomarkers profile at admission, which deteriorated during hospitalization, and it was related with poor prognosis

Biomarker	Measurement	G1 (mean \pm SD)	G2 (mean \pm SD)	G3 (mean \pm SD)	p
Creatinine (mg/dl)	Admission	2.12 \pm 1.26	1.25 \pm 0.68	1.17 \pm 0.4	< 0.001
Nt proBNP (pg/ml)	Admission	19822 \pm 16020	10200 \pm 13300	12545 \pm 13232	0.006
	Discharge	18854 \pm 15872	6846 \pm 10303	7880 \pm 11028	< 0.001
Hs-TnT (ng/l)	Admission	70.4 \pm 68	45 \pm 51	41 \pm 62	0.051

Soluble ST2 in heart failure patients using a point-of-care-testing system

M Michel Noutsias¹; P Aftanski²; L Seres-Sturm²; T Bekfani²; PC Schulze²; JG Westphal²

¹Charité - University Medicine, Campus Benjamin Franklin, Berlin, Germany;

²University Hospital Jena, Department of Cardiology, KIM I, Jena, Germany

Introduction: Soluble ST2 (sST2; suppressor of tumorigenicity 2) is a member of the IL-1 receptor family. ST interferes with the signal cascade of IL-33/ST2, which inhibits the cardioprotective effects of IL-33. ST2 is therefore classified as a novel biomarker for heart failure patients, which might provide additive information as compared to natriuretic peptides.

Purpose: Investigation of ST2 levels in various clinical settings of heart failure patients with diverse clinical presentations and brain natriuretic peptide (BNP) levels.

Methods: sST2 measurements were performed using a point-of-care-testing (POCT) analysis system (Aspect Reader; bestbion dx) in serial heart failure patients in addition to clinical routine workup. The sST2 values were obtained employing 35 µl EDTA plasma in Aspect-Plus POCT cassettes within a processing time of 20 minutes per sample.

Results: sST2 values were measured in n=17 heart failure patients (age: 66±4.3 years; men: 76%) with known or newly diagnosed heart failure, and in n=10 control patients (age: 55±5.6 years, men: 80%; healthy volunteers: n=4; coronary artery disease patients without heart failure and LVEF > 50%: n=6). The range of sST2 values in all measurements was 12.5-250 ng/ml. The range of BNP-values was 29-16,601 pg/ml. Heart failure patients presented significantly higher sST2 values compared to controls (100.4±81.5 versus 35.5±21.0 ng/ml; p=0.021). Heart failure patients presenting with acute decompensated heart failure (ADHF) and NYHA functional class IV (n=4) had significantly (p<0.0001) higher sST2 values (224.9±50.1 ng/ml) compared to controls, and to patients with chronic heart failure NYHA I-III (62.1±38.3 ng/ml). There was no significant association between sST2 and BNP (p=0.21). In n=2 patients presenting with Takotsubo cardiomyopathy (TTCM), a substantial decrease of sST2 by 70% was observed within 8 days after the initial evaluation, accompanying the resolution of TTCM under heart failure medication.

Conclusions: These data confirm the practicability of sST2 measurements by POCT in serial heart failure patients, revealing a broad range of sST2 values, available within 20 minutes processing time. They indicate an additional value of ST2 for biomarker based evaluation of heart failure patients as compared to BNP values, with emphasis on ADHF and NYHA functional class IV. Preliminary serial data on TTCM patients indicate the dynamics of sST2 in the evolution of heart failure.

Cystatin C and global longitudinal strain in patients with chagas disease: just a marker of kidney function?

COLCIENCIAS and RED CHAGAS COLOMBIA. BIOCHAGAS project, code 501453730398, CT 380-2011.

LE Luis Eduardo Echeverria¹; LS Calvo-Betancourt¹; ZM Roa-Diaz¹; LZ Rojas-Sanchez¹; RL Campo-Torrenegra¹; AM Redondo-Gelvez¹; AM Torres-Bustamante¹; MC Villamizar¹

¹Foundation Cardiovascular of Colombia, Heart failure and cardiac transplant, Floridablanca, Colombia

Purpose: Cystatin C (CysC) is an inhibitor of the cysteine protease constantly produced by all nucleated cells and is freely filtered by the glomerulus, due to its low molecular weight (13kDa). In patients with Chronic Heart Failure (CHF) is an independent predictor of adverse events (death, myocardial infarction, stroke) even after adjusting for traditional risk factors and BNP. Global Longitudinal Strain (GLS) has proven to be a sensitive marker of myocardial dysfunction, allowing to discriminate between patients with cardiac events and those with a better prognosis. In the present study, the correlation between the levels of CysC and GLS in patients with chronic chagas disease was determined, which has not been previously reported in the literature.

Methods: Analytical cross-sectional study. Patients older than 18 years with chagas disease were included. Those patients with uncontrolled hypertension, diabetes, history of coronary artery disease and valvular disease were excluded. The GLS was established by speckle tracking electrocardiography and blood levels of CysC were determined, both measures were taken the same day. A descriptive analysis was performed, the correlation between the GLS and CysC was evaluated by scatter plot and Spearman's rank correlation coefficient. Finally, a multiple linear regression analysis adjusted by sex, age and GFR was performed.

Results

A total of 100 patients were analyzed, 55% (55/100) were men; the mean age was 61 years (SD±12 years); the median and interquartile range of LVEF was 42% (Q1=27; Q3=56), of CysC was 1.14 mg / L (Q1=0.91, Q3=1.37); of GLS was -12.6% (Q1=-17.8; Q3=-8.1); 40% (40/100) of the patients had a GFR < 60 mL / min / 1.73 m². A positive correlation between GLS and CysC values (rho=0.579, p=0.000) was established; on the other hand, CysC and LVEF presented a

negative correlation (rho=-0.639, p=0.000). Finally, an association between GLS and CysC (β=6.079, p=0.032) was established; as well as between LVEF and CysC (β=24.324; p=0.000), both models adjusted by sex, age and GFR.

Conclusions: In patients with Chagas cardiomyopathy, CysC showed a moderate positive correlation with the GLS, and a moderate negative correlation with LVEF, suggesting a potential utility as a marker of myocardial dysfunction in this setting. Remarkably, when evaluating the association of the CysC and the GLS on a linear regression model adjusted for age, sex and GFR it remained significant, suggesting that CysC is a marker of early myocardial dysfunction even in patients with preserved renal function.

P1666

Galectin-3 and ST-2: association with inflammation and renal dysfunction in patients with chronic heart failure

EA Elena Medvedeva¹; NV Shiljaeva¹; YV Shchukin¹

¹Samara State medical university, Samara, Russian Federation

Purpose: To evaluate the connection between plasma level of galectin-3, ST-2 and biomarkers for inflammation and renal dysfunction in patients with chronic heart failure (CHF).

Methods: 167 patients (age, 64.4±3.8 years) with documented prior myocardial infarction, were included in the study. Patients were divided into 3 basic groups according functional class (FC) CHF (NYHA). 1 group (n=56) - patients with II FC CHF, 2 - 67 patients with III FC, and 3 group (n=44) - IV FC. There was valued the level of galectin-3, ST-2 and cystatin-C by immunoassay analysis. The estimated glomerular filtration rate (e-GFR) was calculated using the Modification of Diet in Renal Disease (MDRD) equation. Biomarkers for inflammation included hs-CRP, interleukin-6 (IL-6). All statistical analysis was performed with Statistica 6.0. Continuous variables were described by median. Comparisons of continuous variables were performed using Mann-Whitney, U-test. Spearman's rank correlation coefficient was calculated to measure dependence between two variables.

Results: Galectin-3 values increased in parallel with the clinical severity of CHF (NYHA classification): II FC - 9.8 ng/ml, III FC - 18.6 ng/ml, the highest levels being reached in class IV patients 34.1 ng/ml. We observed significant difference between groups (p < 0.001). The level of hs-CRP in patients with CHF was 1.8; 3.3 and 6.5 mg/l. We also demonstrated a significant positive correlation between galectin-3 and hs-CRP in groups: r1=0.573, p=0.00085; r2=0.784, p=0.00001; r3=0.687, p=0.00007. We found a significant increase in the level of IL-6 in the 1st (7.8 pg/ml), 2nd (17.7 pg/ml) and 3d (38.9 pg/ml) groups. We observed a positive correlation between levels of galectin-3 and IL-6 in all groups of patients (r1=0.546, p=0.0001 and r2=0.746, p=0.00002; r3=0.615, p=0.00005). The levels of ST-2 in the 1st, 2 and 3 groups were 22.58, 26.27, 36.7 ng/l accordingly. The correlation analysis showed the following significant correlations: ST-2 correlated with NYHA FC (r=0.35; =0.009), with concentration of hs-CRP (r=0.33; =0.006) in the cohort of observed patients. We also found an increase in the level of cystatin-C: 1800, 2800, 4600 pg/ml accordingly with a significant difference between groups (p<0.05). Strong correlations were also observed between galectin-3-cystatin C (r1=0.61, r2=0.64, r3=0.72, p<0.01.) and galectin-3-GFR (r1=-0.49, r2=-0.57, r3=-0.72, p<0.01.).

Conclusion: The plasma levels of galectin-3, ST-2 in patients with CHF were closely connected with indicators of inflammation and renal dysfunction beyond NYHA functional class.

P1667

Salivary biomarkers related to cardiovascular parameters during physical effort challenge in menopausal women

LC Dima-Cozma¹; G Perrone²; CM Ghiciuc¹; M Bernardi²; L Fattorini²; MR Squeo²; P Gallopi²; F Ferrante²; V Pasquali²; FR Patacchioli²

¹Gr. T. Popa University of Medicine and Pharmacy, Iasi, Romania; ²Sapienza University of Rome, Rome, Italy

Background: Changes in autonomic nervous system and hypothalamus pituitary adrenal axis activity have been related to different challenges, like physical exercise or emotional stress. Salivary alpha-amylase and salivary cortisol are non-invasive, reliable biomarkers, potentially available for the evaluation of this 2 systems respectively. Our purpose was to examine whether variations of cardiovascular parameters during cardio-pulmonary effort test are related to salivary alpha-amylase and salivary cortisol response in menopausal women.

Methods: 30 postmenopausal women (15 hormone replacement therapy users and 15 never treated) were recruited and salivary biomarkers were measured in a rest day (at awake, 12:00, 17:00, 20:00) and in the day with the effort test (at the same hours and an additional sample 30 minutes after the effort test). During cardio-pulmonary effort test systolic and diastolic blood pressure and electrocardiogram were monitored. The effort session consisted by a 3 - min warm - up phase at 10 W, followed by a ramp effort phase increasing 10 W/minute. Heart rate was measured and reported at baseline, during the effort and at 1 and 2 min during recovery and

heart rate reserve was calculated as the difference between the heart rate at maximum effort and heart rate at rest. The total diurnal salivary alpha-amylase and cortisol production were calculated using the trapezoidal method. We used SigmaPlot 11 for statistical analysis, applying repeated measures ANOVAs and multiple linear regression analysis for salivary alpha – amylase and cortisol as independent and cardiovascular parameters as dependent variables.

Results: Postmenopausal women using hormone replacement therapy exhibited a cardiorespiratory functional capacity that was significantly ($p < 0.05$) higher than that of non-users. In the rest day, treated women had significantly decreased daily production of alpha amylase (487 ± 93 vs 575 ± 82 , $p < 0.05$) which increased significantly after effort (581 ± 64 vs 487 ± 93 , $p < 0.05$). Multiple linear regression analysis revealed significantly correlations between systolic blood pressure and daily production of salivary cortisol in the effort day ($r = -0.537$, $p = 0.025$), diastolic blood pressure baseline and salivary alpha-amylase daily production in the rest day ($r = 0.132$, $p = 0.015$), salivary cortisol and maximal heart rate ($r = 0.805$, $p = 0.03$).

Conclusions: The influences of physical stress on autonomic nervous system could be detected using the salivary biomarkers and the values are related to cardiovascular parameters in menopausal women.

Mid-regional pro-adrenomedullin as a prognostic indicator of 1-year mortality after acute heart failure. MOLITOR substudy.

D Dragana Stanojevic¹; S Apostolovic¹; R Jankovic-Tomasevic¹; S Salinger-Martino¹; S Dakic¹; S Obradovic²; E Tahirovic³; S Radenovic³; HD Dungen³

¹Clinic for Cardiovascular Diseases, Nis, Serbia; ²Military Medical Academy of Belgrade, Belgrade, Serbia; ³Charite - Campus Virchow-Klinikum, Department of Internal Medicine-Cardiology, Berlin, Germany

Background: Adrenomedullin (ADM) is a vasodilatory peptide hormone with potent hypotensive effects. It is expressed in many different tissues, including myocardium and endothelium. Its plasma levels are elevated in patients with chronic heart failure (HF) and increase with disease severity. Mid-regional pro-ADM (MR-proADM) is a stable and reliable surrogate marker for ADM release.

Aim. The aim of our study was to investigate the predictive role of MR-proADM on 1-year mortality in patients admitted to hospital due to acute HF and to compare it with N-terminal pro-brain natriuretic peptide (NT-proBNP) which is an established diagnostic/prognostic marker in this setting.

Methods. We included 168 patients, age 68.18 ± 9.9 years, 70.8% being males, 83.7% having HF with reduced ejection fraction (HFrEF). Patients were followed for 1 year after acute HF.

Results: Median MR-proADM levels at admission and after 1 year of follow up were: 1.12 ($0.88-1.53$) / 1.01 ($0.81-1.22$) nmol/L, $p = n.s.$ Median NT-proBNP concentrations at admission and after 1 year of follow up were: 2870 ($1240-7542$) / 969.6 ($428.5-2212$) pg/mL, $p < 0.001$. We found significant correlation between NT-proBNP at admission with left ventricle ejection fraction- LVEF ($33.57 \pm 12.49\%$) ($\rho = -0.370$, $p < 0.01$) and with MR-proADM ($\rho = 0.483$, $p < 0.01$). NT-proBNP measured after 1 year correlated with MR-proADM ($\rho = 0.521$, $p < 0.01$) but not with LVEF ($36.89 \pm 12.57\%$) measured at that time. 37 patients (22%) died during one year. Median MR-proADM and NT-proBNP values at admission in patients who died compared to survivors were: 2.09 ($1.35-3.4$) vs. 1.09 ($0.80-1.67$) nmol/L, $p < 0.001$ and 14493.5 ($3470-25223.0$) vs. 3350.5 ($1044.0-8414.0$) pg/mL, $p < 0.001$.

Conclusions: In our patients, MR-proADM concentration did not significantly change 1 year after acute HF. However, patients who died during 1 year had significantly higher concentrations of this marker at hospital admission. We found a significant correlation between MR-proADM with NT-proBNP in acute HF and in a stable phase of the disease. Unlike NT-proBNP, levels of MR-proADM did not correlate with LVEF. Although little is known about the role of ADM in HF, it seems that MR-proADM has similar predictive properties compared to NT-proBNP for 1 year all-cause mortality in acute HF.

The impact of biological variability on biomarker monitoring.

British Heart Foundation Pump Priming Grant (RE/08/003)

S Susan Piper¹; J Decourcey²; R Sherwood²; G Amin-Youssef²; TA McDonagh¹

¹King's College London, London, United Kingdom; ²King's College Hospital, London, United Kingdom

Background: NTproBNP is an established marker for diagnostic and prognostic use in heart failure patients. Evidence for serial monitoring to predict decompensation has, however, been mixed. This has, in part, been ascribed to its high biological variability, with weekly reference change values of 49% to 92%. We examined the biological variability of four novel biomarkers, sST2, galectin-3, apelin and mid-regional pro-adrenomedullin (MRproADM), and compared this with the ability of changes in serial concentrations to predict cardiovascular (CV) admission.

Purpose: To assess the relationship between biological variability and serial monitoring.

Methods: 50 patients with stable chronic heart failure due to LV systolic dysfunction and on optimum doses of prognostically indicated medications were studied. Mean age 67.3 years (SD 11.568), 82% male. Mean LVEF 30.7%. Patients were followed for a period of 6 months with clinical review and blood samples drawn at baseline and 6 months. Biological variability was assessed by the variables of intra-individual coefficient of variability (CVi) and reference change value (RCV). Receiver Operating Characteristic (ROC) analysis and area under curve (AUC) was used to assess the ability of percentage change and absolute change in biomarker concentrations to predict CV admission.

Results: Results for each biomarker at the 6-month end-point are shown in table 1. All novel biomarkers examined demonstrated lower biological variability than NTproBNP. Despite this, only galectin-3 showed significant ability to predict CV admission over the 6-month study period.

Conclusion: Our results suggest there is no relationship between biological variability and the monitoring ability of biomarkers. The value of using biological variability as a discriminator for using particular biomarkers for monitoring is unclear, and candidate markers should not be targeted on this basis alone.

Biological variability and ROC analyses

	Mean CV _i	RCV (%)	AUC % change	AUC Absolute change
NTproBNP	46.02	128	0.571 ($p = 0.553$)	0.579 ($p = 0.511$)
sST2	16.41	47	0.734 ($p = 0.052$)	0.734 ($p = 0.052$)
Galectin-3	18.13	51	0.803 ($p = 0.012$)	0.807 ($p = 0.011$)
Apelin	10.19	30	0.571 ($p = 0.553$)	0.417 ($p = 0.490$)
MRproADM	18.93	54	0.506 ($p = 0.962$)	0.546 ($p = 0.700$)

NTproBNP = N-terminal pro-natriuretic peptide, sST2 = soluble suppression of tumorigenicity 2, MRproADM = mid-regional pro-adrenomedullin, AUC = area under curve, RCV = reference change value, CV_i = inter individual coefficient of variability

Combining collagen type I-related biomarkers identifies a malignant phenotype of myocardial fibrosis in hypertensive heart failure

European Commission FP7 (FIBRO-TARGETS, HOMAGE and EU-MASCARA) and Ministry of Economy and Competitiveness (Spain; RD12/0042/0009 and PI15/01909)

A Gonzalez Miqueo¹; B Lopez¹; S Ravassa¹; R Querejeta²; K Echegaray²; J Diez¹

¹CIMA, University of Navarra, Program of Cardiovascular Diseases, Pamplona, Spain; ²Donostia University Hospital, Department of Cardiology, San Sebastian, Spain

Background: Myocardial fibrosis present in heart failure (HF) is the result of variable alterations in the quality (e.g. degree of collagen cross-linking; CCL) and quantity (i.e. collagen deposition; CD) of collagen, mainly collagen type I. Myocardial fibrosis contributes to the impairment of cardiac function and some studies suggest that it may have an impact on clinical outcome.

Purpose: To evaluate whether the combination of circulating biomarkers of myocardial CCL and CD identifies myocardial fibrosis phenotypes with distinct clinical outcomes in HF patients of hypertensive etiology. Since cross-linked collagen is more resistant to degradation a decrease in the ratio between the carboxy-terminal telopeptide of collagen type I (CITP) and matrix metalloproteinase-1 (MMP-1; CITP:MMP-1) has been shown to reflect increased collagen cross-linking. On the other hand, the carboxy-terminal propeptide of procollagen type I (PICP) has been proven to associate with the extent of myocardial CD.

Methods: Endomyocardial biopsies and blood samples from 38 patients (small cohort) and blood samples from 203 patients (large cohort) with clinical HF were analysed. Myocardial CCL and CD were assessed by histological methods. Serum PICP, CITP and MMP-1 were determined by ELISA.

Results: Compared with controls, patients from the small cohort exhibited increased ($P < 0.001$) CCL and CD. CCL was above the upper limit of normality of control subjects (CCL+) in 71% of the patients and was normal (CCL-) in the remaining 29%. All patients presented CD values above the upper limit of normality, therefore, the severity of CD was established according to its median value (6.87%) in HF patients: non severe fibrosis (CD-) for values below the median and severe fibrosis (CD+) for patients above it. Using ROC curves a CITP:MMP-1 cut-off ≤ 1.968 and a PICP cut-off ≥ 110.8 ng/mL were selected to identify CCL+ and CD+, respectively. Participants from the large cohort were categorized in 4 subgroups based on the presence or absence of high CCL and severe CD considering the biomarker levels defined by the above thresholds: 37 (18.2%) patients presented CCL-CD-, 52 (25.6%) presented CCL-CD+, 56 (27.6%) presented CCL+CD- and 58 (28.6%) presented CCL+CD+. Compared to CCL-CD-, the adjusted hazard ratios for a composite end-point of HF hospitalization or cardiovascular death over 4 years were 1.11 ($P = 0.79$) in CCL-CD+, 1.99 ($P = 0.07$) in CCL+CD- and 2.18 ($P < 0.05$) in CCL+CD+ (P for trend < 0.01). In addition, the categorization based in CCL plus CD yielded significant ($P < 0.05$) integrated discrimination and net reclassification improvements for the mentioned outcome.

Conclusion: The combination of serum C1P:MMP-1 ratio and PICP identifies patients with hypertensive HF and a malignant phenotype of myocardial fibrosis. The poor outcome associated with the concurrence of high CCL and severe fibrosis supports the necessity of a therapy targeting these alterations in this subgroup of patients.

Estimated plasma volume as a determinant of heart failure hospitalization: TREAT-HF data

I Sari¹; H Kaya²; G Acar³; Y Cavusoglu⁴; M Demir⁵; H Gungor⁶; D Oguz⁷; L Bekar⁸; AA Sahin¹; MB Yilmaz²

¹Marmara University, Faculty of Medicine, Department of Cardiology, Istanbul, Turkey; ²Cumhuriyet University, Cardiology, Sivas, Turkey; ³Kahramanmaraş Sutcu Imam University, Cardiology, Kahramanmaraş, Turkey; ⁴Eskişehir Osmangazi University, Cardiology, Eskişehir, Turkey; ⁵Türkiye Yüksek İhtisas Hospital, Cardiology, Ankara, Turkey; ⁶Adnan Menderes University, Cardiology, Aydın, Turkey; ⁷Baskent University, Cardiology, Ankara, Turkey; ⁸Hitit University, Cardiology, Corum, Turkey

Background: In heart failure patients, assessing presence and severity of congestion is of paramount importance but not always easy. In this regard a new method for non-invasive plasma volume measurement might be helpful. However, to our knowledge there is no data regarding the importance of estimated plasma volume (ePV) in the out-patient heart failure setting.

Purpose: The aim of this study was to assess the importance of ePV in predicting heart failure related hospitalization in an out-patient cohort of heart failure patients.

Methods: TREAT-HF (Turkish Research Team-Heart Failure) is a network of 16 heart failure centers in Turkey. Herein, we evaluated combined cohort of 2013-2014 and 610 patients who had data for calculating ePV were included into the study. Strauss formula was used to calculate ePV (ePV: $[1 - \text{hemotocrit}] / [\text{hemoglobin} \times 0.01]$).

Results: Mean age of the cohort was 60.7 ± 13.8 years (430 male, 180 female). In a median follow-up of 15 months, 439 of 610 patients were hospitalized for heart failure however 171 of them were not. Patients who were hospitalized for heart failure had higher ePV (5.29 ± 1.47 vs 4.57 ± 1.22 , $p < 0.001$), were older (62.8 ± 13 vs 58.7 ± 13.6 , $p < 0.001$), had higher systolic pulmonary artery pressure (43.8 ± 14.9 vs 39.8 ± 16.3 , $p < 0.015$), lower left ventricular ejection fraction (31 ± 8.4 vs 32.7 ± 7.7 , $p < 0.014$), higher creatinine level (1.44 ± 0.7 vs $1.13 \pm .5$, $p < 0.001$), lower hemoglobin level (12.2 ± 2.1 vs 13.4 ± 2 , $p < 0.001$), lower hemotocrit level (38 ± 5.9 vs 41 ± 5.9 , $p < 0.001$) and had more patients with NYHA class 3-4 (79% vs 65%, $p < 0.001$). In univariate analysis ePV, age, NYHA class 3-4, creatinine, systolic pulmonary artery pressure, ejection fraction and hemoglobin were predictors of heart failure related hospitalization. However in multivariate analysis only age, NYHA class 3-4 and ejection fraction were independent predictors of heart failure related hospitalization.

Conclusion(s): In the setting of out-patient heart failure cohort although ePV was helpful, it was not an independent predictors of heart failure related hospitalization. Prospective outcome studies evaluating the role of ePV in heart failure are warranted.

P1672

Galectin-3 serum levels are not associated with left ventricular remodeling in chronic heart failure outpatients

MS Lattarulo¹; M Leone¹; F Monitillo¹; C Rizzo¹; D Grande¹; P Terlizze¹; V Antoncicchi²; N Aspromonte³; M Iacoviello⁴

¹University of Bari, School of Cardiology, Bari, Italy; ²San Paolo Hospital, Cardiovascular Department, Bari, Italy; ³San Filippo Neri Hospital, Cardiology Unit, Rome, Italy; ⁴Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

Background and aim of the study: Galectin-3 (Gal-3) is an emerging biomarker which has been demonstrated to be related to inflammation status and fibrosis, two conditions that play a key role in ventricular remodeling in patients with chronic heart failure (CHF). The aim of this study was to evaluate the relationship among Gal-3 serum levels and left ventricular (LV) remodeling in a group of CHF outpatients.

Methods: We enrolled 152 outpatients (83% males, 64 ± 13 years, NYHA class 2.3 ± 0.6 , left ventricular ejection fraction, LVEF, $32 \pm 8\%$) with CHF (ESC criteria) due to left ventricular systolic dysfunction, in stable clinical conditions (> 1 month) and in conventional therapy. All patients underwent a clinical evaluation, a routine chemistry and an echocardiogram at baseline and at one year. Ventricular remodelling was determined assessing changes of left ventricular end diastolic volume (LVEDV), left ventricular end systolic volume (LVESV) and left ventricular ejection fraction (LVEF), calculated using Simpson's rule. Progression of ventricular remodelling was defined as an increase in LVESV $> 15\%$ at one year follow-up.

Results: At one year follow-up, 18 patients (12%) showed progression of ventricular remodelling. As shown in the table, patients with left ventricular remodeling showed, at baseline, a greater NYHA class, larger LVESV, lower LVEF and higher NT-proBNP serum levels. At one year LVESV further increased in patients with left ventricular remodelling and LVEF further decreased. No differences were found when baseline Gal-3 serum levels were considered.

Conclusions: Our findings demonstrate the Gal-3 serum levels are not associated with left ventricular remodeling in a population of patients with CHF and reduced ejection fraction. Further studies should assess the existence of other prominent mechanisms in determining Gal-3 prognostic role in these patients.

Variable	Pts without ventricular remodeling	Pts with ventricular remodeling	p
Baseline NYHA	2.2 ± 0.6	2.6 ± 0.5	0.034
Baseline LVESV	108 ± 46	142 ± 46	< 0.001
One year LVESV	102 ± 43	182 ± 54	< 0.001
Baseline LVEF	33 ± 8	26 ± 6	< 0.001
One year LVEF	35 ± 8	24 ± 7	< 0.001
Baseline NT-proBNP*	1703 ± 2823	2758 ± 3745	0.007
Baseline Gal-3	15.8 ± 7.1	15.3 ± 6.2	0.773

Clinical value of cystatin-c levels in elderly patients with chronic heart failure preserved ejection fraction independent of renal function

Y Mitsuke¹; C Kiriba¹; Y Suzuki¹; H Tsutani¹

¹NHO Awara Hospital, Fukui, Japan

Background: The association between renal dysfunction and increased mortality has been reported in patients with chronic heart failure. Cystatin C, a novel endogenous marker of glomerular filtration rate, has been reported as more sensitive to detect renal insufficiency than creatinine, but its usefulness in elderly patients with heart failure with preserved ejection fraction (HFpEF) is less well defined.

Methods: We studied consecutive 98 Japanese HFpEF patients older than 80 years of age (42 males, 84.1 ± 3.2 years, all serum creatinine levels were < 1.1 mg/dl, NYHA II-III, LVEF $> 50\%$). We measured circulating levels of cystatin C, C-reactive protein, natriuretic peptide (BNP), B-type natriuretic peptides (BNP), and cytokine (interleukin(IL)-1beta, IL-6, and tumor necrosis factor(TNF)-alpha). None had evidence of unstable angina, chronic inflammatory disease, collagen disease, or cancer at the time of evaluation. Patients were followed up for an average of 24.1 months, and 19 of 98 patients had cardiac and non-cardiac death.

Results: The mean (\pm SD) serum concentrations of cystatin C were 1.24 ± 0.22 ng/dl. Patients with events had significantly higher cystatin C, NAD, uric acid, BNP, and IL-6. By multivariate Cox proportional hazard analysis, cystatin C and IL-6 were significant predictors for death in those patients.

Conclusions: These findings indicate that cystatin C measurement provides additional prognostic information in those elderly patients with HFpEF independent of renal function

P1674

Pre-discharge high sensitivity cardiac troponin T predicts heart failure rehospitalisation and cardiac death in non-ischaemic acute heart failure: Marker of residual congestion?

T Teerapat Yingchoncharoen¹; N Suvachittanon¹; M Chandavimol¹; P Vathesatogkit¹; S Yamwong¹; P Sritara¹

¹Faculty of Medicine Ramathibodi Hospital-Department of Medicine of Mahidol University, Bangkok, Thailand

Background: High sensitivity cardiac troponin T (hs-cTnT) in patients with acute heart failure without clinically apparent myocardial ischemia is related to myocardial injury and maybe useful for prognostication. We sought to examine the value of hs-cTnT at the time of discharge in predicting 30-day rehospitalisation and cardiac death.

Methods: Fifty-one hospitalised patients with non-ischemic acute heart failure (49% men; mean age 70 ± 14 years) from October 2014 to December 2015 were studied. Hs-cTnT was measured and echocardiography was performed at the time of discharge. Patients were followed over a median time of 4.5 months (interquartile range, 0.6, 10.5 months) for heart failure rehospitalisation and cardiac mortality. A multivariate Cox regression analysis was performed to identify associations with events.

Results: Heart failure rehospitalisation was found in 10 patients (20 %), and 3 patients (6%) had cardiac death. HF rehospitalisation and cardiac death was associated with pre-discharge hs-cTnT (hazard ratio 1.002; 95% CI 1.001-1.003) independent of YALE CORE HF readmission score (calculated from 20 parameters of history, physical examination, laboratory and echo results). There was modest association between pre-discharge hs-cTnT and medial E/e' ($R = 0.32$, $p = 0.025$).

Predischarge hs-cTnT of >100 ng/L identified the subgroup of highest risk for 30-day rehospitalisation and cardiac death.

Conclusion: Predischarge hs-cTnT, marker associated with LV filling pressure, is an independent predictor of heart failure rehospitalisation and cardiac death in patients with non-ischemic acute heart failure.

KM Curve as stratified by hs-cTnT

The prognostic value of red cell distribution width and markers of inflammation in acute decompensated heart failure

P Pavel Lazarev¹; E Kotova¹; A Shavarov¹; IU Karaulova¹; V Filatov²; G Kiyakbaev¹; V Moiseev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation;

²Moscow State University, Moscow, Russian Federation

Background: Red cell distribution width (RDW) and markers of inflammation are considered to be risk predictors in patients with acute decompensated heart failure (ADHF). Their relative significance and associations haven't been, nevertheless, thoroughly investigated.

Purpose: We aimed to evaluate the role of RDW together with inflammatory markers in predicting short-term major adverse cardiovascular events in ADHF patients.

Methods: Consecutive patients hospitalized with ADHF [n = 49; 51% male, median age 76 (68-80) years old, LVEF 49% (29-58%)] were included. RDW, NT-proBNP, erythrocyte sedimentation rate (ESR), high-sensitivity C-reactive protein (hsCRP), and interleukin-6 (IL-6) were measured within 48 hours of admission. The composite primary end-point was the occurrence of major adverse cardiovascular events (total mortality, MI, stroke, cardiovascular hospitalisations, urgent revascularization) during the median follow-up period of 111 (109-113) days. The association of aforementioned markers with the primary outcome was tested in ROC-curve analysis and univariable Cox regression with subsequent adjustment for significant predictors and possible confounders in multivariable analysis. Correlation was estimated with the use of Spearman's rank correlation coefficient (rho).

Results: On admission 31 (63%) patients had NYHA class 3, and another 18 (37%) class 4 heart failure. Average RDW values on admission were 15,4% (14,7-17,1%). The primary endpoint occurred in 29 (59%) patients; 12 (25%) participants died during follow-up. RDW values > 15,35% [relative risk (RR) 10,49, 95% CI 3,86-28,56, p<0,001], hsCRP > 10,11 mg/l (RR 10,24, 95% CI 2,42-43,36, p=0,002), IL-6 > 19,3 pg/ml (RR 2,73, 95% CI 1,31-5,72 p=0,008), and NT-proBNP > 4075 pg/ml (RR 7,18, 95% CI 2,99-17,24 p<0,001) were associated with the primary outcome in univariate analysis. ESR (p=0,965), total WBC count (p=0,063) and neutrophil-to-lymphocyte ratio (p=0,266) did not play a significant role. In multivariate analysis after adjustment for HF severity NT-proBNP (RR 3,77, 95% CI 1,42-10,05, p=0,008) still predicted the primary endpoint, and association of RDW with outcomes became borderline significant (RR 3,25, 95% CI 1,00-10,69, p=0,050). RDW correlated with hsCRP (rho=0,655, p<0,001), IL6 (rho=0,477, p<0,001), lymphocyte count (rho=-0,307, p=0,030) and NT-proBNP (rho=0,610, p<0,001).

Conclusions: RDW values correlated positively with markers of inflammation and independently predicted short-term negative outcomes in patients with ADHF. However, its prognostic significance is relatively weak in comparison to NT-proBNP.

P1676

Haemoglobin - a simple biochemical variable in prediction of in-hospital mortality in heart failure patients

M Marija Vavlukis¹; I Bojoski¹; F Taneski¹; S Paljoskovska¹; I Kotlar¹; H Taravari¹; E Shehu¹; D Kitanoski¹; S Kedev¹

¹University Clinic for Cardiology, Skopje, Macedonia The Former Yugoslav Republic of

Aim of the study: identifying predictors of in-hospital mortality in heart failure patients.

Methods: 451 patients admitted to ICCU with symptomatic HF were analyzed for: age, gender, co-morbidities, anemia, renal failure, parameters: heart rate, systolic and diastolic BP, Hgb, sodium, BUN, creatinine, ejection fraction (based on which patients were divided in PEF-HF and REF-HF), and calculated GWTG-HF score (Get with the Guidelines-HF risk score). Statistical analyze: descriptive, t-test, Chi square, uni and multivariate logistic regression, ROC Curve.

Results: mean age $69,9 \pm 10,8$, of 201(44,6%) f. and 250(55,4%) m. included. Presence of co-morbidities: Afib 41,0%; COPD 23,5%; DM 41,5%; HTA 71,6%; CAD 41,2%; preexisting-HF 34,8%; CRF 12,0%. Mean EF $42,5 \pm 10,5$ (26,1% with PEF-HF, and 73,9% with REF-HF). A total of 108 (23,9%) cardiac deaths were registered (IHD group), with the highest mortality rate during the first 48 hours (67,6%) of all. Univariate predictors: Afib: beta 0.383, p=0.085, exp(B) 1.466; HTA: beta -0.751, p=0.001, exp(B) 0.472; CRF: beta 0.819, p=0.007, exp(B) 2.268; DBP: beta -0.034, p=0.000, exp(B) 0.967; SBP: beta -0.017, p=0.000, exp(B) 0.983; sodium: beta -0.040, p=0.028, exp(B) 0.961; anemia: beta 0.951, p=0.000, exp(B) 2.588; Hgb: -0.190, p=0.000, exp(B) 0.827; creatinine: beta.248, p=0.000, exp(B) 1.282; BUN: beta.016, p=0.001, exp(B) 1.016; EF(%): beta -0.048, p=0.000, exp(B) 0.953; reduced EF: beta 0.989, p=0.000, exp(B) 2.687. In multivariate analyze four independent predictors identified: ejection fraction (beta -1.034, p=0.004), DBP (beta -0.032, p<0.000), BUN (beta 0.021, p<0.000) and Hgb (beta -0.119, p<0.039). Patients with REF-HF had significantly higher mortality rate in comparison with PEF-HF (OR 2.687, p=0.000). Mean GWTG-HF score was $39,5 \pm 9,9$ ($37,7 \pm 9,4$; $45,3 \pm 9,7$; p 0.000, non-IHD vs IHD pts). It had excellent discriminative function (ROC Curve: Area under the Curve.718, p< 0.000 (CI.663-.772) (image 1), in predicting IHD.

Conclusion: It seems reasonable to include Hgb - a simple biochemical marker, in GWTG-HF score and increase its predictive value.

ROC Curve of IHD with GWTG-HF score

Cardiovascular biomarkers and severity of dyspnea predict readmission and death in patients hospitalised for acute dyspnea

N Nathalie Lund¹; K Gransbo¹; O Melander¹

¹Skane University Hospital, Malmö, Sweden

Background: Patients with acute dyspnea is a large heterogeneous patient group with high mortality and readmission rates. Risk assessment of in-patients is crucial for optimizing treatment and length of stay.

Purpose: To investigate the prognostic value of cardiovascular biomarkers and clinical characteristics for readmission and death in patients hospitalized for acute dyspnea.

Methods: We studied 65 dyspnea patients at a general internal medicine ward and followed them for 6 months. Death or readmission was considered as the combined endpoint. Measurements and

Results: A cardiovascular risk score of inflammatory and vascular stress biomarkers was related to the endpoint and adjusted for clinical characteristics by using Cox proportional hazard models (adjusted for sex, age, saturation, respiratory rate and CRP). The parameters were divided into tertiles and the bottom tertile was used as the reference group. The biomarkers Tissue-type plasminogen activator (tPA), Prolactin (PRL), Tumor necrosis factor receptor superfamily member 6 (FAS) and C-C motif chemokine 3 (CCL3) were independently significant and combined into a risk score. Each SD increment of the score conferred a hazard ratio (HR) of 2.03 (1.34-3.05) $P=0.001$. The top tertile conferred a HR of 2.81 (1.25-6.32) $P=0.01$. High severity of dyspnea (by modified NYHA-class) was also associated with worse outcome HR=2.68 (1.03-7.02) $P=0.041$.

Conclusion: Dyspnea level and a score of tPA, PRL, FAS and CCL3 predict 6-month death and readmission in patients hospitalised for acute dyspnea and may be used to optimise hospital care.

Cardiovascular risk biomarker score *

	HR (95 % CI)	P	HR (95% CI) P-trend		
			Tertile 1	Tertile 2	Tertile 3
Biomarker score	2.03 (1.34-3.05)	0.001	REF (1.0)	1.58 (0.68-3.67)	2.81 (1.25-6.32) 0.01
Modified NYHA-class	NA	NA	REF (1.0)	1.73 (0.72-4.12)	2.68 (1.03-7.02) 0.041

* adjusted for age, sex, respiratory rate, saturation and C-reactive protein. Biomarker score of tPA, PRL, FAS and CCL3. M-NYHA; modified NYHA-class. Dyspnea severity derived from the New York Heart Association (NYHA) Functional Classification.

Prognostic impact of C-reactive protein level on admission in patients with acute decompensated heart failure

H Matsumoto¹; T Kasai¹; S Yatsu²; A Murata²; T Kato²; S Shoko¹; M Hiki²; A Takagi²; K Miyauchi²; H Daida²

¹Juntendo University School of Medicine, Department of Cardiovascular Medicine, Cardiovascular Respiratory Sleep Medicine, Tokyo, Japan; ²Juntendo University School of Medicine, Department of Cardiovascular Medicine, Tokyo, Japan

Background: C-reactive protein (CRP) level on admission has been related with the prognosis of several cardiovascular diseases such as acute coronary syndrome. Although admission CRP level was associated with in-hospital mortality in patients with acute decompensated heart failure (ADHF), association between admission CRP level and long-term mortality in patients with ADHF remains to be clarified.

Methods: A cohort of 1684 consecutive patients admitted to the cardiac intensive-care unit from 2007 to 2011 was studied. Among them, patients with acute coronary syndrome and neoplasms were excluded, and then patients with ADHF were divided into 5 groups based on quintiles of admission CRP level. Association between admission CRP level and long-term mortality was assessed by multivariable Cox proportional analysis including other independent variables which showed <0.1 in univariable analyses.

Results: Overall, 527 patients were assessed. There were 142 deaths (27%) during a median follow-up of 2.0 years. In the multivariable analysis, hazard ratio (HR) increased with admission CRP levels in a significant dose-dependent manner for mortality (p for trend=0.045). Multivariable analysis also showed a significant relationship between admission CRP level, when treated as a natural logarithm-transformed continuous variable, and increased mortality (HR, 1.18; $P=0.023$).

Conclusion: In patients with ADHF, admission CRP level is associated with increased risk of long-term mortality.

P1679

Prognostic value of biomarkers and co-morbidities in patients with acute heart failure: one year follow up

D Petrovic¹; M Deljanin Ilic¹; S Stojanovic¹; S Ilic¹

¹Institute of Cardiology, Medical Faculty University of Nis, Niska Banja, Serbia

Purpose: To evaluate the prognostic value of biomarkers B-type natriuretic peptide (BNP), troponin I (TnI) and high-sensitivity C-reactive protein (hsCRP) and co-morbidities on one-year mortality in patients with acute heart failure (AHF).

Methods: A total of 124 patients (pts) (70.69±9.76 years, 76 male) who were admitted to intensive care unit due to signs and symptoms of AHF were enrolled in the study. During the first 24 hours after admission, values of both standard biochemical parameters as well as of BNP, TnI and hsCRP were determined.

In all pts echocardiography examination was performed and data on existing co-morbidities (chronic renal failure, cerebrovascular insult, myocardial infarction, angina pectoris, hypertension, peripheral arterial disease, diabetes mellitus, chronic obstructive pulmonary disease, depression) were collected. After discharge clinical one year follow-up was performed. All medical therapy was documented, and for this analysis, we focused on mortality.

Results: During one year follow up 37(29.8%) pts died. Value of serum BNP was higher in the group of non-survivors compared to the group of survivors (13538.84±5078.32 vs 7184.84±3876.95 pg/mL, $p<0.001$), as well as value of TnI (3.26±11.94 vs 1.07±2.72 ng/ml, $p=0.402$) and hsCRP (15.10±13.21 vs 13.02±16.04 mg/L, $p=0.140$).

By applying Cox regression analysis the most important predictors for one year mortality were: BNP (HR 1.000, CI 1.000-1.000, $p<0.001$), hypotension at admission (HR 7.226, CI 3.692-14.143, $p<0.001$), left bundle branch block (HR 5.708, CI 2.746-11.863, $p<0.001$), presence of chronic renal failure (HR 3.780, CI 1.943-7.356, $p<0.001$), left ventricular ejection fraction (HR 0.925, CI 0.889-0.962, $p<0.001$), right ventricular systolic pressure (HR 1.066, CI 1.043-1.089, $p<0.001$), the size of left atria (HR 1.052, CI 1.025-1.081, $p<0.001$). Weaker, but significant predictors of mortality were: TnI (HR 1.042, CI 1.011-1.074, $p<0.007$) ventricular arrhythmias (HR 2.115, CI 1.099-4.071, $p<0.025$), depression (HR 2.602, CI 1.346-5.029, $p<0.004$) left ventricular end-diastolic diameter (HR 1.056, CI 1.022-1.091, $p=0.001$) and the presence of diastolic dysfunction (HR 2.946, CI 1.048-8.383, $p<0.041$).

Conclusion: Our results showed that in patients with acute heart failure the most significant influence on one-year mortality out of biomarkers had level of BNP and TnI, and out of co-morbidities chronic renal failure and depression. Level of BNP and chronic renal failure stood out as the strong predictors of one-year mortality.

Neutrophil-to-lymphocyte ratio is a better marker for progression of renal dysfunction than neutrophil gelatinase associated lipocalin in heart failure

Kocaeli University Scientific Research Unit

D Dilek Ural¹; O Argan¹; G Kozdag¹; S Bozyel¹; M Aktas¹; K Karazum¹;

I Yilmaz¹; E Dervis¹; A Agir¹

¹Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey

Background: Neutrophil gelatinase-associated lipocalin (NGAL) is a biomarker for tubular kidney injury and inflammation. Previous studies have shown that high NGAL values in acute and chronic heart failure patients are associated with worse functional capacity, and adverse clinical outcome. The aim of the present study was to assess the utility of serum NGAL level to predict progression of kidney disease in heart failure patients with reduced ejection fraction (HFrEF).

Methods: Serum NGAL levels and markers of inflammation [hs-CRP, neutrophil-to-lymphocyte ratio (NLR)] were assessed from venous blood samples of 121 patients with chronic HFrEF. Primary endpoints were progression of kidney dysfunction (defined as a decline in eGFR category accompanied by a $>=25\%$ decrease in eGFR from baseline), and composite of all-cause mortality and re-hospitalization.

Results: Data for follow-up eGFR was available for 85 patients during a median 16 months follow-up period, and progression of kidney disease was detected in 28 patients (33%). In univariate analysis, baseline functional class, NT-proBNP, hs-CRP, NGAL, and NLR were significantly higher, baseline eGFR, hemoglobin and albumin were significantly lower in patients with worsening kidney function. In Cox regression analysis, NLR [Exp(B)=1.374, $p=0.001$] and hs-CRP [Exp(B)=1.148, $p=0.019$] were independent predictors of worsening kidney function. Composite endpoint could be assessed in all patients [observed in 68 patients (56%)]. Signs of right heart failure in the initial visit [Exp(B)=0.465, $p=0.010$] and hs-CRP [Exp(B)=1.077, $p=0.024$] were the two independent predictors for all-cause mortality and re-hospitalization.

Conclusion: Simple markers of systemic inflammation (i.e. NLR and hs-CRP) are better predictors for progression of kidney dysfunction and for composite of all-cause death and rehospitalization than serum NGAL levels.

P1681

The effect of early increases of alanine aminotransferase on mortality in cardiogenic shock: the CardShock study

T A J Toni Antti Juhani Jantti¹; JP Lassus¹; J Parissis²; J Tolonen¹; A Sionis³; J Spinar⁴; M Banaszewski⁵; K Pulkkis⁶; A Mebazaa⁷; V-P Harjola¹

¹Helsinki University Central Hospital, Helsinki, Finland; ²Attikon University Hospital,

Athens, Greece; ³Hospital de la Santa Creu i Sant Pau, Barcelona, Spain;

⁴University Hospital Brno, Brno, Czech Republic; ⁵Institute of Cardiology, Warsaw,

Poland; ⁶Eastern Finland Laboratory Centre, Kuopio, Finland; ⁷Inserm UMR-S 942, Paris, France

Purpose: To assess the prognostic value of early alanine aminotransferase (ALT) changes in cardiogenic shock patients.

Methods: Serial blood sampling (12h intervals for 24 hrs after study enrolment) was performed in 156 patients enrolled in the prospective multicenter CardShock study.

ALT levels were analyzed in a central laboratory. Associations of ALT levels with clinical data and outcomes were analysed using SPSS statistical software.

Results: Patients were on average 66 years old, and 26 % were women. The etiology of cardiogenic shock was mainly acute coronary syndrome, comprising 80% of the patients in the cohort. Mean systolic blood pressure was 77 mmHg (standard deviation 12 mmHg), and median lactate 2.5 mmol/l (interquartile range 1.6-5.1 mmol/l). The overall 90-day mortality was 42.0%. An increase in ALT of over 20% within 24 h of enrolment (ALT > +20%) was observed in 24% (38/156) of patients. ALT > +20% was associated with signs of hypoperfusion (higher lactate, oliguria, lower left ventricular ejection fraction, with p-values of <0.001, 0.02 and <0.01, respectively). ALT > +20% was also associated with a lower cardiac index (p < 0.01 for time points 24h, 36h and 48h after study enrolment) and a higher CVP (p < 0.01 for time points 12h and 24h after study enrolment). ALT > +20% was associated with an over two-fold increase in mortality compared with those with stable ALT (72% and 31%, respectively, p < 0.001) with a univariate Cox proportional hazard ratio of 3.7 (95% CI 2.2-6.3, p < 0.0001) for death at 90 days. In multivariate analysis adjusting for the initial level of ALT, highest TnT level within 24 hrs and the change in lactate levels within 24 hrs in addition to the risk factors included in the previously published CardShock risk score, the association remained statistically significant (HR 2.9, 95% CI 1.6-5.5, p = 0.001), showing that a greater than 20% increase in ALT levels within 24 h was strongly associated with 90-day mortality (Figure 1).

Conclusions: An increase in ALT of +20% or more within 24h is strongly associated with mortality and an independent predictor of 90-day mortality in cardiogenic shock.

Kaplan-Meier survival curves

P1682

Significance of soluble ST2-receptor and NT-proBNP concentrations in acute decompensated heart failure patients long-term risk stratification

V N Protasov¹; AA Skvortsov¹; D Koshkina¹; OY Narusov¹; GA Tkachev¹; VP Masenko¹; SN Tereshchenko¹

¹Russian Cardiology Research and Production Complex, Moscow, Russian Federation

Background: sST2 and NT-proBNP concentrations are strong predictors for the adverse long-term prognosis in pts with ADHF.

Purpose: to evaluate the significance of sST2 and NT-proBNP concentrations in risk stratification in patients (pts) with ADHF in one year follow-up period.

Methods: In our study were included 159 pts with ADHF III-IV FC NYHA. Blood samples to determine NT-proBNP, sST2, hsTnT, NGAL and galectin-3 concentrations were collected at the admission and at discharge from the hospital, and after 3, 6 and 12 months of follow-up. The primary end point was total cardiovascular events that included cardiovascular (CV) death and hospitalization due to HF.

Results: At admission all pts had elevated biomarker concentrations: NT-proBNP 3615,5(1578,0;6289,3) pg/ml, sST2 60,49(41,95;92,87)ng/ml, and at discharge: NT-proBNP 2165,5(982,7;4221,2)pg/ml and sST2 38,43(24,67;63,72)ng/ml. During 1-year follow-up (mean 277 ± 115 days) 54 pts (33,96%) had CV events. Biomarker concentrations in low risk pts (without CV events) were significantly lower compared with high risk pts (with CV events): at the admission NT-proBNP 2819 (1233;4912,7)pg/ml vs 5215,5 (3010; 8768,5)pg/ml, p < 0,0001; sST2 53,64(37,04;72,35)ng/ml vs 72,07(59,27;117,75)ng/ml, p < 0,0001; and at discharge from the hospital NT-proBNP 1439 (753,3;2604,5)pg/ml vs

3358 (1623,7;5432,7)pg/ml, p < 0,0001; sST2 31,28(21,68;48,00)ng/ml vs 60,19(37,25;98,35)ng/ml, p < 0,0001. At the discharge from the hospital NT-proBNP and sST2 concentrations had the most predictive capacity relatively the primary end point during 1-year follow-up: AUC=0,726 (0,637-0,816), <0,0001, sensitivity 75%, specificity 58,1% and AUC=0,768 (0,682-0,854), <0,0001, sensitivity 75,5%, specificity 64,3% respectively. Lack of NT-proBNP and sST2 concentrations decrease below 1696pg/ml and 37,8ng/ml was associated with the highest risk of CV events (OR 4,1(1,91-9,01), p < 0,0001 and OR 5,89(2,66-13,08), p < 0,0001, respectively). Changes of sST2 concentration during the period of pts hospitalization have had prognostic significance, AUC=0,696 (0,596-0,796), p < 0,0001. At the same time, insufficient degree of sST2 concentrations reduction during the period of hospitalization (Δ % <26,9%) have had the worst short-term and long-term prognosis (OR 3,68 (2,05-6,64), p < 0,0001).

Conclusion: The values of soluble ST2-receptor over 37,8ng/ml and NT-proBNP over 1696pg/ml at the discharge from the hospital reflects the adverse long term prognosis in patients with ADHF. sST2 concentration was an independent predictor of adverse prognosis in the multivariate analysis.

Risk-stratifying biomarkers to predict new onset HFpEF: potential roles for BNP, hsTroponin and galectin-3

CJ Watson¹; E O'connell²; J O'reilly³; S James²; J Gallagher²; M Ledwidge²; K McDonald²

¹Queen's University of Belfast, Belfast, United Kingdom; ²Heart Failure Unit, St Vincent's University Hospital, Dublin, Ireland; ³University College Dublin, Dublin, Ireland

Introduction: The future prediction of new onset heart failure with preserved ejection fraction (HFpEF) is an important component of disease prevention strategies. HFpEF is characterised by progressive onset of cardiac remodelling and ventricular dysfunction providing opportunities to detect these disease manifestations earlier and therefore enabling timely intervention. Based on HFpEF pathogenesis, potential biomarker candidates in the future prediction of new onset HFpEF include natriuretic peptides, high sensitivity Troponins, and galectin-3. The purpose of this study was to investigate the utility of these biomarker candidates in predicting new onset HFpEF in asymptomatic, event-free patients with CVD risk-factors.

Methods: The study population consisted of 90 patients selected from within the longitudinal STOP-HF study (Ireland) which comprises asymptomatic patients with CVD risk factors. Thirty of these patients developed HFpEF over time, and were propensity matched 2:1 by age and sex to a cohort that did not develop HFpEF (n = 60) over a similar time period. BNP, hsTroponin I, and galectin-3 were quantified in all patients at two time points. Median time between measurements was 1.2 years. In the new onset HFpEF cohort, all analyses were done before the event, and median time between follow-up measurement and future HFpEF event was 1.6 years. Results Biomarker analysis of hsTroponin I and BNP at baseline and follow-up were statistically significant predictors of future new onset HFpEF, whereas galectin-3 at follow-up only was a significant predictor. A logistic regression model indicated that unadjusted biomarker combinations could significantly predict future HFpEF using both baseline (AUC 0.77 [0.68,0.87]) and follow-up data (AUC 0.86 [0.79,0.94]). NRI between adjusted models indicate that it is not necessary to take account of patient medications at 80% sensitivity. A simple clinical prediction rule to approximate the probability of future HFpEF development within the next 1-2 years was developed. Low and high risk was determined using BNP and galectin-3, with hsTroponin I being required to differentiate the intermediates. Applying this rule to the follow-up dataset yields sensitivity and specificity values of 83% and 71%, respectively. Discussion We provided evidence for the utility of BNP, hsTroponin I, and Galectin-3 in the prediction of future HFpEF in asymptomatic event-free populations with CVD risk-factors. Validation of our biomarker combination models and clinical prediction rule in an independent population is required.

NT-proBNP, ST2 and Galectin3: a multiparametric approach based on biomarkers to predict the risk of heart failure progression

D Grande¹; M Leone¹; F Monitillo¹; C Rizzo¹; MS Lattarulo¹; P Terlizze¹; N Aspromonte²; F Di Serio³; M Iacoviello⁴

¹University of Bari, School of Cardiology, Bari, Italy; ²San Filippo Neri Hospital, Cardiology Unit, Rome, Italy; ³Polyclinic Hospital of Bari, Clinical Pathology Unit, Bari, Italy; ⁴Polyclinic Hospital of Bari, Cardiology Unit, Cardiothoracic Department, Bari, Italy

The aim of this study was to evaluate the possible integration of information carried by NT-proBNP, Galectin-3 (Gal-3) and ST-2 in order to better stratify the risk of heart failure progression in a group of outpatients affected by chronic heart failure (CHF)

Methods: We enrolled 215 outpatients (81% males, 64 ± 13 years, NYHA class 2.3 ± 0.6, left ventricular ejection fraction, LVEF, 33 ± 10% with CHF (ESC criteria) due to left ventricular systolic dysfunction, in stable clinical conditions (>1 month) and in conventional therapy. Plasma levels of NT-proBNP (mean 2447 ± 4018

pg/ml), Gal-3 (mean 15.6 ± 7.1 pg/ml) and ST2 (mean 41.9 ± 21.6 pg/ml) were assessed. During follow-up heart failure progression was defined as the occurrence of hospitalization and/or heart transplantation and or death due to worsening of heart failure.

Results: During a mean follow-up of 16 ± 10 months, 48 patients showed heart failure progression.

At Cox univariate regression analysis NT-proBNP (after log transformation HR 10.9; 95%CI: 4.44-26.9; $p < 0.001$), Gal-3 (HR 1.05; 95%CI: 1.02-1.08; $p < 0.001$; C index 0.66) and ST-2 (HR: 3.51; 95%CI: 1.9-6.35; $p < 0.001$; C index 0.66) were all associated to heart failure progression. However, accuracy of NT-proBNP (C-index 0.79) was greater than those observed for Gal-3 (C-index 0.66) and ST2 (C-index 0.66). At ROC curves for one year events, the best cut-offs observed were 1000 for NT-proBNP (sensitivity 94% and specificity 58%), 17.1 for Gal-3 (sensitivity 66% and specificity 67%) and 39.1 for ST-2 (sensitivity 69% and specificity 70%). Although less accurate in predicting events, when combined to NT-proBNP, ST2 and Gal-3 were able to better discriminate patients with and without events (free NRI p : 0.019 for Gal-3 > 17.1 and $p < 0.001$ for ST-2 > 39.1). In a Cox multivariate analysis, when the information concerning the presence of a high ST-2 and/or Gal-3 was added to that related to the presence or not of a high NT-proBNP, a significant association with events was found for ST-2/Gal-3 (HR 2.07; 95%CI: 1.35-3.16; p : 0.001).

Panel A of figure shows the risk of heart failure progression according to the presence or not of high NT-proBNP and of high ST-2/Gal-3. In panel B Kaplan Meier curves for events according to the number of altered biomarkers (none, one, two or three) are shown.

Conclusions: Our findings demonstrate that combination of Gal-3, ST2 and NT-proBNP is able to identify patients with the highest risk of heart failure progression. This can be due to the fact that these biomarkers can integrate each other because reflect different pathophysiological substrates leading to heart failure worsening.

P1685

Biomarkers of oxidative stress and heart failure

G Kamceva¹; M Vavluks²; D Kitanoski²; M Zdravkovska³; S Dokuzova¹; S Kedev²

¹Clinical Hospital, Internal Medicine, Stip, Macedonia The Former Yugoslav Republic of; ²University Clinic of Cardiology, Medical Faculty, Skopje, Macedonia The Former Yugoslav Republic of; ³Goce Delcev University, Faculty of Medical Sciences, Stip, Macedonia, Stip, Macedonia The Former Yugoslav Republic of

Aim: of the study was to evaluate association between biomarkers of oxidative stress and development of heart failure in patients with coronary artery disease (CAD).

Methods: Patients treated because of CAD were analyzed for their demographic, LV functional, risk factors, biochemical variables: lipids, DM variables, Hgb, and markers of oxidative stress: oxidative stress markers: malondialdehyde and total hydroperoxides, and antioxidant enzymes: superoxide dismutase, catalase and glutathione peroxidase. They were divided in two groups: preserved and reduced EF (EF ≥ 40 or $< 40\%$). Statistical analyze: descriptive, t-test, Chi square test, correlation, uni and multivariate logistic regression analyze. Significance was determined at level of 0.05.

Results: 134 pts. 94(70.1%) males and 40(29.9%) females at mean age of 64.3 ± 11.2 years were analyzed. 99(73.9%) had A presence of REF-HFS, and 35(26.1%) had CCAD. 62.2% of pts. had HTA, 38.1% HLP, 33.6% DM, 59.7% were active or past smokers, 11.9% had anemia. Mean EF was $50.9 \pm 10.2\%$, 45.5% had reduced EF ($< 40\%$). Mean values of all of the markers of oxidative stress are presented in Table 1. Statistically significant difference existed only for MDA. We found significant positive association with univariate logistic regression only for MDA and HF (beta.228, $p=0.008$), same result was confirmed when we took ACS as selection variable (beta.197, $p=0.050$), but statistical significance wasn't found in CCAD patients (beta.305, $p=0.074$). Significant association was found between age and MDA (beta=.177, $p=0.041$), especially with HF as selection variable (beta =.356, $p=0.005$), and HP (beta.155, $p=0.074$).

Conclusion: Chronic heart failure, regardless of etiology, is associated with abnormalities of a range of markers of oxidative stress, we managed to find significant

association for one of them - malondialdehyde. Also, it seems that there is an age dependency, we registered significantly higher levels of MDA and total HP in older patients with CAD and HF.

Table 1. Mean values of oxidative stress

OS marker	EF 0/1	N	mean \pm SD	p
MDA	0 1	73 61	31,85 \pm 7,17 36,73 \pm 13,35	0,008
Total HP	0 1	73 61	281,83 \pm 66,14 289,46 \pm 73,99	0,530
SOD	0 1	73 61	106,39 \pm 94,33 139,19 \pm 131,67	0,096
CAT	0 1	73 61	63,13 \pm 43,40 59,27 \pm 36,55	0,583
GPX	0 1	73 61	6,39 \pm 4,94 5,94 \pm 6,80	0,759

Legend: OS-oxidative stress; 0- EF $> 40\%$; 1- EF $< 40\%$; MDA-malondialdehyde; HP-hydroperoxides; SOD- superoxide dismutase; CAT-catalase; GPX- glutathione peroxidase.

P1686

Some aspects of the effect of coenzyme Q10 on inflammatory processes, remodeling and functional status of endothelium in chronic heart failure

G Kukharchik¹; L Sichinava¹; L Gaykovaya¹; A Burbello¹; I Yubrina¹; L Sorokin²

¹North-West State Medical University named after I.I.Mechnikov, Saint-Petersburg, Russian Federation; ²Hospital St. Elizabeth, Saint-Petersburg, Russian Federation

Aim: To evaluate the effect of coenzyme Q10 on biomarkers associated with inflammatory processes, remodeling and functional status of the endothelium of patients with chronic heart failure (CHF) in functional NYHA class II-III.

Method: 108 patients, with class II-III CHF and a history of myocardial infarction, were entered into the study. The patients were randomized into two groups: group I which received coenzyme Q10 at a dose 120 mg/day over 3 months in addition to the standard optimal treatment; and group II who received the standard optimal treatment only. All patients were tested at the start of the study and again at 3 months for blood serum levels of the following: galectin-3, ST2, high sensitivity C-reactive protein (hs-CRP), N-terminal pro B-type natriuretic peptide (NT-proBNP), circulating endothelial cells (CEs), matrix metalloproteinases-9 (MM-9). Endothelial dysfunction was evaluated by peripheral arterial tonometry (PAT). All patients had an echocardiogram (Echo-CG) performed at the start of the study and again at 3 months.

Results: At 3 months, patients in both therapy groups showed clinical benefits of treatment for their CHF. Patients in group I showed a decrease of left ventricular diastolic and systolic end volumes and an increase of the ejection fraction. Both groups of patients showed a decline of hs-CRP-concentration in comparison with initial testing: group I from 3.4 (1.8; 6.7) mg/L to 1.5 (0.8; 3.0) mg/L (< 0.05), and group II from 3.85 (2.15; 8.70) mg/L to 1.35 (0.73; 3.4) mg/L (< 0.05). Over the same period of 3 months the concentration of galectine-3 decreased from 19.22 (10.88; 43.50) ng/ml to 16.76 (9.92; 34.50) ng/ml only in group I, and levels of ST-2 decreased from 75.11 (63.36; 100.43) ng/ml to 54.02 (48.84; 86.79) ng/ml (< 0.05) only in patients of group I; in group II patients ST-2 concentration was unchanged. The level of NT-proBNP during therapy was significantly decreased in both groups. Using the Wilcoxon rank-sum test, paired comparisons of MM-9 concentration made in depended samplings decreased in group I patients. After 3 months of therapy the level of CEs (< 0.05) decreased in both groups. According to the PAT data the reactive hyperemia index (RHI) increased in both groups: in group I patients from 1.38 (1.14; 1.50) to 1.87 (1.39; 2.57) and in group II from 1.33 (1.22; 1.50) to 1.44 (1.33; 1.74). However, only group I patients showed an increase in the median value of RHI of more than 1.67 over the 3 months of treatment.

Summary: Adding coenzyme Q10 to the standard treatment of patients with CHF with a history of myocardial infarction, led to progress in the management of post myocardial infarction remodeling according to Echo-CG findings, with improvement of endothelium function, decrease in inflammatory activity and fibrosis development, as evidenced by changes in the level of biomarkers associated with these processes.

P1687

Neutrophil to lymphocyte ratio - an independent predictor of mortality in patients with heart failure

C Delcea¹; CA Buzea²; A Dima¹; A Breha¹; RA Popescu²; M Dobranici²;

C Stanescu²; AR Dan²; C Baicus²; GA Dan²

¹Colentina University Hospital, Bucharest, Romania; ²University of Medicine and Pharmacy Carol Davila, Colentina Clinical Hospital, Bucharest, Romania

Background: Neutrophil to lymphocyte ratio (NLR), a marker of inflammation, was initially used as a prognostic factor in infectious and neoplastic diseases. Recently, NLR was associated with increased morbidity and mortality in different cardiovascular diseases.

Purpose: Our aim was to validate the prognostic utility of NLR in predicting 3-year survival in heart failure (HF) patients and to determine a cut-off level for this biomarker.

Methods: We retrospectively analyzed data from all adult HF patients admitted to our clinic during a two year period (after excluding those with acute coronary syndromes, pulmonary embolisms, readmissions and in hospital mortality). Survival was determined at 3 years after hospital discharge for each subject.

Results: Our sample consisted of 424 patients with a mean age of 69.47 ± 11.06 years and female predominance (56.97%). Median NLR was 2.66 (interquartile range 1.92; 3.65). 3-year survival was 77.07%. Surviving patients had a median NLR of 2.44 (1.81; 3.31) compared to 3.65 (2.83; 5.77) in non-survivors ($p < 0.0001$). All-cause mortality increased proportionally to the NLR quartiles from 7 (6.66%) patients in the lowest quartile to 48 (45.28%) patients in the highest quartile (p for trend < 0.0001).

In ROC curve analysis, NLR predicted all-cause mortality with an AUC of 0.753 (95% CI 0.709 - 0.794), $p < 0.0001$ and a Youden index associated criterion of NLR > 2.76 with a sensitivity of 78.4% and specificity of 62%. We therefore established the cut-off level at 3. Patients with a NLR > 3 had a fatality OR of 5.33 (95% CI 3.24 - 8.77), $p < 0.0001$.

In multivariate analysis, NLR > 3 was an independent predictor of all-cause mortality with an OR of 2.86 (95% CI 1.58 - 5.15), $p < 0.0001$, alongside the ejection fraction, NYHA class IV, potassium and hemoglobin levels. In this model, the NT pro-BNP no longer remained an independent predictor.

The all-cause mortality prediction model using NLR > 3 , increased NT-pro BNP, ejection fraction, NYHA class IV, age, potassium and hemoglobin trended towards outperforming the NT-pro BNP level alone with a ROC curve of 0.837 (95% CI 0.793 - 0.882) versus 0.804 (95% CI 0.755 - 0.853), $p = 0.07$.

Conclusions: NLR > 3 is an independent prognostic factor for 3-year all-cause mortality in heart failure patients. Using this easily available, cost-efficient biomarker alongside the already validated parameters increases the accuracy of fatality prediction in these patients.

P1688

Combining natriuretic peptides and 1, 25-dihydroxyvitamin D testing improves the predictive value for cardiovascular death in heart failure

D Damien Gruson¹; B Ferracin¹; S Ahn¹; M Rousseau¹

¹ Saint-Luc University Clinics, Brussels, Belgium

Background: B-type natriuretic peptides (BNP) and N-terminal pro-BNP (NT-proBNP) are reference biomarkers in heart failure (HF). A growing body of evidence supports the role of vitamin D and parathyroid hormone in cardiac remodeling and HF worsening. However, the prognosis value of the 1,25-dihydroxyvitamin D (1,25(OH)₂D), the most potent active metabolite of vitamin D, remains to be investigated.

Purpose: We therefore evaluated a multimarker strategy based on the combination of 1,25(OH)₂D and natriuretic peptides measurement to predict cardiovascular (CV) death.

Methods: 170 HF patients (females $n = 36$; males $n = 134$; NYHA II-IV; mean age: 67 years; etiology: ischemic $n = 119$, dilated cardiomyopathy $n = 51$; median LVEF: 24%) were included in this study. The primary outcome (PO) was CV death. Circulating levels of BNP, NT-proBNP and 1,25(OH)₂D were determined with automated immunoassays.

Results: Serum levels of 1,25(OH)₂D decreased markedly with HF severity. Medians were 33.3 pg/mL for NYHA-II patients, 23.4 pg/mL for NYHA-III, and 14.0 pg/mL for NYHA-IV patients ($p < 0.001$). The NT-proBNP to 1,25(OH)₂D and the BNP to 1,25(OH)₂D ratios were also significantly related to HF severity. Over a mean follow-up of 4 years, 106 out of 170 patients reached the PO. Cox proportional hazard modeling revealed that the ratios were strongly predictive of CV death. In ROC analysis, the area under the curve (AUC) for CV death for NT-proBNP/1,25(OH)₂D and BNP/1,25(OH)₂D ratios were respectively 0.769 and 0.782 (higher than BNP (AUC 0.744) and NT-proBNP (AUC 0.730)).

Conclusions: In heart failure, the ratios between natriuretic peptides and 1,25(OH)₂D strongly and independently predict cardiovascular mortality and are more efficient than single natriuretic peptides testing. These simple new tools contribute to a more personalized management of heart failure patients.

P1689

Comparing baseline, admission and discharge natriuretic peptide levels (NT-proBNP) during admissions for acute decompensated heart failure: insights for a relative approach in guided treatment

S Susan Stienen¹; YM Pinto¹; PG Meregalli¹; WE Kok¹

¹ Academic Medical Center, University of Amsterdam, Department of Cardiology, Amsterdam, Netherlands

Background: In a previous study, we demonstrated that either an absolute or relative natriuretic peptide (NT-proBNP) discharge target may be used to guide treatment during admissions for acute decompensated heart failure (ADHF), as both can predict survival and readmissions. A $>30\%$ relative NT-proBNP reduction during admissions seems to be an attractive target for most patients, in which

the admission level is the first available measurement. Another approach may be an NT-proBNP reduction back to 'stable' baseline levels. We explored the relative changes in NT-proBNP levels in ADHF patients at baseline, admission and discharge, to better understand the proposed relative discharge target of $>30\%$ reduction in NT-proBNP.

Methods: Our study population comprised ADHF patients admitted between Dec 2004 and Dec 2008 in our academic hospital in whom admission and discharge NT-proBNP levels were available. In addition, an NT-proBNP measurement was available during stable condition within < 12 months before admission at the outpatient HF clinic. We assessed the relationship between percentage NT-proBNP increase from baseline to admission, and the percentage NT-proBNP reduction from admission to discharge. Patients achieved an "ideal percentage reduction" when they attained their baseline NT-proBNP levels at discharge. We compared percentages of patients attaining "ideal percentages reduction" between patients attaining $>30\%$ vs $<30\%$ NT-proBNP reduction at discharge.

Results: A total of 44 patients (median age 70 (57-76), 57% males) were studied. Median percentage NT-proBNP increase from baseline to admission was 106% (48-220%). Median percentage NT-proBNP reduction from admission to discharge was 40% (20-72%). In 19 patients (43%), an NT-proBNP reduction below or at baseline levels was attained at discharge (Figure). Patients with an NT-proBNP reduction of $\leq 30\%$ at discharge were significantly less often at baseline levels at discharge compared to patients with an NT-proBNP reduction of $>30\%$ at discharge (3/17 patients (18%) vs. 16/27 patients (59%), $p = 0.01$).

Conclusion: Admissions for ADHF are accompanied by a median increase of 106% in NT-proBNP from baseline levels, but with a wide variation of increases. At discharge, 43% of ADHF patients attain their baseline NT-proBNP level again. A discharge level of $>30\%$ NT-proBNP reduction indicates that 3/5 of patients reach baseline NT-proBNP levels.

P1690

Diagnostic utility of cardiac biomarkers in discriminating takotsubo syndrome from acute myocardial infarction

C Carina Arantes¹; S Fonseca¹; C Quina-Rodrigues¹; G Abreu¹; J Martins¹;

C Braga¹; P Azevedo¹; A Gaspar¹; S Rocha¹; J Marques¹

¹ HOSPITAL DE BRAGA, BRAGA, Portugal

Introduction: Takotsubo syndrome (TS) has a clinical and echocardiographic presentation similar to acute myocardial infarction (AMI), especially anterior AMI. Ideally the differential diagnosis should be done early and preferably non-invasively. However, in the majority of patients, TS is not recognized until cardiac catheterization reveals typical wall motion abnormalities in the absence of significant coronary artery disease. In TS the rise in serum troponin seems to be disproportionately low relative to the extent of cardiac dysfunction, which may be useful in the differential diagnosis.

Purpose: To test the ejection fraction/troponin I (EFT) index and the NT-proBNP/troponin I (BNPT) index as non invasive methods to identify the TS.

Methods: We have included 49 patients with TS and 49 patients with anterior AMI (34 AMI with ST elevation and 15 AMI without ST elevation) matched by left ventricular ejection fraction (LVEF) (mean = $36.5 \pm 7.4\%$) and age (mean = 66.7 ± 9.1 years). We calculate the EFT and BNPT indexes and their receiver operator characteristic (ROC) curves to evaluate the discriminatory power.

Results: We observed a female predominance in patients with TS (81.6% vs 22.4%, $p < 0.001$), with no difference in relation to the cardiovascular risk profile. The troponin I peak was lower in TS (median = 2.4, IQ 1.4 - 5.1 vs 44.4 IQ 5.6 - 134.0 ng/ml, $p < 0.001$), but the NT-proBNP levels were higher (median = 5542, IQ 2849 - 8753 vs 1324, IQ 801 - 1959 pg/ml, $p < 0.001$).

In TS both indexes were higher (EFT: median = 14.6, IQ 5.5 - 24.1 vs 0.92, IQ 0.22 - 6.27, $p < 0.001$; BNPT: median = 1721, IQ 718-4595 vs 37.5, IQ 13.7 - 147.3, $p < 0.001$). After analyzing the ROC curves, it was found that both indexes showed good discriminatory power for TS (EFT: area under the curve (AUC) = 0.859, $p < 0.001$; BNPT: AUC = 0.930, $p < 0.001$).

Conclusion: In our population, the profile of cardiac biomarkers identified the patients with TS among patients presenting with anterior AMI. The construction of models based on cardiac biomarkers may be a useful tool in the non invasive diagnosis of TS, which is particularly important when coronary angiography is not risk-free for the patient.

P1691

The effect of guided web-based cognitive behavioral therapy on patients with depressive symptoms and heart failure- a randomized controlled trial

The Swedish Heart and Lung Association, Region Östergötland, the Medical Research Council of Southeast Sweden

J Johan Lundgren¹; Ö Dahlström²; G Andersson²; T Jaarsma¹; A Karner Kohlner¹; P Johansson³

¹Linköping University, Department of Social and Welfare Studies, Linköping, Sweden; ²Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden; ³Linköping University Hospital, Department of Cardiology, Linköping, Sweden

Background: Depressive symptoms, and the associated coexistence of symptoms of anxiety and decreased quality of life (QoL), are a common problem in patients with heart failure (HF). However, treatment strategies for depressive symptoms in patients with HF still remain to be established. Cognitive behavioral therapy (CBT) and its Internet-based version as guided self-help CBT programs (ICBT) have shown good effects in the treatment of depression, but ICBT has not previously been evaluated in patients with HF and depressive symptoms.

Objective: The aims of this study were to: (I) evaluate the effect of a nine-week ICBT program on depressive symptoms in patients with HF; (II) to assess factors associated with the change in depressive symptoms; and (III) to investigate the effect of the ICBT program on cardiac anxiety and QoL.

Methods: Fifty participants were included and randomized into two treatment arms: ICBT or an online moderated discussion forum (DF). The Patient Health Questionnaire -9 (PHQ-9) was used to measure depressive symptoms, the Cardiac Anxiety Questionnaire (CAQ) was used to measure cardiac-related anxiety, and the Minnesota Living with Heart Failure questionnaire (MLHF) was used to measure QoL. Data were collected at baseline and at the nine-week follow-up.

Results: In the ICBT group, depressive symptoms ($M=10.8$ vs. $M=8.6$, $P=.02$) and cardiac anxiety in the subscale of fear ($M=1.55$ vs. $M=1.35$, $P=.04$) improved significantly. QoL improved in the ICBT group by 6 points in the total score and 2.4 points in the physical factor, but this was not significant ($P=.09$ and $P=.12$). In the DF group, only a small reduction in the level of depressive symptoms was detected ($M=10.6$ SD=5.0, vs. $M=9.8$ SD=4.3, $P=.36$). Despite improvement in the ICBT group this was not significantly different compared to the DF group (ANCOVA analyses: depressive symptoms, $P=.21$; cardiac-related anxiety subscale of fear, $P=.22$; QoL total scale score, $P=.09$ and physical factors, $P=.07$). In the ICBT group, the number of logins to the web-portal correlated significantly with improvement in depressive symptoms ($P=.02$), whereas higher age ($P=.01$) and male sex ($P=.048$) were associated with less change in depressive symptoms.

Conclusions: Guided ICBT adapted for persons with HF and depressive symptoms can potentially reduce depressive symptoms, cardiac anxiety and increased QoL, but is not statistically superior to participation in an online discussion forum.

P1692

Social support and adherence to the therapy in patients with heart failure: a systematic review

K Philippou¹; E Lambrinou¹; S Ktisti²; M Kyriakou³; N Middleton¹

¹Nursing Department, Cyprus University of Technology, Limassol, Cyprus; ²Nicosia General Hospital, Intensive Care Unit, Nicosia, Cyprus; ³American Medical Center, American Heart Institute, Nicosia, Cyprus

Purpose: To systematically review trials, examining the role of social support to the adherence to the therapy of patients with heart failure (HF).

Methods: A systematic search of PubMed, Cumulative Index to Nursing and Allied Health Literature (CINAHL) and Cochrane Library, was performed to locate relative randomized controlled trials (RCTs). Search was done from the beginning of December 2015 until the end of December 2015. "Heart failure", "Social support", and "adherence to therapy" were used as key words in various combinations using the word "AND". The tool "related articles" of the PubMed was also used. Inclusion and exclusion criteria were pre-specified. Quality assessment was done by two reviewers separately. The search yielded eight RCTs.

Results: HF patients whose family member followed the low sodium diet (LSD) were 1.6 times more adherent than those, whose family member did not follow the LSD. Patients whose spouse did not adherence the LSD were found to have 804 mg more sodium excretion than those whose spouse was adherent to the LSD ($p=0.012$) and 1139 mg more sodium excretion than those who had a non-spousal family member that was adherence to a LSD ($p=0.015$). The family partnership intervention and the patient-family member education reduced the urine sodium at 4 months and family partnership intervention differed from usual care at 8 months ($p=0.016$). Dietary sodium was found to be decreased from baseline to 4 months for both, patient-family member education ($p=0.04$) and family partnership intervention ($p=0.018$). Medication adherence was not found to be different among groups. The level of social support was related to the level of self-care and the patients with high

level of support stated better self-care ($p=0.003$). The Reciprocal Peer Support and Nurse Care Management groups had no differences in the improvement in 6-month measures, either on HF quality of life or social support. Many HF patients stated that support for exercise was very meaningful and appreciated from family and friends.

Conclusions: Family members' education and encouragement to follow LSD may be beneficial for the self-care of patients with HF. The role of partner, family or social support is also found to be important for patients' participation in physical activity and exercise.

P1693

The effect of therapeutic education on self-care in patients with heart failure and implantable cardioverter defibrillator: study protocol for a randomised controlled trial

A Angela Durante¹; MMG Maria Michela Gianino²; RS Riccardo Sperlinga²; EV Ercole Vellone³

¹G. Salvini Hospital, Passirana-Rho, Italy; ²University of Turin, Turin, Italy;

³University Hospital Policlinico Tor Vergata, Rome, Italy

Background: Therapeutic education has been shown to improve the quality of life of patients with heart disease. However little is known about the effects of a therapeutic education on self-care in patients with heart failure (HF) during the follow-up period after the implantation of implantable cardioverter defibrillator (ICD). This study aims to examine the effect of a nursing educational intervention to improve self-care in HF patients with ICD.

Methods/Design: A multicenter, double-blind, parallel-group randomized trial will be conducted in Italy. A sample size of 128 patients hospitalized for an ICD implantation due to an arrhythmia and/or ischemia will be randomly assigned to the intervention or control group. Intervention group will be undergo to the educational intervention during the first follow-up (10 days from Implantation) and at 3,6,12 months after. The intervention will be focused on: 1) pharmacological adherence, weigh monitoring, how routinely do about diet, smoking, alcohol, job and sex; 2) signs of dyspnea, how to identify the edema through the fovea, how to recognize rapid weight gain, appetite loss, fatigue, asthenia, insomnia, mental confusion; 3) recognition the symptoms of inflammation of the surgical site of implantation. For each control (3, 6, 12 months), the patient will undergo an electrocardiogram. Additionally, between one follow-up visit and another, patients will be undergone to the execution of blood tests, Brain Natriuretic Peptide (BNP), renal function, indices of hepatobiliary stasis and serum protein parameters (creatinine, blood count, ast, alt, albumin, total serum protein). The primary outcomes will be: Self-care levels, measured by Self-Care Heart Failure Index, SCHFI v 6.2 and Quality of life perception measured using a Visual Analogic Scale from 0 to 100. The secondary outcomes are adverse events measured using: incidence of Emergency Department visits and/or hospitalizations at 12 months; mortality rate at 180 days after ICD implantation and infection rate in the ICD device pocket. Randomization is computer-generated, with allocation concealment by opaque sequentially numbered sealed envelopes. Patients and professionals outside of the research team are blinded to group assignment.

Discussion: We expect participants to be compliant with the intervention and therapeutic education to be effective, satisfying and money-saving.

Educational intervention

Items	Actions
1) Appropriate lifestyles 2) Early recognition of signs/prodromal symptoms of HF 3) Early recognition of signs of inflammation of the ICD-pocket 4) Good management of the device	1) how adhering to the therapy such as how weigh yourself and how routinely do about diet, smoking, alcohol, job and sex will be explained and shown; 2) signs of dyspnea will be illustrated; how to identify the edema through the pitting edema, how to recognize rapid weight gain, loss of appetite, fatigue, asthenia, insomnia, mental confusion, will be shown; 3) recognition the symptoms of inflammation (hyperpyrexia, heat, pain, redness and swelling) will be taught even with images illustrating the signs; 4) how to manage the presence of device will be explained simulating multiple situations: use of metal detectors, air travel, use of electronic devices, access to diagnostic imaging services (as PET and MRI)

P1694

Sodium intake by patients with chronic heart failure in relation to hospitalisation for chronic heart failure.

R Ronald Bakker¹; S Kok¹; K De Boer¹

¹VU Medical Center, Cardiology, Amsterdam, Netherlands

Introduction: Sodium restriction is frequently advised for patients with chronic heart failure (CHF) despite the gap of evidence relating to this lifestyle advice.

The European Society of Cardiology (ESC) advises to avoid an excessive intake of salt. The World health Organisation advises a salt intake of 2 grams per day. Previous studies on dietary salt restrictions are often done in combination with a fluid restriction, therefore it is not clear which intervention (the salt or fluid restriction) is responsible for the

Results: In studies based on only a dietary salt restriction, the salt intake was measured via questionnaires or estimated in 24 hours urine collections by a single portion of urine which are both not very reliable. The golden standard for measuring the sodium intake, is to collect 24 hour urine. The result of these studies are variable.

Purpose: The purpose of this study is to investigate the effect on hospitalisation of sodium intake in patients with CHF in functional New York Heart Association (NYHA) class I – III. Primary endpoint is hospitalisation for CHF.

Methods: In this observational study 30 patients were included, 10 in each NYHA class I – III. Sodium intake was measured by collecting 24 hour urine at baseline, 6 months and 12 months. A blood sample was taken (including N-terminal pro-Brain Natriuretic Peptide (NT-proBNP), NYHA class was determined, medication use was asked, quality of life was measured by the Minnesota Living With Heart Failure Questionnaire, and feeling of thirst was measured by a Numeric Rating Scale. During the follow-up visits at 6 months and 12 months, hospitalisation for CHF was also asked.

Results: The majority of the patients was male (90%). Mean age was 66.9 12.3 years (mean \pm SD). (Table 1.) Unto January 2016 (92% of the follow up, which ends in February) 2 patients have withdrawn from the study. Four patients (13%) were hospitalised for CHF of which 3 of them (10%) had <90 mmol sodium in 24 hour urine (is <2 gram salt intake). All were in NYHA class III. Of these 4 patients 2 died and one has withdrawn from the study. On the other hand there were 5 patients (17%) which had <90 mmol sodium in 24 hour urine but were not hospitalised for CHF (2 in NYHA class II and 3 in NYHA class III).

Conclusion: In this small observational study, the preliminary results shows no difference in a low salt intake (<2 gram/day) in relation to hospitalisation for CHF. More research is needed with a greater number of patients.

N	Male	Female	Mean age \pm SD	Age: range
30	90%	10%	66.9 \pm 12.3	37-90 y/o

The role of heart failure nurses in the up-titration of sacubitril/valsartan (LCZ-696)

M Mercedes Faraudo¹; P Beltran¹; R Freixa¹; O Guri¹; J Masip¹

¹ Hospital de Sant Joan Despi-Moises Broggi, Haert Failure Unit, Sant Joan Despi, Spain

Background: Heart failure (HF) nurses (HFN) are the most implicated professionals in HF programs. A recent European survey has shown that 85% of HFN have been trained specifically in HF, nearly 75% of them up-titrate angiotensin converter enzyme inhibitors (ACEI), diuretics and beta-blockers and about 50% up-titrate angiotensin receptors blockers (ARB) and mineralocorticoid receptor antagonists. The standard requirements for an up-titration program are: HFN training, appropriate protocols developed by the HF team, a previous prescription of the drug by HF physicians and their availability for consultation. LCZ 696 is a new drug that has demonstrated to reduce the risk of cardiovascular death and hospitalization of chronic HF patients, with NYHA class II-IV and reduced left ventricular ejection fraction. It should be expected a worldwide prescription of this drug in these patients.

Purpose: To design a protocol for HFN up-titration of LCZ-696

Methods: review of the evidence based literature, the rules of the European Medicine Agency (EMA), European Public Assessment Report (EPAR) summary for the public and risk-management-plan-summary for Sacubitril/Valsartan and finally, the trademark's dosing and titration guide.

Results: The protocol describes how HF nurse could up-titrate LCZ696. On the first visit the physician prescribes the drug, establishes the maximal doses and points out the titration step-up. HFN explains the patient and his relatives the aim of titration, reviews all the pharmaceutical treatment ensuring that ACEI or ARB are not included, recommends the timing for the control of blood pressure (BP) and heart rate, gives a contact phone number and schedules next visit with control of renal function and electrolytes after 2-4 weeks, according to the physician's prescription. On the next visits HFN will check BP and laboratory tests, analyzing the tolerance of the drug, increasing the doses following physician's plan to reach the maximal doses prescribed and tolerated. Special attention will be paid to adverse effects like angioedema, hypotension, hyperkalemia, cough, dizziness and impairment of renal function. In case of detection of any abnormality or doubts, HFN should contact the cardiologist to make decisions about the best therapeutical approach.

Conclusion: The application by HFN of a consensus protocol for LCZ696

up-titration will facilitate HF patients to safely reach the target doses with a reduction in the number of medical visits.

P1696

Healthcare providers' perception of exercise for heart failure patients: a qualitative study

L Linnea Almstedt¹; A Ed¹; T Jaarsma¹; L Klompstra¹; V Yaari²; B Ben Avraham²; T Ben Gal²

¹Linköping University, Linköping, Sweden; ²Rabin Medical Center, Petah Tikva, Israel

Introduction: Although exercise is widely known to be beneficial for patients with heart failure (HF) and is recommended in the ESC guidelines, not all healthcare providers recommend exercise to these patients. It is vital to evaluate and understand the reasons why or why not healthcare providers advise exercise to be able to implement exercise in the rehabilitation for the patients with HF.

Purpose: To gain a deeper understanding of healthcare providers' perception of exercise for HF patients.

Methods: A qualitative study was performed. Interviews with 8 healthcare providers (2 nurses, 3 physicians and 3 physiotherapists) in a university hospital in Israel were conducted. Healthcare providers working with HF patients were asked to participate. The interviews were semi-structured and addressed attitudes, actions and knowledge about exercise for patients with HF. Qualitative content analysis was used to analyse the data.

Results: One overall theme and six categories were found. The overall theme identified was; Exercise for HF patient is important but can be hard and complex with barriers and struggles. The categories found were; 1. Exercise is important for every HF patient because of its beneficial effects; 2. Healthcare providers have several barriers in the recommendation of exercise to HF patients; 3. Exercise can be difficult for a HF patient; 4. How to overcome barriers and get the patients to exercise; 5. Patient motivation is vital and 6. Prescribing exercise in heart failure patients can be complex. The beneficial effects for patients were described as physical, psychological and emotional. The barriers to prescribe exercise included the unstable status and high symptom burden of the patients. Furthermore, participants described that not all healthcare providers are aware of the benefits of exercise and not all have resources to offer an exercise program to their patients. Patients may need different advices, the motivation to do life style changes can be low and there is a lack of clinics specialized in HF rehabilitation. Solutions described on how to overcome the barriers were related to motivating the patients, fit the exercise into daily life or arrange social support.

Conclusion: From the interviews it can be concluded that exercise is perceived an important part of the rehabilitation program for patients with HF because of its beneficial effects. However, the respondents who were specialized in HF identified the complexity to recommend exercise to the patients. It is therefore reasonable to assume that other healthcare providers share the same opinion and education and implementation activities are vital.

P1697

Characteristics of patients in a heart failure unit according to two admission periods: 2001-2008 vs. 2009-2015

B Gonzalez¹; R Cabanes¹; M Rodriguez¹; C Rivas¹; N Benito¹; A Ros¹; M Domingo¹; M De Antonio¹; J Lupon¹; A Bayes-Genis¹

¹Germans Trias i Pujol University Hospital, Badalona, Spain

Background: Heart failure (HF) units and programmes are key in HF management. Advances in HF treatment together with the higher widespread implementation of the HF programmes in the last two decades, and a better in-hospital patient's information and education may have modified the clinical characteristics of patients referred to HF units.

Objective: To compare the clinical characteristics, baseline knowledge and understanding of HF, self-care behaviour and treatments of ambulatory patients referred to a HF Unit of a tertiary university hospital, according to two admission periods.

Patients and Method: Patients were divided in two groups based on their admission date: 2001-2008 (period 1) vs. 2009-2015 (period 2). These periods divide our cohort in two groups of similar size and are grossly related to the pre- and post- definitive implementation of a program of primary coronary intervention for AMI. Patients were evaluated with three questionnaires: an own and previously published nurse questionnaire (knowledge and self-care), the European HF Self-care Behaviour scale (EHFScBS) and the Minnesota Living with Heart Failure Questionnaire (MLWHFQ).

Results: Out of 1921 patients admitted to the HF Unit (960 during the first period and 961 during the second), 1901 patients (946 and 955 respectively) filled in our own nurse questionnaire. Patients of both periods had similar age (66.6 \pm 12.1 vs. 66.9 \pm 13.3, $p=0.58$) and sex (male 70.8% vs. 70.7%, $p=0.95$). Duration of HF tended to be higher in period 1, without reaching statistical significance (median 12 months [IQR 2-48] vs. 6 months [IQR 2-39], $p=0.13$). Knowledge and understanding of the disease were higher in the second period ($p<0.001$), with better awareness of alarm signs ($p<0.001$) and name of prescribed drugs ($p<0.001$), but not better

knowledge of the action of the drugs ($p=0.3$). The EHFSBS was available at first visit in 633 patients during the first period and in 916 during the second. Global score was 24.8 vs. 20.5 ($p<0.001$), respectively. All items except "I take a rest during the day" and "I get a flu shot every year" were significantly better in the second period from the statistical point of view, although mean differences were always less than 1 point on the scale. Perception of quality of life was quite similar from the clinical point of view, although statistically worse in the second period (MLWHFQ 30.8 vs. 32.8, $p=0.03$). Differences in treatments at first visit also differed; among others: different use in beta-blocker (61.3% vs. 79.5%, $p<0.001$), ARM (25% vs. 41.5%, $p=0.001$), ICD (4.2% vs. 8.8%, $p<0.001$), CRT (1.4% vs. 4.6%, $p<0.001$) was observed.

Conclusion: Although of similar age and sex, patients referred to a multidisciplinary HF Unit between the years 2001-2008 and 2009-2015 differed in multiple items at the moment of admission. Knowledge and understanding of the disease and self-care behaviour seem to be better in the second period, but perception of QOL remained similar.

P1698

Supporting patient's decision making: putting patients in the driving seat

Heart Failure Association of the European Society of Cardiology

SP Sophie Penelope Welch¹; AR Lyon¹; JP Riley¹

¹Imperial College London, London, United Kingdom

Background: Developments in biomedical science and advanced heart failure treatments have resulted in patients facing complex healthcare decisions at different stages in the disease trajectory. Shared decision-making, with its emphasis on patient-centred care, has emerged as a major driver in healthcare policy. Its aim is to empower patients to enable them to be involved in decision-making. This approach requires a partnership between patients and professionals, and the sharing of information. To provide effective support, professionals need an increased understanding of the influences on how patients' make healthcare decisions.

Purpose: To explore patients' decision-making in their heart failure management.

Method:

A qualitative study using semi-structured interviews with patients recruited from a specialist hospital in the UK who were taking part in a study of gene therapy in advanced heart failure. These data were analysed using thematic analysis.

Results: Nine patients with a mean age of 57 years (34 to 74 years), 7 (77%) male, 3 (33%) lived alone, and 5 (55%) symptomatic on mild exertion (NYHA III). Here we report on 3 major themes: symptom relief, "burden" of treatment and information sourcing. Patients' experience of symptom relief influenced their beliefs about their heart failure management. Patients (5 (55%)) who experienced immediate symptom relief from a 'one off' invasive intervention (such as PCI) described a value to these treatments. However, they did not describe the same value to 'ongoing' treatments (such as medication) and where they did not experience an immediate improvement in their functional ability. Patients' decisions were influenced by information from friends, more than professionals and by information that validated their own views. No patient demonstrated understanding of treatment based on heart failure aetiology or LVEF. We noted no difference with age, gender and disease trajectory, but the major limitation was small numbers.

Conclusion: Factors that influence patients' health decisions differ according to the impact of the treatment and its ongoing monitoring on their daily life. Patients' decision-making was influenced by friends, symptom relief and treatment burden. These findings have important implications for the way in which professionals provide information about different treatment options and work with patients to support their decision-making. Further exploration in a larger sample and at different stages in the disease progression are required to confirm these provisional findings.

the subjects studied. Bicuspid aortic valve was the next most common diagnosis accounting for 0.5 % of our findings.

Conclusion: Normal echocardiogram was the commonest echocardiographic finding. 2.34 % was the prevalence of congenital heart diseases and mitral valve prolapse was the commonest congenital heart disease detected.

The common echocardiographic findings

Type of echocardiography abnormality	No. of subjects	Percentage of subjects
Mitral valve prolapse	7	1.5%
Bicuspid aortic valve	2	0.5%
Aortic valve prolapse	2	0.5%

Bicuspid aortic valve

Trajectory and predominant diagnoses of readmissions after hospitalization for heart failure

J T Niedziela¹; D Pres¹; P Rozentryt¹; J Nowak¹; Z Kalarus²; W Wojakowski³; K Mizia-Steć³; Z Gasior²; L Polonski¹; M Gasior¹

¹Medical University of Silesia, 3rd Department of Cardiology, SMDZ in Zabrze, Katowice, Poland; ²Medical University of Silesia, Department of Cardiology, Congenital Heart Diseases, and Electrotherapy, SMDZ in Zabrze, Katowice, Poland; ³Medical University of Silesia, 3rd Department of Cardiology, Katowice, Poland

Background: Despite the great progress of medicine, the medical and economic problem of heart failure (HF) continue unabated. HF is associated with high mortality and rehospitalization rates. Hospital readmissions worsen patients' quality of life and generates a significant financial burden for the health care system. Aim The aim of the study was to analyze the magnitude, trajectory and cardiovascular causes of 1-year readmissions after heart failure hospitalizations.

Methods: The study is a retrospective analysis of all first-time HF hospitalizations reported by 310 Silesian hospitals to the Polish National Health Fund from 2006 to 2014. The HF hospitalizations were selected when any of I50 or I42 or R57 codes according to the International Classification of Diseases (ICD-10) were reported as a main disease at hospital discharge. The main ICD-10 codes of readmissions during following 1-year were obtained, as well as time since discharge to the first any-cause readmission. Results Throughout 9 years (from 2006 to 2014) the 92,348 hospitalizations due to HF were reported. The annual number of 1-year readmissions after hospitalization for heart failure varied between 47.3% and 50.2% across the years. The distribution of readmissions during the first year after hospital discharge was shown on Figure. More than 50% of 1-year readmissions were noted in the first 3 months after discharge. The most frequent causes of readmissions were presented in the Table, with HF as a leading diagnosis (26.8%). Non-cardiovascular diagnosis was found in 42.9% of readmissions. Conclusions The risk of 1-year readmission after hospitalization for heart failure remains high, with more than a half events in the first 3 months after discharge. The predominant diagnoses were heart failure and coronary artery disease.

2.34% is the prevalence of congenital heart diseases in pre-employment echocardiography studies in egyptian adults

A Ahmed Al-Habbab¹

¹Al-Azhar University, Department of Cardiology, Cairo, Egypt

Objectives: We investigated the prevalence of congenital heart diseases in pre-employment echocardiography in Egyptian adults.

Patients and methods: The study included 469 peoples referred for pre-employment echocardiographic assessment for detection of any abnormalities in cardiac structure or function. All subjects had been subjected to the following: informed consent, routine medical screening, chest X-ray, laboratory tests and transthoracic echocardiography assessment.

Results: A total of 469 subjects were examined, comprising of 316 males (67.38 %) and 153 females (32.62 %), the age range of the subjects was 20 - 50 years (mean 27 ± 7.45 years). The echocardiogram was normal in 96.2 % of the subjects. The commonest abnormality detected was mitral valve prolapse, accounting 1.5 % of

Background: Heart failure (HF) Clinics are key in HF management. Its implementation has become widespread in the past two decades. Advances in drug therapy, devices and coronary revascularization –mainly with the advent of primary percutaneous coronary intervention (PCI)– have become widespread.

Objective: To compare the clinical characteristics, treatment and baseline knowledge and self-care of ambulatory patients referred to a HF Clinic of a tertiary university hospital in two admission periods.

Patients and Method: Patients were divided in two groups based on their admission date: 2001–2008 (pre primary PCI period: pre-PPCI) vs. 2009–2015 (primary PCI period: PPCI). A regional STEMI network was implanted in Catalonia in the year 2009 (the “Codi IAM” network), which prioritized primary PCI in STEMI.

Results: 1921 patients were admitted to the HF Clinic: 960 in pre-PPCI period and 961 in PPCI period. Patients of both periods had similar age (66.7 ± 12.1 vs. 66.9 ± 13.3 , $p = 0.73$) and sex (male 70.9% vs. 70.7%, $p = 0.89$). HF duration tended to be higher in pre-PPCI, without reaching statistical significance (median 12 months [IQR 2–48] vs. 6 months [IQR 2–39], $p = 0.1$). We found significant differences in HF aetiology: less ischemic 55.5% vs. 45.8%, $p < 0.001$, and more DCM 9.5% vs. 16.5%, $p < 0.001$ in the PPCI period. Patients with a previous AMI also decreased: 49% vs. 32.3%, $p < 0.001$. Patients in pre-PPCI period were in worse NYHA functional class (III/IV 39.3% vs. 22.9%, $p < 0.001$) and had slightly lower LVEF (32.8% vs. 34.9%, $p = 0.001$). Baseline treatments also significantly differed: beta-blocker use (61.3% vs. 79.5%, $p < 0.001$), ARM (25% vs. 41.5%, $p = 0.001$), ICD (4.2% vs. 8.8%, $p < 0.001$), CRT (1.4% vs. 4.6%, $p < 0.001$) were significantly higher in the PPCI period. Self-care behaviour improved in PPCI patients according to the EHF-ScBS (24.8 vs. 20.5, $p < 0.001$), while perception of quality of life did not (MLWHFQ 30.8 vs. 32.8, $p = 0.03$).

Conclusion: Patients referred to a multidisciplinary HF Clinic between the years 2001–2008 (pre-PPCI period) and 2009–2015 (PPCI period) differed in multiple items. Lower ischemic aetiology and AMI history may reflex, at least in part, the implementation of a network for the treatment of STEMI using PPCI.

P1702

The incidence of diabetes mellitus type II in patients with acute coronary syndromes in an urban population during the last decade

A Alexios Samentzas¹; D Papadimitriou¹; D Papasaikas¹; G Sionis¹; G Papagiannis¹; A Paschalis¹; P Stougiannos¹; A Zikos¹; A Trikas¹

¹Elpis General Hospital, CARDIOLOGY, Athens, Greece

Introduction: Diabetes mellitus type II (DMtII) has an increasing incidence worldwide, while diabetic patients emerge an increased risk for acute coronary syndromes (ACS). Coronary disease is responsible for the 70–80% of deaths in diabetic patients, while 50% of newly diagnosed diabetics already have cardiovascular disease.

Purpose: The purpose of the present study was to evaluate the incidence of DMtII in men and women with ACS. The evaluation of this incidence bears both a scientific and social interest taking the fact that the study data were retrieved from the cardiology department of a central Hospital during the period of financial crisis (2008–2012).

Methods: This retrospective study included both male and female patients who were admitted in the cardiology department of a general hospital for ACS (acute myocardial infarction, unstable angina) during the last decade (2003–2012). The emergence of DMtII was also evaluated in both males and females.

Results: A total number of 7280 patients were admitted in the cardiology department of a general hospital between 2003 and 2012 of which 3918 were men and 3362 were women. Among the total male patients 1210 were admitted due to ACS and 362 of them had already been diagnosed with DMtII. Among the total female patients 724 were admitted with ACS and 298 of them were diabetic. The above results are demonstrated on Table 1.

Conclusions: The above results indicate a high percentage of coexistence of DMtII and ACS in both male and female, but the coexistence is more prevalent in men (41%) compared to women (30%) ($p < 0.005$). These observations underline the importance of DMtII as a major risk factor for ACS.

A retrospective evaluation of the incidence of DMtII in ACS patients in the financial crisis period compared to precrisis period was also performed and showed an increased incidence of coexistence of the two syndromes during the crisis period especially in males ($P < 0.01$)

TABLE 1

	ACS	ACS+DMtII
MALE	1210	362
FEMALE	724	298
MALE+FEMALE	1934	660

ACS: acute coronary syndromes, DMtII: diabetes mellitus type II

P1703

Effect of heart failure prevention strategy on lifestyle behaviour

SI James¹; E Tallon²; D Connell²; E O'Connell²; MD Wilkinson¹; C Watson³; J Gallagher²; M Ledwidge²; K McDonald¹

¹St Vincent's University Hospital, Cardiology, Dublin, Ireland; ²Heart Beat Trust, Dublin, Ireland; ³Conway Institute, Dublin, Ireland

Introduction: The St Vincent's Screening To Prevent Heart Failure (STOP-HF) Programme has shown the clinical effectiveness of a HF prevention strategy in individuals at risk for HF. The strategy has proven to be cost effective. Reduction in the cardiovascular and HF endpoints was in part attributed to the use of RAAS modifying in the strategy. Beneficial lifestyle adjustment behaviour might add additional explanation to the success of the STOP-HF Programme. However, the impact of the strategy on lifestyle factors had not been fully examined. Thus, we aim to assess the lifestyle behaviour in the STOP-HF Programme. Method: 739 at risk individuals attending the STOP-HF Programme were included in this analysis. The demographic, characteristic, biomarkers and lifestyle behaviour were recorded. The lifestyle behaviour questionnaires were collected at two-time points, year 2004 and 2010, included smoking, alcohol intake, salt intake, 30-minute walk, and exercise habits. The exercise habit was reported as intensity of exercise by multiplying the frequency with level of exercise. Frequency is determined as times in a week of minimum 20-minute exercise. Level of exercise is graded as 1 (mild), 1.5 (moderate) and 2.5 (strenuous). Comparison within and between study arms was calculated according to appropriate statistical analysis.

Results: 350 (65.99 years; 44.86% male) were in control arm and 389 (63.68 years; 54.76% male) in intervention arm. The dominant co-morbidities were hypertension (71.71% vs. 69.67%), ischaemic heart disease (33.72% vs. 36.25%), diabetes mellitus (13.71% vs. 13.11%), and atrial fibrillation (10.57% vs. 12.85%). The BP (144/80mmHg vs. 143/82mmHg), BMI (27 vs. 27), and abdominal girth (38.5inch vs. 39inch) were similar at baseline. Level of BNP (21pg/ml vs. 22pg/ml), cholesterol (5mmol/L vs. 5mmol/L), LDL (2.65 mmol/L vs. 2.6mmol/L) and HDL (1.28mmol/L vs. 1.26mmol/L) were similar. The reduction of total cigarette per day within the intervention arm (-1.47 ± 7.929 ; $p = 0.0295$) was significant compared to control arm (-0.476 ± 5.934 ; $p = 0.5964$). Both control arm (1.238 ± 7.89 ; $p = 0.0063$) and intervention arm (1.257 ± 0.002 ; $p = 0.002$) showed significant increase in exercise intensity. The 30-minute walk habit did not significantly change within each study arms (-0.1466 ± 3.081 vs. 0.0842 ± 3.351). There were non-significant reduction of total alcohol intake per week in both control arm (-2.041 ± 21.19) and intervention arm (-0.1277 ± 11.87). The change of salt habit at table and during cooking also was not significant.

Conclusion: These data demonstrated that despite promising significant changes of reduction in smoking habit and increase in exercise intensity within each study arm, the between study arm changes are not significant. The alcohol intake, salt intake, and 30-minute walk habits did not change significantly. These observations support the initial inference of RAAS modifying therapies role in the positive clinical outcome of STOP-HF Programme.

P1704

Chronic heart failure and medication adherence in elderly patients: results from heart failure unit, mohamed the 6th university hospital, marrakech, morocco

M Mounia Khramaz¹; M Elhattaoui¹; S Elkari¹; D Benzeroual¹

¹Marrakech University Hospital, Cardiology, Marrakech, Morocco

Background: All research are focusing on the causes and treatment of heart failure, but the variables identifying factors contributing to manage medication are not routinely assessed. This study was conducted to evaluate the factors affecting medication adherence in elderly patients with chronic heart failure.

Method: We prospectively evaluated 100 patients, 65 years or older that had been seen with documented congestive heart failure. We included patients who had been taking heart failure medication for longer than 6 months and who were treated at our medical institution for longer than 6 months. Each patient completed a structured questionnaire and an interview survey with same examiner who asked questions and recorded the answers. Therapeutic adherence means that the patient observes the medical recommendations, taking the medication, and maintaining a lifestyle as recommended by his clinician. In our study, we focused on medication adherence.

Results: The frequency of medication non-adherence in elderly patients was high (75%). The results showed that daily number of drugs were associated with medication adherence. The medication adherence was significantly lower in patients whose financial state were lower and higher in cases of proper drug storage and in patients with higher self-efficacy (83%), and in case of recognition of the seriousness of heart failure complications. Both poor cognition (Using Mini Mental State) and low education were significantly associated with non-adherence. Among patients, 14% were readmitted within 90 days after discharged for recurrent heart failure. Conclusion : Medication non-adherence lowers the effectiveness of treatments and raises medical costs. Different strategies should be used to increase medication adherence in geriatric heart failure patients, depending on institutions whether they are treated.

P1705

External validation of the Redin-SCORE in a contemporary cohort of outpatients with advanced heart failure

This work was supported by Red de Investigación Cardiovascular (RD12/0042/0002), Instituto de Salud Carlos III and FEDER (J. Alvarez-Garcia¹; E. Eduard Sole Gonzalez¹; A. Ferrero-Gregori²; S. Mirabet Perez¹; V. Brossa Loidi¹; J. Sanchez Vega¹; N. Mesado Batalla¹; MJ. Pirla Buxo¹; J. Cinca Cusculola¹; E. Roig Minguell¹

¹Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain; ²Hospital de la Santa Creu i Sant Pau, Epidemiology Department, Barcelona, Spain

Background: There are many tools to stratify the prognosis of patients with heart failure (HF), however most of them are not usually validated in other populations to prove their real clinical utility. Recently, the Redin-SCORE was proposed to predict 1-month and 1-year risk of HF-readmission of ambulatory patients.

Purpose: To validate the Redin-SCORE in a contemporary cohort of outpatients with advanced HF.

Methods: A cohort of 240 ambulatory patients with HF was prospectively followed in a tertiary HF clinic during the 2012-2014 period. The discrimination ability was validated using the C-statistics. The Redin-SCORE used six variables: left signs of HF, heart rate higher than 70 beats/min, hemoglobin less than 120/130 g/L (women/men), NT-ProBNP higher than 1000 ng/L, estimated GFR less than 60 ml/min/m² and atrial size higher than 26 mm/m².

Results: Table resumes the main characteristics of both populations. Compared with the Redin-SCORE sample, patients of the validation group showed: a) less history of ischemic heart disease, b) less prevalence of diabetes, c) higher rates of atrial fibrillation, and d) better left ventricular ejection fraction. The 1-month (5.4 vs 3.1%; $p=0.055$) and 1-year (29.5 vs 16.9%; $p<0.001$) HF readmission rates were higher in the validation cohort, but only the last reached statistically significant difference. The C-statistics for 1-month and 1-year risk remained consistent after the application of homogeneity test (0.77 vs 0.72, $p=0.477$; 0.70 vs 0.66, $p=0.417$, respectively).

Conclusions: The Redin-SCORE is a useful tool to predict the short- and long-term risk of HF-readmission after the external validation in a more complex cohort of advanced HF outpatients.

Clinical characteristics

	Redin-SCORE (n = 2507)	Validation cohort (n = 240)	p-value
Age, years	66.7 (12.9)	66.6 (13.3)	0.911
Male, n (%)	1731 (69%)	165 (69%)	0.924
Ischemic heart disease, n (%)	1192 (48%)	76 (32%)	<0.001
Hypertension, n (%)	1700 (68%)	175 (73%)	0.132
Diabetes, n (%)	1058 (42%)	85 (35%)	0.037
Atrial fibrillation, n (%)	589 (24%)	91 (38%)	<0.001
Estimated GFR<60 ml/min/m ² , n (%)	1127 (45%)	105 (44%)	0.704
III NYHA class, n (%)	983 (39%)	99 (41%)	0.537
LVEF, mean (SD)	35.7 (14.6)	40.6 (17.2)	<0.001

Clinical characteristics and outcomes of young adults hospitalised with heart failure in Asia

M R Michael Macdonald¹; S. Lee¹; DM Yang¹; Y. Cao¹; K. Wong¹; KL Tong¹; KT Leong¹

¹Changi General Hospital, Cardiology, Singapore, Singapore

Introduction: Our understanding of heart failure (HF) in younger patients is limited. No previous studies have examined the demographics and outcomes of young Asian adults with HF.

Purpose: This study sought to compare the characteristics and outcomes of young versus old Asian adults hospitalised with HF. Methods: We prospectively collected data on 1828 consecutive admissions with a primary diagnosis of HF to an urban hospital from 2010 to 2013. Diagnosis of HF was based on Framingham criteria and NTproBNP. All hospitalisations and deaths within 1 year were recorded. Patients were categorised into 4 age groups: <50, 51-65, 66-76, >75. Means were compared with a t-test and proportions with a z-test. Results: The youngest patients (<50 years of age) were more likely to be male and of Malay ethnicity. Younger patients had fewer comorbidities than their older counterparts. On admission, younger patients were more likely to have paroxysmal nocturnal dyspnea and orthopnea, but less likely to have rales than older patients. Left ventricular ejection fraction and NTproBNP were lowest in the youngest group at (27% vs 42%, $p<0.05$) and (5272 v 6958pg/ml, $p<0.05$) respectively. At 1 year, HF readmission rate was similar in all age

groups. Increasing age was associated with a greater burden of non cardiovascular (CV) admissions and higher mortality.

Conclusions: Young Asian patients show marked differences in symptoms and signs of HF compared with their older counterparts. Despite younger patients having lower rates of 1 year mortality and non-CV readmission, all age groups had similar rates of HF hospitalisation at 1 year, this disparity warrants further investigation.

Characteristics and outcomes

	≤50 years (n = 168)	51-65 years (n = 547)	66-75 years (n = 430)	> 75 years (n = 683)	p-value (≤50 vs > 75)
Female (%)	26.2	22.5	41.2	58.7	< 0.05
Chinese (%)	46.4	45.7	59.3	66.2	< 0.05

Trends in heart failure hospitalizations, patient characteristics, in-hospital and 1-year mortality: a population study, from 2000 to 2012.

Italian Ministry of Health grant, RF 2009-1483329, and Lombardy Region M. Frigerio¹; S. Scavini²; O. Agostoni³; C. Mazzali⁴; P. Barbieri⁵; F. Ieva⁶; M. Maistrello⁷; C. Masella⁴; AM. Paganoni⁸; L. Merlino⁹

¹Niguarda Ca' Granda Hospital, "De Gasperi" CardioCenter, Milan, Italy; ²IRCCS "Salvatore Maugeri" Foundation, Lumezzane, Italy; ³San Carlo Hospital, Cardiology, Milan, Italy; ⁴Milan Polytechnic, Dept. of Management Economics and Industrial Engineering, Milan, Italy; ⁵Uboldo Hospital, Cardiology, Melegnano, Italy; ⁶University of Milan, "F. Enriques" Dept. of Mathematics, Milan, Italy; ⁷Uboldo Hospital, Melegnano, Italy; ⁸Milan Polytechnic, Dept. of Mathematics, Milan, Italy; ⁹Region of Lombardy, Directorate of Welfare, Milan, Italy

Background: Heart failure (HF) is the main medical cause for hospital admission. This study was undertaken to evaluate trends in HF hospitalizations (HFH), in-hospital and 1-year mortality, across 13 years in the largest Italian region.

Methods: Hospital discharge forms recorded in the regional healthcare system database from 2000 to 2012, with HF-related diagnosis according to the Agency for Healthcare Research and Quality (AHRQ) and/or to the Center for Medicare/Medicaid Services, Hierarchical Condition Categories (CMS-HCC) criteria, were analyzed with respect to age (y, 18-74; 75-84; 85+) and gender. Based on the combination of all ICD-9 CM codes, three Groups (G) were identified: in summary, G1 included most acute HF episodes with primary cardiac diagnosis; G2, included primary/secondary cardiomyopathy without acute HF codes; G3 included mixed non-cardiac conditions with HF as secondary diagnosis. Pts experiencing an HFH since 2005 without prior (2000 to 2004) admissions were analyzed as incident cases.

Results: 699797 HFH occurring in 370538 adults were evaluated. Regarding all HFH episodes, 70% were classified as G1, 17% as G2, and 13% as G3. Groups were different in terms of gender (F 34% in G2 vs 50% in G1 and 51% in G3, $p<.0001$) and age (mean age G1: F 80 ± 10, M 74 ± 11y; G2: F 73 ± 13, M 69 ± 12y; G3: F 82 ± 9, M 77 ± 10y, $p<.0001$ both for F and M). Annual HFH number (average 53830) and in-hospital mortality (9.4%) did not change over the years, the latter being associated with age (M: 18-74y, 5.19%; 75-84y, 10.07%; 85+y, 17.54%, $p<.0001$; F: 18-74y, 5.19%; 75-84y, 8.87%; 85+y: 15.18%, $p<.0001$) and with diagnosis Group (G1 9.1%, G2 5.6%, G3 15.9%, $p<.0001$). One-year mortality (28.4%) was also stable over time. New, incident cases from 2005 to 2012 were 216782 (F 51%, M 49%), with decreasing incidence (3.62 [IC 3.58-3.67] to 3.13 [IC 3.09-3.17] per 1000 adult inhabitants/y, $p<.0001$), and with higher proportion of 85+y pts (22.3% to 31.4%, $p<.0001$, Cochran-Armitage trend test) over the years. Among incident cases, distribution of diagnosis Groups and differences between Groups in terms

of gender, age, and in-hospital mortality paralleled those observed in all the hospitalizations, 2000 to 2012. However, mortality lowered over time in 18-74y incident cases, both in-hospital (5.15% to 4.36%, $p < .0001$) and at 1-year (14.8% to 12.9%, $p = .0006$, Cochran-Armitage trend test). Inferences. While the overall burden and short to mid term mortality of HFH appear stable over the years, the analysis of incident cases, 2005 to 2012, shows favourable changes: lower incidence, higher age at first hospitalization, and higher discharge rate and 1-y survival in pts aged 18-74y, possibly reflecting improvements in heart failure prevention and management both in the acute and chronic setting.

P1708

Poor heart failure epidemiology knowledge due to incomplete clinical diagnosis at discharge. Analysis of administrative data of a nationwide population

A Esteban¹; RBF Ramon Bover Freire²; C Fernandez³; J Elola⁴; JL Bernal⁵; JV Segura⁶; V Bertomeu⁷; I Vilacosta²; C Macaya²
¹Hospital Clinic San Carlos, Instituto de Investigación Sanitaria San Carlos, Madrid, Spain; ²Hospital Clinic San Carlos, Madrid, Spain; ³Hospital Clinic San Carlos, Preventive Medicine, Madrid, Spain; ⁴Hospital Clinic San Carlos, Foundation Institute for Healthcare Improvement, Madrid, Spain; ⁵University Hospital 12 de Octubre, Control Management Service, Madrid, Spain; ⁶IUI Operative Research Center, Miguel Hernández University, This author is partially supported by Ministerio de Economía y Competitividad of Spain (Grant N°. MT, Alicante, Spain; ⁷University Hospital San Juan de Alicante, Cardiology, Alicante, Spain

Introduction: Heart failure (HF) is a common diagnosis in hospital, whose correct encoding at discharge (primary and secondary diagnoses) is relevant to obtain accurate epidemiological information, which could improve HF knowledge and management.

Purpose: To evaluate the current HF encoding quality in all hospitals in Spain. **Methods:** All the discharges from Spanish hospitals corresponding to 2012-2013 with a primary diagnosis of HF, according to the ICD-9-CM classification were analyzed. HF was encoded as: systolic (HF-ref), diastolic (HF-pef), systolic and diastolic (HF-both), hypertensive disease with HF (HF-hyp) and HF unspecified (HF-uns). We also considered the departments where patients were admitted: Cardiology, Internal Medicine, Geriatrics, Emergency service and others.

Results: 400,861 hospital admissions were recorded, 77,652 with HF as primary diagnosis. The frequency of each diagnosis was: 59,531 HF-uns (76.7%), 11,581 HF-hyp (14.9%), 4,241 HF-ref (5.5%), 1,752 HF-pef (2.3%) and 547 HF-both (0.7%). HF admissions were mainly in Internal Medicine (60.08%), and then Cardiology (21.51%), Emergencies (7.29%), Geriatrics (3.36%) and other services (7.76%). HF accounts for 14.3% and 48.73% of all cardiovascular diagnoses at discharged in Cardiology and Internal Medicine, respectively, and up to 61.28% in Geriatrics and 61.35% in Emergencies. Surprisingly, 47.3% and 45.8% of HF-ref as primary or secondary diagnosis was established at discharged in Cardiology and Internal Medicine, respectively, which shows a homogeneous distribution of these patients in the two specialties. In contrast, only 22.9% of HF-pef diagnoses came from Cardiology vs. 65.4% from Internal Medicine.

Conclusions: The inaccurate HF diagnosis at discharge leads to an unacceptable high percentage of HF unspecified codification. Cardiology and Internal Medicine have almost the same proportion of total HF-ref diagnoses.

EXERCISE TESTING & TRAINING

P1709

Motivation and daily physical activity in heart failure patients - a cross sectional pilot study

A Anna Ed¹; L Almstedt¹; T Jaarsma¹; L Klompstra¹; V Yaari²; B Ben Avraham²; T Ben Gal²

¹Linköping University, Linköping, Sweden; ²Rabin Medical Center, Cardiology Department, Petah Tikva, Israel

Background: Patients with heart failure (HF) might find it difficult to perform physical activity. One reason for physical inactivity is different barriers that the patients need to overcome to get a more active lifestyle. One of the barriers is lack of motivation. Motivation includes advice from healthcare workers, influence from the family, physical and motoric improvement, health benefits and psychosocial reasons.

Purpose: The aim of this study was to investigate motivation and exercise capacity in HF patients. **Methods:** A cross-sectional explorative study was conducted in a university hospital in Israel, including 18 HF patients (mean age 60, 72% male, 56 % NYHA class \geq II, mean ejection fraction 31%). To measure motivation towards physical activity, the Exercise Motivation Index Questionnaire was used which is a valid and reliable tool for investigating how the patient is influenced by different motivation to exercise, such as physical, psychological and social aspects. Scores

range from 0 to 4, where a score of 3-4 is considered as high motivation. Data on steps walked was collected using an activity monitor. **Results:** The motivation "I want to be healthier and perhaps live longer" was high rated by all patients (100%) and "I want to develop stamina and feel strong" was reported by 89% of the patients. "Working out in groups or with others is fun" had the lowest rate, rated by 39% of the patients as a high motivation. The motivations are divided in three different subscales and a total motivation. Physical motivation was the most important motivation for the patients, with a score within the range of high motivation (score 3,35). The least important motivation was the social motivation (score 2,58), with a score below the range of high motivation. There is a strong negative correlation between social motivation and total amount of steps walked ($r = -0.91$, $p = 0.03$).

Conclusions: The most important motivation for the patients to perform physical activity is to become healthier and live longer as well as to feel stronger and develop stamina. They also consider it important to have more control over their lives. These results need to be confirmed in a larger study, however they can be seen as a first step in the development of future intervention to motivate HF patients to be active.

P1710

Effects of aerobic interval training on quality of life and on exercise capacity in patients with heart failure and CRT

T Tatiana Lelyavina¹; MYU Sitnikova¹; VL Galenko¹

¹Almazov Federal Center of Heart Blood & Endocrinology, Saint Petersburg, Russian Federation

To evaluate the long-term effects of aerobic interval training on quality of life and on exercise capacity in patients with ischaemic heart failure and CRT. **Methods:** 58 patients were enrolled, 30 pts- in the aerobic training group (TG) and 28 pts - in control group (GP). 30 patients with ischaemic heart failure and CRT performed 24-month individualized aerobic training program. All patients performed a symptom-limited cardiopulmonary exercise test (CPET) on a treadmill with gas exchange system "Oxycon Pro" (Germany) initially and after 24 months. We measured oxygen uptake at exercise peak (VO2peak). All patients were evaluated with the MLHFQ at baseline and in 24 months.

Results: At baseline VO2peak were similar in TG and CG, 13.5 ± 0.9 ml/min/kg and 13.6 ± 1.2 ml/min/kg, respectively ($p_{VO2peakTG-CG} = 0.09$). Also at baseline MLHFQ scores in both groups not differ, 64 ± 1.3 and 62 ± 2.0 ml/min/kg, respectively ($p_{VO2peakTG-CG} = 0.07$). Patients of TG were trained 40 minutes every day on treadmill with individualized exercise intensity, every month after control CPET exercise intensity was increased gradually. Before and after training 5 minutes morning exercises were made. After 24 months VO2peak and MLHFQ scores were better in TG than in CG. VO2peak in 24 months were 21.5 ± 1.1 ml/min/kg and 14.6 ± 1.2 ml/min/kg, respectively ($p_{MLHFQTG-CG} < 0.01$). MLHFQ scores in 24 months were 43.2 ± 2.5 and 55.6 ± 2.8 respectively ($p_{MLHFQTG-CG} < 0.01$).

Conclusions: Participation in a 24-month individualized aerobic training program resulted in significant improvements in exercise capacity and quality of life in patients with ischaemic heart failure and CRT.

Predictors of low functional capacity in moderate-severe left ventricular systolic dysfunction patients included in a cardiac rehabilitation program.

O Oscar Gonzalez Fernandez¹; P Meras Colunga¹; V Rial Baston¹; J Irazusta Cordoba¹; R Dalmáu Gonzalez-Gallarza¹; C Alvarez Ortega¹; R Mori Junco¹; I Ponz De Antonio¹; A Castro Conde¹; JL Lopez Sendon¹

¹University Hospital La Paz, Cardiology, Madrid, Spain

Introduction: Cardiac rehabilitation programs (CRPs) in left ventricular systolic dysfunction (LVSD) patients (p.) provide optimal medical treatment (OMT), close monitoring, exercise, education and counselling. LVSD has been considered an important predictor of low functional capacity (FC). Our purpose was to describe predictors of low FC in moderate-severe LVSD p. performing a CRP.

Methods: We made an observational retrospective study including p. with moderate-severe LVSD admitted to a CRP between 2006 and 2015. Physical training, OMT, medical counselling, education, and smoking cessation support, were supplied for 8 to 10 weeks. Left ventricular ejection fraction (LVEF) was assessed before and after the program using TTE. FC was tested before and after the CRP in accordance with the NYHA Classification, besides a treadmill stress test (TST). Exercise capacity (EC) was reported in METs.

Results: A total of 298 p. were included, mean age 58.1 ± 11.2 years, male 89.6%. Baseline characteristics are shown in graphic 1. In most p. (91.2%), cardiac rehabilitation was due to a recent acute coronary syndrome. No statistically significant differences depending on the previous cardiovascular risk factors (CVRf) and comorbidities among moderate (LVEF 30-40%) and severe (<30%) LVSD p. were found. Medical therapy when starting the program showed a significantly higher use of MRAs, diuretics and anticoagulants in severe than moderate LVSD p. ($p = 0.007$, $p < 0.001$, $p = 0.032$; respectively), with no other differences among them. FC assessed by NYHA class, considering class I vs class II or III p., revealed significant differences in hypertension, diabetes and current smoking. Severe LVSD p. had a

higher NYHA class than moderate LVSD p. before(II-III: 74.1% vs 46.4%; $p < 0.001$) and after the program(41.5% vs 17.3%; $p < 0.001$). NYHA II or III was associated with a higher prevalence of comorbidities: chronic pulmonary obstructive disease(CPOD), cerebrovascular disease(CD) and peripheral artery disease(PAD). P. who had low EC(<7 METs) had significantly more CVRF. Severe LVSD p. had a lower EC than moderate LVSD p. before(5.7 ± 2.8 vs 6.9 ± 2.6 ; $p < 0.001$) and after the CPR(9.4 ± 2.8 vs 10.4 ± 2.7 ; $p = 0.008$). Regarding comorbidities, a worst EC was associated with a higher prevalence of chronic kidney disease, CD and a non-significant trend of CPOD. The dropout rate was superior in p. with low EC(13.9% vs 5.6%; $p = 0.027$), not depending on NYHA(8.9% vs 10.9%, NS).

Conclusions: Severe LVSD p. included in a CRP have a lower FC and EC than moderate LVSD p.. Previous CVRF and comorbidities in moderate and severe LVSD p. associate a lower FC and EC regardless of their LVEF.

CVRFs and comorbidities prevalence

P1712

Predictors of post-rehabilitation exercise capacity in heart failure patients

T Tatiana Lelyavina¹; MYU Sitnikova¹; VL Galenko¹

¹Almazov Federal Center of Heart Blood & Endocrinology, Saint Petersburg, Russian Federation

The aim of this study was to determine predictors of exercise capacity after exercise training rehabilitation in heart failure patients. Methods. We evaluated 85 hospitalized patients 41-68 years old, mean age 53 ± 1.8 , 65 men, with HF NYHA class III, ejection fraction (LVEF) $40.8 \pm 0.3\%$. All patients performed a symptom-limited cardiopulmonary exercise test (CPET) on a treadmill with gas exchange system "Oxycon Pro" (Jaeger, Germany) initially and after 6 months. We measured oxygen uptake at lactate threshold (VO₂LT), pH-threshold (VO₂pH-T) and at exercise peak (VO₂peak). The cubital venous catheter was installed in all subjects before exercise test. Blood samples were taken at baseline and at 1-minute intervals during test. PH, lactate and HCO₃- concentration were estimated using analyzer i-STAT, cartridge CG4 (Abbott, USA). Lactate threshold (LT) and pH-threshold (pH-T) were determined by changes in pH and lactate levels in correlation with dynamics of oxygen uptake (VO₂), carbon dioxide output (VCO₂), minute ventilation (VE), ventilatory equivalent of carbon dioxide (VE/VCO₂), respiratory exchange ratio (RER). All patients underwent physical rehabilitation program (PRP), calculated based on individualized approach of exercise physiological stages: lactate threshold and pH-threshold, that characterized the biological reserves of adaptation to physical activity. Meta-regression used to assess the association between exercise capacity and various factors.

Results: Variants, such: age, aetiology of heart failure, diabetes, ACE-inhibitors and β -blockers therapy, tachycardia, low blood pressure, low body mass index, marked elevation of BNP, creatinin, bilirubin, anemia, hyponatriemia, low left ventricular ejection fraction, restrictive mitral filling pattern had no influence on exercise capacity after physical rehabilitation. MLHFQ score at baseline ($p < 0.01$), length of heart failure ($p < 0.01$), exercise intensity ($p < 0.05$) were found to be significantly associated with VO₂max.

Conclusion: Lower MLHFQ score at baseline, longer duration of heart failure and higher exercise intensities were associated with a greater level of post-rehabilitation exercise capacity.

P1713

Usefulness of exercised-based cardiac rehabilitation in heart failure patients after myocardial infarction

I Burazor¹; S Susak²; P Seferovic³; Z Cosic¹; M Andjic¹; J Stepanovic³; S Kostic¹; A Yehuda⁴

¹Institute for rehabilitation, Belgrade, Serbia; ²Institute of Cardiovascular Diseases of Vojvodina, Sremska Kamenica, Serbia; ³Clinical center of Serbia, Belgrade, Serbia; ⁴Tel Aviv University, Sheba Medical Center, Tel Aviv, Israel

Chronic heart failure (CHF) is highly prevalent in myocardial infarction survivors and is a major cause of morbidity, mortality an re- hospitalizations Cardiac rehabilitation (CR) exercise training and CHF self-care counseling have each been shown to

improve clinical status and clinical outcomes in CHF. The aim of this study was to evaluate the usefulness of exercise based in house cardiac rehabilitation in patients with left ventricle dysfunction after myocardial infarction

Patients and methods: Out of 1854 patients who were admitted to our three weeks in- hospital rehabilitation program, we analyze a total of 189 patients who were admitted early after coronary revascularization (percutaneous coronary interventions or coronary bypass surgery) with ejection fraction below 40%. The majority of patients were males (62%). The oldest patient was 82 years of age. Ejection fraction below 25% was detected in 40%. We noted risk factors and co morbidities. Patients were selected for exercise training after six minute walking test (82%) or cardiopulmonary exercise test. After 3 weeks in hospital cardiac rehabilitation the patients were re-tested.

Results: The major comorbidities in our patient population were as follows: diabetes, hypertension and previous stroke. Six minutes walking test was performed and the total distance walked ranged from 180 to 380 meters and the beginning of the program. Patient had 7- days a week training program. After the 3 weeks in hospital exercise rehabilitation the improvement in the test was ~35%. Cardiopulmonary test showed also improvement of functional capacity. We noted several rhythm disturbance complications by telemetry (VT, VES, SVES, and new on set of AF) and when needed the amiodaron or beta blockers were added. Also we noted silent ischemia in 13% after CABG with ST segment depression detected by telemetry. None had acutisation of chronic heart failure (with peripheral edema and congestion). All patients fulfilled cardiac rehabilitation program.

Conclusions: The study showed usefulness and safety of exercised -based in-hospital cardiac rehabilitation program. Supervised multidisciplinary cardiac rehabilitation program, including an individualized exercise component is safe and can improve functional status and exercise tolerance in patient with left ventricle dysfunction after myocardial infarction

P1714

Power spectral analysis of heart rate variability during the postural change from sitting to upright position reveal sympathetic hyperactivity

T Taishi Miyata¹; S Oishi¹; Y Taniguchi¹; H Kawai¹; Y Yasaka¹; H Yokoyama¹

¹Himeji Cardiovascular Center, Himeji, Japan

Background: Power spectrum analysis (PSA) of heart rate variability (HRV) is a noninvasive technique providing a dynamic assessment of sympathetic tone.

Methods: We evaluated sympathetic activity with PSA of HRV of 105 CHF patients, such as coefficient of variation of RR intervals (CVRR), low-frequency (LF), high-frequency (HF) component during postural change from sitting to upright position. We compared parameters from PSA and clinical characteristics, exercise parameters from CPET, and index of MIBG scintigraphy.

Results: There were no significant correlation between sympathetic activity parameters and patient clinical characteristics. MIBG scintigraphy was performed in 19 patients, and early H/M was significantly correlated with sympathetic response calculated LF/HF at upright position divided by LF/HF at sitting position ($R = 0.48$, $p = 0.038$).

Conclusion: PSA of HRV during postural change might reveal sympathetic hyperactivity which is obscure at rest.

Correlation between sympathetic response* and early H/M,

* Sympathetic response
= LF/HF at upright position
LF/HF at sitting position

Chronotropic Incompetence and dynamic post-exercise autonomic dysfunction are associated with the presence and severity of erectile dysfunction

A Alexios Samentzas¹; C Vlachopoulos²; N Ioakeimidis²; D Terentes-Printzios²; A Angelis²; P Xaplanteris²; P Pietri²; A Trikas¹; D Tousoulis¹

¹Elpis General Hospital, CARDIOLOGY, Athens, Greece; ²Hippokraton Hospital, Athens Medical School, First Department of Cardiology, CARDIOLOGY, Athens, Greece

Introduction-Purpose: In men with erectile dysfunction (ED), exercise stress testing (EST), while principally important to detect coronary artery disease, it is also essential to define cardiovascular (CV) risk through evaluation of maximal exercise capacity and autonomic pathologies. Aim of this study was to investigate the association between ED and EST parameters.

Methods: 180 ED patients and 50 men without ED underwent maximal EST. Exercise parameters including exercise capacity (metabolic equivalents, METS), peak exercise time, heart rate (HR) at 6 METS, peak exercise, HR recovery (HRR) at 1 and 2 min and chronotropic index (CI) were evaluated in all individuals. Endothelial function was evaluated with brachial flow-mediated dilatation (FMD).

Results: Table shows EST parameters of the two study groups. ED patients had lower peak exercise time and exercise capacity ($P < 0.001$) and reduced CI ($P < 0.01$) compared to men without ED. There was a significant association of ED severity with exercise duration, peak workload, HRR 2 minutes after exercise, and CI (all $P < 0.05$). There also was a positive correlation of HRR and CI with FMD (all $P < 0.05$).

Conclusions: This study shows interrelationships between exercise capacity, HRR, CI and ED. Abnormal HRR and CI are associated with systemic endothelial dysfunction. These findings elucidate pathophysiological links and may have important implications for the estimation of CV risk in ED patients.

Reproducibility of 6-minute walk test in hemodialysed heart failure patients

B Leskovaar¹; T Furlan¹; B Kljucsek¹; A Adamlje¹; M Lainscak²

¹Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia;

²Celje General Hospital, Department of Cardiology, Celje, Slovenia

Background: Six minute walk test (6MWT) is one of established performance-based measures of functional capacity in heart failure (HF) patients.

Purpose: We wanted to evaluate reproducibility of 6MWT and its correlation to basic echocardiographic and laboratory parameters in patients with heart failure treated with chronic hemodialysis.

Methods: Chronic hemodialysis patients walked the 6MWT after three consecutive hemodialysis sessions. On the first test day, blood was taken for laboratory testing and echocardiographic imaging was performed. We tested reproducibility of 6MWT and its correlation with laboratory and echocardiographic parameters in both groups of patients (HD patients with chronic HF and general population of HD patients). Reproducibility of 6MWT was evaluated with interclass correlation and multivariate regression was used to establish potential correlation of walking distance in 6MWT with laboratory and echocardiographic parameters.

Results: We tested 29 hemodialysis patients (59% men, mean age 64.5 ± 12.6 years, 90% with arteriovenous fistula, 10% with central venous catheter, mean

NTproBNP 1403 ± 1306 pg/ml, mean 6MWT distance 355 ± 88 m), of which 22 (76%) had chronic heart failure (50% men, mean age 65.5 ± 11.7 years, mean NTproBNP 1425 ± 1226 pg/ml, 91% with arteriovenous fistula, 9% with central venous catheter, 45% had heart failure with reduced ejection fraction, mean 6MWT distance 355 ± 90 m). Reproducibility of 6MWT was high in both groups of patients (HD patients with HF: IC 0.964, 95% CI 0.913-0.985, $p = 0.000$; general HD population: IC 0.964, 95% CI 0.927-0.983, $p = 0.000$). None of the echocardiographic (LVEF, VTI, LVEDV, LVEDVI, LVESV, LVESVI, E/A, E/Em, Em, Sm) or basic laboratory parameters (NTproBNP, troponine T, hemoglobin) correlated with 6MWT distance.

Conclusions: The 6MWT has excellent reproducibility patients with heart failure treated with chronic hemodialysis. We found no significant correlation of 6MWT distance with echocardiographic or laboratory parameters.

P1717

The usual physical activity predicts mortality in elderly patients with advanced heart failure.

F Cacciatore¹; F Mazzella²; N Ferrara³; G Furgi¹; F Rengo¹; E Della Valle⁴; P Abete³

¹Salvatore Maugeri Foundation, IRCCS, Department of Cardiac Rehabilitation, Telesse Terme, Italy; ²Cardarelli Hospital, Emergency, Naples, Italy; ³University Hospital Federico II, Naples, Italy; ⁴University of Naples "Federico II", Public Health, Naples, Italy

Objectives: to evaluate the role of usual physical activity (PASE) on mortality in elderly patients with advanced heart failure (HF).

Methods and Results: 216 elderly patients (≥65 years) consecutively admitted to Cardiac Rehabilitation soon after HF decompensation, between January 2009 and July 2010 were enrolled. Mortality was collected in October 2015. Age, sex, NYHA class, Comorbidity by Cumulative Index Rating Scale (CIRS), Frailty by means of Fried criteria. 6-minute walk test (6-MWT), Barthel Index (BI), Geriatric Depression Scale (GDS), Mini Mental State Examination (MMSE), Physical Activity Scale for the Elderly (PASE) were measured. The mean age was 74 ± 6.1. Previous infarction and angina were present in 54.3%, 14.3% have had PTCA. The value of CIRS was 2.1 ± 0.6, BI of 69.6 ± 23.4 and PASE 53.1 ± 23.4. Cognitive impairment (MMSE < 24) was present in 32.1% while depression (GDS ≥ 5) in 48.6%. The prevalence of frailty was 61.1%, 6-MWT at entrance was 194.8 ± 104.8 meters and difference in meters between entry and discharge was 58.4 ± 60.2 96 (44%) patients died after a follow-up of 44.1 ± 21.1 months. Cox regression analysis showed that PA usually held in the week before the HF instabilization, measured with PASE, predicts mortality independently by frailty, CIRS, BI, MMSE, GDS, 6-MWT at entry and delta 6-MWT.

Conclusions: Advanced HF patients were characterized by high mortality, co-morbidity, disability and frailty. Low level of PA predicts mortality regardless of comorbidity, disability, cognitive function and depression.

Predictors of mortality in advanced HF

Variable	HR	95%CI	p
Age	0.910	0.822-1.008	0.072
Frailty (≥ 3)	6.692	1.293-30.608	0.023
CIRS	2.504	1.058-5.926	0.004
MMSE	1.008	0.923-1.101	0.854
GDS	1.109	0.888-1.386	0.049
PASE	0.983	0.967-0.998	0.031
6MWT	1.011	1.004-1.018	0.001
Barthel Index -at entry	0.928	0.895-0.962	0.027
Barthel Index - at dismissal	0.920	0.869-0.973	0.003
Delta 6MWT	0.999	0.993-1.006	0.852

CIRS=Cumulative Index Rating Scale, MMSE=Mini Mental State Examination, GDS=Geriatric Depression Scale, PASE=Physical Activity Scale Elderly, 6-MWT=Six minute walking test, Delta 6MWT=Difference in meters between dismissal and entry.

Pase and Mortality in advanced HF

P1718 Regional differences in exercise training implementation in heart failure: subanalyses from the ESC ExtraHF survey

Unrestricted grant from the Heart Failure Association

S Binno¹; A Verde¹; GQ Villani¹; U Corra²; P Seferovic³; T Jaarsma⁴; JP Schmid⁵; G Filippatos⁶; PP Ponikowski⁷; MF Piepoli¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy;

²Fondazione Maugeri, Department of Cardiology, Veruno, Italy; ³University Belgrade Medical School, Department of Cardiology, Belgrade, Serbia; ⁴Linköping University, Department of Social and Welfare studies, Linköping, Sweden;

⁵University of Bern, Bern, Switzerland; ⁶Attikon University Hospital, Heart Failure Unit at Department of Cardiology, Athens, Greece; ⁷Wrocław Medical University, Department of Heart Disease, Wrocław, Poland

Introduction: Exercise training programmes (ETPs) are crucial component in cardiac rehabilitation to help heart failure (HF) patients to recover and to stay healthy. Despite this, ETPs are not routinely implemented for HF patient. We performed a sub-analysis from the data of the ESC ExtraHF survey to investigate the presence of regional variation in use of ETPs for HF patients

Purpose: To investigate the presence of geographical difference in ETP availabilities, modalities, structure characteristics, and to identify the specific barriers in implementation.

Methods: The study was designed as a web-based survey of cardiac units in countries affiliated to the ESC. The data collected were subsequently divided in five areas, according to the UNO division of the countries involved: Northern, Southern, Eastern and Western Europe, and extra European.

Results 172 centers replied to the survey, in charge of 78,514 patients: Northern 52 centers, 15040 patients, Southern 48 centers, (27127 patients), Western Europe 34 centers, (11769 patients), Eastern Europe 24 centers, (12748 patients), ESC countries extra-Europe 14 centers, (11830 patients).

Larger rate of ETP implementation was detected in the Western (76%), Northern (63%), with lower rates in Southern (58%), Eastern (50%) and ExtraEurope (36%) regions. The leading barrier reported was lack of resources in all areas but in Western region where the patients are admitted to another cardiac rehabilitation programme (Table 1) In 40 % of the cases, the non-inclusion of the ETP in the national or local guideline pathway was responsible for lack of implementation

Discussion: A highly recommended therapeutic tool is still poorly implemented in Europe, mainly due to lack of resources, but not in western Europe where patients had the benefit to be referred to other Centers for ETP. The fact that ETP is frequently not included in the local or national guideline pathway needs a more active role from the Scientific Organization such as HFA of the ESC

Table 1

	Northern	Southern	Western	Eastern	Extra-Europe
N° of Centers, patients	19 6677	20 13743	8 4350	12 5370	9 6870
Primary cause	Lack of resources (68%)	Lack of resources (65%)	Admission to another ETP (75%)	Lack of resources (83%)	Lack of resources (78%)
Secondary cause	Admission to another ETP (42%)	ETP not included in national/local guideline (40%)	Lack of resources (37%)	ETP not included in national/local guideline (41%)	ETP not included in national/local guideline (66%)

In Table 1 are depicted the two major causes of not implementation of ETP among the five ESC-areas. The % is over the 100% because multiple answers were admitted.

P1719

Additional criteria of urgency of heart transplantation for patients in UNOS-2 status according to spiroergometry stress testing

V A Volha Sujayeva¹

¹Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Background: There is significant mismatch between the demand for heart transplantation (HT) and the number of donor hearts. That's why development of additional selection criteria for patients placed in the "waiting list" in status UNOS 2 is very important now.

Objective: to develop the algorithm for selection of stable patients with severe heart failure (HF) for heart transplantation based on spiroergometry stress test's results.

Methods: We studied 32 patients with HF NYHA III-IV, 30 (94%) - male, 2 - female, average age was 46,4 ± 12,1 years. 19 (60%) of 32 patients had ischemic cardiomyopathy, 9 (28%) - dilated cardiomyopathy, two (6%) - rheumatic heart disease, 2 (6%) - congenital valve diseases. During the follow-up of 1 year, 3 (9%) of 32 patients died, HT was performed in 8 patients (25%), in others 2 mechanical assistant devices were implanted, in 2 - cardiac resynchronization devices were implanted. In other 10 (31%) pts optimization of medical therapy led to decreasing of HF symptoms and they were removed from the "waiting list". We used cardiopulmonary bicycle ergometry test (BET) to estimate not only common used predictors of mortality such as tolerance to physical loading and maximal oxygen consumption (VO2max) but also other criteria of ventilation such as carbon dioxide production relationship (VE/VCO2 slope), time of aerobic threshold destination, oxygen consumption at time of aerobic threshold destination etc. Based on all revealed in BET data we created enough accurate mathematical model of survival and death prediction during 1 year. BET was performed in vertical position of the patient using stress ergometry system 'Schiller AG' AT-104 ErgoSpiro. We started from 25 Wt with increasing in load power every 3 minutes at 25 Wt until maximal tolerated level of dyspnea appeared.

Results: We established additional criteria of death during 1 year based on BET results. These criteria were: the maximal oxygen consumption VO2max <30% of expected; VD/VT (ratio of physiologic dead space over tidal volume) increasing during the test; maximal tolerance to physical loading ≤50 Wt and/or <20% of expected. We used mathematical factor analysis (principal component analysis) to create predictive survival model. Sensitivity of death prediction was 100%. Based on above mentioned predictive model we created new algorithm of recipient's selection for HT using 'R' software

PROGNOSIS

P1720

Two-year follow-up of patients with acute myocardial infarction with ST elevation and new onset atrial fibrillation in relation to fibrinolytic therapy or primary PCI

This study was supported by the program grant of the Ministry of Science of Montenegro.

AB Aneta Boskovic¹; M Vukmircovic¹; M Rabrenovic¹; S Dragic¹; O Orlandic¹; A Nenezic¹; S Vujosevic¹; M Medenica¹; G Nikolic¹

¹CC of Montenegro - Medical Faculty, Podgorica, Montenegro

Purpose: Patients with acute myocardial infarction with ST elevation (STEMI) have many complications and new-onset atrial fibrillation (AF) is one of them. The aim of the study was to evaluate the prognosis of patients with STEMI and new onset AF during the 2-year follow-up in relation to fibrinolytic therapy or primary PCI.

Methods: We enrolled 290 patients with STEMI in the study. At entry, all patients were in sinus rhythm and patients with congenital cardiac disease, organic mitral regurgitation, healed endocarditis and any other disease limiting survival were excluded. The primary PCI (PPCI) group included patients with STEMI treated with primary PCI and fibrinolytic group included patients with STEMI treated with fibrinolytic therapy during the hospital course. The patients were followed up for two years with visits every 6 months.

Results: We included 290 patients with STEMI, 53 patients were treated with primary PCI (18.28%) and 209 patients (72.07%) were treated with fibrinolytic therapy, the minority of 28 patients (9.65%) were not treated either with PPCI or either with fibrinolytic therapy. There was no significant difference in mean age, male/female ratio and BMI between patients treated with PPCI and patients treated with fibrinolytic therapy. In the PPCI group there were 4 patients (7.55%) with AF and in the fibrinolytic group there were 17 patients (8.13%) with AF, p>0.05. During the hospital course died 1 patient (1.89%) in PPCI group without AF and 7 patients (3.35%) in fibrinolytic group, 1 of them with AF and 6 without AF, p>0.05. During the follow up period died 3 patients (5.66%) in PPCI group, 1 patient (1.89%) with AF and 2 patients (3.77%) without AF versus 23 patients (11.00%) in fibrinolytic group, 6 of them (2.87%) with AF and 17 patients (8.13%) without AF, p>0.05. After all, mortality was 7.55% in PPCI group vs. 14.35% in the fibrinolytic group, p>0.05.

Conclusions: There was no difference in incidence of new-onset AF in STEMI patients in relation to fibrinolytic therapy or PPCI. Mortality was lower in PPCI group (7.55%) then in fibrinolytic group (14.35%), but there was no difference in mortality in patients with new-onset AF and without AF.

P1721

Predictors of hospital mortality in a specific population of women with acute myocardial infarction and an ejection fraction lesser than 40%C Catia Costa¹; D Durao¹; M Leal¹¹Hospital of Santarem, Cardiology, Santarem, Portugal

Introduction: Hospital mortality in patients with acute myocardial infarction (AMI) constitutes an indicator of good health care; therefore, the knowledge of its predictors is a critical issue.

Aims: Assess the predictors of hospital mortality in a population of women with AMI and an ejection fraction (EF) lesser than 40% (EF < 40%).

Methods: Retrospective study, including 533 women with AMI and an EF < 40%. The population was divided in two groups: A, including patients with AMI who survived the event (n = 447); B, including patients with AMI who died at hospital (n = 86). Univariate and multivariate analysis were performed to find predictors of hospital death.

Results: Univariate analysis revealed a correlation between higher mortality with age (p < 0.001), history of stroke, peripheral arterial disease, dementia (p < 0.05), AMI with ST elevation (p < 0.001), lower blood pressure, lower EF, higher Killip class (KK) and the presence of atrial fibrillation (AF) (p < 0.001). Multivariate analysis confirmed AMI with ST segment elevation (OR 3.24, p 0.025), history of stroke (OR 3.3, p 0.013), KK (OR 2.55, p 0.018), the presence of AF (OR 2.43, p 0.021) and lower EF (OR 3.47, p 0.001) to be independent predictors of hospital mortality.

Conclusions: In this registry of women with EF lesser than 40%, not just common factors as the type of AMI or lower EF were predictors of hospital mortality. Other factors as history of stroke and the presence of AF were also predictors of a worst prognosis. This knowledge can lead to a better assessment of the patients and definition of therapeutic strategies.

P1722

Cardiac cachexia and its impact on survival in Asian patientsA Aninka Saboe¹; B B Tiksnadi¹; A Purnomowati¹; T M Aprami¹¹Padjajaran University, Cardiology, Bandung, Indonesia

Background: Cardiac cachexia (CC) is one of indicator of poor prognosis in heart failure. Unfortunately, its existence is often overlooked by many cardiologists, this is further complicated by small number of study concerning CC, and the controversial issues they encompasses. There was no previous study about cardiac cachexia in Asian population.

Purpose: The aim of this study is to analyze the survival in heart failure (HF) patients with cachexia complications in Asian population. **Methods:** A retrospective cohort study was conducted on the data from Hasan Sadikin General Hospital HF registry from March 2013 – August 2014. The inclusion criterias were asian population with HF patients above 18 years of age with left ventricle ejection fraction (LVEF) below 40%, time onset of HF more than 6 months and exclusion criterias were valvular diseases as primary etiology of HF and comorbid of other chronic disease (COPD, CKD, cancer). Cardiac cachexia was diagnosed in patients fulfilling the criteria from international cachexia consensus.

Results: There were 39 patients, most of them were female (61.5%), with mean LVEF 28.5% (+6.7). Cardiac cachexia was diagnosed in 6 (15.3%) patients. At 6 months of follow-up after initial enrollment, the cumulative rate of death from cardiovascular cause was 83% among cachectic as compared 37.5% among non-cachectic patients (p = 0.001, Adjusted HR (95%CI) = 8.05 (2.40–27.04). There were no association between mortality with sex (p = 0.268), etiology of HF (p = 0.288), LVEF (p = 0.061), comorbid condition (hypertension p = 0.237, diabetes mellitus p = 0.163).

Conclusions: We conclude that cardiac cachexia is an independent predictor of death in HF patients in 6 months in Asian population.

P1723

The heart failure marker TWEAK predicts survival in critically ill patientsM Mark Luedde¹; C Roderburg²; F Benz²; A Koch²; C Trautwein²; T Luedde²; F Tacke²; N Frey¹¹University Hospital of Schleswig-Holstein, Campus Kiel, Medical Clinic III, Kiel, Germany; ²RWTH University Hospital Aachen, Internal Medicine III, Aachen, Germany

Introduction: TNF superfamily members, including TNF-related weak inducer of apoptosis (TWEAK) have been described as serum based biomarkers for heart failure. A novel theory proposes an important contribution of heart failure in septic disease. We therefore investigated the role of Serum TWEAK Levels and other members of the TNF superfamily in critical illness.

Methods: GITRL and TWEAK serum concentrations were measured in critically ill patients in comparison to healthy controls. Clinical data were recorded and correlated with GITRL and TWEAK serum levels.

Results: Serum levels of TWEAK and GITRL were strongly decreased in critically ill patients compared with healthy controls. Concentrations of TWEAK (and not GITRL) were further decreased when septic disease was present and was correlated with routinely used markers of inflammation and bacterial infection such as C-reactive

protein, procalcitonin and Interleukin-6. Notably, we failed to detect a correlation to other TNFR ligands such as TNF or APRIL. Finally, alterations in TWEAK levels were prognostic for patients fate during ICU treatment.

Conclusion: Serum levels of TWEAK and GITRL were significantly decreased in intensive care unit patients. Concentrations of TWEAK were further decreased in septic patients and alterations in TWEAK levels were associated with an unfavorable outcome. Together with recently published results on other TNFR ligands, these data for the first time highlight specific functions of the heart failure marker TWEAK in the pathophysiology of septic diseases.

P1724

Influence of cardiopulmonary exercise test results on mortality after cardiac transplantCMF Christopher Strong¹; P Freitas¹; C Aguiar¹; A Ferreira¹; S Guerreiro¹; G Rodrigues¹; A Ventosa¹; MJ Rebocho¹; JP Neves²; M Mendes¹¹Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; ²Hospital de Santa Cruz, Lisbon, Portugal

Purpose: This study aims to describe a population of patients with heart failure and the results of cardiopulmonary exercise test (CPET), and to evaluate the potential impact of these results on mortality at 6 months and 10 years after heart transplantation.

Methods: Retrospective single center study which included 44 patients with heart failure NYHA class III-IV who underwent CPET between 1998-2013. Clinical data of the population and follow-up at 6 months and at 10 years after cardiac transplantation were collected.

Results: The mean age of the population was 49 ± 11 years, with 75% of males. The most frequent causes of heart failure were idiopathic (34.1%), ischemic (29.5%), hypertrophic in dilated phase (15.9%) and valvular (11.4%). The mean left ventricle ejection fraction was 24 ± 7.8%, the average NYHA class was III, the average Meckel score was 34.1 ± 18.8. Most patients were treated with beta-adrenergic blocker (86%), ACEI / ARB (96%) and spironolactone (50%), with the maximum tolerated dose. The mean VO2 max was 12.1 ± 2.6 ml / kg / min; the average % provided for VO2 max was 39 ± 11.6%; and the average of the VE / VCO2 slope was 49.8 ± 14.3. All patients underwent cardiac transplantation, in most cases between 6 months and 1 year after CPET. It was found that 7 patients died within the first 6 months, and at 10 years post-transplant a total of 10 patients died. At 6 months, mortality was 23.1% in patients who were submitted to heart transplant in Weber class D and 12.9% in Weber class C (p 0.4); at 10 years, mortality was 30.8% in patients who performed heart transplant in Weber class D and 19.4% in Weber class C (p 0.4) - see figure. The VE / VCO slope and the predicted % for VO2max were not predictors of mortality at 6 months or at 10 years.

Conclusion: The mortality after heart transplantation was greater in patients with worse results on CPET carried out in recent months before transplantation.

Kaplan - Meier curve

P1725

Abnormal liver function and renal function impairment as an expression of multiorgan failure in acute decompensated cardiac failureM L Talavera¹; I Chillik²; A Acosta¹; R Campos²; MS Trivi²; M Diez¹¹Cardiovascular Institute of Buenos Aires (ICBA), Heart Failure, Buenos Aires, Argentina; ²Cardiovascular Institute of Buenos Aires (ICBA), Cardiology, Buenos Aires, Argentina

Background: renal function impairment is a well known risk factor in acute decompensated cardiac failure (ADHF) and abnormal liver function tests (LFT) are related to bad outcome in this setting as well. These abnormalities are usually related with

low cardiac output and multiorgan failure.

Objective: to evaluate the prevalence of renal function impairment and abnormal LFT in patients (pts) with ADHF and to establish the relationship between those and death during hospitalization.

Methods: 223 consecutive pts admitted with ADHF between January-2013 and August-2014 were selected; Patients' basic characteristic data including sex, age, past medical history, medications, as well as blood exam results, were analyzed. Renal function impairment was defined by a >0.3 mg/dl in creatinin value and abnormal liver function as an any upper limit increment in alanine aminotransferase, aspartyl aminotransferase, total bilirubin and/or alkaline phosphatase. The primary endpoint was death during hospitalization. Logistic regression analysis was used to evaluate factors associated to death. $P < 0.05$ was considered statistically significant.

Results: mean age was 79 years old (DS +/−11) and 60% (134 pts) were male, mean left ventricle ejection fraction was 40% (IQR25-75: 29-59) and 43% (97 pts) had an ischemic etiology; abnormal LFT was present in 62% (138 pts) at admission and previous renal failure was recorded in 37% (83 pts); during in-hospital, 68% (153 pts) and 46% (104 pts) developed any liver enzyme enchainment or renal function impairment, respectively. There were 16 deaths (7.1%) during hospitalization. Regression analysis showed that highest bilirubin levels (OR 2.04, CI95%: 1.04-3.98, $p = 0.036$) and renal function impairment (OR 5.41 CI95% 1.09-27, $p = 0.039$) were associated to death among others LFT variations and biomarkers like high sensitive troponin levels.

Conclusions: in ADHF, abnormal LFT and renal function impairment are easy and useful prognostic tools that help to estimate risk of death during hospitalization; they probably express multiorgan failure due to low cardiac output as a background physiopathology.

P1726

Heart failure admission: does the phenotype matter?

JM Joana Maria Ribeiro¹; M Madeira¹; R Teixeira¹; S Alexandrina¹; L Puga¹; L Gonçalves¹

¹Centro Hospitalar e Universitário de Coimbra - Hospital Geral, Serviço de Cardiologia, Coimbra, Portugal

Background: Heart failure (HF) with preserved ejection fraction (HFpEF) is a prevalent cause of hospital admission. Although left ventricle systolic dysfunction has been associated with a poor outcome, the prognosis in patients with preserved ejection fraction once the clinical syndrome of heart failure sets in is still ill defined.

Purpose: To compare the in-hospital and long term outcomes of patients with HFpEF and HF with reduced ejection fraction (HFrEF).

Methods: We included all patients admitted for acute heart failure in a single centre (cardiology ward and coronary intensive care unit). We created two groups: HFpEF – group 1 ($n = 34$) – and HFrEF – group 2 ($n = 216$).

Results: HFpEF patients were older (78 ± 9 vs 67 ± 14 , $P < 0.01$), more often females (67.6 vs 18.7% $P < 0.01$) and had a shorter hospital stay (8 ± 8 vs 13 ± 11 days, $P = 0.02$). In-hospital mortality was similar between the two groups (14.7 vs 15.4%, $P = 0.92$). Concerning long term follow-up, group 1 had a better two-year event free survival (figure 1). On the contrary, there was a trend for a higher HF readmission rate in the group with HFpEF (63.0% vs 47.3%, $P = 0.15$).

Conclusion: Our data showed that HFpEF patients had a similar in-hospital prognosis, but an improved 2-year survival. Yet, this group showed a trend to a higher HF readmission rate.

Figure 1

The relationship between smoking habits and depressive symptoms in patients with systolic heart failure

G Guliz Kozdag¹; K Hebert²; D Ural¹; I Gogichaishvili³; L Arcement⁴; O Argan¹; A Agacik Agir¹

¹Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey;

²General Electric, Waukegan Wisconsin, United States of America;

³Cleveland Clinic, Cleveland, Ohio, United States of America; ⁴Chabert medical center, Houma Louisiana, United States of America

Background: Depressive symptoms are common and associated with poor prognosis in chronic heart failure (CHF). Smoking is one of the most important risk factor for the development of coronary artery disease. The aims of this study were to identify the relationship between history of smoking (current smoker and ex-smoker) and depressive symptoms and to determine the effects of history smoking on Minnesota living with heart failure questionnaire (MLHFQ) and the hospitalization in CHF.

Methods and Results: Patient Health Questionnaire (PHQ-9) does not establish a diagnosis of depression, but screens patients who are at risk. Scores between 0 and 4 identified patients at no risk for depression, scores between 5 and 9 represented patients who screened positive for mild depressive symptoms, and patients who scored 10 were tentatively diagnosed with moderate depression. For the purposes of this study, the PHQ-9 score was dichotomized to a 'non-depressed' (PHQ-9: 0–9) and a 'depressed' cohort (PHQ-9: ≥ 10). Patients in this study were enlisted in the country of Georgia from a hospital-affiliated outpatient HFDMP for systolic HF located in our Central University Hospital in Georgia. 377 patients (109 female, 268 male, mean age: 64 ± 13 years, mean ejection fraction: $32\% \pm 6$) were enrolled between in August 2007 and July 2008. 15% of patients' PHQ-9 score were ≥ 10 . 162 (43%) patients had history of smoking in the group. While 22% of patients with smoking history were depressed 11% of patients without smoking history were depressed ($p = 0.004$). Depressive patients had a tendency to smoke more than patients without depression (17 ± 12 cigarettes/day vs 12 ± 13 , $p = 0.003$). Depressive patients' MLHFQ score were higher (64 ± 14 vs 58 ± 15 , $p < 0.001$) and hospitalization rate increased (73% vs 53%, $p < 0.001$) compared to non-depressive patients.

Conclusion: It was determined that patients with history of smoking had more depression than patients without history of smoking. Patients with history of smoking were more hospitalized and their MLHFQ scores higher than patients without smoking history in CHF.

P1728

Heart failure determines survival in haemodialysis patients

I Simova¹; L Kambova²; G Bortolan³; I Christov⁴; T Katova¹; A Nossikoff⁵

¹National Heart Hospital, Department of Noninvasive Cardiovascular Imaging and

Functional Diagnostics, Sofia, Bulgaria; ²National Heart Hospital, Department of

Haemodialysis, Sofia, Bulgaria; ³Institute of Neuroscience IN, Padova, Italy;

⁴Bulgarian Academy of Sciences, Institute of Biophysics and Biomedical

Engineering, Sofia, Bulgaria; ⁵University Hospital "Lozenets", Clinic of Cardiology, Sofia, Bulgaria

Objective: Patients with end-stage renal disease on haemodialysis (HD) treatment have increased mortality and cardiovascular risk. We aimed to determine if the presence of heart failure (HF) has an additional prognostic implication in HD patients.

Methods: We studied 59 HD patients, 59 ± 2.4 years, 28 (47%) – female, renal disease from 10.1 ± 7 years and duration of HD 5.6 ± 5.1 years, of whom 7 patients (12%) had HF with documented left ventricular systolic dysfunction. Other clinical characteristics were as follows: arterial hypertension – 93%, diabetes – 12%, dyslipidemia – 27%, smokers/ former smokers – 53%, family history of premature coronary artery disease (CAD) – 10%, established CAD – 14%, peripheral artery disease – 5%, cerebrovascular disease – 9%.

Results: We followed-up our patients for 14.5 ± 3.8 months. Major adverse cardiac event (MACE), defined as cardiovascular death, acute coronary syndrome (ACS), coronary revascularization, stroke and hospitalization due to cardiovascular reasons, occurred in 17 patients (29%) during follow-up; 14 patients (24%) died [9 of them (16%) of cardiovascular death]; 26 subjects (45%) were hospitalized [15 of them (26%) had cardiovascular hospitalizations]; one patient (2%) had ACS; 6 subjects (10%) experienced stroke. Patients with HF at baseline were more likely to die during follow-up (71% vs 18%, $p = 0.007$), to experience cardiovascular death (57% vs 10%, $p = 0.008$), hospitalization (86% vs 39%, $p = 0.04$) and stroke (43% vs 6%, $p = 0.02$) and to visit emergency department (43% vs 4%, $p = 0.01$) compared to those without HF. Presence of HF was the strongest independent predictor for the occurrence of MACE, total and cardiovascular death during follow-up. Kaplan-Meier survival analysis demonstrated that time to death was significantly shorter in HD patients who had HF at baseline (12.7 ± 1.7 months), compared to those without HF (15.4 ± 0.5 months), $p = 0.002$. Time to cardiovascular death was also significantly shorter in HF patients (14.3 ± 1 months) compared to the rest of the group (15.8 ± 0.4 months), $p = 0.001$. Time to MACE did not differ in the groups with and without HF at baseline.

Conclusions: Presence of HF significantly influences prognosis in HD patients, increasing mortality and untoward cardiovascular events, and shortening the time to total and cardiovascular death.

Kaplan-Meier Survival curve

P1729

Annual prognostic factors in chronic heart failure in octogenarians and nonagenarians

The study was supported by a Medical University grant.

A Cichocka-Radwan¹; M Lelonek¹

¹Medical University of Lodz, Chair of Cardiology and Cardiac Surgery, Department of Cardiology, Lodz, Poland

Introduction: In the elderly the most common cause of hospitalization and the leading cause of death is heart failure.

Purpose: The aim of this study was to determine the annual prognostic factors in chronic heart failure (CHF) in patients over 80 years old.

Methods: The analysis included 197 patients 80+ years old (mean age 83.6 ± 3.0 years; 46.2% of men) hospitalized in 2010-2013 in the Department of Cardiology due to CHF. Sixty two parameters were investigated: age, gender, NYHA class, body mass index, blood pressure, comorbidities, parameters of 12-lead ECG and echocardiography, results of basic laboratory tests and selected biomarkers (NT-proBNP, hs-TnT, hs-CRP). All participants remained in prospective follow-up for 12 months. We defined the primary endpoint as the cardiovascular death and the composite endpoint, which was consisted of cardiovascular death and/or hospitalization due to exacerbation of CHF. The multivariate logistic regression stepwise analysis was performed for whole population, according to left ventricular ejection fraction (LVEF < 45% and $\geq 45\%$) and in group with glomerular filtration rate (GFR) < 60ml/min/1.72m² to identify the prognostic factors for the mentioned endpoints.

Results: In one year observation 21 patients died (11%). From multivariate analysis four variables were independently associated with the primary endpoint: GFR (OR=0.92), hypertension (OR=0.19), lung diseases (OR=9.36) and vascular diseases (OR=6.07). In turn, in patients who reached the composite endpoint (n=55), the only statistically significant was anemia (OR=4.71). In patients with LVEF < 45% for each endpoint prognostic were vascular and lung diseases (OR range: 10 to 24). In group with LVEF $\geq 45\%$ with composite endpoint was associated hemoglobin (OR=0.61) and with death: white blood cell count, hs-TnT and vascular diseases (respectively OR=1.30; OR=1.04; OR=3.96). And in population with GFR < 60ml/min/1.72m² the independent variables for composite endpoint were: red blood cell distribution width (OR=1.42) and anemia (OR=3.79), while for the primary endpoint the same two variables as for entire population: vascular (OR=5.16) and lung diseases (OR=4.72).

Conclusions: In octogenarians and nonagenarians with CHF comorbidities have important prognostic value for annual prognosis. The most aggravating factors were lung diseases.

P1730

New clinical assessment scale - useful tool to analysis effect of treatment and prognosis of patients with heart failure

Y Mareev¹; V Mareev²

¹Royal Brompton & Harefield Hospitals, Imperial College, London, United Kingdom; ²M.V. Lomonosov Moscow State University, Faculty of Basic Medicine, Moscow, Russian Federation

Background: Patients with heart failure (HF) are at substantial risk of recurrent hospitalization and death. There is a need for tools to assess the success of treatment and evaluate patients' prognosis.

Propose: To develop a simple clinical scale [Scale for HF to Optimize Clinical Status (SHOCS)] to assess the prognosis of patients with HF in everyday practice.

Material: The SHOCS tool is based on patients managed in Russia by cardiology departments. Its ability to predict mortality was investigated in two single-centre studies and confirmed in two multicenter randomized trials (RT).

Results: The scale combines symptoms and a simple clinical assessment aligned to routine care (table1). Each NYHA class has a different SHOCS score; the correlation between NYHA and SHOCS in the study was - 0.679. This was also validated in two RT in Russia (FASON, n = 1879 and BESE, n = 1437). The prognostic value of SHOCS was investigated in two single center studies: The first study comprised 718 patients hospitalized due to decompensated HF. Patients with median SHOCS < 8.3 on admission to the hospital had a hazard ratio (HR) of 0.59 95% CL 0.49-0.71; $p < 0.00012$ for 5-year mortality. The second study (n 195) compared SHOCS at hospital admission and discharge and followed patients for seven years. Median SHOCS on admission and discharge was 5 IQR [3;7] and 2 IQR [1;2]. Patients with SHOCS < 5 on admission had better survival. (HR=0.540, 95%CL 0.359-0.812). HR of highest versus lowest quartile was 2.46 95% CL [1.44 to 4.21]. Moreover, patients who remained symptomatic at discharge (SHOCS ≥ 2) had a greater risk of death. (HR 1.59 95% CL 1.06 to 2.37). Multivariable analysis showed that SHOCS is an independent predictor of mortality.

Conclusion: SHOCS is a simple and powerful tool to investigate the prognosis of patients admitted with decompensated HF and the effect of treatment.

Clinical assessment scale

1. Breathlessness	0 - no; 1 - during exercise; 2 - at rest
2. Increase in weight over the last week	0 - no; 1 - yes
3. Palpitations	0 - no; 1 - yes
4. Orthopnoea	0 - no; 1 - yes (2+ pillows); 2 - yes (2+ pillows) + woken up due to breathlessness; 3 - Yes + and can only sleep sitting up
5. Jugular vein distension	0 - no; 1 - yes when patient lying flat; 2 - yes when patient standing up
6. Rales	0 - No; 1 - lung bases (1/3 of lungs area); 2 - up to scapula's angle (2/3 of lungs area); 3 - throughout the lungs
7. Third heart sound	0 - no; 1 - yes
8. liver	0 - normal; 1 - enlargement up to 5cm below subcostal border 2 - enlargement greater than 5cm below subcostal border
9. Peripheral edema	0 - no; 1 - minimal ankle oedema; 2 - moderate ankle edema; 3 - ascites/anasarca/generalised oedema
10. Systolic Blood pressure	0 - > 120 mmHg; 1 - 100-120 mmHg; 2 - <100 mmHg

Differential prognostic impact of atrial fibrillation in non-obese vs. obese patients with heart failure with preserved ejection fraction

Grant-in-Aid for Scientific Research (#20174906)

M Yagawa¹; Y Nagatomo¹; Y Izumi¹; K Mahara¹; Y Shiraishi²; T Inohara²; A Mizuno³; A Goda⁴; S Kohsaka²; T Yoshikawa¹

¹Sakakibara Heart Institute, Department of Cardiology, Fuchu, Japan; ²Keio University School of Medicine, Department of Cardiology, Tokyo, Japan; ³St. Luke's International Hospital, Department of Cardiology, Tokyo, Japan; ⁴Kyorin University, Department of Cardiology, Mitaka, Japan

Background: The presence of atrial fibrillation (AF) is associated with adverse clinical outcomes in patients with heart failure (HF). On the other hand, obesity is associated with left ventricular hypertrophy, diastolic dysfunction and the occurrence of AF. Nevertheless, it has been reported that in HF population, obese patients have more favorable clinical outcomes, often referred to as "obesity paradox". In this context, the clinical impact of AF in obese/non-obese patients has not been characterized.

Purpose: We sought to determine the prognostic impact of AF in HF patients with different body mass index (BMI).

Methods: West Tokyo Heart Failure Registry (WET-HF) is the multi-center registry enrolling acute decompensated HF (ADHF) patients who were hospitalized at the 4 major teaching hospitals in western Tokyo area. We analyzed 1,681 patients who were enrolled from 2005 to 2013. We categorized them into 3 groups of low/medium/high BMI (low, BMI < 20, L; medium, $20 \leq \text{BMI} \leq 24$, M; high, BMI > 24, H; n = 344/621/539). Furthermore, we categorized them into HF with preserved ejection fraction (HFpEF) group which was defined as EF of 40% or more (n = 681) and HF with reduced EF (HFrEF) group which was defined as EF of less than 40%

(n=633). The clinical endpoint was defined as all cause death or readmission for ADHF.

Results: The median follow-up was 411 days in overall population. In the Kaplan-Meier analysis, the occurrence of clinical endpoint was more common in patients with AF than those without AF ($P=0.007$, Log rank test). Patients who had AF on admission was associated with higher probability of endpoint in HFpEF group ($P=0.006$, Log rank test), but not in HFrEF group. On the other hand, endpoint was more common in lower BMI groups ($P<0.0001$, Log rank test) in overall population. AF was associated with higher rate of endpoint in L ($P=0.02$) and H ($P=0.04$), but not in M. When study subjects were further divided into HFpEF and HFrEF groups, AF was associated with higher rate of endpoint in HFpEF, but not in HFrEF for L and M ($P=0.006$ and 0.02 , respectively). Conversely, AF was associated with higher rate of endpoint in HFrEF instead of HFpEF for H ($P=0.02$). **Conclusions:** Presence of AF had a significant impact on clinical outcomes in L and M with HFpEF. Further investigation will be warranted to identify its underlying mechanisms.

Validation of the MAGGIC heart failure risk score in Korean heart failure registry

BS Byungsu Yoo¹; EH Choi¹; SS Khanam¹; MC Cho²; ES Jeon³; DJ Choi⁴; BH Oh⁵; SH Baek⁶

¹Wonju College of Medicine, Yonsei University, Division of Cardiology, Department of Internal Medicine, Wonju, Korea Republic of; ²Chungbuk National University Hospital, Cheongju, Korea Republic of; ³Samsung Medical Center, Seoul, Korea Republic of; ⁴Seoul National University Bundang Hospital, Seongnam, Korea Republic of; ⁵Seoul National University College of Medicine, Seoul, Korea Republic of; ⁶The Catholic University of Korea, Seoul, Korea Republic of

Background: There exist previous risk models for patients with HF. But, each uses a single cohort of patients and hence their generalizability to other populations is questionable. The aim of this study was to evaluate the performance of a recently developed risk score from the meta-analysis for mortality in heart failure by external validation in a national heart failure registry. **Method:** We included 5265 patients from the Korean acute heart failure registry (KorAHF) and excluded patients with in-hospital death. From 13 routinely available patient characteristics (Age, gender, diabetes, COPD, HF diagnosed within the last 18 months, current smokers, NYHA class, use of beta blocker, ACEI or ARB, BMI, systolic BP, Cr and EF), the Meta-analysis Global Group in Chronic Heart Failure (MAGGIC) constructed a risk score for prediction of mortality in heart failure. The risk score was calculated for each patient by summing the individual contribution from all 13 risk factors as described in the MAGGIC project heart failure risk score publication. The outcome measure was 1-year mortality. The predicted probability of death obtained from the calculated risk score was compared with the observed 1- and 2-year mortality, and model discrimination and calibration were assessed by formal tests.

Results: Among total 5625 patients, we included 4783 patients without in-hospital death and missing value of 13 routinely available clinical characteristics. Of 13 variables, sex, systolic BP, smoking and ejection fraction were not significant independent risk variables. The overall 1-year and 2-year mortality in the study population was 17.58% and 30.64% respectively. The risk score were significantly different between alive and died group (30.19 ± 6.12 vs. 25.24 ± 6.88 , $p<0.001$ at 1 year, 30.76 ± 6.24 vs. 25.96 ± 6.91 , $p<0.001$ at 2 year) which means risk score revealed good discrimination. To test calibration of model, we used a Hosmer-Lemeshow goodness-of-fit test. There was not a significant differences between observed and model-predicted 1-year and 2-year mortality ($p=0.5463$ and 0.6905 , respectively).

Conclusion: In the Korean heart failure registry, the MAGGIC project heart failure risk score performed good in a large nationwide contemporary external validation cohort.

Impact on late clinical outcomes of permanent pacemaker implantation after transcatheter aortic valve implantation.

E Munoz-Garcia¹; A Ruiz-Salas²; M Munoz-Garcia³; AJ Antonio Jesus Munoz Garcia²; J Fernandez-Pastor²; J Pena²; AJ Dominguez-Franco²; JM Hernandez-Garcia²; J Alzueta-Rodriguez²; E De Teresa-Galvan²

¹Department of Cardiology, Malaga, Spain; ²University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain; ³Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain

Very few data exist on the clinical impact of permanent pacemaker implantation (PPI) after transcatheter aortic valve implantation. The aim of this study was to assess the impact of PPI after transcatheter aortic valve implantation on late outcomes

Methods and Results: A total of 456 consecutive patients without prior PPI undergoing transcatheter aortic valve implantation were included. Of them, 112 patients (24.2%) required a PPI within the first 30 days after transcatheter aortic valve implantation, mean time 53.7 ± 38 hours. At a mean follow-up of 30.4 ± 20 months, there was more mortality in patients with PPI 32.7% vs. 22.3%, OR = 1.69 (95% CI

1.04-2.75), $p=0.0024$, but no association was observed between the need for PPI and all-cause mortality (hazard ratio, 1.39; 95% confidence interval, 0.918-2.411; $P=0.120$), cardiovascular mortality (hazard ratio, 0.74; 95% confidence interval, 0.311-1.795; $P=0.515$), and rehospitalisation for heart failure (hazard ratio, 1.67; 95% confidence interval, 0.738-3.76; $P=0.219$). There were 5 cases of unexpected (sudden or unknown) death was observed in patients without PPI. Patients with new PPI showed a poorer evolution of left ventricular ejection fraction over time. Mean left ventricular ejection fraction increased from 60.7 ± 14 mmHg to 63.2 ± 15 mmHg after TAVI and decreased to 61.2 ± 10 mmHg at 1 years and 45.8 ± 20 mmHg at 2 years (p for post-TAVI trend 0.102).

Conclusions: The need for PPI was a frequent complication of transcatheter aortic valve implantation, but it was not associated with any increase in overall or cardiovascular death or rehospitalization for heart failure. However, new PPI did have a negative effect on left ventricular function over time.

P1734

Prognostic value of diuretic dose in ambulatory patients with chronic heart failure

E Rocco¹; A Manerba¹; M Triggiani¹; C Villa¹; P Sacristani¹; I Papa¹; N Dasseni¹; S Nodari¹

¹University of Brescia, Brescia, Italy

Background: diuretics, such as furosemide, are deemed essential for the treatment of patients with chronic heart failure (HF), but it is not well known whether increasing doses of furosemide are associated with increased mortality or hospitalization in this population of patients.

Purpose: evaluate of the prognostic impact of diuretic dose in ambulatory patients with chronic HF and to evaluate whether this relationship remains significant after considering the state of congestion.

Methods: we conducted a retrospective analysis of patients with chronic HF and reduced left ventricular ejection fraction (LVEF $\leq 45\%$) in follow-up at our HF Center. Inclusion criteria were optimized therapy and clinical stability (neither events nor therapeutic changes) in the previous three months. Daily diuretic dose was considered as continue variable and as a categorical variables (≤ 50 mg/die vs >50 mg/die; 50 mg was the median diuretic daily dose). Volemia status (congestion or hypervolemia vs euvolemia) was defined according to the Sodium Retention Score, calculated by assigning a score of 1 for each of the following signs or symptoms: weight gain, hepatomegaly, gallop rhythm, and increased jugular venous pressure; a score of 1 to 3 in presence of rales; a score of 1 to 4 in presence of peripheral edema; a score ≥ 3 indicates a state of hypervolemia. The median follow-up was 43 months; the end-point was a composite of all cause death and hospitalizations for HF or cardiovascular causes.

Results: a total of 570 patients were enrolled (mean age 67 ± 12 years, 83% male); during the follow-up; the composite end-point occurred in 294 patients (52%). Diuretic dose was a predictor of events in the overall population in both univariable (p -value < 0.001) and multivariable analysis (p -value = 0.026), together with age (p -value = 0.001), LVEF (p -value = 0.005) and congestion state (p -value < 0.001). In the sub-group of euvolemic patients, in a multivariable model (including NYHA classes, sex, serum creatinine, hemoglobin, mitral regurgitation and heart rate) age ($p=0.017$), LVEF ($p=0.006$) and high diuretic dose (p value = 0.043) were independent markers of worse prognosis. In hypervolemic patients only age ($p=0.039$) and LVEF ($p=0.047$) were independently associated with adverse events.

Conclusion: increasing doses of furosemide are associated with adverse outcomes, after adjustment for other predictors of poor prognosis, only in patients without clinical congestion. In hypervolemic patients higher diuretic dose remains an indirect measure of the severity of the disease.

P1735

Effect of left ventricular systolic dysfunction on clinical outcome after transcatheter aortic valve implantation

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; F Carrasco-Chinchilla³; I Rodriguez-Bailon³; JM Garcia-Pinilla³; MF Jimenez-Navarro³; JH Alonso-Brailes³; JM Hernandez-Garcia³; E De Teresa-Galvan³

¹Department of Cardiology, Malaga, Spain; ²Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background: Patients with severe aortic stenosis and reduced left ventricular ejection fraction (LVEF) have a poor prognosis with conservative therapy but a high operative mortality when treated surgically. Recently, transcatheter aortic valve implantation (TAVI) has emerged as an alternative to surgical aortic valve replacement for patients considered at high or prohibitive operative risk. The objective of this study was to analyze the impact the TAVI in patients with severe aortic stenosis with reduced left ventricular ejection fraction.

Methods and results: Between April 2008 and December 2015, 500 patients with symptomatic aortic valve stenosis who were considered high risk or non surgical

candidates underwent implantation with the CoreValve prosthesis. Echocardiographic data were collected before and after the procedure. Impaired LV function was defined by a left ventricular ejection fraction (LVEF < 40%). In 85 patients (17%) had reduced left ventricular ejection function (LVEF < 40%).

Results: The patients with reduced LVEF had more comorbidities compared with normal function: Charlson index 4 ± 1.8 vs. 3.2 ± 1.7 , $P = 0.001$; Karnofsky index 49 ± 18 vs. 63.8 ± 17.6 , $P = 0.001$; Frailty 29.4% vs. 15.4%, $P = 0.002$, worse Logistic EuroSCORE 26.9 ± 16 vs. 15.4 ± 9.7 , $P < 0.001$, were more often males (58.8% vs. 37.2%, $P = 0.01$, more symptomatic (NYHA class IV 58.8% vs. 24.3%, $p < 0.001$, were younger (75.7 ± 7.4 vs. 79.8 ± 5 , $P = 0.001$) and had a higher prevalence of prior coronary artery disease (62.4% vs. 39%, $p = 0.001$). Patients with reduced LVEF showed a good evolution of left ventricular ejection fraction over time (pre, post-procedure and 1 years): 33.9 ± 5 vs. 44.2 ± 11 vs. $51.7 \pm 12\%$, respectively $p = 0.001$. No difference was observed between the 2 groups in in-hospital mortality (4.7% vs. 3.4%, $P = 0.548$). At a mean follow-up of 34.3 ± 23 months, there was a trend to lower mortality in patients with reduced LVEF (12.2% vs. 21.4%, $p = 0.057$).

Conclusions: In patients with severe aortic stenosis and depressed LV systolic function, TAVI is associated with better LVEF recovery and the immediate and long-term outcome after TAVI did not differ between patients with an impaired and preserved LVEF.

P1736

Mortality risk of chronic heart failure patients according to non-invasive lung impedance and New York heart association class in the impedance-HF trial

M Michael Shochat¹; A Shotan¹; I Kleiner²; M Kazatsker¹; I Dahan¹; D Blondheim¹; A Asif¹; J Weinstein²; S Meisel¹

¹Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; ²Saroka Medical Center, Cardiology, Beer Sheva, Israel

Background: stratification of Chronic Heart Failure (CHF) patients by their risk of death is important. The most common predictor used for this purpose is the New York Heart Association (NYHA) class. Such an analysis was performed on data from the IMPEDANCE-HF trial where CHF patients were randomly (1:1) treated in the outpatient clinic with or without measuring lung impedance (LI) to evaluate its impact on recurrent hospitalizations for heart failure (HF).

Methods: Hazard Ratio (HR) was calculated (by Cox regression analyses) for all-cause and HF-related death according to NYHA and LI values. Study population was 256 CHF patients with LVEF $\leq 35\%$ in NYHA class I-IV. NYHA and LI were evaluated during monthly visits in outpatient clinics for average a follow-up of 4 years. Average NYHA and LI values throughout follow up by quartiles were used for analysis. NYHA quartiles were defined as follow: I: 0-1.4 (usual NYHA class), II: 1.41-2.19, III: 2.2-3, and IV: 3-4. Measured LI was presented as deviation from normal baseline in percent with quartiles defined as follows: I: 0 to -17.4%, II: -17.5 to -25%, III: -25.1 to -33.6% and IV: <-33.7%. Quartiles for NYHA and LI were normalized by 1st quartile for the calculation of HR.

Results: HR for all-cause mortality according to NYHA class were found: 1.1 (95% CI: 0.7-1.9, $p = 0.6$) for 2nd quartile, 4.6 (95% CI: 2.7-8.0, $p < 0.0001$) for 3rd quartile and 22.2 (95% CI: 7.7-66.7, $p < 0.0001$) for 4th quartile. HR for HF-related death based by NYHA class were: 1.6 (95% CI: 0.8-3.2, $p = 0.15$) for 2nd quartile, 9.5 (95% CI: 4.2-22.2, $p < 0.0001$) for 3rd quartile and 34.2 (95% CI: 7.7-87, $p < 0.0001$) for the 4th quartile. The HR for all-cause death based on LI quartiles were: 2.7 (95% CI: 1.6-4.6, $p < 0.001$) for the 2nd quartile, 4.4 (95% CI: 2.5-7.7, $p < 0.0001$) for the 3rd quartile and 10.0 (95% CI: 5.3-18.9, $p < 0.0001$) for the 4th quartile. HR for HF-related death according to LI were: 4.9 (95% CI: 2.4-10.2, $p < 0.0001$) for the 2nd quartile, 12.7 (95% CI: 5.1-31.3, $p < 0.0001$) for the 3rd quartile and 31.3 (95% CI: 10.0-90.9, $p < 0.0001$) for the 4th quartile.

Conclusion: Results demonstrate that both NYHA class and LI strongly predict all-cause and HF-related mortality but LI is more strong and specific predictor.

P1737

Prognostic impact of acute heart failure on long-term mortality in patients with ST-elevation myocardial infarction

L Savic¹; I Mrdovic¹; M Asanin¹; G Krljanac¹; R Lasica¹; D Rajic¹

¹Clinical Center of Serbia, Institute for Cardiovascular Disease, Emergency Hospital, Belgrade, Serbia

Purpose: Acute heart failure (AHF) has an adverse impact on outcome in patients with ST-elevation myocardial infarction (STEMI). AHF at admission and AHF which developed during hospitalization have different prognostic impact on short-term mortality in STEMI patients treated with primary percutaneous coronary intervention (pPCI). The aim of this study is to evaluate the prognostic impact of AHF on long-term mortality in patients with STEMI treated with pPCI.

Method: We analysed 1719 consecutive STEMI patients treated with pPCI included in Clinical Center of Serbia STEMI Register. Patients presenting with cardiogenic shock were excluded. The follow-up period was 5 years.

Results: AHF was registered in 396 (23%) patients. Among patients with AHF

288 (72.7%) presented with HF and 108 (27.2%) developed HF during hospitalization. In comparison with patients without HF, patients with AHF were more likely to be older and to be female; they were more likely to have previous myocardial infarction, longer pain duration (before first medical contact), diabetes, lower creatinine clearance, anterior myocardial infarction, lower left ventricular ejection fraction (EF), 3-vessel coronary disease (on initial angiogram), significant left main stenosis, pre-procedural flow TIMI=0 and post-procedural flow TIMI < 3. Five year mortality rates in patients with AHF at admission, in patients who developed HF during hospitalization and in patients without HF were 31.7%, 15.8% and 3.8% ($p < 0.001$) respectively (Figure 1). In Cox regression model AHF (at any time) was a strong independent predictor of 5-year mortality -HR 2.92, (95%CI 1.21-3.39), $p < 0.001$. The risk of 5-year mortality differed in patients with AHF at admission and in those who developed HF during hospitalization: AHF at admission- HR 3.45 (95%CI 2.02-6.03), $p < 0.001$; AHF during hospitalization- HR 1.96 (95%CI 1.13-3.04), $p = 0.039$. Other independent predictors of 5-year mortality were: (older) age HR 1.04 (95%CI 1.03-1.06), $p < 0.001$; EF < 40% HR 2.91 (95%CI 1.72-4.92) $p < 0.001$ and post-procedural flow TIMI < 3 HR 1.79 (95%CI 1.12-2.87), $p = 0.015$.

Conclusion: AHF in patients with STEMI treated with pPCI was a strong independent predictor of 5-year mortality. The risk of 5-year mortality was higher in patients who presented with AHF than in patients who developed HF during hospitalization. AHF at admission was the strongest independent predictor of long-term outcome in analysed patients.

P1738

Differential prognostic value of post-exercise heart rate recovery in patients with chronic heart failure according to etiology

Basic Science Research Program through the NRF of Korea funded by the Ministry of Science, ICT & Future Planning (2015-036645)

JC Youn¹; SY Lee²; SW Choi¹; SW Han¹; KH Ryu¹; SM Kang²

¹Dongtan Sacred Heart Hospital, Hallym University, Division of Cardiology, Hwaseong, Korea Republic of; ²Yonsei University College of Medicine, Seoul, Korea Republic of

Background: Heart rate recovery (HRR) after exercise is an index of parasympathetic function associated with clinical outcomes in patients with chronic heart failure (CHF). However, its differential prognostic value according to the etiology of cardiomyopathy (CMP) is not well investigated.

Purpose: We aimed to evaluate the differential clinical impact of HRR according to etiologies of CHF in consecutively enrolled cohort.

Methods: We measured HRR (calculated as the difference between heart rate at peak exercise and after 2 minute of recovery) in 318 consecutively enrolled CHF patients (255 male, 114 idiopathic dilated CMP, 134 ischemic CMP, 55 ± 13 years, mean ejection fraction $34.1 \pm 9.9\%$). Primary endpoint was cardiovascular (CV) events defined as CV mortality, cardiac transplantation or rehospitalization due to HF aggravation.

Results: The CV events occurred in 37 (11.6%) patients (6 cardiovascular deaths and 6 cardiac transplantations) during follow up period (median 567 days). When the overall patients were divided by HRR according to Contal and O'Quigley's method, low HRR was associated with poor clinical outcome ($P = 0.021$). Multivariate Cox regression analysis revealed that HRR was found to be an independent predictor of CV events in overall CHF patients ($P = 0.043$) and also in idiopathic dilated CMP ($P = 0.01$) but not in ischemic CMP ($P = 0.118$) or in CHF of other etiologies ($P = 0.057$) when controlled for age, body mass index, renal function and beta-blocker use.

Conclusion: HRR is an independent prognostic marker in patients with CHF and its prognostic value is more prominent in patients with idiopathic dilated CMP but not in

ischemic CMP or CHF of other etiologies. These findings may explain the differential relationship between autonomic dysfunction and clinical outcome in these patients.

10.7% PAH-connective tissue and 17.9% type 3/4 of ISHLT classification. Total mortality was 14.3%; 0% for RVSRI $\leq -0.6\text{cm}^2$ and 26.7% for RVSRI $> -0.6\text{cm}^2$

Angiotensin-converting enzyme inhibitors, angiotensin-II receptor antagonists, beta-blockers and ivabradine as supportive therapy in pulmonary hypertension: drug safety and tolerability

M Michele Correale¹; S Quiret¹; R Petrucci¹; A Ferraretti¹; G Padovano¹; S Zichino¹; I Monaco¹; R Ieva¹; ND Brunetti¹; M Di Biase¹

¹University of Foggia, Foggia, Italy

Background: In the 2015 ESC/ERS Guidelines for diagnosis and treatment of pulmonary hypertension (PH), the use of angiotensin-converting enzyme inhibitors (ACEi), angiotensin-II receptor blockers (ARBs), beta-blockers (BBs) and ivabradine (Iva) is not recommended in patients with PAH unless required by co-morbidities, because no convincing data are available on the efficacy and safety of such drugs in patients with PAH. Aim of the study was to therefore evaluate safety and tolerability of these drugs in patients with PH enrolled in the Daunia Heart Failure registry.

Materials and Methods: the study retrospectively analyzed a total of 55 consecutive outpatients with PH. Medical history, heart rate, systolic blood pressure, Body Mass Index, NYHA class, and medications were recorded. Clinical follow up was performed every 4 months. Clinical follow up was anticipated in case of worsening decompensated right heart failure. Drug withdrawal was reported when occurred.

Results: after a mean 2133 ± 289 days of follow-up, only three patients stopped treatment with Iva (15% withdrawal rate), while nine patients stopped treatment with ACEi/ARBs (42%) and nine BBs (40% tolerability). Considering the occurrence of death and hospitalization for heart failure, non-significant rates were found comparing ivabradine group vs non-ivabradine group (46% and 50% vs 24% and 41%, p: ns), ACEi/ARBs group vs non-ACEi/ARBs group (p: ns) and BB group vs non-BB group (p: ns). When considering the combined use of Iva and BBs, different rates of hospitalization for heart failure and mortality were observed (4 groups according to the use of ivabradine and beta-blockers (Iva-/BBs-10% and 0% respectively; Iva-/BBs+64% and 21%; Iva+/BBs- 69% and 54%; Iva+/BBs+31% and 38%).

Conclusions: non-significant differences in terms of safety and survival were found in PH patients with supportive therapies based on ACEi, ARBs, BBs and ivabradine in PH patients.

P1740

Right ventricle systolic remodeling index is a new echocardiography parameter that predicts long time survival in patients with pulmonary hypertension

V Violeta Illatopa¹; F Cordova¹; J Ortega¹; O Aguirre¹

¹EsSalud, Lima, Peru

Purpose: Pulmonary hypertension (PH) is a progressive multifactorial disease. PH mortality is related to right ventricle (RV) ability to adapt in a high afterload environment. We purposed to evaluate a novel parameter defined: "RV systolic remodelling index (RVSRI) (%/cm²)" for long time survival prediction in PH patients.

Method: No left ventricle related PH patients were enrolled. 2D trans thoracic (TTE) speckle tracking echocardiography (Vivid 7500 GE) was performed by two expert operators in RV 4C modified view. RVSRI was defined as a ratio: RV free wall longitudinal strain (RVFWL)/ RV area (RVA)cm²; that ratio represents myocardium systolic function by cm² of RV. Cardiac death was the final point. Baseline evaluation included complete RV TTE, clinical evaluation and hemodynamic PH confirmation. The study adhered to Helsinki and Istanbul declaration.

Results: We followed 28 patients, main follow 19.1 months, main age 43.3 ± 13.4 ; 25% were idiopathic pulmonary artery hypertension (PAH); 46.4% PAH-congenital;

(Log Rank p 0.02). RV heart failure was the final cause of death in all. No differences were found in: TAPSE, RV S', main PA pressure, maximal tricuspid regurgitation velocity or RV tei index between groups according to RVSRI. RVSRI correlated with cardiac index (CI) Pearson 0.49, p 0.013. RVSRI showed a no significant deterioration according to Post tricuspid PAH, Eisenmenger, idiopathic PAH or PAH-connective tissue.

Conclusion: RVSRI is an ETT parameter that describes two types of RV remodelling and predicts long time survival in different aetiologies of PH patients.

P1741

Exercise-induced oxygen desaturation in patients with idiopathic pulmonary arterial hypertension

R Demir¹; UY Sinan¹; MS Kucukoglu¹

¹Istanbul University Cardiology Institute, Department of Cardiology, Istanbul, Turkey

Exercise-induced oxygen desaturation (EID) is associated with increased risk of mortality in idiopathic pulmonary arterial hypertension (IPAH). The aim of this study was to investigate the characteristics of patients who had EID during six minute walking test (6 MWT). Fifty-seven patients were included in the study. Rest and post-exercise SpO₂ were measured using a pulse oximeter with a nger probe. Borg scale was used to measure the levels of dyspnea and fatigue. Pulmonary functions were assessed with spirometry. Twenty-one (36.8%) patients (group I) had EID (14F/7M; mean age 41.8) and 36 were non-desaturated (22F/14M; mean age 44.1). Groups had similar 6MWT distances. Group I had significantly higher post exercise dyspnea, fatigue and had higher change in post exercise dyspnea and fatigue scores. FEV1/FVC was significantly lower in group I. Resting SpO₂ values showed significantly negative correlation with the resting fatigue, post-exercise dyspnea and fatigue, and positive correlation with FVC%, FEV1%, FEV1/FVC. Change in SpO₂ values showed significantly negative correlation with resting fatigue, post-exercise dyspnea and fatigue, and post-exercise change in dyspnea and fatigue. FEV1/FVC was positively correlated with change in SpO₂. In conclusion, IPAH patients with EID despite walking similar distances perceived more dyspnea, fatigue and they had worse pulmonary function as assessed by FEV1/FVC ratio.

Accuracy and precision of systolic pulmonary pressure assessed by echocardiography among patients with pulmonary hypertension

A Adrian Lescano¹; A Lavalle Cobo¹; H Santa Maria¹; G Damianich¹; A Ferro¹; N Gonzalez¹; C Musante²; G Dionisio³; M Gonzalez³; H Grancelli³
¹Finochietto Clinic, Buenos Aires, Argentina; ²Sanatorio de la Trinidad, Quilmes, Argentina; ³Hospital Santojanni, CABA, Argentina

Background: Non-invasive estimation of pulmonary pressures by Doppler echocardiography (DE) is an important tool for the management of pulmonary hypertension (PH) patients. Previous reports suggested the use of the velocity-time integral of the tricuspid reflux (VTI-TR) for estimating the mean pulmonary pressure (MPP). However, there is limited information regarding precision and accuracy of the VTI-TR.

Objective: Estimate the correlation between mean pulmonary pressures assessed by DE using the tricuspid VTI and right heart catheterization (RHC).

Material and methods: Patients with confirmed PH diagnosis (MPP \geq 25 mm Hg) that underwent RHC between March 2012 and May 2015 from three heart failure centers were included in the analysis. The echocardiographic studies were performed using two ultrasound systems (Vivid 5s and Esaote 30 Gold). The MPP was obtained by adding the VTI-TR to the estimated right atrial pressure (RAP), determined by the variation in the size of the inferior vena cava with inspiration. Hemodynamic confirmation of pulmonary pressures was obtained by a RHC using a Swan-Ganz catheter. RHC and DE were performed with less than 24 hours of difference between them and the physicians were blind to echocardiography results. The MPP obtained by the two methods were compared using Lin's concordance correlation coefficient and Bland Altman plot. MPP was categorized in 11 groups per 10 mmHg increase and quadratic weighted kappa (k) was performed for qualitative agreement measures.

Results: A total of 80 patients with diagnosis of PH were included. Mean age was 57.5 years (SD 19) and 73% were women. PH group (G) distribution was GI 64%; GII 16%; GIII 8%; GIV 6% and GV 6%. 79% had heart failure, 26% syncope and 23% chest pain; mean distance in the 6 minute walk test was 326 meters (SD 137). Mean RHC pressures (mm Hg) were: MPP 48 (SD 15), systolic pulmonary pressure (SPP) 76 (SD 20), diastolic pulmonary pressure (DPP) 34 (SD 12), RAP 10 (SD 5.1). The transpulmonary gradient was 35 and mean cardiac index 2.7 liters/min/m². Analysis of DE data shown: mean TAPSE 18 mm (SD 4), SPP 73 mm Hg (SD 16) and MPP 45.6 mm Hg (SD 12.1). The concordance correlation coefficient resulted in 0.83 (95% CI 0.74-0.88), with a Pearson r of 0.84 (precision) and a Cb correction factor of 0.97 (accuracy) (figure 1). The Bland Altman plot shows a mean difference of 2 mmHg (SD 7.6). The k coefficient was 0.80 (95% CI 0.70-0.90). Although related to a small number of observations, DE underestimated MPP above 70 mmHg.

Conclusion: A moderate to high correlation in MPP assessment between a non-invasive technique (VTI-TR) and right heart catheterization was observed among patients with PH. These results supports the use of DE as a reliable diagnosis measure of MPP among patients with PH. Further research may be needed to assess accuracy in very high PH patients (MPP above 70 mmHg).

Correlation of Mean Pulmonary Pressure

P1743

Prevalence of adverse prognostic factors at diagnosis of pulmonary hypertension

A Lavalle Cobo¹; A Ferro¹; H Gomez Santamaria¹; G Damianich¹; N Gonzalez¹; E Bezmalinovich¹; V Daru¹; M Gonzalez¹; H Grancelli¹; AJ Lescano¹
¹Finochietto Clinic, Buenos Aires, Argentina

Background: Pulmonary hypertension (PH) is a multifactorial condition associated with high morbidity and mortality. Multidisciplinary approach is required for its diagnosis and treatment. In the past decades there have been many advances in the epidemiological, pathophysiological and therapeutic knowledge of the disease. However, there is little information available regarding clinical and prognostic factors in patients diagnosed with PH in Latin America.

Aims: Determine the prevalence and clinical characteristics of adverse prognostic factors in a population with initial diagnosis of PH.

Methods: Patients with initial diagnosis of PH (<7 days) confirmed by right heart catheterization (RHC)(mean pulmonary-artery pressure (MPP) \geq 25 mm Hg) from three heart failure and pulmonary hypertension services were analyzed between March 2012 and May 2015. Data recorded included: Personal data, PH group (G), clinical features, direct hemodynamic parameters by RHC, 6 minute walk (6MW) test distance and echocardiographic variables. We defined as adverse prognosis factors: history of heart failure (HF), syncope, advance functional class (FC) (NYHA III-IV), performance in the 6MW test \leq 350 meters (m), presence of pericardial effusion (PE), tricuspid annular plane systolic excursion (TAPSE) \leq 15 mm right atrial pressure (RAP) \geq 12 mm Hg and cardiac index (CI) \leq 2.2 litros/min/m². Data obtained were analyzed with BioEstat 5.3 program.

Results: Multicenter, consecutive and prospective study. A total of 80 patients were included, 73% women. Mean age was 57.5 years (SD 19), 33% \geq 70 years. The mean delay in diagnosis was 26 months after the first sign or symptom recorded. PH group distribution: GI 64%, GII 16%, GIII 8%, GIV 6% and GV6%. FC of presentation: I 4%, II 41%, III 34% and IV 21%. 6MW test mean distance was 315 m (SD 145). RHC: MPP 51 mm Hg (SD 15), systolic pulmonary pressure (SPP) 78 mm Hg (SD 20), diastolic pulmonary pressure 34 mm Hg (SD 12), RAP 10 mm Hg (\pm 5.1), CI 2.7 litros/min/m². Ecocardiographic data: right ventricle systolic function impaired in 85% (slight 45%, moderate 25% and severe 15%). Mean TAPSE 18 mm (SD 4), SPP 73 mm Hg (SD 16). Adverse prognostic factors prevalence was: HF: 75%, syncope: 26%, advance FC: 55%, 6 MW test \leq 350 m: 32%, TAPSE \leq 15 mm: 22%, PE: 31%, RAP \geq 12 mm Hg: 27%, CI \leq 2.2 litros/min/m²: 18%

Conclusions: In this population with initial diagnosis of pulmonary hypertension an elevated proportion of men and patients over 70 years old was observed. At diagnosis time a high number of patients present adverse prognosis factors. This findings remark the need to use early diagnosis and therapeutic strategies.

P1744

Right ventricle characterization in patients with severe pulmonary hypertension due to post tricuspid shunts in contrast with other etiologies.

V Violeta Illatopa¹; F Cordova¹; J Ortega¹; O Aguirre¹
¹EsSalud, Lima, Peru

Purpose: Pulmonary artery hypertension (PAH) due to post tricuspid (PTS) shunt defects have better prognosis compared with other etiologies. Right ventricle (RV) seems to be the key for better survival. The main of the study was determinate differences in RV characteristics of PTS vs other etiologies in PAH.

Methods: Trans thoracic echo was done by two operators. We evaluated: Longitudinal strain (LS) 2D speckle tracking, TAPSE, RV fractional shortening (RVFS); RV tissular systolic peak (RVSP); TEI RV index (TEIRV); RV diastolic area (RVdA); RV systolic area (RVsA); RV basal diameter(d) (RVBd); RV outflow tract d (RVOTd), RVOT fractional shortening (RVOTFS); main PA pressure (mPAP); tricuspid regurgitation velocity (TRV); left ventricle ejection fraction (LVEF); RV global LS (RVGLS); free wall RV LS (FWRVLS); RV basal segment LS (BRVLS); inter ventricular septum LS (IVSLS); posteroseptal medial segment LS (PSmLS) and cardiac index(CI). RV remodeling was defined as RVR =FWRVLS/RVdA(€/cm2). Groups were: groupA(gA): PTS PAH and groupB(gB): pre tricuspid shunts, idiopathic PAH and type 3/ 4 PAH according ISHLT.

Results: We followed 46 patients only in sildenafil. The 15.2% were in gA; in gB: 30.4% idiopathic; 45.7% congenital; 23.9% type 3/4 ISHLT. Mortality: gA 28.5% vs gB 14.38%. Age 41.9 \pm 14.4 years. As expected gA vs gB showed longer RV: (RVsA p 0.02; RVdA p 0.003; RVBd p 0.003); higher mPAP: 68.8 \pm 2.9 vs 46.2 \pm 10 mmHg (p 0.0002) and TRV 7.5 \pm 4.9 vs 4.2 \pm 0.6m/s(p 0.0001). No differences in TAPSE (17.5mm); TEIRV (0.8); RVSP(10.3cm/s); RVGLS (-14.9%) or RVFS (33.8 \pm 11.3 %). Between gA and gB there was a trend in less dilated (RVOTd \geq 35mm(0 vs 27%), better RVOTFS \leq 30%(33.3 vs 71.4%), worse PSmLS(-9.5 \pm 9 vs -14.4 \pm 5.4) and IVSLS%(-10.0 \pm 6 vs -14.5 \pm 6). Segmental RV asses showed gA vs gB: FWRVLS %(-20 \pm 3.4 vs -14 \pm 6.9 p 0.05), BRVLS %(-22 \pm 9 vs -13 \pm 9 p 0.03) and CI (4.2 \pm 1.1 vs 2.8 \pm 0.9 ml/min/m²). RVR showed inverse correlation with CI pw -0.5 (p 0.01); and it was twice in gA than gB 2: -1 \pm 0.4 vs -0.5 \pm 0.4 (p 0.02 IC -0.8 - -0.08).

Conclusion: PTS PAH patients show longer RV. Despite higher mPAP and RTV, PTS patients have better LS of RV free wall; better RV remodeling and CI than gB. RVR described as FWRVLS/RVdA relation is a parameter that should be more studied as possible good marker of RV remodeling by echo.

P1745

Right ventricular vascularization in patients with pulmonary arterial hypertension.

W Magon¹; J Stepniewski¹; M Waligora¹; P Podolec¹; G Kopec¹
¹Jagiellonian University Medical College, Department of Cardiac and Vascular Diseases, Krakow, Poland

Introduction: Chronic pressure overload of the right ventricle (RV) leads to increased oxygen and metabolic demand which are important triggers of angiogenesis. Aim

To determine vascularization of RV in patients with pulmonary arterial hypertension (PAH) and its impact on survival.

Methods: We enrolled consecutive patients with PAH diagnosed in single pulmonary hypertension centre between 2011 and 2015, who underwent routine coronary angiography. Control group comprised of age- and sex-matched subjects without PAH who were diagnosed for ischemic heart disease but had normal coronary vessels. Artery branches from segments I-III of the right coronary artery (right ventricular branches, RVB) and branches of the left coronary artery (LVB) were assessed by investigator blinded to diagnosis. The mean diameter of RVBs calculated as a sum of diameters of all RVBs divided by the number of all RVBs was used as a marker of right ventricle vascularisation. For survival analysis we used univariate Cox proportional hazard model. Results We recruited 37 PAH patients (idiopathic, n=25; associated with connective tissue disease, n=12) and 37 controls of similar age (56 ± 18 vs 56 ± 13 years, $p=0.99$) and sex (73% vs 73% of women, $p=0.99$). PAH patients were in World Health Organization class: II (n=10), III (n=24), and IV (n=3), mean distance in 6-minute walking test was 302 ± 110 m, median pulmonary artery pressure: $45 [35-57]$ mmHg, median pulmonary vascular resistance: $10.8 [7.3-16.0]$ WU, and median cardiac index: $1.88 [1.45-2.45]$ L/m²/min. PAH patients as compared to control group had more RVBs (7.2 ± 1.6 vs 6.2 ± 1.3 , $p=0.01$) and mean diameter of RVBs (1.35 ± 0.20 mm vs 1.22 ± 0.14 mm, $p=0.001$). We did not find any difference in the number of the branches of left coronary artery (4.5 ± 1.0 vs 4.1 ± 0.9 , $p=0.14$). In univariate Cox model mean RVB diameter predicted survival of PAH patients (HR=0.01 [0.001-0.35], $p=0.03$). Conclusion Vascularization of the right ventricle is increased in patients with PAH than in controls without pulmonary hypertension. Increased mean diameter of RVBs is associated with better survival.

RIGHT VENTRICULAR FUNCTION

Assessment of right ventricular to pulmonary circulation uncoupling at peak exercise in heart failure by the relationship between pulmonary systolic pressure vs free-wall right ventricular strain

V Valeria Donghi¹; F Bandera¹; V Labate¹; G Generati¹; M Pellegrino¹; E Alfonzetti¹; M Guazzi¹

¹IRCCS Policlinico San Donato, Heart failure unit, San Donato Milanese, Milan, Italy

Background: Speckle tracking analysis is an emerging technique that can be useful to assess abnormalities in cardiac contractility before traditional echo parameters, with particular interest to right ventricle (RV) performance.

Purpose: To investigate whether RV 2D speckle tracking analysis at peak exercise could stratify a heart failure reduced ejection fraction (HFrEF) population in different functional phenotypes, with particular emphasis on RV to pulmonary circulation relationship.

Methods: 36 HFrEF patients (mean age 69 ± 12 ; male 69%; NYHA I-II-III-IV 19-17-25-5 %) underwent a maximal cardiopulmonary exercise testing evaluation (bike, incremental ramp protocol) combined with Echo-Doppler and off-line speckle tracking analysis. Study population was divided in two groups according to median value of 2D right ventricle free-wall longitudinal strain at peak exercise (Group A RVLS at peak < -19 , 17 patients vs Group B ≥ -19 , 19 patients). In all patients we performed traditional echo and 2D longitudinal speckle tracking analysis at rest and peak exercise.

Results: Despite similar left ventricle ejection fraction (Group A $36 \pm 9\%$ vs Group B $32 \pm 9\%$, $p=ns$) and right ventricle longitudinal strain (RVLS) at rest (Group A $-23.2 \pm 7\%$ vs Group B $-18.8 \pm 9.1\%$, $p=ns$), Group B patients showed a similar exercise performance (Peak VO₂ Group A 31.6 ± 7.4 vs Group B 31.6 ± 3.4 mlO₂/Kg/min, $p=ns$) but more impaired ventilation (VE/VO₂ slope Group A 31.6 ± 7.4 vs Group B 37.4 ± 8.8 , $p < 0.05$), and a clear RV to PC uncoupling at peak exercise as assessed by the relationship between pulmonary systolic pressure vs free-wall RVLS (see figure below). Strain data were according to traditional echo parameters.

Conclusions: In HFrEF RV speckle tracking analysis at peak exercise seems a useful technique for unmasking RV to PC uncoupling and the unfavorable gas exchange and ventilatory phenotypes.

Pediatric heart transplantation recipients: echocardiographic evaluation of right heart structure and function

R Rita Gravino¹; G Limongelli¹; A Petraio²; R Vastarella¹; D Masarone¹; T Marrazzo¹; C Amarelli²; C Maiello²; MG Russo³; G Pacileo¹

¹Heart Failure Unit, AO dei Colli-Monaldi Hospital, Department of Cardiology, Second University of Naples, Naples, Italy; ²Cardiac Transplantation Unit, AO dei Colli-Monaldi Hospital, Naples, Italy; ³Pediatric Cardiology Unit, AO dei Colli-Monaldi Hospital, Department of Cardiology, Second University of Naples, Naples, Italy

Introduction: Although in adult cardiac transplant recipient patients the right heart is a major determinant of prognosis, its impact in pediatric age has not been adequately investigated.

Purpose: To investigate right ventricular (RV) morphology and function in pediatric cardiac transplant recipient patients using both standard transthoracic echocardiography and new echocardiographic techniques (2D-strain).

Methods: 20 relatively stable pediatric cardiac transplant recipient patients (M/F: 11/9; mean age 14.5 ± 4.5 years; length of follow-up: 3.8 ± 3 years) (Group A) and 40 healthy age and sex matched controls (Group B) underwent standard echocardiography, tissue Doppler imaging (TDI), and 2D-strain, focused on RV analysis. Along with left ventricular (LV) heart parameters, RV measurements included end-diastolic diameters at basal and mid-cavity level; base-to-apex length; tricuspid annulus plane systolic excursion (TAPSE); TDI RV systolic peak velocity (Sm); and global 2D-strain. Finally pulmonary artery systolic pressure (PASP) was calculated using the peak systolic tricuspid regurgitation velocity (TRV).

Results: LV diameters and ejection fraction did not significantly differ between two groups. On the other hand, in Group A patients mass index was increased and RV diameters were significantly increased ($p < 0.001$), whereas TAPSE and RV Sm were significantly lower ($p < 0.05$). Furthermore, in Group A patients, 2D RV strain was significantly reduced ($p < 0.001$) regardless PASP. By multivariable analysis, in Group A patients age at transplantation was the only independent determinant of RV diameters and 2D-strain ($p < 0.01$).

Conclusions: Pediatric population heart transplant recipient patients show a reduction of RV performance function assessed by TAPSE, right ventricular Sm and global 2D-strain. Of interest, there is a significant correlation between RV dysfunction and length of follow-up. However, further studies with larger populations are needed to confirm these data to define the role of new echocardiographic technologies in their clinical management.

P1748

Echocardiography predicts right ventricular size and function in patients with dilated cardiomyopathy: a comparison with magnetic resonance imaging

Supported by unrestricted grants to the Dept of Cardiology, Oslo University Hospital from Inger and John Fredriksen and an anonymous donor

K Kaspar Broch¹; E Hopp²; L Gullestad³; S Aakhus³

¹University of Oslo, Rikshospitalet University Hospital, Department of Cardiology, Oslo, Norway; ²Oslo University Hospital, Rikshospitalet, Department of Radiology and Nuclear Medicine, Oslo, Norway; ³Oslo University Hospital, Rikshospitalet, Department of cardiology, Oslo, Norway

Introduction: Right ventricular (RV) size and function can be difficult to estimate by echocardiography due to the complex geometric shape of the right ventricle. Magnetic resonance imaging (MRI) is the gold standard when assessing RV size and function, but is costly and resource demanding.

Purpose: We aimed to assess echocardiographic indices of RV size and function in a prospectively recruited population of patients with dilated cardiomyopathy (DCM). We compared results with those obtained by MRI.

Methods: In 44 patients with idiopathic DCM and an LV ejection fraction (EF) $< 40\%$, we performed echocardiography and cardiac MRI. Image analysis was performed blinded to patient characteristics and to the results of the other image modality. The echocardiograms were analysed off-line according to current recommendations with particular focus on RV function. For the MRI measurements, RV endocardial borders were traced manually, and volumes and ejection fractions were calculated by short axis slice summation.

Results: RV end diastolic and end systolic volumes were 198 ± 76 ml and 124 ± 74 ml, and RV ejection fraction (EF) was $40 \pm 14\%$ as measured by MRI. Left ventricular EF was $28 \pm 12\%$. End diastolic and end systolic RV area were firmly associated with corresponding RV volumes as measured by MRI ($r=0.79$; $p < 0.001$ and $r=0.86$; $p < 0.001$, respectively). All pre-specified measures of RV function: fractional area change; tricuspid annulus plane systolic excursion (TAPSE); and RV peak strain were associated with RV EF as measured by MRI. (Table). The association was somewhat weaker for TAPSE, even after adjusting for right ventricular long axis dimension by echocardiography. The relatively low association between TAPSE and RV EF might be due to translational movement of the right ventricle in these patients with severely dilated and dysfunctional left ventricles.

Conclusions: Indices of RV function obtained by echocardiography, in particular RV strain, correlates strongly with RV EF as measured by MRI in patients with dilated cardiomyopathy. TAPSE may be less reliable in this population.

Echo parameter	Value	Association with RV EF by MRI	
r	p		
RV fractional area change	19 ± 6	0.69	< 0.001
RV global strain	-13.5 ± 4.2	-0.76	< 0.001
RV free wall strain	-17.8 ± 5.2	-0.77	< 0.001
TAPSE (mm)	19 ± 6	0.46	0.002
Adjusted TAPSE (mm/cm)	2.2 ± 0.7	0.53	< 0.001

P1749

Right ventricular improvement parallels left ventricular improvement after introduction of therapy for dilated cardiomyopathy

Supported by unrestricted grants to the Dept of Cardiology, Oslo University Hospital from Inger and John Fredriksen and an anonymous donor K Kasper Broch¹; E Hopp²; AK Andreassen³; S Aakhus³; L Gullestad³
¹University of Oslo, Rikshospitalet University Hospital, Department of Cardiology, Oslo, Norway; ²Oslo University Hospital, Rikshospitalet, Department of Radiology and Nuclear Medicine, Oslo, Norway; ³Oslo University Hospital, Rikshospitalet, Department of cardiology, Oslo, Norway

Introduction: Dilated cardiomyopathy (DCM) is characterised by left ventricular (LV) dilation and functional impairment, but also affects right ventricular (RV) function. Magnetic resonance imaging (MRI) is considered the gold standard when assessing RV size and function. RV function has not been well characterised in patients with DCM.

Purpose: We aimed to assess RV function in patients with recent-onset DCM, and to determine whether RV functional improvement occurred with the introduction of pharmacological treatment for heart failure.

Methods: We prospectively recruited 88 patients aged 52 ± 13 years, 30 % females, with idiopathic DCM and an LV ejection fraction (EF) <40 %. Baseline work-up included cardiac MRI, echocardiography, and right sided heart catheterisation. MRI was repeated in 59 patients after one year. Predictors of baseline RV EF were analysed by regression analyses. Changes from baseline to one year were assessed by paired t-tests.

Results: At baseline, RV end diastolic and end systolic volumes were 206 ± 75 ml and 131 ± 71 ml. RV EF was 39 ± 13%, and 71 patients (81%) had an RV EF <50%. LV and RV EFs were strongly associated ($r = 0.73$; $p < 0.001$). LV EF by MRI, pulmonary capillary wedge pressure, and E/e', representing LV diastolic function, were all independently associated with RV EF (Table). After one year on drug therapy for heart failure, LV and RV EFs improved by 14 ± 13 and 8 ± 12 percentage points, respectively. The improvement in RV EF closely paralleled the improvement in LV EF ($r = 0.76$; $p < 0.001$), and was more pronounced in patients with a poor RV EF at baseline ($r = 0.68$; $p < 0.001$).

Conclusions: In DCM, RV function is reduced, but improves in parallel with LV functional improvement after the initiation of therapy for heart failure. LV systolic and diastolic function and filling pressure are determinants of RV function in these patients.

Variable	Baseline value	Univariate analysis	Multivariate analysis	
r	p	Beta	p

Value of global longitudinal strain in right ventricle myocardial infarction diagnosis

BASSEM Reikik¹; R Hammami¹; FATEN Triki¹; NADA Tabebi¹; MOURAD Hentati¹; LEILA Abid¹; SAMIR Kammoun¹
¹Hedi Cheker Hospital, Department of Cardiology, Sfax, Tunisia

Background: Right ventricular (RV) dysfunction after inferior acute myocardial infarction (AMI) is frequent and associated with a poor prognosis. Quantification of RV deformation by speckle-tracking echocardiography is a widely available and reproducible technique that readily provides an integrated analysis of all segments of the right ventricle. The aim of this study was to investigate the accuracy of conventional echocardiographic parameters and speckle-tracking echocardiographic strain parameters in assessing RV function after inferior AMI.

Methods: Thirty one patients admitted for inferior AMI were prospectively studied. Right ventricular function was assessed by echocardiography within 2 to 4 days of hospital admission. Right ventricular infarction was defined by ST elevation in rights leads (V3R and V4R). Right ventricular global peak longitudinal systolic strain (GLPSS) was calculated by averaging the strain values of the apex, base, and mid cavity.

Results: In patients with inferior myocardial infarction, right ventricular dysfunction was documented in 10 patients. There was significant difference between group 1 (n = 10) and group 2 (n = 21) in TAPSE (13.20 ± 1.3 vs 20.59 ± 5.5, $p < 0.001$), MPI by tissue Doppler (0. ± 0.65 vs 0.39 ± 0.1, $p < 0.001$) and in tissue Doppler systolic velocity from RV free wall (S' 8.80 ± 1.1 vs 13.29 ± 2.5, $p = 0.01$). Right ventricular fractional area change (RVFAC) (0.29 ± 0.9 vs 0.39 ± 0.9, $p = 0.02$). Right ventricular GLPSS was the best echographic parameter correlate with RVFAC ($r = -0.48$, $P = 0.006$) and possessed good diagnostic value for RV dysfunction, which was comparable with tricuspid annular plane systolic excursion (TAPSE) ($r = -0.47$, $P = 0.007$) and doppler systolic velocity from RV free wall ($r = -0.66$, $P < 0.001$).

Conclusions: In patients with inferior AMIs, RV GLPSS displays higher diagnostic value than conventional echocardiographic parameters.

P1751

Correlation of ST-2 blood levels and the condition of the right heart departments in patients with severe heart failure

M G Koliadko¹; A K Alena Kurlianskaya¹; T L Denisevich¹; Y P Ostrovsky¹
¹Research & Practical Centre "Cardiology", Minsk, Belarus

Aim: To investigate a relationship of biomarkers ST-2 and right heart hemodynamic, laboratory indices (NT-proBNP, C-reactive protein (CRP)) in patients with end stage of heart failure (HF).

Methods: ST2 blood assessment and hemodynamic of right heart (tricuspid regurgitation (TR), systolic pressure of pulmonary artery (SP PA, mm Hg), right ventricular end-systolic (ESS RV, mm2) and end-diastolic square (EDS RV, mm2)) were assessed. This study involved pts 18 - 65 years old, with end-stage chronic heart failure (III-IV functional class), with a poor prognosis, no remaining alternative treatment options, accepted in the transplant waiting list.

Results: In vivo ST2 blood level and hemodynamic parameters that characterize right heart function in patients with severe HF showed significant and strong correlation: with ESS RV ($r_s = 0.72$, $=0.008$), EDS RV ($r_s = 0.64$, $=0.009$), TR ($r_s = 0.70$, $=0.011$). The correlative connection of medium strength was revealed with the indices of SP PA ($r_s = 0.42$, $=0.008$). And was performed the comparative analysis of echocardiography parameters in groups of patients with HF formed on the basis of the primary levels of ST2 (tabl. 1). Our results demonstrate that in patients with ST2 ≥ 30 ng/ml all crucial echocardiography parameters were significantly higher: SP PA – by 25,0% ($=0.009$), ESS RV – by 50,0% ($=0.007$), EDS RV – by 32,0% ($=0.011$), TR – by 20,0% ($p=0.031$).

But was founded weak significant correlation between group of laboratory markers of the severity of heart failure: NTproBNP and CRP blood levels ($r_s = 0.29$, $=0.049$) with ST2.

Conclusions: Serum levels of the interleukin-1 receptor family member ST2 is independent of traditional factors, such as age and body mass index and hemodynamic of the left part of heart in the end stage of heart failure before transplantation, which usually affect levels of CRP, NTproBNP. Soluble ST2 could reflect the state of right ventricular and can be used for diagnosis of chronic heart failure that depending of insufficiency of the right heart.

Parameter	ST-2 < 30 ng/ml (Me (LQ-UQ))	ST-2 ≥ 30 ng/ml (Me (LQ-UQ))	
SP PA, mm Hg	44,0 (38,0-52,0)	55,0 (51,0-57,5)	0,009
TR, degree	2,5 (1,0-3,0)	3,0 (2,5-4,0)	0,031
EDS RV, cm ²	76,0 (45,0-96,0)	114,0 (75,0-159,0)	0,011
ESS RV, cm ²	50,0 (27,0-77,0)	66,0 (50,0-113,0)	0,007

P1752

Clinical scores for right ventricular failure prediction after left ventricular assist device implantation: should we trust them?P Piergiorgio Tozzi¹; R Hullin²; F Gronchi³; G Siniscalchi¹; P Yerly²; C Marcucci³¹University Hospital Centre Vaudois (CHUV), Cardiac Surgery, Lausanne, Switzerland; ²University Hospital Centre Vaudois (CHUV), Cardiology, Lausanne, Switzerland; ³University Hospital Centre Vaudois (CHUV), Anesthesiology, Lausanne, Switzerland

Background: In the era of continuous flow left ventricular assist devices (LVAD), the decision of whether a patient will tolerate isolated LVAD support or will need biventricular support (BIVAD) can be challenging. Incorrect decision making with delayed right ventricular (RV) assist device implantation results in increased morbidity and mortality. Several risk stratification tools have been recently developed to predict the need of right assist device (RVAD) implant concomitant to continuous flow LVAD implantation, but none seems to outperform the others. We reviewed our experience to validate the most recent strategies that should be able to identify patients who are at risk of post LVAD right ventricular failure (RVF).

Methods: We retrospectively collected demographic, hemodynamic, and echocardiographic variables for 34 consecutive patients who underwent VAD implant from 2010 through June 2015 (LVAD=32, BIVAD=2). We defined pre-operative RVF based upon echocardiographic parameters, taking into account RV contractility, tricuspid regurgitation, and tricuspid annular motion (TAPSE). Post-operative RV failure was defined according to INTERMACS Protocol 3 definition (CVP>18mmHg, CI < 2 l/min/m², need for nitric oxide or inotrope therapy > 7 days after LVAD implant). For each patient, we calculated the CRITT score (CVP > 15 mmHg, RV Dysfunction, Intubation preoperatively, Tricuspid regurgitation, Tachycardia > 100 and each variable is assigned a score of 0 or 1) and applied the Pittsburgh Decision Tree (PDT) specifically designed for continuous flow circulatory support devices. We assessed the performance of the score by entering it in a logistic regression model with RV failure as the outcome. The PDT was entered as a single binary predictor.

Results: The mean age was 52 ± 12; 70.5% were men. The indication was bridge to transplant in 100%. Etiology was ischemic in 42%; 14.7% required additional mechanical circulatory support after LVAD implant (BVAD=2, ECMO=3). All patients received continuous flow LVADs (Heartmate II=13, HeartWare=21). By 30 days, 22 patients (64.7%) developed RVF defined as the need for RVAD (n=2); pulmonary vasodilator use > 48h (n=18); inotropes for > 14 days post LVAD (n=22). According to CRITT score the RVF expected rate was 29% (10 patients had 4 or 5 corresponding to 80% risk of RVF). According to PDT, 8 patients needed BVAD. CRITT score achieved best performances (C statistics = 0.60; CI 95%; sensitivity = 90%; specificity 8.3%; accuracy 61.8%).

Conclusions: These data indicate that even clinical RVF risk prediction models developed in the era of continuous flow pumps have rather limited clinical applicability. We definitely need new clinical test based on quantitative pre-operative imaging data, able to quantify the functional reserve of RV to drive our clinical decision about using an isolated LVAD versus BIVAD, especially in the destination therapy perspective.

LEFT VENTRICULAR FUNCTION

Inducible myocardial ischemia due to obstructive coronary artery disease is associated with subclinical LV dysfunction in patients with stable anginaC Caselli¹; V Lorenzoni²; M Lombardi³; R Sicari¹; AJ Scholte⁴; J Knuuti⁵; SR Underwood⁶; A Clerico²; M Emdin⁷; D Neglia⁷¹Institute of Clinical Physiology of CNR, Pisa, Italy; ²Scuola Superiore Sant'Anna, Pisa, Italy; ³IRCCS, Policlinico San Donato, San Donato Milanese, Italy; ⁴Leiden University Medical Center, Leiden, Netherlands; ⁵University of Turku and Turku University Hospital, Turku, Finland; ⁶Imperial College London, London, United Kingdom; ⁷Gabriele Monasterio Foundation, Pisa, Italy

Background: Repetitive myocardial ischemia might impair LV function in patients with stable coronary artery macrovascular and/or microvascular disease (CAD).

Purpose: To assess the relationship between inducible myocardial ischemia, presence of obstructive CAD and LV function in patients with stable angina.

Methods: Clinical, functional and imaging data were collected in 362 patients (212 males, 150 females, mean age 60 ± 9 years) with stable angina and suspected CAD enrolled in the Evaluation of Integrated Cardiac Imaging (EVINCI) study. All patients underwent echocardiography and circulating NT-proBNP measurements to assess LV function, stress imaging to detect myocardial ischemia and coronary computed tomography angiography (CCTA) to assess the presence of obstructive CAD (>50% stenosis of a major coronary vessel). Only patients with LVEF ≥ 50% were included in this substudy.

Results: LVEF was 60 [55-66] %, median [25-75 percentiles], and NT-proBNP was 60.7 [30.7-128.0] ng/L in the whole population. Patients were subdivided in 4 groups according to the presence/absence of myocardial ischemia and obstructive CAD.

LVEF and NT-proBNP values are compared among groups in Figure 1. Patients with obstructive CAD+Ischemia had significantly lower LVEF and significantly higher NT-proBNP values than the other groups. At multivariate analysis including age, sex, cardiovascular risk factors, drugs, CTA and stress imaging results, presence of obstructive CAD+Ischemia was the only coronary pattern predicting both LVEF (Coefficient: - 0.119 ± 0.03 (SE), p < 0.0001) and NT-proBNP (0.512 ± 0.15, p = 0.0009) values.

Conclusions: In patients with stable angina, inducible myocardial ischemia caused by macrovascular obstructive CAD is associated with early impairment of LV function.

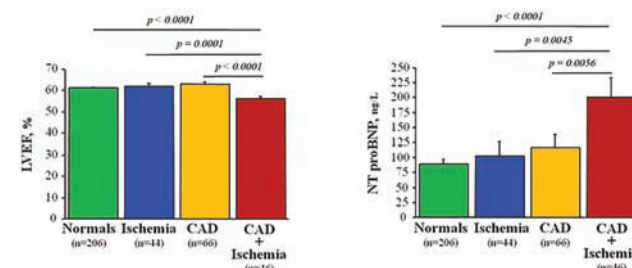

Figure 1

P1754

Correlates of reduced left ventricle ejection fraction in young patients with acute myocardial infarction

Odeus project supported by Sectoral Operational Programme Human Resources Development 2007-2013, under the contract POSDRU/6/1.5/S/17

A M Andronescu¹; C S Stamate¹; A Nechita¹; V Enache¹; R L Ploesteanu¹; M Dorobantu²¹St. Pantelimon Emergency Hospital, Bucharest, Romania; ²Emergency Clinical Hospital Floreasca, Bucharest, Romania

Background: Acute myocardial infarction (AMI) is an important cause of left ventricular systolic dysfunction in young patients.

Purposes: To identify the clinical, biological, electrocardiographic and angiographic factors associated with reduced left ventricle ejection fraction (LVEF) after AMI in patients younger than 45 years and to evaluate its impact on long-term outcome.

Methods: The studied population consisted of 168 consecutive young adults (mean age 39 ± 5 years) admitted for AMI in two acute cardiac care units between January 2009 and December 2011. The baseline characteristics, procedures and treatment were collected at the time of the index event and analyzed for the two groups: patients with LVEF ≥ 50% and those with LVEF < 50%. The patients were followed-up for up to 4 years (mean 3 ± 1 years); the main outcome was a composite of major adverse cardiac events (MACE): cardiovascular death, new myocardial infarction, further revascularization and emergency cardiac readmissions.

Results: Reduced LVEF was found in 64 patients (38%) with no significant difference between men and women (40% vs 28.6%, p = 0.2). There was a strong negative correlation between LVEF and admittance glycemia (r = -0.2247, p = 0.003), white blood cells number (r = -0.3290, p < 0.001) and hs C-reactive protein (r = -0.5095, p = 0.006). Mean heart rate was significantly higher in the reduced LVEF group on both initial (89 ± 20 vs. 82 ± 18 bpm, p = 0.02) and at 24 hours after admission measurements (81 ± 17 vs. 72 ± 13 bpm, p < 0.001). In the STEMI patients, the median "symptom onset - reperfusion" time (LVEF < 50%: 307 [217-465] min vs LVEF ≥ 50%: 250 [180-420] min, p = 0.2) and TIMI 3 flow in the culprit artery (84% vs. 79%, p = 0.4) were similar between the two groups but the persistence of ST elevation > 50% post-reperfusion correlated with LVEF < 50% even in patients with TIMI 3 flow (OR 0.19, IC 95% 0.06-0.57). Regardless of the AMI type, factors independently associated with reduced LVEF were left anterior descendant artery significant stenosis (OR 5.00, IC 95% 1.81-13.80), tri-vessel disease (OR 40.6, IC 95% 4.70-350.08), admission leucocyte number (OR 1.002, IC 95% 1.00-1.003), 24 hours heart rate (OR 1.04, IC 95% 1.00-1.08), pathological Q waves (OR 6.24, IC 95% 1.32-29.46) while positive history of premature CVD was still associated with LVEF > 50% (0.05, IC 95% 0.00-0.48).

In survival analysis, 3 years MACE rate was higher in the LVEF < 50% group of young patients (40.7% vs 23.1%, logrank 8.28, p = 0.004).

Conclusions: 1) The mechanisms for reduced EF after AMI in young are likely to be multifactorial. Beside established factors like severe and extensive atherosclerotic coronary disease, admission leucocyte count and some early electrocardiogram signs may predict LV systolic dysfunction after AMI in young patients.

2) LVEF < 50% is correlated with poor outcome after AMI in patients younger than 45 years of age.

P1755

Recovery of left ventricular systolic function: implications for the implantation of ICD and CRT-D?

S Sofia Alegria¹; O Simoes¹; R Miranda¹; S Almeida¹; AR Almeida¹; L Lopes¹; D Caldeira¹; C Gomes¹; L Brandao¹; H Pereira¹

¹Hospital Garcia de Orta, Cardiology, Almada, Portugal

Introduction: Implantation of cardioverter-defibrillator (ICD) is a well established therapy for primary prevention of sudden death in patients with left ventricular (LV) systolic dysfunction. Nevertheless, questions remain about the indication for maintaining this therapy at the time of generator replacement, in patients with LV function improvement and no dysrhythmic events.

Purpose: To evaluate the prevalence of LV function recovery in patients with ICD for primary prevention of sudden death, and the associated variables.

Methods: Retrospective analysis including patients with ischemic cardiomyopathy or non-ischemic dilated cardiomyopathy and LV ejection fraction (EF) $\leq 35\%$ submitted to implantation of ICD, with or without associated cardiac resynchronization therapy (CRT), for primary prevention of sudden death, between 2011 and 2014.

Results: Fifty-nine patients, with mean age 61 ± 10 years and male predominance (68%) were included. There was a higher prevalence of ischemic cardiomyopathy (66%), 71% were submitted to implantation of an ICD and 29% of a CRT-D. The baseline mean EF was $28 \pm 6\%$ and the median NT-proBNP was 1565 pg/ml (interquartile range 315-3456 pg/ml). During a mean follow-up of 825 ± 412 days, 34.9% of the 43 patients with available data had LV function recovery (defined as final EF $> 35\%$, with improvement $\geq 5\%$). The incidence of appropriate therapies was 17% and the mortality rate 15%. LV function recovery was more common in patients with associated CRT, although this difference did not reach statistical significance (54% vs. 27%, $p=0.086$). The variables associated with LV function recovery were non-ischemic etiology (53% vs. 23%, $p=0.045$; OR 3.8, 95% CI 1.0-14.0), absence of late enhancement on cardiac MRI (100% vs. 0%, $p=0.025$) and NT-proBNP < 1500 pg/ml (73% vs. 17%, $p=0.007$; OR 13.3 95% CI 1.78-100.0). ROC curve analysis showed that baseline NT-proBNP had a good discriminative capacity for LV function recovery (AUC = 0.74, $p=0.033$); the best cut-off was 1320 pg/ml (sensitivity 77%, specificity 71%). LV function recovery was also associated with a lower risk of death during follow-up (0% vs. 25%, $p=0.034$; OR 1.33 95% CI 1.1-1.7).

Conclusions: In this study of patients submitted to implantation of ICD or CRT-D for primary prevention of sudden death, LV function recovery was common, and associated with a lower long-term mortality. We found that LV systolic function recovery was associated with non-ischemic etiology, absence of late enhancement on cardiac MRI and baseline NT-proBNP. These data may contribute for a better identification of patients who will benefit the most from this therapy.

P1756

Three-dimensional and speckle tracking echocardiography application for early identification of left ventricular remodelling after myocardial infarction

A Arnas Karuzas¹; T Ptasiński¹; J Atkocaitytė²; E Tamulevičiūtė-Prasčiene²; G Muckienė²; E Jankauskienė²; D Zaliaduonytė-Peksiene²

¹Lithuanian University of Health Sciences, Cardiology, Kaunas, Lithuania; ²Hospital of Lithuanian University of Health Sciences, Cardiology department, Kaunas, Lithuania

Introduction: Cardiac remodelling is generally accepted as a determinant of the clinical course of heart failure. The usefulness of 3D echocardiography (3DE) has been demonstrated in the evaluation of cardiac chamber volumes and mass, which avoids geometric assumptions. Speckle-tracking echocardiography (STE) has emerged also as a novel technique for left ventricular (LV) functional assessment, but both techniques have a lack of information about its prognostic value for LV remodelling after acute myocardial infarction (AMI).

Purpose: To determine the prognostic value of 3DE and STE parameters for LV remodelling after AMI.

Methods: This was a prospective study where 75 AMI patients were included and underwent 3DE and STE examination within 3 days of AMI and at 6-month follow-up. LV remodelling was defined as a $\geq 15\%$ increase in the LV end-diastolic volume (EDV) at follow-up compared with the baseline. Statistical analysis was performed using Kruskal-Wallis analysis ((median (min-max)), ROC curves and logistic regression.

Results: At follow-up, 22 patients (27%) were classified as having LV remodelling. Morphometric parameters of LV measured by 3DE were significant between LV remodeling group and non-remodeling group patients: EDV-140.9 ml (66.3-255.95) vs. 115.2 ml (53.3-156.9) ($p=0.006$), end-systolic volume (ESV) - 89 ml (25.9-139.2) vs. 66.9 ml (35.28-111.63) ($p=0.003$), sphericity index (SI) - 0.43 (0.23-0.66) vs. 0.31 (0.14-0.74) ($p=0.001$) and systolic dyssynchrony index (SDI) - 4.75% (2-11.1) vs. 3.6% (0.5-8.1) ($p=0.034$), respectively). Echocardiographic parameters measured by STE were the same in both groups, except for LV torsion ($1.53^\circ/\text{cm}$ (0.56-1.98) and $2.02^\circ/\text{cm}$ (0.72-2.93), $p=0.008$). Logistic regression and ROC analysis revealed that some 3DE parameters and LV torsion had significant predictive value for occurrence of LV remodeling (Table 1).

Conclusions: 3DE parameters had a high prognostic value for prediction of LV remodelling after AMI where sphericity index is superior. LV torsion as STE parameter could also be a useful parameter of LV remodelling prediction when 3DE is not applicable.

Table 1

Parameters	Cut- off value	Sensitivity (%)	Specificity (%)	AUC	p-value
3D EDV (ml)	> 115.3	71	79	0.74	0.028
3D ESV (ml)	> 69.8	69	78	0.73	0.042
3D SDI (%)	> 4.6	73	77	0.78	< 0.001
3D SI	> 0.50	90	91	0.96	< 0.001
LV torsion ($^\circ/\text{cm}$)	< 1.34	62	74	0.70	0.038

Predictive value of echocardiographic parameters measured by 3DE and STE for LV remodelling development

P1757

Left ventricular remodeling in women with surgical and natural menopause

N Natalia Lareva¹; A Govorin¹; E Luzina¹

¹Chita State Medical Academy, Chita, Russian Federation

Purpose: To assess structural and functional changes of left ventricle in postmenopausal women in dependence on menopause type and arterial hypertension characteristics.

Methods: 203 postmenopausal women were included in the investigation: the 1st group - 61 women with natural menopause (average age 46.2 ± 4.7 years, menopause duration 4.3 ± 2.1 years); and the 2nd group - 142 women with surgical menopause (average age 44.3 ± 5.4 years, menopause duration 3.8 ± 2.4 years). All patients underwent general clinical examination, menopausal index evaluation, ambulatory blood pressure (BP) monitoring (Cardiotens-01, Meditech, Hungary), echocardiographic examination with systolic and diastolic left ventricular (LV) function assessment. Statistical methods such as Cruskal-Wallis criteria and χ^2 test were used.

Results: The frequency of arterial hypertension in women with natural and surgical menopause was the same: 42.3% (60 pts) in the 1st group and 45.9% (28 pts) in the 2nd group, respectively ($p>0.05$). Only 39 postmenopausal women (19.2%) had normal LV geometry; 57 pts (28.1%) demonstrated concentric remodeling, 89 pts (43.8%) - LV concentric hypertrophy, and 18 women (8.9%) - eccentric hypertrophy. The frequency of LV concentric hypertrophy in the 2nd group was wider than in the 1st group (47.9% (68 pts) vs 24.4% (21 pts), $p=0.049$); while women of the 1st group more often had LV eccentric hypertrophy (19.7% (12 pts) vs 4.9% (7 pts), $p=0.0002$) and normal geometry (26.2% (16 pts) vs 15.5% (22 pts), $p=0.0017$). Hypertensive postmenopausal women more often had LV concentric hypertrophy (60.2% (53 pts) vs 31.3% (36 pts) in normotensive women, $p=0.005$), while normotensive postmenopausal women more often demonstrated LV concentric remodeling (33.9% (39 pts) vs 20.5% (18 pts), $p=0.042$) and LV normal geometry (23.5% (27 pts) vs 12.5% (11 pts), $p=0.034$).

Nobody of included postmenopausal women had LV reduced ejection fraction. Presence of LV diastolic function disturbance was the same in the 1st and in the 2nd groups (59.2 (84 pts) and 56.8% (50 pts), respectively, $p=0.231$) and did not depend on BP level: 56.8% (50 pts) in hypertensive and 59.1% (68 pts) in normotensive women, $p=0.118$. Patients with LV concentric hypertrophy had LV diastolic dysfunction in 84.3% cases (75 pts); with LV concentric remodeling - in 52.6% cases (30 pts) - with LV eccentric hypertrophy - in 31.6% cases (6 pts), this difference was statistically significant.

Conclusions: Patterns of LV remodeling development in postmenopausal women depend on menopause type and BP level. LV diastolic function evolution for the most part depends on LV remodeling type, but not on menopause type or arterial hypertension presence.

P1758

ST-elevation myocardial infarction with reduced left ventricular ejection fraction: insights into persisting left ventricular dysfunction. A pPCI-Registry analysis.

D Davide Stolfo¹; M Cinquetti¹; M Merlo¹; S Santangelo¹; G Barbati¹; M Alonge¹; A Salvi¹; A Perkan¹; G Sinagra¹

¹University Hospital "Riuniti", Department of Cardiology, Trieste, Italy

Background: Primary percutaneous coronary intervention (pPCI) largely reduced the rate of left ventricular (LV) dysfunction after ST-segment elevation acute myocardial infarction (STEMI). Though LV recovery begins early following revascularization, the optimal timing for re-assessment of LV function is still unclear.

Purpose: To assess the proportion and timing of LV recovery in STEMI patients presenting with LV dysfunction treated by pPCI and to identify possible early predictors of adverse LV remodeling.

Methods and Results: STEMI patients with LV ejection fraction (LVEF<40%) at presentation treated by pPCI from 2007 to 2013 were included whether they had an available 3-step LVEF assessment (<24 hours post-pPCI, discharge and follow-up). Primary endpoint was LVEF≤35% at follow-up. At a median time of 3 months, 43 out of 154 patients (28%) had LVEF≤35%. In patients with persistent LV dysfunction, LVEF was lower at admission and increased less during hospitalization (from 31 ± 6 to 35 ± 4% Vs 35 ± 5 to 43 ± 8% for patients with 3-months LVEF>35%, p < 0.001). Independent predictors of 3-months LVEF≤35% were creatinine at admission, peak troponin I and LVEF. Of note, LVEF re-assessment at discharge (median time 6 days, IQR 4-9) showed an increased accuracy to predict 3-months LV dysfunction compared to LVEF at admission (AUC 0.80, 95%CI 0.72-0.88 Vs AUC 0.69, 95%CI 0.58-0.79 respectively, p = 0.03).

Conclusions: In most of patients presenting with STEMI and LV dysfunction, a significant LV recovery can be observed early following pPCI. LVEF measurement at discharge indeed emerged as the best indicator of late persistence of severe LV dysfunction.

P1759

Systolic performance of the left ventricle after myocardial infarction. The absence of ST elevation costs myocardium

K Keramida¹; N Kouris²; CD Olympos²; P Nihoyannopoulos³

¹Hammersmith Hospital, London, United Kingdom; ²Thriassio General Hospital, Athens, Greece; ³Imperial College Healthcare NHS Trust, Hammersmith Hospital, London, United Kingdom

Treatment of acute coronary syndromes (ACS) depend upon their clinical and electrocardiographic (ECG) presentation. However, both acute myocardial infarctions with (STEMI) and without (NSTEMI) ST elevation affect left ventricular (LV) function, which may be assessed by conventional echocardiography but also lately using 2D speckle tracking (2D STE). The aim of this study was to compare the effect of STEMI and NSTEMIs on global longitudinal deformation of the LV (LVGLS).

We studied 28 consecutive patients (pts) with inferior STEMI, as well as 31 pts with NSTEMI. All had echocardiographic evidence of hypokinesia/akinesia of the inferior wall. All pts with STEMI underwent primary percutaneous coronary angioplasty of the culprit lesion, while pts with NSTEMI underwent a coronary angiogram with subsequent angioplasty within 72 hours from the onset of pain. In both STEMI and NSTEMI pts, PTCA was performed at the right or the circumflex coronary artery, depending on the dominance. In all pts the echocardiographic study (TTE) was carried out the day after revascularization. The findings of the TTE are presented on the Table. While there was no difference in LVEDD between pts with STEMI and NSTEMI (p = 0.836), EF and LVGLS differ significantly (p = 0.015 and p = 0.043, respectively). Surprisingly, although in STEMI, ischemia was likely affecting a greater proportion of myocardium, LVGLS and LVEF were worse in patients with NSTEMIs. This may be due to delayed revascularization in NSTEMIs, that provides the necessary ischemic time for greater myocardial damage to occur. The time at which revascularization takes place in ACS, may have a direct effect in systolic performance of the LV. It is possible that the worst prognosis of NSTEMIs compared to STEMI in the medium term, may be related to this difference.

Table 1

	STEMI	NSTEMI	p value
LVEDD (mm)	49.64 ± 3.93	49.87 ± 4.87	0.836
EF (%)	54.07 ± 5.42	50.23 ± 6.31	0.015
LVGLS (%)	-15.03 ± 3.75	-12.93 ± 4.06	0.043

HFpEF - HEART FAILURE WITH PRESERVED EJECTION FRACTION

P1760

The role of diastolic heart failure in the development of atrial fibrillation paroxysms in patients with hypertension

DA Pilant¹; VA Lollini²

¹Vitebsk regional clinical hospital, Vitebsk, Belarus; ²Vitebsk State Medical University, Vitebsk, Belarus

Background: in patients with AH and paroxysmal AF myocardial hypertrophy, high LV myocardial stiffness is in some cases associated with increased LV filling pressure. In turn, the high LV filling pressure may result in development of occult diastolic HF and AF paroxysms. EchoCG detection of this condition involves certain challenges.

Purpose: to increase the diagnostic efficiency of diastolic heart failure and to estimate its role in the development of atrial fibrillation in patients with hypertension based on laboratory, electrophysiological, structural data and stress induced changes.

Methods: clinical, instrumental (stress echocardiography, transesophageal electrophysiological study), laboratory and statistical.

Results: it was established that patients with HTN and AF paroxysms with clinical signs of low functional HF classes (NYHA I-II) are predominantly female (65%). In this group of patients heart remodeling includes LV concentric hypertrophy and diastolic dysfunction with HF development. Diastolic functional reserve index cut-off value (DFRI=14) for identifying HF patients was calculated. The relationship between DFRI, clinical signs, heart remodeling, NT-proBNP and characteristics of AF was defined. During the electrical remodeling parameter assessment it was also proved the relationship of atrial conduction disorders, with clinical, laboratory and echocardiographic data, reflecting the development of diastolic HF, which confirms its impact on myocardial electrophysiological properties and AF development.

Conclusion: stress echocardiography can be used for early detection of diastolic heart failure in patients with AF paroxysms, AH and LV diastolic dysfunction; values of DFRI <14 conv. units indicate development of HF induced by low LV diastolic reserve.

P1761

Features of very elderly heart failure patients between heart failure with preserved ejection fraction and heart failure with reduced ejection fraction.

K Keisuke Satogami¹; Y Nozawa¹; T Akasaka²

¹Arida Municipal Hospital, Cardiology, Arida, Japan; ²Wakayama Medical University, Cardiovascular medicine, Wakayama, Japan

Background: Heart failure (HF) is principally a disorder of older adults with prevalence and incidence rates that increase progressively with age. Although heart failure (HF) affects all segments of populations, older patients have been markedly underrepresented in most major HF trial. Incident heart failure in older adult patients is predominantly characterized by the phenotype of HF with normal or preserved left ventricular (LV) systolic function (HFpEF). Patients with HFpEF have lower risk of in-hospital mortality, and a similar post-discharge mortality risk and equally rehospitalization as patients with HF and LV systolic dysfunction. We investigate the features of very high aged heart failure patients between HFpEF and HF with reduced EF (HFrEF).

Methods: We examined 73 patients who were 90 years old and more, and were admitted in our hospital for acute decompensated heart failure from April 1, 2010 through March 31, 2014. The patients were divided into three groups: those with an ejection fraction of less than 40 percent (HFrEF), those with an ejection fraction of 40 to 50 percent (heart failure with borderline ejection fraction), and those with an ejection fraction of more than 50 percent (HFpEF). Two groups were studied in detail: those with an ejection fraction of less than 40 percent and those with an ejection fraction of more than 50 percent. The main outcome measures were death within one year and readmission to the hospital for heart failure.

Results: There were 48 (65.8%) HFpEF patients and 25 (34.2%) HFrEF patients. The length of hospital stay was similar in both groups (40.2 ± 30.7 days vs. 38.4 ± 33.1 days; p = 0.654). Patients with HFpEF had similar risk of in-hospital mortality (12.5% vs. 16.0%; p = 0.680). During 1 year follow-up, patients with HFpEF had a similar mortality risk (14.6% vs. 16.0%; p = 0.872) and rehospitalization rates (33.3% vs. 36.0%; p = 0.820) compared with patients in HFrEF.

Conclusion: 90 years old or more heart failure patients has similar prognosis in both HFpEF and HFrEF.

P1762

Heart failure with preserved ejection fraction: is the role of arterial stiffness established?

E Elio Gorga¹; E Sciatti¹; V Regazzoni¹; M Gavazzoni¹; E Trichaki¹; F Pasini¹;

E Vizzardi¹; I Bonadei¹; M Metra¹; R Raddino¹

¹University of Brescia, Brescia, Italy

Background: heart failure with preserved ejection fraction (HFpEF) amounts the 50% of cases of heart failure. Diagnosis and prognosis of this disease are still uncertain. The diagnosis of HFpEF is based on signs and symptoms of heart failure, normal or mildly abnormal left ventricular ejection fraction (LVEF) and evidence of left ventricular (LV) diastolic dysfunction identified by Doppler report of increased LV filling pressure. We aimed at correlating LV diastolic parameters with central haemodynamics ones.

Methods: we prospectively enrolled 25 outpatients affected by HFpEF followed by our Heart Failure Center. They underwent transthoracic echocardiography and applanation tonometry. We focused on echocardiographic parameters meeting the criteria previously established to diagnose HFpEF: LVEF, E/E', E/A and DT, Ard and Ad, left atrial volume index (LAVI), LV mass index (LVMI). Applanation tonometry was carried on the right radial artery to calculate aortic blood pressure, augmentation pressure (AP) and augmentation index (AIx@75).

Results: 15 (60%) were male; mean age was 75 ± 8 years. 89% were hypertensive, 44% diabetic, 33% obese, 20% in atrial fibrillation. Mean LVEF was 64 ± 7%; all patients had E/E' between 8 and 15; none had E/A < 0.5 and DT > 280 ms; 93% had Ard-Ad > 30; 50% had LAVI > 40 mL/m²; 50% had LVMI > 122g/m² for women

and $>149\text{g/m}^2$ for men. Aortic pressures were: $124 \pm 16 / 77 \pm 9$ mmHg (mean 96 ± 10 , pulse 47 ± 15 mmHg); AP was 15 ± 8 mmHg and Alx@75 $26 \pm 7\%$. We found no correlation between the echocardiographic and the tonometric parameters considered.

Conclusion: HFpEF is a frequent condition which still remains without a specific therapy. Its aetiopathology is heterogeneous. A recent meta-analysis strongly linked arterial stiffness with LV diastolic function in patients with HFpEF. Our data seem to suggest that this relationship exists in hypertensive patients, but different subgroups of subjects affected by HFpEF (e.g., diabetes mellitus, atrial fibrillation, obesity) may share different pathogenic pathways.

P1763

Timing of left ventricular deformation and dyssynchrony in HFpEF and treated arterial hypertension

The EXCEED and PARAMOUNT trials were funded by Novartis
M Cikes¹; T Biering-Sorensen²; A Santos³; E Kraigher-Krainer⁴; S Cheng²; SD Solomon²

¹University of Zagreb School of Medicine, Department of Cardiovascular Diseases, Zagreb, Croatia; ²Brigham and Women's Hospital, Cardiovascular Division, Boston, United States of America; ³University Porto Alegre, Porto Alegre, Brazil; ⁴Charite University Hospital, Berlin, Germany

Purpose: Hypertension (HTN) is a relevant precursor of heart failure, especially with preserved ejection fraction (HFpEF), and treatment of HTN has been shown to reduce this risk.

Methods: We studied 215 HFpEF patients enrolled in the PARAMOUNT HFpEF trial, 179 patients with uncontrolled HTN, preserved EF and without heart failure from the EXCEED trial, and 45 healthy controls. Hypertensive patients were treated with blood pressure lowering for 24 weeks. We assessed LV synchrony and time to peak contraction (longitudinal strain), indexed to RR interval, in 6 LV segments.

Results: Time to peak contraction was greatest in the hypertensive group and directly related to systolic blood pressure. LV dyssynchrony was highest in patients with HFpEF, followed by hypertensives, and significantly different from normal in both groups (Table). After anti-HTN therapy for 24 weeks, SBP in HTN was reduced to values similar to HFpEF, with overall improvement in both measures of synchrony and time to peak strain. Despite similar achieved SBP, patients with HFpEF remained significantly more dyssynchronous than those with HTN.

Conclusion: Intensive therapy in HTN without heart failure significantly reduces time to peak strain and mildly abnormal ventricular synchrony. Prolonged antihypertensive treatment might attenuate the progression from hypertension to HFpEF by improving these measures of cardiac mechanics in vulnerable patients.

Table

	Controls	HFpEF	HTN baseline	HTN following treatment	P-value
SBP (mmHg)	128.97 ± 15.18	136.52 ± 15.18	164.32 ± 15.73	133.62 ± 13.02	< 0.0001
Dyssynchrony (ms)	49.05 ± 40.54	86.97 ± 57.33	71.14 ± 55.80	66.32 ± 49.25	< 0.0001
T_PLS/RR (ms)	0.44 ± 0.07	0.46 ± 0.10	0.48 ± 0.10	0.45 ± 0.08	< 0.003

T_PLS/RR = time to peak longitudinal strain indexed by RR interval. Values are given as mean \pm standard deviation. P values for group.

Reporting quality of randomised controlled trials investigating efficacy of pharmacological therapies for heart failure with preserved ejection fraction

S Sean Zheng¹; FT Chan²; E Maclean³; S Jayakumar⁴; A Nabeebaccus¹

¹King's College Hospital, London, United Kingdom; ²Eastbourne District General Hospital, Eastbourne, United Kingdom; ³Royal Brompton Hospital, London, United Kingdom; ⁴King's College London, London, United Kingdom

Introduction: Randomised controlled trials (RCT) provide the highest level of evidence on healthcare interventions. Accurate interpretation of results and inclusion in meta-analysis require clear and adequate reporting, particularly of the methods and results. The CONSORT statement, first published in 1996 and later revised in 2001 and 2010, aims to improve reporting quality of RCTs. It includes 37 points covering 25 areas of trial reporting. Heart failure with preserved ejection fraction (HFpEF) is a major cause of morbidity and mortality, comparable to heart failure with reduced ejection fraction. While many studies have investigated the efficacy of various pharmacological agents, scarcity of consensus guidelines reflects the conflicting results generated from RCTs.

Purpose: We aim to systematically identify RCTs of pharmacological interventions

in HFpEF, assess reporting quality using the CONSORT 2010 statement, and identify trends and areas for improvement.

Methods: Medline, EMBASE and CENTRAL databases were systematically searched from 1 January 1996 to 1 September 2015 and assessed for inclusion using pre-specified inclusion-exclusion criteria. Reporting quality was assessed by two authors using the CONSORT 2010 score. Each item was scored and weighted equally. An overall reporting quality score was calculated for each study. Statistical analysis was performed with SPSS.

Results: Initial search identified 3426 studies, with 32 included in the final analysis. There was inter-observer agreement for 91% of marks (1078/1184); Cohen's kappa score 0.85. The mean overall score was 55.3% (range 23.3-93.8%, SD 17.3%). The mean score for methods and results were 51.0% (15.4-92.9%, 19.4%) and 51.9% (12.5-100.0%, 23.4%) respectively. The best reported criteria, where applicable, were protocol referencing (100%), interim statistical analysis (100%), changes to methods (100%), statistical methods (97%), result interpretation (97%) and eligibility criteria (97%). The worst reported were reporting of binary outcomes (0%, 0/7), abstract (9%), allocation concealment mechanism (12%), trial ending (12%), settings and locations (21%) and implementation of randomization (21%). The reporting scores showed significant correlation with journal impact factor ($r = 0.54$, $P < 0.01$), 5-year impact factor ($r = 0.49$, $P < 0.01$) and publication year ($r = 0.49$, $P < 0.01$). Mean scores increased after publication of each updated CONSORT statement: from 41.0% (range 38.7-43.3%, SD 3.3) to 48.6% (30.0-77.8%, SD 14.5) after CONSORT 2001 ($p = 0.53$), and from 48.6% to 63.3% (23.3-93.8% SD 17.6) after CONSORT 2010 ($P = 0.02$) (Figure).

Conclusion: This study identified all RCTs of pharmacological interventions in HFpEF. We demonstrate that while reporting standards have improved with time, the majority of HFpEF studies did not meet the CONSORT standards. Better compliance with reporting standards is needed in future HFpEF trials.

Individual study CONSORT 2010 scores

Diagnosis, clinical course and one-year outcome in patients hospitalized for heart failure with preserved ejection fraction - results from the polish cohort of the ESC-HF long-term registry

A Kaplon Cieslicka¹; A Tyminska¹; M Peller¹; P Balsam¹; K Ozieranski¹; M Marchel¹; MG Crespo-Leiro²; AP Maggioni³; J Drozd⁴; G Opolski¹

¹Medical University of Warsaw, 1st Chair and Department of Cardiology, Warsaw, Poland; ²Complejo Hospitalario Universitario A Coruña (CHUAC), La Coruña, Spain; ³Associazione Nazionale Medici Cardiologi Ospedalieri Research Center,

Florence, Italy; ⁴Medical University of Lodz, Department of Cardiology, 1st Chair of Cardiology and Cardiac Surgery, Lodz, Poland

Background: Compared to heart failure with reduced ejection fraction (HF-REF), far less is known about clinical course of heart failure with preserved ejection fraction (HF-PEF) and the diagnosis of HF-PEF is more challenging.

Purpose: To assess the prevalence of HF-PEF among Polish patients hospitalized for HF, to evaluate the pertinence of HF-PEF diagnosis and to compare HF-PEF and HF-REF patients with respect to clinical course and one-year outcomes.

Methods: The analysis included 661 Polish patients hospitalized for HF, selected from the ESC-HF Long-Term Registry. Patients with an ejection fraction (EF) of $\geq 50\%$ were included in the HF-PEF group and patients with an EF of $< 50\%$ - in the HF-REF group. The primary endpoint was all-cause death at one year. The secondary endpoint was a composite of all-cause death and rehospitalization for HF at one year.

Results: HF-PEF was present in 187 (28%) patients. Out of those 187 patients, mitral inflow pattern (E/A ratio) was echocardiographically assessed in 116 (62%) patients and classified as restrictive/pseudonormal in 37 (20%) patients. Compared to HF-REF subjects, patients with HF-PEF were characterized by older age, higher prevalence of female gender, hypertension, atrial fibrillation and sleep apnea, lower prevalence of coronary artery disease and smoking, lower hemoglobin and creatinine concentrations and higher serum sodium level. Despite lower B-type natriuretic peptide concentrations and lower prevalence of moderate-to-severe mitral regurgitation in HF-PEF patients, congestive symptoms at admission were as severe as in patients with HF-REF. There were no significant differences in in-hospital mortality between the two groups. One-year mortality was high in both groups (16.5% in HF-PEF vs 21.0% in HF-REF, $P = 0.22$). There was a trend towards a lower frequency of the secondary endpoint in the HF-PEF group (31.9% in HF-PEF vs 40.0% in HF-REF, $P = 0.07$). Independent risk factors of unfavorable one-year outcome in HF-PEF patients included older age, worse clinical status at hospital admission, the presence of moderate-to-severe aortic stenosis and lower serum sodium concentration.

Conclusions: In clinical practice, even easily obtainable echocardiographic indices of diastolic dysfunction are relatively rarely acquired. One-year survival of HF-PEF patients is not significantly better than that of HF-REF patients.

P1766

Myocardial contraction fraction stratifies prognosis in HFpEF caused by AL of m-ATTR cardiac amyloidosis

S. Perlini¹; P. Milani²; L. Obici²; F. Musca³; F. Salinaro¹; R. Mussinelli¹; M. Boldrini¹; G. Rizzola¹; G. Palladini²; G. Merlini²

¹Dept. Internal Medicine, University of Pavia, Amyloidosis Research and Treatment Center, IRCCS S. Matteo, Pavia, Italy; ²Amyloidosis Research and Treatment Center, Dept. Molecular Medicine, IRCCS S. Matteo, University of Pavia, Pavia, Italy; ³IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Cardiology, Milan, Italy

Background: In cardiac amyloidosis ejection fraction (EF) is often preserved until the late stage of the disease in the vast majority of patients, who therefore fulfil the definition of heart failure with preserved ejection fraction (HFpEF). However, many indices of systolic function – such as midwall fractional shortening (MWFS), mitral annulus longitudinal systolic excursion (MAPSE), and tissue Doppler systolic peak (TDI-S2) – are depressed, showing evidence of systolic impairment despite preserved ejection fraction. A relatively new index of chamber systolic function is the myocardial contraction fraction (MCF), a volumetric measure of myocardial shortening that is defined as the ratio between stroke volume (SV) and myocardial volume (MV, i.e. left ventricular mass divided by the 1.05 g/ml, the mean density of myocardium).

Objective and Methods: To compare MCF with other indices of systolic function, i.e. EF, MWFS, MAPSE, and TDI-S2 in different aetiologies of cardiac amyloidosis, 173 cardiac light-chain (AL) and 102 mutated transthyretin (m-ATTR) amyloidosis patients underwent two-dimensional echocardiography at diagnosis. Cox proportional hazard modeling was used to determine the association of the different systolic indices with survival, over a median follow-up of 38.9 months (range, 19-75 months).

Results: When comparing m-TTR with AL cardiac amyloidosis, no difference was observed in EF (57 ± 9 vs. 58 ± 10 %; $p = \text{ns}$), MAPSE (9.3 ± 3.4 vs. 8.6 ± 3.4 mm, $p = \text{ns}$), and TDI-S2 (9.0 ± 3.6 vs. 8.6 ± 3.5 mm, $p = \text{ns}$). In contrast, both MWFS (10.3 ± 1.4 vs. 11.2 ± 1.5 %; $p < 0.05$) and MCF (21.9 ± 9.8 vs. 28.5 ± 11.1 %; $p < 0.001$) were lower in cardiac m-ATTR, indicating a higher degree of systolic impairment in the mutated transthyretin-related when compared with the light-chain cardiac amyloidosis aetiologies. In cardiac AL, MWFS% and MCF – but not EF – resulted independent predictors of overall survival. In contrast, in cardiac m-ATTR amyloidosis the only independent prognostic factor was MCF, whereas the other indices of systolic function did not enter the model.

Conclusions: Myocardial contraction fraction is superior to ejection fraction in predicting overall survival among HFpEF patients caused by either AL or m-ATTR cardiac amyloidosis.

P1767

Additional value of Galectin-3 respect to BNP in acute heart failure patients with preserved ejection fraction

M. Beltrami¹; G. Ruocco¹; B. Franci¹; B. Luciani¹; E. Aloia¹; R. Nuti¹; A. Palazzuoli¹

¹University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine, Siena, Italy

Background: Almost half of patients with acute heart failure (AHF) experienced a Heart failure with preserved ejection fraction (HFpEF). HFpEF diagnosis is difficult using traditional diagnostic tools; specific laboratory markers able to recognize this setting are lacking. Galectin-3 (Gal-3) is an emerging biomarker useful in individuals at risk for HF, in both acute and chronic HF.

Purpose: The aim of our study is to analyse the relation and prognostic value of Gal-3, BNP and renal dysfunction in patients with HFpEF compared to patients with Heart Failure and reduced ejection fraction (HFrEF). We also evaluated the association between Gal-3 and the degree of diastolic dysfunction, LV geometry and stiffness.

Methods: We enrolled 98 patients with AHF and we measured Gal-3, BNP, C-reactive protein (CRP) and estimated glomerular filtration rate (eGFR) within 12 hours since hospital admission. On the basis of echocardiographic findings we divided our sample into two groups: patients with HFrEF (ejection fraction $< 50\%$) or HFpEF (ejection fraction $> 50\%$).

Results: No differences in Gal-3 levels were found in the two subgroups (HFrEF: 19.5 ± 5.1 ng/mL; HFpEF: 20.5 ± 8.7 ng/mL, $p = 0.56$). Gal-3 was inversely related to renal dysfunction (Gal-3 vs eGFR $r = -0.30$, $p = 0.01$) but did not correlate with BNP levels ($r = 0.22$, $p = 0.06$). Higher levels of Gal-3 were associated with more advanced diastolic dysfunction only in HFpEF (Impaired relaxation pattern: Gal-3 $= 15.2 \pm 4.3$ ng/mL; pseudo-normal filling pattern: Gal-3 $= 18.7 \pm 7.1$ ng/mL and restrictive filling pattern: Gal-3 $= 27.5 \pm 10.1$ ng/mL, $p = 0.009$). In addition Gal-3 was related to diastolic LV stiffness (all patients; $r = 0.4$, $p = 0.01$; HFpEF $r = 0.58$, $p < 0.001$). Cox regression analysis showed that Gal-3 was related to poor outcome independently from renal dysfunction and other risk factors in HFpEF patients. (2,59 [HR] 1,27-5,26; $p < 0.008$). Oppositely in HFrEF patients, Gal-3 was related to poor outcome only when associated to renal dysfunction. (1,45 [HR] 1,12-1,88; $p < 0.01$)

Conclusions: Gal-3 is not able to discern HFrEF respect to HFpEF patients. Unlike BNP, it is related to diastolic dysfunction severity and LV stiffness in HFpEF. Gal-3 has a prognostic role independently from renal dysfunction in subjects with HFpEF but not in HFrEF.

Complex effects of the myosin activator omecamtiv mecarbil on cardiac contractility

The Norwegian Council on Cardiovascular Diseases; The Research Council of Norway; The K.G. Jebsen Foundation; Anders Jahre's Foundation
F O Finn Olav Levy¹; O Orstavik¹; S J Sollie¹; K W Andressen¹; T Skomedal¹; J-B Osnes¹; K A Krobret¹

¹University of Oslo, Department of Pharmacology, Oslo, Norway

Background: Omecamtiv mecarbil (OM) is a novel inotrope in evaluation for heart failure treatment. Currently, the effects of OM upon contractile function of intact cardiac tissue are relatively unknown.

Objective: The objective of the study was to characterize the contractile effects of OM.

Methods: Contractility and kinetics of the contraction-relaxation cycle (CRC) were measured in rat left ventricular strips. Sarcomere shortening and CRC were measured in isolated rat ventricular cardiomyocytes.

Results: In ventricular strips, OM ($1 \mu\text{M}$) increased contractile force (F_{max}), reaching a maximum of $8 \pm 1\%$ above control. In cardiomyocytes, OM increased sarcomere shortening by $48 \pm 16\%$ above baseline. OM increased time to peak force (TPF) in ventricular strips, time to peak shortening (TPS) in unloaded cardiomyocytes and relaxation time (RT) in both preparations, with RT being substantially increased compared to TPF in ventricular strips. OM slowed the diastolic relengthening rate in cardiomyocytes and increased diastolic tension at stimulation frequencies greater than 2 Hz in ventricular strips at 31°C . Higher concentrations of OM were required to increase diastolic tension when temperature was increased to 37°C . OM sensitized the concentration-response relationship to Ca^{2+} in the lower range of $[\text{Ca}^{2+}]$, but reduced the maximum inotropic response (IR) to Ca^{2+} . OM reduced the maximum IR to β -AR stimulation without altering the EC_{50} of β - or α 1-adrenoceptors.

Conclusion: This study demonstrates that in addition to increasing F_{max} and sarcomere shortening and sensitizing the myocardium to Ca^{2+} , OM also substantially slowed the kinetics of relaxation in rat myocardium, resulting in increased diastolic tension at higher heart rates, more at lower temperature. Finally, OM reduced maximal β -AR-evoked IR. Further evaluation of the potential clinical utility of OM should take its complex effects on cardiac contractility into account.

P1770

Comparative bioenergetic effects of levosimendan and omecamtiv mecarbil in guinea-pig cardiac myocytesD Puetz¹; M Michael Kohlhaas¹; C Maack¹¹Saarland University Hospital, Department of Internal Medicine III, Homburg, Germany

Background: Cardiogenic shock is an unmet clinical need since current inotropic drugs (in particular, catecholamines) increase mortality in patients with acute heart failure. As underlying reasons, pro-arrhythmic effects and elevated oxygen consumption of catecholamines have been put forward. Levosimendan (Levo) was originally considered as a calcium-sensitizer that elevates contractile force without increasing intracellular calcium, while other reports suggested that Levo is an inhibitor of phosphodiesterases (PDEs), a property deemed adverse in heart failure. In contrast, omecamtiv mecarbil (OM) is a myosin activator that prolongs cardiac contraction without elevating oxygen consumption in dogs with heart failure. In humans, OM improves cardiac output and tended to improve symptoms in patients with acute heart failure. We have recently discovered that increasing calcium affinity of myofilaments with the pure calcium-sensitizer EMD-57033 increased systolic force development, but this was associated with oxidation of mitochondrial redox state of NAD(P)H/FAD, which was associated with pronounced mitochondrial emission of reactive oxygen species (ROS). Here, we evaluated the bioenergetic (redox) properties of Levo in comparison with OM in guinea-pig cardiac myocytes.

Methods and Results: Here, cardiac myocytes were isolated from guinea pig hearts and field-stimulated at 1 Hz and 37°C. OM substantially prolonged the time to peak of cell shortening in a concentration-dependent manner (0.01-30 µM). This was associated with an increase in diastolic tension but only minor increases in systolic sarcomere shortening (optimum at 3 µM). Despite the substantial increase in diastolic tension, the redox states of NAD(P)H/FAD remained stable, in agreement with the previously reported unchanged oxygen consumption. Levo (up to 10 µM) had overall minimal effects on sarcomere shortening, diastolic tension and NAD(P)H/FAD redox states. However, the concentration-dependent increase of sarcomere shortening was shifted to the left (increased potency) and its maximal effect became potentiated (increased efficacy) by pre-incubation of cardiac myocytes with a sub-threshold concentration of isoproterenol (1 nM). Under all conditions, the redox states of NAD(P)H and FAD remained stable in response to Levo (with or without isoproterenol).

Conclusions: Levosimendan does not behave as a calcium-sensitizer, but rather as a PDE-inhibitor, since its stimulating effect on sarcomere shortening becomes apparent only after beta-adrenergic prestimulation. In contrast, OM induces diastolic dysfunction rather than increasing sarcomere shortening, however, the prolongation of systolic sarcomere shortening came at no elevated oxygen demand. Together, while the PDE-inhibiting effects of Levo may predispose to arrhythmias, OM may induce diastolic dysfunction at concentrations that reasonably affect systolic sarcomere shortening.

P1771

Circulating blood levels of growth differentiation factor 11 are decreased in dogs with heart failure and restored after long-term therapy with elamipretide (Bendavia, MTP-131)HN Hani Sabbah¹; RC Gupta¹; V Sing-Gupta¹¹Henry Ford Hospital, Detroit, United States of America

Introduction: Growth differentiation factor 11 (GDF11), a member of the transforming growth factor beta superfamily, has been shown to decrease with advanced age. GDF11 is implicated as having a role in the stem cell differentiation into cardiomyocytes, in reducing brain natriuretic peptide (BNP) and increasing expression of SERCA-2a, an enzyme necessary for myocardial contraction and relaxation. Supplementation of GDF11 protein in mice has been shown to ameliorate age-related dysfunction of skeletal muscle (SM). Many of the abnormalities seen with advanced age also manifest in heart failure (HF) including cardiomyocyte dysfunction and loss, SM dysfunction and reduced SERCA-2a activity and expression. We previously showed that these abnormalities can be reversed in dogs with HF following long-term therapy with elamipretide (Bendavia, MTP-131), a novel mitochondria targeting peptide.

Purpose/Hypothesis: In the present study, we tested the hypothesis that plasma level of GDF11 is reduced in dogs with chronic HF and are restored following long-term therapy with elamipretide.

Methods: Venous blood samples were obtained from 14 dogs at baseline (normal state) prior to induction of HF, after the induction of HF by intracoronary microembolizations but prior to any therapy and again at 3 months after initiating therapy with either subcutaneous elamipretide (0.5 mg/kg/day, n = 7) or saline v/v (Control, n = 7). Plasma levels of GDF11 were measured using a dog specific commercially available (MyBioSource, San Diego, CA) enzyme-linked immunosorbent assay (ELISA) kit.

Results: In control dogs, plasma level of GDF11 was 61.3 ± 3.8 pg/ml at baseline and decreased to 36.2 ± 0.9 pg/ml (p < 0.05) when dogs were in HF and remained lower at 3 months after initiating therapy with saline (36.1 ± 0.7 pg/ml). In dogs treated with elamipretide, plasma level of GDF11 was 62.9 ± 5.6 pg/ml at baseline,

decreased to 37.4 ± 1.0 pg/ml (p < 0.05) when dogs were in HF and increased to near normal levels (59.3 ± 4.0 pg/ml) at 3 months after initiating therapy with elamipretide.

Conclusions: As in aging, circulating plasma levels of GDF11 are decreased in HF dogs. Long-term treatment with elamipretide reverses this decline. These findings are consistent with previous observations of improved cardiomyocyte function, increased SERCA-2a activity, decreased circulating levels of BNP and improved SM structure in dogs with HF treated with elamipretide.

P1772

Trimetazidine effects on the quality of life of women with chronic heart failureNA Koriagina¹; AV Petrisheva¹; AA Shadrin¹; LM Vasilts¹; VV Schekotov¹¹Medical Academy, Perm, Russian Federation

Objective: To evaluate the effect of trimetazidine on the quality of life of women with chronic heart failure (CHF) of ischemic etiology.

Methods: 100 patients ischemic CHF, II-IV (NYHA) at the age of 65.7 ± 8.7 years, were divided into two groups. 1 group (n = 50) in addition to standard CHF therapy received trimetazidine 35 mg 2 times a day for 6 months. Patients 2 groups (n = 50) were in the basic therapy. Determination of the quality of life was carried out using the Minnesota questionnaire for heart failure at baseline and after 6 months of continuous administration of trimetazidine, and Hospital Anxiety and Depression Scale. 0 points consistent with the best quality of life, 105 points - the worst.

Results: against addition of trimetazidine to standard therapy of CHF mean score in group 1 decreased by 28.7 ± 20.1%, while in the 2nd - on 5.7 ± 3.5% (p < 0.01), as well as reducing symptoms of anxiety in Group 1 with 10 points to 7 points, and depression with 11 ballvol to 6 points, 2 group level of anxiety and depression remained unchanged.

Conclusions: The addition of trimetazidine to standard heart failure therapy has a positive effect on quality of life and manifestations of anxiety and depressive syndrome in patients with chronic heart failure.

Finerenone inhibits mechanisms of cardiac fibrosis in vitro

Bayer Pharma AG

D Daniel Lavall¹; N Jacobs¹; P Kolkhof²; M Boehm¹; U Laufs¹¹Saarland University Hospital, Department of Internal Medicine III, Cardiology, Homburg, Germany; ²Bayer Pharma AG, Cardiology Research, Wuppertal, Germany

Purpose: Aldosterone induces cardiac fibrosis via activation of the mineralocorticoid receptor (MR) that predisposes to arrhythmias and heart failure. We studied the role finerenone, a selective non-steroidal MR antagonist, for the molecular mechanisms of fibrotic remodeling in cultured cardiac fibroblasts.

Methods and Results: Aldosterone exposure in cardiac fibroblasts induced a nuclear translocation of MR (nuclear to cytoplasm MR localization, control 2.3 ± 4.0 vs. aldosterone 6.8 ± 5.7, p < 0.001) that was prevented by finerenone (2.1 ± 2.5, p < 0.0001 vs. control). Finerenone dose-dependently decreased the protein expression of connective tissue growth factor (CTGF). This effect of finerenone 500nM was comparable to that of spironolactone 500nM (74 ± 15% and 70 ± 19%, respectively; both p < 0.01 vs. control). Finerenone prevented the aldosterone induced CTGF overexpression (187 ± 42%, p < 0.01 vs. control, and 89 ± 34%, p < 0.01 vs. aldosterone, respectively). Co-treatment with angiotensin II in addition to aldosterone enhanced CTGF upregulation (210 ± 69%, p < 0.0001 vs. control) that was completely prevented by finerenone (100 ± 10%, p < 0.001 vs. aldosterone+angiotensin II). Aldosterone did not alter the transforming growth factor β (TGF-β) expression whereas angiotensin II (172 ± 34%, p < 0.0001 vs. control) did. Conclusively, the TGF-β expression was unaffected by finerenone but the angiotensin II induced TGF-β overexpression was prevented with telmisartan (117 ± 29%, p < 0.01 vs. angiotensin II). Finerenone inhibited the aldosterone-induced upregulation of microRNA-21 expression (354 ± 229%, p < 0.01 vs. control, and 130 ± 46%, p < 0.05 vs. aldosterone, respectively). The increase in fibronectin expression induced by the co-treatment aldosterone and angiotensin II (187 ± 45%, p < 0.0001 vs. control) was prevented with finerenone pre-treatment (116 ± 28%, p < 0.001 vs. aldosterone+angiotensin II) as well as the aldosterone-induced upregulation of the lysyl oxidase (149 ± 19%, p < 0.001 vs. control, and 85 ± 29%, p < 0.0001 vs. aldosterone, respectively).

Conclusion: Finerenone prevents nuclear translocation of the mineralocorticoid receptor and is a potent inhibitor of the pro-fibrotic factors CTGF, microRNA-21,

fibronectin and lysyl oxidase. Therefore, finerenone may represent a novel substance to prevent maladaptive cardiac structural remodelling.

Effect of neuregulin-1 on angiotensin II-induced ventricular inflammation, fibrosis and stiffening

FWO (Application number, G0C5214), a grant from the European Commission (FP7-HEALTH-F2-2010-261409), IOF POC of the University of Antwerp Z Zarha Vermeulen¹; L. Vandekerckhove¹; VFS Segers¹; AS Hervet¹; GW De Keulenaer¹

¹University of Antwerp, Antwerp, Belgium

Purpose: Heart failure mitigating effects of the endothelium-derived growth factor Neuregulin-1 (NRG-1) are currently tested in clinical trials. Surprisingly, however, NRG-1's underlying mechanisms of cardiac protection remain poorly understood. Here, we hypothesized that NRG-1/ErbB4 signaling attenuates left ventricular (LV) fibrosis and stiffening, and regulates cardiac fibroblast function.

Methods: LV fibrosis and stiffening were induced by treatment of mice with Angiotensin II (Ang II, osmotic mini-pumps, 1000 ng.kg⁻¹.day⁻¹, 4 weeks). NRG-1/ErbB4 signaling was either activated by co-treatment with rhNRG-1 (20 µg.kg⁻¹.day⁻¹, i.p. injection 5 days/week), or inhibited by fibroblast-specific deletion of ErbB4 (by crossing C57BL/6-ErbB4F/F mice and BALB/c-S100a4-Cre+ mice). The effect of rhNRG-1 on fibroblast gene expression was studied in cultured primary fibroblasts by cDNA MicroArray analysis with the Illumina MouseRef-8 v2.0 Expression BeadChip. Results In wild type mice, rhNRG-1 treatment significantly attenuated Ang II-induced LV fibrosis (quantified by histology and molecular analysis) and prevented Ang II-induced LV passive stiffening (quantified by invasive hemodynamic recordings). Blood pressure was not affected. Consistently, in ErbB4^{-/-};Cre+ mice, LV fibrotic response to Ang II-treatment was robustly enhanced. cDNA MicroArray comparison of PBS- and rhNRG-1-treated primary fibroblasts showed 960 differentially expressed genes of which 450 were down-regulated and 510 were up-regulated. Network and pathway analysis using the Ingenuity Pathway Analysis (IPA) software confirmed that rhNRG-1 significantly inhibited the pathway of connective tissue development, but also unmasked that rhNRG-1 significantly downregulated several inflammatory pathways. Upstream regulator analysis identified the downregulation of several cytokines (mostly from the interleukin family), cytokine receptors and transcription factors of cytokine signaling (mostly from the IRF and STAT family) hence generating the hypothesis that rhNRG-1 also mediates anti-inflammatory effects. To further test this hypothesis, wild type mice were exposed to Ang II for 3 days to induce a myocardial inflammatory response. As expected, co-treatment with rhNRG-1 significantly abrogated myocardial infiltration of both neutrophils and macrophages. Conclusion This study shows a prominent role for NRG-1/ErbB4 signaling in the control of LV fibrosis during Ang II-induced LV remodeling. Both direct anti-fibrotic effects and indirect anti-inflammatory effects seem to underlie this effect. These data contribute to the understanding of the therapeutic effects of rhNRG-1 in heart failure.

Distinct myocardial expression of mitochondrial regulators is associated with characteristic differences of in vivo hemodynamics in physiological and pathological left ventricular hypertrophy

Hungarian Scientific Research Fund (OTKA 105555) to Bela Merkely A Olah¹; BT Nemeth¹; C Matyas¹; A Lux¹; M Ruppert¹; D Kellermayer¹; AA Sayour¹; L Szabo¹; B Merkely¹; T Radovits¹

¹Semmelweis University, Heart and Vascular Center, Budapest, Hungary

Purpose: Left ventricular (LV) hypertrophy is a physiological or pathological response of LV myocardium to increased cardiac load and is associated with characteristic molecular changes. Currently, a direct comparison of functional consequences of physiological (PhyH) and pathological hypertrophy (PaH) is missing. We aimed at comparing hemodynamic alterations in well established rat models of physiological and pathological hypertrophy by using LV pressure-volume (P-V) analysis and investigating possible underlying molecular mechanisms.

Methods: PhyH and PaH were induced in rats by swim training and by abdominal aortic banding, respectively. Morphology of the heart was investigated by echocardiography. Detailed characterization of cardiac function was completed by LV P-V analysis. In addition histological and molecular biological measurements were performed. All data were normalized to the corresponding control group.

Results: Echocardiography revealed myocardial hypertrophy of similar degree in both models (LV mass index: +21.7 ± 2.1% PhyH vs. +27.3 ± 3.3% PaH, n.s.), which was confirmed by post-mortem heart weight data. In aortic-banded rats we detected only subendocardial fibrosis. Reactivation of fetal gene program could be observed only in PaH model. PhyH was associated with increased stroke volume, whereas unaltered stroke volume were detected in PaH along with markedly elevated end-systolic pressure values. Sensitive indices of LV contractility were increased in both models, in parallel with the degree of hypertrophy. Active relaxation was ameliorated in athlete's heart, while it showed marked impairment in PaH (time constant of LV pressure decay (τ): -7.7 ± 2.6% PhyH vs. +37.0 ± 11.1% PaH, p < 0.01). LV mechanical efficiency and ventriculo-arterial coupling were improved in PhyH, whereas remained unchanged in PaH. Myocardial gene expression of mitochondrial regulators showed marked differences between PaH and PhyH (peroxisome proliferator-activated receptor gamma coactivator 1-α (PGC-1α): +19.1 ± 10.3% PhyH vs. -37.8 ± 7.2% PaH, p < 0.01), while markers of oxidative stress and inflammation did not differ between the groups.

Conclusions: We provided the first comparative hemodynamic characterization of PhyH and compensated PaH in relevant rodent models. Increased LV contractility could be observed in both types of LV hypertrophy, characteristic distinction was detected in energy-dependent diastolic function (active relaxation) and mechanoenergetics (mechanical efficiency), which might be explained by mitochondrial differences.

Background: Cardiac tissue engineering combines scaffolds and cells, aiming to renew myocardium and restore cardiac function after myocardial infarction (MI).

Purpose: Herein, we developed a scalable engineered myocardial graft (EMG) and evaluated its impact on cardiac function and scar dynamics in the swine MI model.

Methods: EMG, comprising a decellularized porcine myocardial scaffold repopulated with GFP-labeled porcine adipose tissue-derived progenitor cells (pATDPCs), was engrafted to the myocardial surface of allogeneic swine after MI induction. Cardiac function was assessed using magnetic resonance imaging. Infarct size, scar healing, and vascularization were evaluated using quantitative morphometry and histopathology. Animals were sacrificed one month post-MI.

Results: Compared to control-MI animals, EMG-treated animals exhibited significantly higher left ventricular ejection fraction relative to baseline (3.26 ± 2.85 vs. -7.97 ± 4.29; P = 0.047) and post-MI (61.30 ± 3.07% vs. 50.76 ± 2.62%; P = 0.001). Relative to control-MI animals, EMG-treated animals had a 68% smaller infarct size (2.46 ± 0.60% vs. 7.63 ± 2.26%; P = 0.048) and significantly lower type I/III collagen ratio (2.26 ± 0.72 vs. 13.01 ± 6.85; P = 0.032). GFP+ pATDPCs migrated to underlying ischemic myocardium and expressed cardiac lineage markers (GATA4, MEF2, SERCA2, connexin43, and cTnI) and endothelial makers (IsoB4 and CD31). Newly-formed blood vessels were connected to host myocardium. EMG promoted increased infarct myocardium vascularization, with blood vessel densities of 3.64 ± 0.50% for EMG-treated animals and 1.72 ± 0.12% for control-MI animals (P = 0.011).

Conclusions: In the pre-clinical swine MI model, the newly developed EMG improved cardiac function and injured myocardium neovascularization, reduced infarct size, and limited fibrosis progression. This scalable allogeneic EMG is ready for clinical translation.

Chronic phosphodiesterase-5 inhibition prevents the development of diabetic cardiomyopathy in a rat model of type-2 diabetes mellitus

Hungarian Scientific Research Fund (OTKA PD 100245)

T Radovits¹; C Matyas¹; A Olah¹; BT Nemeth¹; D Kellermayer¹; M Ruppert¹; M Torok¹; L Szabo¹; AA Sayouri¹; B Merkely¹¹Semmelweis University, Heart and Vascular Center, Budapest, Hungary

Purpose: Diabetes mellitus (DM) is associated with characteristic structural and functional changes of the heart, termed diabetic cardiomyopathy. The pathophysiological role of cGMP signaling has been intensively investigated in DM. Elevated levels of the second messenger cGMP have been shown to exert cardioprotective effects in various heart diseases. We investigated the effect of chronic inhibition of the cGMP-degrading enzyme phosphodiesterase-5 (PDE5) by vardenafil in type-2 DM related cardiomyopathy.

Methods: For type-2 DM Zucker Diabetic Fatty (ZDF) rats were used. ZDF Lean (ZDFL) rats served as controls. Animals received either vehicle (ZDFL, ZDF) or 10mg/kg BW vardenafil per os (ZDFLvard, ZDFvard) from 7 to 32 weeks of age. Cardiac morphology was followed by echocardiography. Left ventricular (LV) function was assessed by pressure-volume (P-V) analysis. Gene expression measurements of atrial natriuretic factor (ANF; qRT-PCR), cardiomyocyte diameter/tibia length (CD/TL) and Masson's staining (fibrosis score (FS)) were used to prove pathological myocardium hypertrophy.

Results: Cardiac hypertrophy (echocardiography: LV anterior wall thickness in systole (LVAWs): 2.81 ± 0.1 mm; relative wall thickness (RWT): 0.49 ± 0.02 ; LVmass/TL: 0.30 ± 0.01 g/cm; CD/TL: 3.53 ± 0.02 μ m/cm; ANF: 3.04 ± 0.26 vs ZDFL (LVAWs: 2.53 ± 0.04 mm; RWT: 0.43 ± 0.02 ; LVmass/TL: 0.23 ± 0.004 g/cm; CD/TL: 3.09 ± 0.02 μ m/cm; ANF: 0.92 ± 0.17 ; $p < 0.05$) and fibrotic remodelling (FS: 1.05 ± 0.09 vs ZDFL (0.57 ± 0.13); $p < 0.05$) have been observed in ZDF. Drug treatment significantly decreased myocardial hypertrophy and fibrosis (LVAWs: 2.47 ± 0.05 mm; CD/TL: 3.15 ± 0.02 ; ANF: 1.39 ± 0.21 ; FS: 0.59 ± 0.08 vs ZDF; $p < 0.05$) in DM. PV analysis showed impaired diastolic function and increased cardiac stiffness (time constant of LV pressure decay (τ): 9.17 ± 0.25 ms; slope of end-diastolic P-V relationship (EDPVR): 0.078 ± 0.002 mmHg/ μ l vs ZDFL (τ : 8.18 ± 0.13 ms; EDPVR: 0.045 ± 0.003 mmHg/ μ l); $p < 0.05$) while contractility parameters and blood pressure remained unchanged in ZDF. Vardenafil improved diastolic parameters (τ : 8.62 ± 0.34 ms, EDPVR: 0.062 ± 0.006 mmHg/ μ l vs ZDF; $p < 0.05$). Vardenafil did not have any effects in ZDFL.

Conclusions: We reported that chronic administration of vardenafil prevents DM associated myocardial complications. PDE5 inhibition might be an important target to improve cardiovascular outcome in diabetic patients in the future.

Bicoronary infusion of nitroglycerin and atrial natriuretic peptide improves diastolic distensibility in healthy pigs.A Alogna¹; M Manninger²; B Zirngast³; M Schwarzl⁴; P Steendijk⁵; B Pieske¹; H Post¹

¹Charité - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Medical University of Graz, Department of Cardiology, Graz, Austria; ³Medical University of Graz, Department of Cardiac Surgery, Graz, Austria; ⁴University Heart Center Hamburg, Hamburg, Germany; ⁵Leiden University Medical Center, Department of Cardiology, Leiden, Netherlands

Background: Experimental data indicate that the acute post-translational modification of the myofibrillar titin spring by cGMP-activated protein kinase G can increase left ventricular (LV) end-diastolic distensibility (LVed-Dist). Intracellular cGMP production can be stimulated either by nitric oxide via the soluble guanylate cyclase (sGC), or by the natriuretic peptides via the particulate guanylate cyclase (pGC). We tested the hypothesis that acute intracoronary infusion of nitroglycerin (NTG) or atrial natriuretic peptide (ANP) would exert direct myocardial effects and improve LVed-Dist in healthy myocardium.

Methods: 5 anaesthetized, closed-chest pigs (59 \pm 2kg) were acutely instrumented with a left ventricular (LV) pressure-volume catheter, a Swan-Ganz catheter and an aortic balloon catheter. Two 5F coronary catheters were positioned in the right and left coronary ostia via femoral access. Pressure-volume relationships were derived from short aortic occlusions. Following baseline measurements, NTG was infused bicoronarily at 10, 30 and 100 ng/kg/min over 20 min, respectively. After 30 min wash-out, the same protocol was repeated with ANP at 1, 3 and 10 ng/kg/min. *: $p < 0.05$ vs baseline

Results: LV peak pressure slightly decreased at the highest dose compared to baseline (NTG: $87 \pm 3^*$ vs 94 ± 4 , ANP: $85 \pm 4^*$ vs 96 ± 6) while systemic vascular resistance was not altered during NTG infusion and to a minor extent during the highest dose of ANP ($11.1 \pm 0.6^*$ vs 12.7 ± 0.7 mmHg/l/min). The maximum rate of positive LV pressure change, LV dP/dtmax, decreased and the calculated end-systolic volume at 100 mmHg end-systolic pressure increased dose-dependently, indicating a negative inotropic effect. The end-diastolic pressure volume relationships (EDPVR, graph) before and during infusion of NTG and ANP were shifted rightwards compared to the respective baseline (see graphs).

Conclusion: The acute pharmacological stimulation of cGMP-dependent signalling improves LV end-diastolic distensibility in healthy pigs in vivo. The molecular mechanisms mediating such acute modulation of LV distensibility may represent pharmacological targets to treat a pathological loss of LV distensibility as, for instance, heart failure with preserved ejection fraction (HFpEF).

EDPVRs baseline vs NTG-ANP

Intravenous administration of CoQ10 evokes increase in NO-mediated blood vessels relaxation

Supported by the Grant of Russian Scientific Foundation #14-15-00126

OS Medvedev¹; LP Kozaeva¹; EA Gorodetskaya¹; EI Kalenikova¹¹M.V. Lomonosov Moscow State University, Pharmacology, Moscow, Russian Federation

Introduction: The presence of endothelial dysfunction is associated with an increased mortality risk in patients with chronic heart failure. Coenzyme Q10 (CoQ10) is recommended for treatment of patients with congestive heart failure, but due to its low bioavailability it is necessary long term administration in order to reach therapeutic effect. One of the proposed mechanisms of beneficial effects of Coq10 is improvement in the vasodilating NO-mediated function of endothelium.

Purpose: Investigation of the fast effects of CoQ10, administered intravenously, on the NO-mediated vasorelaxation, evoked by acetylcholine. Methods. Male Wistar rats (300-350g) were anaesthetized with chloralhydrate (400 mg/kg, ip) and placed on a heated surgical pad at constant body temperature $37 \pm 0.5^{\circ}\text{C}$. 3% water-based solution of CoQ10 (30 mg/kg) or saline (0.9% NaCl, 1 mL/kg) were administered intravenously via the femoral vein. 2 h after drugs administration the animals were anaesthetized by chloralhydrate over dose (600 mg kg⁻¹, ip) and decapitated. The descending thoracic aorta was carefully excised and cut into ring segments 3 mm in length and then transferred into 10-ml organ baths containing Krebs solution bubbled with a mixture of 95% O₂ and 5% CO₂. The rings were precontracted with 0.3 μ M Phenylephrine (PE), and after a steady-state tension had been reached, increasing concentrations of ACh (0.001 μ M - 30 μ M) were cumulatively added to the organ bath.

Results: ACh elicited a concentration-dependent relaxation of rat aortic rings. The maximum relaxation (E max, %) was obtained at a ACh concentration of 30 μ M. In the CoQ10-treated group the relaxant responses to ACh were markedly potentiated when compared with the control (saline) group ($94.2 \pm 2.0\%$ vs $68.1 \pm 4.4\%$, respectively, $p < 0.01$). It was significant difference in pD₂ (-lg EC₅₀,) values of the control and treatment groups (5.79 ± 0.29 vs 8.14 ± 0.65 , $p < 0.05$).

Conclusion: 2h duration of CoQ10 (30 mg/kg) action is enough for improving the vasodilating NO-mediated function of endothelium. This mechanism could be partially responsible for positive effects of CoQ10 in congestive heart failure.

P1780

Prolonged dipyridamole use is associated to amelioration of myocardial perfusion disturbance in experimental chronic Chagas cardiomyopathy

Fundação de Amparo à Pesquisa do Estado de São Paulo - FAPESP

D M Tanaka¹; EEV Carvalho¹; LFL Oliveira¹; MMD Romano¹; GG Oliveira¹; ACL Barros-Filho¹; FFF Ribeiro¹; JS Silva¹; JA Marin-Neto¹; MV Simoes¹¹Medical School of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil

Background: Microvascular ischemia is a conspicuous finding in chronic chagasic cardiomyopathy (CCC) that may be involved in the development of left ventricular systolic dysfunction (LVSD).

Purpose: We aimed at assessing the effect of the prolonged use of dipyridamole (DIPY) on myocardial perfusion and left ventricle systolic function in a model of CCC.

Methods: We investigated 3 groups of female hamsters: animals infected with T. cruzi and treated with DIPY (CH+DIPY, n=15), infected and treated with saline (CH+Saline, n=15), non-infected and treated with DIPY (CO+DIPY, n=12) or treated with saline (CO+Saline, n=11). After 6 months of infection (baseline condition), the animals were submitted to echocardiography and to Sestamibi-Tc99m SPECT

myocardial perfusion scintigraphy (MPS). The animals were then treated with DIPY (4 mg/kg ip) twice a day or saline for 4 weeks and then reevaluated using the same imaging methods. The area of resting myocardial perfusion defects (PD) were calculated by computing the pixels exhibiting radiotracer uptake <50% compared to the maximum pixel value.

Results: The baseline and post-treatment results of PD and LVEF are summarized in the table. In the baseline condition, the chagasic animals showed larger area of PD than controls ($p=0.0005$), but similar LVEF ($p=0.3$). After treatment there was a significant reduction of the PD only in the CH+DIPY group ($p=0.004$), but not in the CH+placebo group or the controls ($p>0.05$). After treatment, CH+DIPY animals exhibited a PD area similar to that of treated control animals ($p>0.05$). Both chagasic groups, treated with DIPY and placebo, showed a reduction of LVEF in the post-treatment when compared to baseline. ($p<0.001$). No significant change of the LVEF was observed in controls.

Conclusions: The prolonged use of DIPY in animals with CCC was associated with a significant reduction of PD. However, the resolution of microvascular ischemia using DIPY has not prevented the progression of left ventricular dysfunction. These results suggest that microvascular ischemia may not be a central mechanism of myocardial damage in the physiopathogenic complex of CCC.

The Wilms tumour 1 gene as a molecular discriminator between ischemic and non-ischemic end-stage heart failure

BFU2014-52299-P, Ministerio de Economía y Competitividad, Spain

M Torrado¹; A Mikhailov¹; MG Crespo-Leiro²; C Pradas-Irún²;

D Vazquez-Echeverri²; G Marrón-Linares²; N Suarez-Fuentetaja²;

R Muñoz-Chapuli³

¹Institute of Health Sciences, University of La Coruña, La Coruña, Spain;

²University Hospital Center of La Coruña, La Coruña, Spain; ³University of Málaga, Department of Animal Biology, Málaga, Spain

Purpose: There is evidence suggesting that reactivation of a key embryonic epicardial gene, Wilm's tumour 1 (Wt1) in the adult may lead to better outcomes after cardiac injury. The aim was to study cardiac Wt1 expression across different heart failure (HF) scenarios in patients with end-stage systolic HF with reduced ejection fraction (HFrEF) as well as in the porcine model of HF with preserved EF (HFpEF).

Methods: Levels of Wt1 transcript (by RT-PCR) and protein (by Western blot) variants were determined in left ventricular (LV) samples taken at the time of heart transplantation in patients with end-stage HFrEF (LVEF=18.2 ± 6%) due to idiopathic (n = 10) and ischemic (n = 10) dilated cardiomyopathy (DCM) as well as in LV-samples derived from neonatal piglets (n = 12) with doxorubicin (Dox)-induced HFpEF and pulmonary congestion. The human non-transplantable hearts (n = 11) and cardiac samples from non-failing piglets (n = 8) were used as controls, respectively. Wt1 variants were cloned, expressed in model cell lines and used to verify the specificity of the antibodies to be used in Western blot assays.

Results: Splicing of exon 5 (E5) and of a stretch of nine nucleotides in the 3' end of exon 9 (abbreviated as KTS) give rise to four major Wt1 variants. These Wt1 splicing variants are expressed in non-failing human heart with a relative abundance ranking of Wt1D [+E5/+KTS] > Wt1B [+E5/-KTS] ~ Wt1C [-E5/+KTS] >> Wt1A [-E5/-KTS]. The Wt1D [+E5/+KTS] variant represents nearly 50% of total Wt1 expression being the predominant or the only protein isoform detected by Western blot, mainly as a 60 kDa band, in non-failing human hearts. The same splicing variants are also revealed in non-failing porcine hearts. The expression of the Wt1D [+E5/+KTS] variant is significantly (~3 fold) downregulated (at both transcript and protein levels) in failing LV ventricles from patients with ischemic DCM. However, and in contrast, there were no significant differences in expression of the Wt1D [+E5/+KTS] variant in patients with idiopathic DCM compared to non-failing donor hearts. Other Wt1 splicing variants were expressed at a lower level in ischemic DCM hearts compared to that in non-failing or idiopathic DCM human hearts. Cardiac Wt1 expression was not altered in Dox-induced porcine model of HFpEF.

Conclusions: We demonstrate selective downregulation of cardiac Wt1 expression in patients with ischemic but not idiopathic DCM that is in contrast with the concept of common final pathways in end-stage HF.

Protective effect of doxycycline against the development of isoproterenol induced heart failure

A Adam Riba¹; L Deres¹; K Eros¹; B Sumegi²; T Kalman¹; R Halmosi¹; E Szabados¹

¹University of Pecs, 1st Department of Medicine, Pecs, Hungary; ²University of Pecs, Department of Biochemistry and Medical Chemistry, Pecs, Hungary

Introduction: It has already been proved that doxycycline is able to lessen left ventricular (LV) hypertrophy. In our recent study we examined whether this agent has poly(ADPribose) polymerase (PARP) inhibitor activity and beneficially affects the development of postinfarction heart failure.

Methods: Male, 16weekoldrats were divided into four groups: Group 1: control rats (C); Group 2: doxycycline treated group (DOX); Group 3: isoproterenol stressed group (ISO); Group 4: isoproterenol and doxycycline treated group (ISO+DOX). Heart failure was induced with subcutaneous injection of 80mg/kg isoproterenol on two consecutive days. Afterwards doxycycline treatment was administered for 8 weeks with an oral dosage of 50mg/kg/day. Plasma Btype natriuretic peptide level was measured and echocardiography was performed before and at the end of the treated period. To determine the extent of interstitial fibrosis, Masson's trichrome staining was used. The changes of the activation level of Akt1, GSK3 β , NF κ B, NFATc2, GATA4 and the level of PARylation were quantified by Western blot.

Results: By the end of the study period LV endsystolic volume (LVESV) and systolic leftventricular inner diameter were increased (LVIDs), ejection fraction (EF) significantly decreased in the ISO group. An elevated ventricular weight to tibia length (VW/TL) ratio and plasma BNP level was found in the ISO group ($p<0.05$ vs. Control). Histological analysis revealed increased myocardial fibrosis in ISO groups ($p<0.05$ vs. Control). Isoproterenol induced increased level of PARylation and increased activation of NF κ B and NFATc2. These alterations were significantly attenuated by doxycycline treatment ($p<0.05$ vs. ISO). Phosphorylation of Akt1, GSK3 β and activity of GATA4 were enhanced. Discussion: Doxycycline significantly moderated the development of heart failure after isoproterenol treatment besides the already known MMP2 inhibition viaits PARP inhibitory effect.

Expression of IL-33/ST2 system in non-cardiac tissues after myocardial infarction.

A Lax¹; J Jesus Sanchez-Mas¹; MC Asensio-Lopez¹; I Simon-Saez¹; MJ Fernandez-Del Palacio²; MT Perez-Martinez¹; M Navarro¹; I Garrido-Bravo¹; FJ Pastor-Perez¹; DA Pascual-Figal¹

¹University Hospital Virgen De La Arrixaca, Murcia, Spain; ²Department of Animal Medicine and Surgery, Murcia, Spain

Introduction: Interleukin-33 (IL-33) is a cytokine that binds to the membrane receptor (ST2L) and activates downstream signaling that confers cardioprotection after acute myocardial infarction (MI), whereas the soluble isoform (sST2) acts as a decoy receptor by sequestering IL-33 and blocking the cardioprotective effect of IL-33/ST2L system. In MI patients, plasma sST2 rises early and is associated with adverse remodeling, increased risk of heart failure and death. sST2 can be produced by both cardiac fibroblasts and cardiomyocytes after MI. However, the expression of sST2 could not be exclusive of the heart and other tissues may be a source of sST2 after MI, which is relevant to establish therapeutic strategies that decrease their expression.

Purpose: To assess the kinetics of IL-33, sST2 and ST2L expression in non-cardiac tissues after MI. Methods. 50 Wistar rats were subjected to MI by permanent ligation of the left anterior descending coronary artery and were randomized to be sacrificed 1, 2, 4, 12 or 24 weeks after MI (10 animals per group). In addition, 8 animals underwent surgery without ligation (control group). The mRNA expression of IL-33, sST2 and ST2L was measured by quantitative RT-PCR in lung, liver and kidney. ST2 protein expression was also assessed by immunohistochemical staining. Each value is expressed as fold of control \pm standard error.

Results: Compared to control group, infarcted animals showed an increase in weight of lungs and liver from the first week after MI. The sST2 mRNA level significantly increased in the lungs from the first week after MI (4.3 ± 0.9 , $p=0.004$). This increase remained high until 24 weeks after MI (5.2 ± 1.2 , $p=0.02$). This kinetic

was confirmed by immunohistochemistry. In contrast, expression levels of IL-33 and its receptor (ST2L) decreased acutely after MI, while were normalized after 4 weeks post-MI. No significant changes were observed in the mRNA expression level of sST2, ST2L or IL-33 in liver or kidney compared to control group.

Conclusions: Following MI, early increased expression of sST2 in the lung occurs, which may increase circulating sST2. This increase is long term maintained and could contribute to block the cardioprotective signaling mediated by IL33/ST2L and thus to a worse evolution after MI.

The progressive cardiac dysfunction after myocardial infarction (MI) related with left ventricular fibrosis and remodeling. In previous study, angiotensin receptor blocker (ARB) treatment before the onset or during the acute stage of MI was effectively inhibited the progression of post-MI heart failure. This study investigated whether new ARB 'Fimasartan' is able to protect in the post-MI progression of left ventricular (LV) dysfunction and unknown under lining mechanism. MI was induced in SD rats by permanent ligation of the left anterior descending artery (LAD). Treatment with Fimasartan (10mg/kg) was initiated 24 hours post-MI and continued for 7 weeks through oral administration. All animals performed baseline echocardiography and then randomly assigned into 3 groups; surgery control (Sham group, n=8), MI without fimasartan treatment (MI group, n=11), and MI with fimasartan treatment (MI+Fima group, n=14), respectively. In histologic finding, infarct size and fibrosis were significantly decreased in MI+Fima compare to MI. Echocardiography was performed in 1 week and 7 weeks post-MI and before MI surgery as baseline. LV end-systolic and diastolic dimension, and LV function was dramatically preserved in MI+Fima after 7 weeks compare with MI group (FS, $71.65 \pm 1.49\%$ VS $51.77 \pm 5.14\%$). Hemodynamic measurement was observed 3 days after final echocardiography. Results showed great positive ($+4526 \pm 240$ mmHg/sec) and negative dP/dt (-4187 ± 303) in MI+Fima compare with MI group ($+3670 \pm 239$, -3301 ± 280 mmHg/sec, $p < 0.05$ respectively). From microarray, fimasartan treatment dramatically decreased inflammatory signal and increased lipid metabolic relate genes. In addition, mitochondria membrane ion transport and damage response genes were increased. A new ARB, fimasartan, strongly inhibit LV remodeling and development of cardiac dysfunction in myocardial infarction thorough preserve mitochondria survival. It shows possibility of fimasartan as a clinical treatment option to prevent progression of heart failure after MI.

Introduction: The T-box protein 1 (TBX1) is a key fetal transcription factor in the embryonic heart development. After myocardial infarction (MI), adult heart returns to the fetal gene program, which activates mechanisms such as hypertrophy or fibrosis in order to maintain the contractile capacity of the infarcted heart.

Purpose: To assess the involvement of TBX1 in myocardial remodeling after MI, and if it is modulated by a therapy with proven benefit as mineralocorticoid receptor with eplerenone. **Methods:** 60 rats were subjected to MI by permanent ligation of the left anterior descending coronary artery: 50 animals were randomized to be sacrificed 1, 2, 4, 12 or 24 weeks after MI: 10 animals were treated with eplerenone (100 mg/kg/day) seven days before the MI and sacrificed 4 weeks post-MI. 8 animals underwent surgery without ligation (control group). Cardiac expression of TBX1, fetal genes (ANP, BNP, β -MHC and α -actin-1) and fibrosis markers (collagen-I, collagen-III, TGF- β , galectin-3 and α -SMA) was assessed by quantitative RT-PCR or Western blotting. Left ventricular function variables were assessed before the sacrifice using a transthoracic echocardiographic examination.

Results: Gene and protein expression of TBX1 increased in the infarcted myocardium with a peak of expression after 1-week post-MI ($p < 0.01$), but did not change in the non-infarcted myocardium. The mRNA expression of fetal genes and fibrosis markers also increased, with a maximum of expression after 4-weeks post-MI ($p < 0.01$) and 1-week post-MI ($p < 0.001$), respectively. TBX1 expression correlated to the expression of fibrosis markers ($p < 0.01$), but not fetal genes. Eplerenone reduced the increase of TBX1 and fibrosis induced after MI, which was associated with an improvement of cardiac function analyzed by echocardiography.

Conclusions: The results show the post-MI reactivation of TBX1 expression and

suggest their involvement as pro-fibrotic molecule in the adverse remodeling, it may be involved in the benefit of mineralocorticoid blockade.

¹Health Sciences Research Institute Germans Trias i Pujol, Badalona, Spain;

²Minimally Invasive Surgery Centre Jesus Usón, Cáceres, Spain; ³Center of Regenerative Medicine in Barcelona, Barcelona, Spain; ⁴Germans Trias i Pujol University Hospital, Badalona, Spain

Introduction: Engineered constructs using induced pluripotent stem (iPS) cells to regenerate a myocardial scar may become true regenerative alternatives. 1

Purpose: This work evaluates safety and efficacy of undifferentiated porcine allogeneic GFP+iPS cells in three settings: embedded within an adipose pericardial graft (APG), an acellular pericardial scaffold (Scaffold), or both (APG-Scaffold) after acute myocardial infarction (MI) in swine.

Methods: Porcine iPSs (p-iPS) were derived by transient expression of a single non-viral polycistronic vector in porcine skin fibroblasts. 2 Fifty seven swine underwent MI by coronary artery ligation, and distributed into three groups with biomaterials but p-iPS-free (APG n=6; Scaffold n=13; APG-Scaffold, n=7), and three groups with p-iPS-enriched constructs (p-iPS-APG n=9; p-iPS-Scaffold, n=11; and p-iPS-APG-Scaffold, n=11). Histopathology and cardiac magnetic resonance imaging (MRI) were used.

Results: Histopathology confirmed: first, absence of teratogenesis at multi-organ level after 3 months of follow-up; second, no evidence of p-iPS by immunohistochemistry nor real time-PCR neither within the myocardial scar or biomaterials; third, similar infarct size in all studied groups. Pre-sacrifice cardiac MRI revealed no significant benefit in left ventricular ejection fraction, cardiac output, end diastolic volume, and end systolic volume.

Conclusions: Undifferentiated allogeneic p-iPS delivery within three different engineering approaches is safe. Nevertheless, p-iPS could not be identified upon sacrifice and do not seem to support functional benefit after MI in swine.

Effect of exercise training on cardiac FNDC5 and BDNF post myocardial infarction

University of Ottawa Cellular and Molecular Medicine Department/Cardiac Endowment Fund at the Heart Institute, Canadian Institutes of Health Research HW Heon Won Lee¹; HW Wang¹; C Roeske¹; M Ahmad¹; FHH Leenen¹

¹University of Ottawa Heart Institute, Hypertension Unit, Ottawa, Canada

Introduction: After myocardial infarction (MI), cardiomyocyte apoptosis and fibrosis contribute to the progressive left ventricle (LV) remodeling and dysfunction. Early initiation of exercise training post MI attenuates these cardiac changes. Exercise increases brain-derived neurotrophic factor (BDNF) in the hippocampus, which appears to be initiated by up-regulation of the myokine, fibronectin type III domain-containing protein 5 (FNDC5). In the heart, activation of BDNF may play a cardioprotective role post MI by inhibiting cardiomyocyte apoptosis and causing angiogenesis. Whether increases in FNDC5 and BDNF also occur in the heart by exercise post MI has not yet been studied.

Purpose: To determine changes in cardiac FNDC5 and BDNF and LV function post MI by exercise training.

Methods: After sham surgery (n=7) or ligation of left descending coronary artery, MI rats were divided into sedentary (Sed-MI, n=10) or exercise group (ExT-MI, n=9) for a 4-week exercise program 5 days per week on a motor-driven treadmill. At the end, LV function was assessed by echocardiography and Millar catheter. FNDC5 and BDNF mRNA and protein was measured in non-infarct, peri-infarct and infarct areas of the LV by real-time PCR and western blot.

Results: MI size tended to be lower in ExT-MI compared to Sed-MI ($P = 0.31$). Exercise attenuated the decrease in EF and the increase in LVDP. In Sed-MI, FNDC5 mRNA was decreased in all areas, the most in infarct area. BDNF mRNA was not different in all areas, but mature BDNF (mBDNF) protein decreased significantly in infarct area. Exercise attenuated the reduction in FNDC5 mRNA, and increased BDNF mRNA in peri-infarct area and mBDNF protein in non- and peri-infarct areas. EF correlated with mBDNF protein expression in non-infarct area.

Conclusion: Exercise training post MI attenuates reduction in FNDC5 and increases mBDNF protein in non- and peri-infarct areas of the LV. This may be contribute to improved cardiac function.

Dietary-induced obesity causes cardiomyopathy in Lee-Sung minipigs model – role of mitochondrial dynamics and oxidative stress

MOST 104-2313-B-002-038-MY3 (from Ministry of Science and Technology) and NTU-CRESRP-104R7615-3 (from National Taiwan University)
SJ Li¹; JY Wang¹; CY Ching-Yi Chen¹

¹National Taiwan University, Taipei, Taiwan ROC

Background & Aims: Mitochondrial dynamics, a process of biogenesis, fusion, fission and mitophagy, determine its morphology, quality, and functions; and is essential for maintaining a healthy mitochondrial network. As a highly oxidative tissue, mitochondria play a major role in maintaining the optimal cardiac function. Recently, many studies focus on the link between mitochondrial dysfunctions and cardiovascular diseases. In our previous study, we establish a dietary-induced obese (DIO) minipig model via Western diet feeding. This DIO minipigs have heavier body weight, accumulate more ectopic fat, and exhibit the metabolic syndrome, including hyperglycemia, hyperlipidemia, hypertension and fatty liver. The aim of this study was to elucidate the role of mitochondrial dynamic and oxidative stress in the heart of DIO minipigs.

Methods: Four-month-old Lee-Sung minipigs (LS) (initial body weight: 26.6 ± 1.3 kg) were randomly divided into two groups and fed the control diet (C) or a Western diet (W) for 6 months.

Results: The W pigs displayed a greater heart weight and more collagen accumulation in the heart, demonstrating a DIO-related cardiomyopathy. The W pigs exhibited a lower antioxidant capacity and higher oxidative stress in the left ventricle (LV). A decrease of ATP production was found in the LV of W pigs. Western diet caused a downregulation in the protein expression of PGC-1α (marker of mitochondrial biogenesis) and OPA1 (marker of mitochondrial fusion), and an upregulation in FIS1 (marker of mitochondrial fission) and LC3II (marker of mitophagy) in the LV of W pigs.

Conclusions: The results suggest that mitochondrial dynamics and oxidative stress are involved in the progression of DIO-related cardiac injury. In addition, we provide a novel heart disease minipigs model with characteristic more like human heart diseases which had impaired mitochondrial dynamics and increased oxidative stress.

Zebrafish model to study heart failure progression

I Emens¹; Al Lumley¹; Y Yvan Devaux²; DR Wagner³

¹Luxembourg Institute of Health, CVRU, Strassen, Luxembourg; ²Centre de Recherche Public - Santé, Luxembourg, Luxembourg; ³Hospital Centre, Luxembourg, Luxembourg

Introduction: Current medications used to treat heart failure patients can reverse left ventricular hypertrophy to some extent but are still ineffective against the escalating epidemic of heart failure. Thus, new therapeutic approaches are needed to suppress or ideally reverse heart failure development. Unlike mammals, zebrafish possess the incredible ability to regenerate cardiac tissue. The aim of this study was to evaluate whether zebrafish model can be used to study heart failure progression.

Methods: Eight to ten month old wild-type AB male zebrafish were treated with phenylhydrazine hydrochloride (PHZ) to generate heart failure (n = 86). After 5 weeks of treatment, PHZ was withdrawn and fish were followed up for 3 weeks. Hearts were imaged in living fish by ultrasound to assess ventricle size and function.

Functional capacity was evaluated in a dedicated swim tunnel. After sacrifice, hearts were collected for tissue staining or gene expression analysis.

Results: 5 weeks of PHZ-treatment led to a significant increase of 33% in ventricle size, and a decrease in heart rate (11%), fractional shortening (24%) and swim capacity (29%) (all p < 0.05). Ventricular wall thickness increased by 229%, ANP and BNP expression also increased significantly (p < 0.05). A higher number of apoptotic and proliferative cells were found in the myocardium of treated zebrafish. Two weeks after PHZ withdrawal, the ventricle regained its basal size. The swimming performance normalized after 1 week. ANP and BNP expression returned to basal levels after 2 weeks, and tissue morphology was normal at the end of the 3-week regeneration period. The picture shows photographs of representative hearts at baseline, after 5 weeks of PHZ treatment, and after 3 weeks of drug withdrawal

Conclusion: We showed that zebrafish constitutes an ideal experimental model to study heart failure development and regression. This model represents a unique opportunity to study the mechanisms of heart failure and test novel drugs

Heart Failure Progression in Zebrafish

²Polytechnic University of Catalonia, Barcelona, Spain; ³Minimally Invasive Surgery Centre Jesus Usón, Cáceres, Spain; ⁴Germans Trias i Pujol University Hospital, Badalona, Spain

Introduction: Cardiac tissue engineering, which combines cells and biomaterials, is promising for limiting the sequelae of myocardial infarction (MI).¹ In this context, decellularized tissues offer a natural microenvironment, driving cellular attachment, survival, migration, proliferation, and differentiation.^{2,3}

Purpose: We assessed myocardial function and scar evolution after implantation of an Engineered Bioactive Impedance Graft (EBIG) in a swine MI model.

Methods: The EBIG was made of a scaffold of decellularized human pericardium, GFP-labelled porcine adipose tissue-derived progenitor cells (pATPCs), and a customized-design Electrical Impedance Spectroscopy (EIS) monitoring system (Figure 1). In a non-invasive manner, cardiac function was evaluated by magnetic resonance imaging (MRI), and scar healing by a customized-design EIS system incorporated within the implanted graft. In addition, infarct size, fibrosis, vascular density, and inflammation were also assessed.

Results: Upon sacrifice one month after the intervention, MRI detected a significant improvement in left ventricular ejection fraction (7.5 ± 4.9% vs. 1.4 ± 3.7%; P = 0.038) and stroke volume (11.5 ± 5.9 mL vs. 3 ± 4.5 mL; P = 0.019) in EBIG-treated animals. Non-invasive EIS data analysis showed differences in both impedance magnitude ratio (−0.02 ± 0.04/day vs. −0.48 ± 0.07/day; P = 0.002) and phase angle slope (−0.18 ± 0.24°/day vs. −3.52 ± 0.84°/day; P = 0.004) in EBIG compared to control animals. Moreover, in EBIG-pericardium animals, the infarct size was 48% smaller (3.4 ± 0.6% vs. 6.5 ± 1%; P = 0.015), less inflammation was found by means of CD25+ lymphocytes (0.65 ± 0.12 vs. 1.26 ± 0.2; P = 0.006), and a lower collagen I/III ratio was detected (0.49 ± 0.06 vs. 1.66 ± 0.5; P = 0.019).

Conclusions: An EBIG composed of acellular pericardium with adipose progenitors reduced infarct size and improved cardiac function in a pre-clinical model of MI. Non-invasive EIS monitoring tracked differential scar healing in EBIG treated animals confirmed by less inflammation and altered collagen deposit.

Pulmonary arterial hypertension (PAH), the most serious chronic disorder of the pulmonary circulation, is characterized by pulmonary vasoconstriction and remodelling, resulting in increased afterload on the right ventricle (RV). In fact, RV function is the main determinant of prognosis in PAH. Most frequently used experimental models of PAH include the monocrotaline- and chronic hypoxia induced-PAH, which primarily affect the pulmonary circulation. Alternatively, pulmonary artery banding (PAB) can be performed to achieve RV overload without affecting the pulmonary vasculature, allowing researchers to determine the RV-specific effects of their drugs/interventions.

In this work we characterize in full detail, PAB-induced adaptive and maladaptive remodelling of the RV, 3 weeks after PAB surgery, using two different degrees of pulmonary artery constriction. Our results show that by applying a mild constriction, the RV develops adaptive hypertrophy, with preserved systolic and diastolic function, while application of a severe constriction resulted in maladaptive hypertrophy, with chamber dilation, and systolic and diastolic dysfunction, up to the isolated cardiomyocyte level.

Alternatively to previous works, we describe for the first time a reliable and short-time PAB model, in which RV adaptation can be distinguished 3 weeks after surgery, by applying two different degrees of constriction, allowing researchers to better study RV physiology and transition to dysfunction and failure, as well as to determine the effects of new therapies.

¹Hungarian Academy of Sciences, Center for Biological Research, Szeged, Hungary; ²Department of Microbiology, Faculty of Science and Informatics, University of Szeged, Szeged, Hungary; ³University of Szeged, Department of Otorhinolaryngology-Head and Neck Surgery, Szeged, Hungary; ⁴Szent Istvan University, 5 Department of Anatomy and Histology, Faculty of Veterinary Sciences, Budapest, Hungary

The transient outward (I_{to}) currents are determined by Kv4.2 and kv4.3 ion channels where the activity of I_{to} fast and I_{to} slow currents is not obligately dependent upon the expressed level of Kv4.x transcript. Ophiobolins are major members of the ophiobolin complex of phytotoxic metabolites, and they possess antitumor, antibacterial, antifungal activities. Increasing evidence points to a role of MGB1 as underlying factors and Sap97 related to inflammation. The Sap97 associates with Kv4-type channels in complex modulating their kinetic properties. Our hypothesis was that the Sap97 mainly localizes in the intercalated discs of the cardiac muscle therefore the altered expression of ion channels are presumably involved in the inhibition of normal mechanical parameters and physiological function of I_{to} current. The aim was to use purified ophiobolins as an effective molecular tool in

the study of inflammation. In this swot we have investigated the mechanical factors by atomic force microscope technique (AFM) and the surface expression of Kv4 ion channels on cardiomyocytes using electron microscope and immunofluorescence methods. AFM study showed that the elasticity of the cell surface, the Young modulus is moderately changed as well as cell volume and the highest of the cells in the presence of ophiobolin with low concentration. However after treatment with ophiobolin the binding of Sap97 to Kv4.x channels and distribution of their complexes are altered in the membrane and physiological behaviour of myocytes as compared to control cells. A growing body of research use using these new reductionist models of inflammation on cardiomyocytes are demonstrating a role of Sap97 in specific ion channel stability important for cardiac functions. These results suggest that Sap97 deactivation or reduction can lead (directly or indirectly) to changes in the functional cell surface expression of Kv4.x channels with mechanical parameters, with biophysical and biochemical properties of cardiac I_{to} current.

P1793**The induction of mild hypothermia increases pulmonary vascular resistance in healthy pigs**

A Alogna¹; M Manninger²; B Zirngast³; J Verderber²; D Zweiker²; M Schwarzl⁴; P Steendijk⁵; H Maechler³; B Pieske¹; H Post¹

¹Charité - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Medical University of Graz, Department of Cardiology, Graz, Austria; ³Medical University of Graz, Department of Cardiac Surgery, Graz, Austria; ⁴University Heart Center Hamburg, Hamburg, Germany; ⁵Leiden University Medical Center, Leiden, Netherlands

Introduction: The induction of mild hypothermia increases systemic vascular resistance and reduces the need for vasopressors in resuscitated patients. However, much less is known about the effect of temperature on pulmonary vascular resistance. We therefore retrospectively analysed hemodynamic data obtained in anaesthetized healthy pigs subjected to hyperthermia (40.5°C, HT), normothermia (38.0°C, NT) and mild hypothermia (33.0°C, MH).

Methods: 9 anaesthetized healthy pigs (67 ± 2 kg) were acutely instrumented with a Swan-Ganz and a left ventricular (LV) pressure-volume catheter in a closed-chest setting. Temperature was controlled by an intravascular device. After baseline measurements at HT, pigs were cooled to NT and further down to MH. Total pulmonary vascular resistance (TPVR) was calculated as mean pulmonary arterial pressure (mPAP)/cardiac output (CO), and PVR was estimated as (mPAP minus LV end-diastolic pressure) divided by CO.

Results: CO (6.7 ± 0.3 vs 6.1 ± 0.3 vs 4.4 ± 0.2 l/min) decreased with cooling from HT to MH, while mPAP increased slightly (graph). TPVR and PVR (graph) increased substantially with cooling. Whole body oxygen consumption (WB-VO₂) (395 ± 19 vs 314 ± 24 vs 199 ± 16 ml kg⁻¹ min⁻¹, all p < 0.05) decreased by 50% from HT to MH, while mixed venous oxygen saturation increased (53 ± 2 vs 60 ± 2 vs 66 ± 2 mmHg, all p < 0.05), indicating a preserved systemic oxygen supply-demand balance during cooling.

Conclusion: Cooling from HT to MH increases pulmonary vascular resistance more than twofold. This increase does not result in overt pulmonary hypertension due to the physiologic decrease of cardiac output during hypothermia. However, caution may be advised when MH is induced in resuscitated patients with increased pulmonary vascular resistance (i.e. pulmonary embolism or chronic pulmonary hypertension).

**P1794****Value of amino acids for cardioprotection**

A Alesia Korda¹; AV Iovlev¹

¹Centre of Hygiene, laboratory of occupational medicine, Minsk, Belarus

The main obstacle for the creation of reliable methods of long-term heart preservation is pathological changes in cardiomyocytes (CM) under conditions of ischemia. A key mechanism of CM damage is oxidative stress. The most important components of living cells maintaining homeostasis and exhibiting antioxidant properties are amino acids. However the role of amino acids in maintaining the myocardium antioxidant protection during its preservation is not clear. The aim of our study was to assess antioxidant capacity of myocardium during heart preservation in solutions with different amino acids composition. Methods. The study is based

on experimental studies on 88 adult male Wistar rats weighing 250-300 g were kept under standard vivarium conditions and in compliance with the rules for the humane treatment of laboratory animals. Hearts were excised from anesthetized with 10% sodium thiopental sodium rats and immersed at 4°C for 3 hours in preservation solutions: Krebs-Henseleit solution (control), Custodiol and the Krebs-Henseleit solution with the L-amino acids (AA) or its different combinations. Antioxidant activity (AOA) was determined by the ability of the isolated using bovine serum albumin and collagenase type IV CM to inhibit the radical 2,2'-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS•+) at the 10th minute incubation and expressed as median (25th percentile – 75th percentile)% compared with control probe of reagent kit (Oxistat, Belarus).

Results: AOA of control CM and CM stored with histidine-valine were dramatically decreased to 30.0(20.0;33.3)% and 21.7(16.7;26.7)%, resp. AOA of CM after immersing in solutions with different AA didn't differ from control. At the same time CM stored in Custodiol or the Krebs-Henseleit solution with the another combinations of L-amino acids (tryptophan (2 mM)-arginine (10mM), tryptophan (2mM) - asparagine (4 mM) and tryptophan (2 mM) - glutamine (4 mM)) exhibited more preserved antioxidant activity ($p < 0.001$ compared with control).

Conclusion: For maintaining myocardium AOA heart preservation solution should contain amino acids with different mechanisms of antioxidant action.

We comprehensively characterized alteration in cardiac function in vivo using MRI, and in isolated working heart in relation to capillarization and ACE/ACE-2 angiotensin profile (by LC-MS) in 2,4,6,8,10,12 month-old Tgαq⁴⁴ and FVB mice. In 6 month-old mice Tgαq⁴⁴ mice despite full preservation of cardiac function atrial volumes, ventricle strains, and coronary flow response to increased preload were altered. In 8-9-months-old Tgαq⁴⁴ mice a decreased cardiac performance, with preserved cardiac reserve to dobutamine were observed, while the final stage of HF (12-14-months-old Tgαq⁴⁴ mice) was characterized by decreased global cardiac performance, lack of cardiac reserve, with diminished cardiac capillarization. ACE-2 was progressively activated in 6-8-months old Tgαq⁴⁴ mice as evidenced by increased plasma concentration of angiotensin (1-7), angiotensin (1-9), alamandine, while ACE was progressively activated starting from 8-month old Tgαq⁴⁴ mice as evidenced by increased plasma angiotensin II, III, IV and Ang A. Profile of angiotensins in the heart supported ACE/ACE-2 alterations with Ang (1-12) playing a prominent role. In conclusion, despite cardiomyocytes-specific trigger of the HF pathology in Tgαq⁴⁴ mice the progression of decompensated HF is associated with both systemic and local RAC-ACE activation that is counterbalanced by prominent ACE-2 activation in the adaptive phase of HF.

Mouse cardiac LXRα overexpression as a model to modulate cardiac metabolism and trigger specific fetal gene expression to ameliorate pathological hypertrophy

NWO VIDI

RA Rudolf De Boer¹; MV Cannon¹; JWA Sijbesma¹; I Vreeswijk-Baudoin¹; LJ De Windt²; MAF Khan³; KR Steffensen⁴; HH Sillje¹; WH Van Gilst¹

¹University Medical Center Groningen, Groningen, Netherlands; ²Cardiovascular Research Institute Maastricht (CARIM), Cardiology, Maastricht, Netherlands;

³University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands; ⁴Karolinska Institute, Stockholm, Sweden

Purpose: Liver X receptors (LXRs) are key regulators of glucose and lipid metabolism in cardiac hypertrophic pathogenesis. These metabolic processes are altered in heart failure and in the diabetic heart. Here we explored a mouse model with cardiac LXRα overexpression and subjected these mice either to cardiac pressure overload or to a high fat diet inducing type 2 diabetes.

Methods: Murine Lxrα was cloned behind the α-myosin heavy chain (αMhc) promoter to create transgenic (LXRα-Tg) mice and transgene-negative littermates (WT). Cardiac pressure overload in these mice was generated by transverse aortic constriction (TAC) for 5 weeks. Type 2 diabetes was induced by high fat diet (HFD, 60

kcal% fat) over 16 weeks and compared to low fat diet (LFD, 10 kcal% fat). In vitro studies were performed in isolated primary neonatal rat ventricle myocytes.

Results: Overexpression of LXRα protects the heart against hypertrophy in both the TAC pressure overload model and in type 2 diabetic mice. Overexpression markedly enhanced the capacity for myocardial glucose uptake at baseline and further enhanced this under hypertrophic stress conditions. In the HF-diet mice, increased cardiac glucose uptake was mediated in part through AMPK phosphorylation and restoration of GLUT4 expression. Most fetal gene program genes were less induced in LXRα overexpressing mice, which correlates with the diminished hypertrophic response. Expression of natriuretic peptides, ANP and BNP, was, however, elevated in the LXRα-Tg mice and could mediate the observed anti-hypertrophic effect. LXRα promoted energy independent utilization of glucose via the hexosamine biosynthesis pathway, resulting in O-GlcNAc modification of transcription factors GATA4 and Mef2c, which control the induction of natriuretic peptide expression. Moreover, in silico analysis of the ANP/BNP region using algorithms specific for the identification of LXR binding sites (LXREs), revealed the presence of several conserved LXREs. Cardiac LXRα chromatin immunoprecipitation assays confirmed binding of LXRα to two conserved LXREs in the ANP/BNP promoter region, indicating that these are direct targets of LXRα.

Conclusions: LXRα helps to orchestrate an adaptive metabolic response to chronic cardiac stress, and modulating LXRα may provide a unique opportunity for intervening in myocyte metabolism. We speculate that LXRα controls the expression of ANP and BNP directly via binding to LXRE elements in the promoter regions and indirectly via O-GlcNAc modification of GATA4 and Mef2c transcription factors.

Hypertrophy induced KIF5B controls mitochondrial localization and function in neonatal rat cardiomyocytes

H H W Herman Sillje¹; W Tigchelaar¹; AM De Jong¹; VW Bloks¹; WH Van Gilst¹; RA De Boer¹

¹University medical center Groningen, Groningen, Netherlands

Purpose: Cardiac hypertrophy is associated with growth and functional changes of cardiomyocytes, including mitochondrial alterations, but the latter is still poorly understood. Here we investigated mitochondrial function and dynamics in primary neonatal rat ventricular myocytes (NRVMs) stimulated with insulin growth factor-1 (IGF-1) or phenylephrine (PE), mimicking physiological and pathological hypertrophic responses, respectively.

Methods: Mitochondrial oxidative phosphorylation (OXPHOS) activities were investigated in cultured primary NRVMs treated with PE or IGF-1. Mitochondrial oxygen consumption rates (OCR) were determined with a Seahorse flux analyzer in intact and permeabilized NRVMs. Mitochondrial biogenesis, localization and gene expression profiling was performed and KIF5B function was investigated.

Results: A decreased activity of the mitochondrial electron transport chain (ETC) (state 3) was observed in permeabilized NRVMs stimulated with PE, whereas this was improved in IGF-1 stimulated NRVMs. In intact NRVMs, mitochondrial oxidation capacity rate (OCR) was, increased in PE stimulated NRVMs, but remained constant in IGF-1 stimulated NRVMs. After stimulation with PE, mitochondria localized to the periphery of the cell. To study the differences in more detail, we performed gene array studies. IGF-1 and PE stimulated NRVMs did not reveal major differences in gene expression of mitochondrial encoding proteins, but we identified a motor protein implicated in mitochondrial localization, kinesin5B (KIF5B), which was clearly elevated in PE stimulated NRVMs but not in IGF-1 stimulated NRVMs. We confirmed that KIF5B expression was elevated in animal models with pathological cardiac hypertrophy. Silencing of KIF5B reverted the peripheral mitochondrial localization in PE stimulated NRVMs and diminished PE induced increases in mitochondrial OCR, indicating that KIF5B dependent localization affects mitochondrial respiration in PE stimulated NRVMs.

Conclusions: These results indicate that KIF5B contributes to mitochondrial dynamics and function in cardiomyocytes and may play a role in pathological hypertrophic responses in vivo

Hyperinsulinemia and overweight in obese Zucker rats effectively suppressed by exercise training with hypoxia recovery

WS Hu¹

¹china medical university hospital, cardiology, taichung, Taiwan ROC

It is currently unknown whether hypoxia training can effectively suppress overweight and hyperinsulinemia in genetically obese animals. In this study, both lean and obese Zucker rats were randomly assigned into the following groups: control (CON, n = 7), exercise training (EX, n = 7), hypoxia (HYP, n = 7) and exercise training with hypoxia recovery (EX+HYP, n = 7). During a 6-week training period, rats performed swimming exercise progressively from 30 to 180 min.day⁻¹, and recovered under hypoxia (14%

oxygen for 8 h.day⁻¹). Obese Zucker rats exhibited substantially greater fasting insulin levels, and exaggerated glucose and insulin responses following an oral glucose challenge compared with lean rats. At the beginning of week 6, body weight, fasting glucose, fasting insulin, area under curve of glucose (GAUC) and insulin (IAC) in the EX+HYP group were significantly lower than CON group among the obese rats. Meanwhile, only GAUC was significantly lower in the EX group compared to the CON group. At the end of week 6, capillaries to fibre ratio (C/F), capillary density (CD) and type IIa fibre proportion of the plantaris muscle in the EX group were significantly greater than the CON group (PB0.05), but no additive effect of hypoxia on exercise training was observed. Our data demonstrate that exercise training with prolonged hypoxia recovery offers better metabolic benefits than exercise training alone for the obese Zucker rats. This advantage was closely associated with effective weight reduction.

ERK1/2 mediates lipopolysaccharide-upregulated FGF-2, uPA, MMP-2, MMP-9 and cellular migration in primary cardiac fibroblasts

WS Hu¹

¹china medical university hospital, cardiology, taichung, Taiwan ROC

Upregulation of fibroblast growth factor (FGF), urokinase plasminogen activator (uPA), tissue plasminogen activator (tPA) and matrix metalloproteinases (MMPs) is associated with the development of myocardial infarction (MI), dilated cardiomyopathy, cardiac fibrosis and heart failure (HF). Evidences suggest that lipopolysaccharide (LPS) participates in the inflammatory response in the cardiovascular system; however, it is unknown if LPS is sufficient to upregulate expressions and/or activity of FGF-2, uPA, tPA, MMP-2 and MMP-9 in cardiac fibroblasts. In the present study, we treated primary cardiac fibroblasts with LPS to explore whether LPS upregulates FGF-2, uPA, tPA, MMP-2 and MMP-9 and cellular migration, and further to identify the precise molecular and cellular mechanisms behind these upregulatory responses. Here we show that LPS challenge increased the protein levels of FGF-2, uPA, MMP-2 and MMP-9, and induced the activity of MMP-2 and MMP-9 in cardiac fibroblasts. After administration of inhibitors including U0126 (ERK1/2 inhibitor), SB203580 (p38 MAPK inhibitor), SP600125 (JNK1/2 inhibitor), CsA (calcineurin inhibitor) and QNZ (NFκB inhibitor), the LPS-upregulated expression and/or activity of FGF-2, uPA, MMP-2 and MMP-9 in cardiac fibroblasts is markedly inhibited only by ERK1/2 inhibitors, U0126. Collectively, these results suggest that LPS upregulates the expression and/or activity of FGF-2, uPA, MMP-2 and MMP-9, and the subsequent cell migration through ERK1/2 signaling pathway in primary cardiac fibroblasts. Our findings further provide a link between the LPS-induced cardiac dysfunction and the ERK1/2 signaling pathway that mediates the upregulation of FGF-2, uPA, MMP-2, MMP-9 and cellular migration in primary cardiac fibroblasts

PKA/PKC mediated changes in phosphorylation of inhibitor-1 at residues thr35 and ser67 contribute to elevated intracellular sodium in failing hearts

BHF and Wellcome Trust

D Davor Pavlovic¹; K Wittkopper²; A El-Armouche²; M Shattock¹

¹King's College London, Rayne Institute, London, United Kingdom; ²Dresden University of Technology, Dresden, Germany

Purpose: Inhibitor-1 (I-1) is an endogenous regulator of type-1 protein phosphatase (PP1). I-1 integrates the effects of two major signalling pathways in the heart, β-adrenergic/PKA and calcium/PKC. PKA phosphorylates I-1 at Thr35 thereby reducing PP1 activity, whereas, PKCα phosphorylates I-1 at Ser67 and thus activates PP1. Here we examined the effects of I-1 phosphorylation on intracellular Na concentrations (via Na/K ATPase and its accessory protein phospholemman, PLM) in isolated mouse and rat cardiomyocytes. Furthermore, we examined I-1 phosphorylation status in failing human hearts and donor controls. METHODS AND

Results: Rat and mouse ventricular myocytes were infected with adenoviruses encoding WT I-1 (I-1WT), Ser67A mutant (I-1S67A) or GFP-control. Changes in protein expression and phosphorylation, Na/K ATPase current and intracellular Na were investigated using western blot, patch clamp and sodium-sensitive dye, respectively. Expression of I-1WT significantly increased PLM phosphorylation at its PKA site Ser68, increased Na/K ATPase current and reduced intracellular Na concentrations in cardiomyocytes under basal and β-receptor activated conditions (1 nM of isoprenaline) cf GFP controls. In cells expressing I-1S67A mutant (where PKC cannot phosphorylate I-1 Ser67 residue) further increases in phosphorylation of PLM-Ser68 where observed of I-1WT, under basal conditions (46%) and β-receptor activated conditions (110%). Furthermore, I-1S67A induced a significant decrease in intracellular Na concentration (8.47 ± 0.73 mM), cf I-1WT (10.94 ± 0.87 mM). This decrease in Na was absent in myocytes isolated from mice where all three PLM phospho-residues were mutated to alanines, indicating that the I-1 effects are mediated via PLM. In left ventricular myocardium from patients with heart failure, I-1 expression and phosphorylation at Thr35 residue was reduced and Ser67 increased, indicating upregulated PP-1 activity in failing hearts. Indeed, phosphorylation of major PP1 targets, phospholemman Ser68 and phospholamban Ser16 were both

significantly reduced in failing hearts (n=8). No significant changes were detected in expression of Na/K ATPase, Serca2a, total PLM or in phosphorylation at PLM Ser63 and Thr69 residues.

Conclusions: We provide evidence that in cardiomyocytes intracellular Na is regulated by the phosphorylation status of I-1 and that this mechanism is modulated by the PKA-PKC crosstalk. This novel mechanism, is disrupted in failing hearts favoring reduced Na/K ATPase and SERCA activity and thus may be a major contributor to maladaptive hypertrophy and arrhythmogenesis.

P1801

A new potential strategy for targeting pathological cardiac hypertrophy: the dimer interface of ERK1/2

A Tomasovic¹; M Huemmer¹; K Kristina Lorenz¹

¹Institute of Pharmacology and Toxicology, Würzburg, Germany

Background: The extracellular signal-regulated kinases 1 and 2 (ERK1/2) have a central role in cardiac hypertrophy and cell survival. Hypertrophic stimuli trigger ERK1/2 activation, ERK dimerization and subsequently ERKThr188-autophosphorylation, a prerequisite for ERK1/2-mediated pathological cardiac hypertrophy. Here, we investigated interference with ERK dimerization as a therapeutic strategy to prevent pathological cardiac hypertrophy. Methods. To evaluate the impact of monomeric ERK, we used monomeric ERK2Δ174-177 and a peptide that interferes with ERK dimerization. The effects of ERK2Δ174-177 and the peptide were analyzed with regard to cardiomyocyte size, [3H]-isoleucine incorporation, ERK1/2 target phosphorylation, TUNEL positive cells and confocal ERK localization assays. Transgenic mice with cardiac overexpression of ERK2Δ174-177 were generated to assess cardiac hypertrophy and apoptosis in response to transverse aortic constriction (TAC) or exercise.

Results: Overexpression of monomeric ERK2Δ174-177 in neonatal rat cardiomyocytes (NRCM) resulted in an attenuated hypertrophic response to phenylephrine stimulation. In contrast to ERK1/2 inhibition by PD98059, ERK2Δ174-177 did not induce cardiomyocyte apoptosis. In line with these results, ERK2Δ174-177 expression reduced TAC induced cardiac hypertrophy without exacerbation of cardiomyocyte apoptosis and preserved cardiac function. In addition, mRNA expression levels of collagen and brain natriuretic peptide (BNP) were significantly reduced in ERK2Δ174-177 transgenic mice upon TAC compared to control mice. As cardiac hypertrophy is important under certain physiological conditions, we also analyzed the outcome of ERK2Δ174-177 overexpression in response to a physiological stimulus, i.e. running exercise, which revealed no impairment by monomeric ERK2 on cardiac growth or function. Further, interference with the dimerization of endogenous ERK using the ERK binding peptide significantly reduced ERKThr188 phosphorylation. Subsequently, NRCM expressing the peptide showed less hypertrophy upon phenylephrine stimulation compared to control cells – most likely via prevention of nuclear translocation of ERK2 and nuclear ERK target phosphorylation. Interestingly, the peptide neither impaired overall ERK1/2 activation nor cardiomyocyte survival.

Conclusion: These data indicate that inhibition of ERK dimerization selectively attenuates pathological cardiac growth without cardiac adverse effects. Interference with the ERK dimer interface might therefore be a valuable and promising approach to prevent pathological hypertrophy.

A central role for Hippo pathway and actin filament dynamics in microRNA-induced cardiomyocyte proliferation

C Torrini¹; MI Gutierrez¹; L Zentilin¹; L Braga¹; M Mano¹; S Zacchigna¹;

E Dirks¹; M Giacca¹

¹International Centre for Genetic Engineering and Biotechnology (ICGEB),

Molecular Medicine Laboratory, Trieste, Italy

Background: Loss of cardiac function after myocardial infarction (MI) remains a main cause of heart failure, which might be overcome by innovative, pro-regenerative treatments. By performing a genome-wide microRNA (miRNA) screening, we identified a series of human miRNAs capable of promoting cardiomyocyte proliferation and cardiac regeneration after MI. RNA-seq analysis of the effects induced by these miRNA uncovered a potential link between the Hippo pathway, which is known to regulate cell proliferation in the embryo, and actin filament dynamics.

Hypothesis: We hypothesized that our pro-proliferative miRNAs act by inactivating the Hippo pathway and set out to discover the link between their effect and the regulation of actin filament dynamics.

Methods: We analyzed involvement of the Hippo pathway in mediating the effects of the identified miRNAs by studying activation of Yap (the final effector in the pathway) by transcription reporter, RNAi and gene expression studies. Acting dynamics was investigated by immunofluorescence and specific drug treatment of cardiomyocytes. Final endpoints was cardiomyocyte proliferation by Edu staining (S-phase), phosphoH3 positivity (G2/M) and Aurora B localization in midbodies (kariokinesis).

Results: We discovered that 9 out of the 10 most effective miRNAs in driving cardiomyocytes proliferation also activated Yap-mediated transcription, as concluded by TEAD reporter gene analyses, increased transcription of the endogenous Yap reporter genes *Ctgf*, *Cyr61*, *Birc5* and *Ankd1* and nuclear import of active, unphosphorylated Yap after nuclear-cytoplasmic fractionation. In particular, miR-199a-3p was found to act through the direct downregulation of at least three mRNA targets impinging on the Hippo pathway, namely the upstream inhibitory kinase *Tak1*, the E3 ubiquitin ligase destroying Yap *bTrCP* and the regulator of actin cytoskeleton dynamics *Cofilin 2* (*Cfl2*). We discovered that both miR-199a-3p and *Cfl2* siRNA treatments induced actin polymerization, which was inhibited by the F-actin inhibitor cytochalasin D; treatment with this drug also strongly decreased activation and nuclear localization of Yap.

Conclusion: Induction of cardiomyocyte proliferation by miRNAs involves regulation of the Hippo pathway and modulation of the actin cytoskeleton. These results implicate novel molecular mechanisms able to boost cardiac muscle regeneration after myocardial injury.

Purpose: In the heart, phosphodiesterase type 4 (PDE4) plays a major role in the hydrolysis of cAMP generated by β -adrenergic receptors (β -AR). We have previously shown that invalidation of the PDE4B isoform in mice leads to an increase of the L-type Ca^{2+} current ($I(Ca_L)$) and cardiac arrhythmias upon β -AR stimulation. Here, we characterized the effects of cardiac-specific PDE4B overexpression (α -MHC promoter) on cardiac function and β -AR signaling in male transgenic (TG) mice and WT littermates at 10-16 weeks of age.

Methods and Results: TG mice had 7-fold increase in ventricular cAMP-PDE activity evaluated by radioenzymatic assay, associated with a small (18%) but significant increase in heart weight to body weight ratio as compared to WT. In vivo, telemetry showed similar heart rate and echocardiography revealed a lower ejection fraction in TG vs. WT ($64 \pm 5\%$ vs. $79 \pm 5\%$, $n=6$, $p<0.05$). Nonetheless, TG showed a better performance than WT when subjected to incremental treadmill test to exhaustion ($n=10-11$, $p<0.05$). In Langendorff-perfused hearts, the potency of isoprenaline (Iso) was decreased in TG ($EC_{50}=3.8$ nM vs. 1.4 nM, $n=4$, $p<0.05$), whereas basal cardiac function was unchanged suggesting that the decreased cardiac function observed in vivo was due to decreased responsiveness to catecholamines. Accordingly, basal sarcomere shortening and Ca^{2+} transient amplitude recorded with an Ionoptix[®] system in isolated ventricular myocytes loaded with Fura-2 AM ($3 \mu M$) were unchanged at baseline but their potentiation by Iso ($0.3-100$ nM) was decreased in TG. PDE4 inhibition by Ro 20-1724 (Ro, $10 \mu M$) restored a normal β -AR response. Interestingly, the proportion of cells exhibiting spontaneous Ca^{2+} events and contractions upon Iso was significantly smaller in TG compared to WT (18% vs. 48% at 10 nM and 46% vs. 77% at 100 nM, $n=3$, $n=7-11$, $p<0.05$). β -AR stimulation of $I(Ca_L)$ recorded with the patch-clamp technique was decreased by 60% in TG ($n=4$, $n=16-31$). Similarly, β -AR stimulation of intracellular cAMP levels and PKA activity measured with FRET biosensors were blunted by 75% in TG ($n=3$, $n=7-11$, $p<0.001$) and these differences were abolished by Ro. PLB and TnI levels were unchanged, but their phosphorylation at Ser16 and Thr17 (PLB) and Ser23/24 (TnI) was strongly reduced.

Conclusion: Cardiac PDE4B overexpression decreases β -AR response but preserves exercise capacity and prevents pro-arrhythmic Ca^{2+} events. Thus, PDE4B overexpression could be protective in pathological situations where β -AR stimulation is chronically augmented.

P1804

Evidence and role of neuronal sodium channel Nav1.8 in human failing cardiomyocytes

S Ahmad¹; N Dybkova¹; N Hartmann¹; P Tirilomis¹; TH Fischer¹; N Frey²; G Hasenfuss¹; S Sossalla²
¹University Medical Center Gottingen (UMG), Department of Cardiology and Pneumology, Gottingen, Germany; ²University Medical Center of Schleswig-Holstein, Department of Internal Medicine III, Kiel, Germany

Purpose: In heart failure, persistent current through Na channel (I_{NaL}) is augmented that may lead to arrhythmias. We sought to examine the existence of Nav1.8, its contribution to augmented I_{NaL} thereby to arrhythmias in the human heart and its role for cardiac pathology. Furthermore, we were interested whether CaMKII δ colocalises with Nav1.8 under pathophysiological condition thereby regulating its function.

Methods: For this study, we utilised human myocardium ($n=52$) with different pathophysiological conditions from atrium and ventricle while non-failing myocardium served as control. To investigate Nav1.8 regulation, myocardium homogenates were prepared and performed Western blot. Association and colocalisation of CaMKII δ with Nav1.8 was studied by coimmunoprecipitation and double immunofluorescence staining. Furthermore, to investigate contribution of Nav1.8 on cellular electrophysiology, whole-cell patch-clamp and confocal microscopy was performed in the presence/absence of a novel specific Nav1.8 blocker A-803467 (30 nM/L).

Results: We show for the first time that Nav1.8 was significantly upregulated in hypertrophy and heart failure compared to non-failing myocardium. Most importantly, parallel to Nav1.8 upregulation Nav1.5 was downregulated. However, no significant difference in Nav1.8 was observed between sinus rhythm and atrial fibrillation. There was also a significant increase in association and colocalisation of Nav1.8 with CaMKII δ in failing hearts compared to non-failing, further confirmed by immunofluorescence staining. Interestingly, Nav1.8 showed overlapping with CaMKII δ at both the intercalated-disc and T-tubules. Whole-cell patch-clamp showed a significant reduction in I_{NaL} and abbreviation of APD after addition of a novel specific Nav1.8 blocker in both atrial and ventricular failing cardiomyocytes. Moreover, SR- Ca^{2+} sparks measurement revealed reduction in Ca^{2+} leaks by addition of Nav1.8 blocker suggesting a significant role of Nav1.8 for cellular electrophysiology.

Conclusion: We showed for the first time that neuronal sodium channel Nav1.8 is overexpressed and colocalises with CaMKII δ in the human failing heart. Furthermore, blocking of Nav1.8 by a specific novel blocker reduces the, in heart failure augmented proarrhythmic I_{NaL} , causes abbreviation of APD and also reduces SR- Ca^{2+} leaks in human failing cardiomyocytes. The association of Nav1.8 with CaMKII δ might result in increased I_{NaL} and Ca^{2+} mishandling under condition of enhanced CaMKII δ activity as in heart failure and may serve as an arrhythmogenic trigger which would be of clinical relevance.

P1805

Impact of GMP-PKG pathway modulation on titin phosphorylation and titin-based myocardial passive stiffness

DFG
N Nazha Hamdani¹; M Herwig¹; S Hoepler²; M Krueger²; D Koesling³; M Khun⁴; WA Linke¹
¹Ruhr-University Bochum, Institute of Physiology, Bochum, Germany; ²Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany; ³Ruhr University Bochum (RUB), Pharmacology and Toxicology, Bochum, Germany; ⁴University of Wuerzburg, Wuerzburg, Germany

Rationale: The crucial contribution of the giant myofibrillar protein titin to diastolic stiffness and cardiomyocyte passive force ($F_{passive}$) is dependent, in part, on titin isoform composition and phosphorylation. Phosphorylation of titin by cyclic guanosine monophosphate (cGMP)-dependent protein kinase G (PKG) lowers titin-based stiffness, thus mediating a mechanical signaling process that is disturbed in heart failure.

Objective: To elucidate which elements of the nitric oxide (NO) cGMP-PKG signaling network are critical for titin phosphorylation and stiffness in vivo.

Methods and Results: We employed genetic knockout (KO) mouse models deficient for enzymes of the cGMP-PKG pathway, including cardiomyocyte-specific deletion of the guanylyl cyclase (GC)-A receptor and cGMP-dependent PKG (cGKI), as well as global deletion of soluble GC (sGC). We assessed titin phosphorylation by immunoblotting using phosphoserine-specific titin antibodies and by mass spectrometry quantification using stable isotope labeling of amino acids in mixed cultures of heart tissue from either wild-type (WT) or KO mice. The $F_{passive}$ of single permeabilized cardiomyocytes was recorded before and after administration of PKG. In all three genetic models, all-titin phosphorylation was reduced compared to WT hearts. The important PKG-dependent phospho-S4080 site within the N2-Bus region of mouse titin was hypophosphorylated in all three KO models. Unexpectedly, mass spectrometry analysis revealed that most class 1 titin phospho-sites within the molecular spring segment, including the Ig-domain regions, were hyperphosphorylated. Only a few sites showed a phosphorylation deficit or remaining unchanged. Particularly in the cGKI model many class 1 phospho-sites were hyperphosphorylated compared to WT hearts (see figure), indicative of the presence of compensatory processes following loss of PKG; indeed, this was associated with upregulation of several kinases that phosphorylate titin and a clear rise in $F_{passive}$ in KO vs. WT cardiomyocytes. While administration of PKG lowered $F_{passive}$ of WT and KO cardiomyocytes in all models, this effect was more pronounced in the cGKI KO.

Conclusions: Multiple in vivo phosphorylated class I titin phospho-sites were identified within the molecular spring segment, some of which depended on the cGMP-PKG pathway. While cGMP-activated PKG remains an important titin-targeting kinase, many titin phospho-sites may be regulated through a network of protein kinases/phosphatases.

C-kit+ resident cardiac stem cells improve left ventricular fibrosis in pressure overload

Deutsche Forschungsgemeinschaft, Bonn, Germany (KFO 196; LA997/6-1); Universität des Saarlandes, Homburg/Saar, Germany (HOMFOR2013) A Andrey Kazakov¹; T Meier¹; C Werner¹; R Hall²; B Klemmer¹; C Koerber³; F Lammert²; C Maack¹; M Bohm¹; U Laufs¹

¹Saarland University Hospital, Department of Internal Medicine III, Cardiology, Homburg, Germany; ²Saarland University Hospital, Department of Internal Medicine II, Gastroenterology, Homburg, Germany; ³Saarland University Hospital, Institute for Clinic-experimental surgery, Homburg, Germany

Aims: The role of c-kit (CD117)+ resident cardiac stem cells (RCSC) in cardiac fibrogenesis is not completely understood.

Methods & Results: To investigate the effect of RCSC on myocardial remodeling, c-kit+ RCSC were isolated from hearts of C57/Bl6-Tg (ACTb-EGFP)10sb/J mice expressing green fluorescent protein (GFP) and expanded in vitro. All cells were c-kit+Sca-1-CD45-CD31-CD34-tryptase- and 80% expressed Oct3/4 and Klf4 in the nucleus. c-kit+RCSC cultivated in the Ham's F-12 stem cell medium until the third passage spontaneously differentiated and expressed markers of main cardiac lineages, podocalyxin, CD31, von Willebrand factor, troponin T-C, α -smooth muscle actin, DDR2 and SDF-1 receptor CXCR4. The most pronounced increase was observed for podocalyxin and von Willebrand factor (20 to 30-fold). Cultivation for 5 weeks in differentiation medium induced differentiation of c-kit+GFP+RCSC mainly towards a smooth muscle phenotype. C57/Bl6N wildtype mice were subjected to transverse aortic constriction (TAC, 360 μ m) or sham-operation. 5×10^5 c-kit+RCSC or c-kit- cardiac cells or cell buffer were infused intravenously 24h post surgery (n = 11-24 per group). The mRNA-expression level of Oct3/4 and hypoxia-inducible factor-1 α in the left ventricles (LV) of TAC mice was enhanced 24h after transplantation. 35 days post TAC, the density of GFP+ cells in the myocardium was increased by two-fold. Infusion of c-kit+RCSC post TAC markedly reduced myocardial fibrosis, the number of cardiac fibroblasts identified by immunostaining for intracellular fibronectin and DDR2 and the expression of collagen I α 2 and connective tissue growth factor. Infusion of c-kit- cardiac cells did not ameliorate cardiac fibrosis. In parallel, expression of pro-angiogenic mediators (FGFb, IL-4, IL-6, TGF β , leptin) and the density of CD31+ and CD31+GFP+ endothelial cells were increased. Transplantation reduced brain- and atrial natriuretic peptides and the cardiomyocyte cross-sectional area. Infusion of c-kit+RCSC reduced rate of apoptosis and oxidative stress in cardiomyocytes and in non-cardiomyocyte cells. Transplantation of c-kit+RCSC increased the percentage of cycling Ki67+ cardiomyocytes in the SHAM group, the percentage of cycling Ki67+ non-cardiomyocytes in both experimental groups, the number of nestin+GFP- cardiomyocytes and the percentage of nestin+Ki67+ non-cardiomyocytes in pressure-overloaded LV.

Conclusions: Transplantation of c-kit+ resident cardiac stem cells ameliorates cardiac fibrosis in pressure overload in mice.

An in vivo selection strategy for the identification of novel cytokines inducing cardiac retention of murine mesenchymal stromal cells after myocardial infarction

F Francesca Bortolotti¹; G Ruozzi¹; A Falcione¹; L Zentilin¹; S Zacchigna²; M Giacca¹

¹International Centre for Genetic Engineering and Biotechnology (ICGEB), Molecular Medicine Laboratory, Trieste, Italy; ²International Centre for Genetic Engineering and Biotechnology (ICGEB), Cardiovascular Biology Laboratory, Trieste, Italy

Purpose: Numerous studies have shown that transplantation of mesenchymal stromal cells (MSCs) in the infarcted heart improves cardiac function through paracrine mechanisms. However, the injected cells are gradually lost at the site of injury, thus limiting the window of therapeutic efficacy. To identify novel factors able to improve engraftment and long-term survival of MSCs, we developed an innovative Functional Selection (FunSel) procedure aimed at the in vivo identification of effective molecules.

Methods: A collection of 80 murine cytokines cloned into AAV2 vectors was used for the batch transduction of MSCs ex vivo, followed by intracardiac administration of the cells in non-ischemic or ischemic conditions. Three weeks after injection, when most cells were normally lost, viral genomes were recovered from the few persisting cells and their relative abundance was analyzed by next generation sequencing. We expected that protective factors mediating cell retention would be enriched over the others. The identified cytokines were tested individually in tracking experiments in the myocardium and the efficacy of top hit was assessed in a model of myocardial infarction by echocardiography, histology and molecular analysis. The molecular mechanisms were investigated by immunofluorescence, apoptosis and adhesion assays.

Results: Among the in vivo selected cytokines, we found factor already associated with MSC homing and survival, such as Ccl2 and Ccl7. Unexpectedly, the most effective factor in mediating cardiac MSC retention was Cardiotrophin1 (Ct1), a pro-hypertrophic cytokine never associated with this property before. We found that the effect of Ct1 was the consequence of the induction of MSC survival through STAT3 activation and, most notably, the promotion of MSC adhesive properties by the dynamic activation of Focal Adhesion Kinase (FAK). In vivo, AAV2-Ct1-transduced MSCs preserved cardiac function and reduced infarct size after myocardial infarction. These effects strictly correlated with the persistence of Ct1-expressing cells in the healing hearts for at least two months and with the consequent prolonged release of soluble molecules by MSCs.

Conclusions: These results support the feasibility of the in vivo FunSel approach and identify Ct1 as a powerful cytokine supporting MSC adhesion and retention in the ischemic myocardium, thus providing benefit after cardiac damage.

P1808

The H19 long non-coding RNA regulates pathological cardiac hypertrophy

JA Kleeberger¹; J Viereck¹; R Kumarswamy¹; S Batkai¹; A Foinquinos¹; F Weidemann²; T Thum¹

¹Hannover Medical School, Institute of Molecular and Translational Therapeutic Strategies (IMTTS), Hannover, Germany; ²University Hospital of Würzburg, Department of Cardiology, Würzburg, Germany

Objective: It has been shown in the past that small regulatory RNAs, called microRNAs, are key players in the development of cardiovascular diseases. Notably, long-non coding RNAs are an emerging entity under investigation. Since heart failure is the most deadly, yet still not curatively treatable ailment, it makes sense to look for new means to tackle this issue. The H19 gene has been well described as an orchestrator of several genetic disorders and other maladies, for example gastric cancer. Nevertheless its function in the heart remains unidentified. Consequently, we investigate the role and functional implications of H19 in cardiac hypertrophy as a hallmark of heart failure.

Methods and Results: In adult mice, H19 is globally repressed in several tissues, but is abundantly expressed in the skeletal and cardiac muscle. Furthermore, this transcript can be detected in all cardiac cell types, including cardiomyocytes. Cardiac hypertrophy induced by pressure overload or by angiotensin II infusion lead to a significant reduction of H19 expression in mouse hearts. To mimic this situation in vitro, we modulated the lncRNA levels in cardiac cell lines as well as primary cardiomyocytes. Silencing of H19 by esiRNAs induces a hypertrophic response including an increase in cardiomyocyte cell size and an alteration of the cardiac expression pattern. Since the sequence and genomic organization of H19 is well conserved between rodents, pig and humans, we assessed its role in failing human hearts. In accordance with our findings in the mouse model, hypertrophic heart tissue from aortic stenosis patients demonstrates a strong downregulation of H19, suggesting an analogy in cardiac disease between different mammals.

Conclusion: In this report we identified the lncRNA H19 as a key player in cardiac hypertrophy. A decrease in H19 expression level in pressure-overloaded murine hearts and in hypertrophic human hearts is related to an increase in cardiomyocyte

cell size. To put it in a nutshell, H19 is a prospective therapeutic target in order to halt the genesis of heart failure.

Safety and efficacy of transcatheter injection of induced-pluripotent stem cells-derived mesenchymal cells in a swine subacute model of myocardial ischemia.

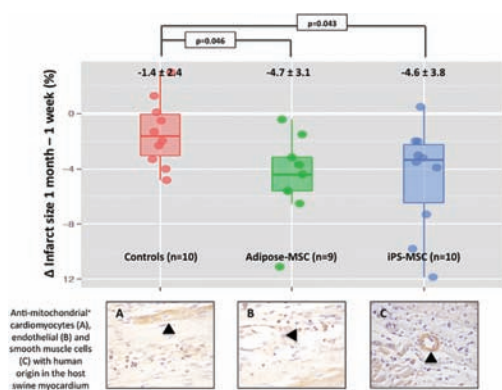

National Program for Internationalization of R&D (PLE2009-0147, Regenerative Therapies with Stem Cells for Heart Failure), Spanish Ministry of Economy R Ricardo Sanz Ruiz¹; V Crisostomo Ayala²; A Casado Plasencia¹; ME Fernandez Santos¹; N Montserrat Pulido³; S Suarez Sancho¹; AM Climent¹; F Aienza Fernandez¹; FM Sanchez Margallo²; F Fernandez-Aviles¹

Purpose Mesenchymal stem cells (MSC) are the most promising cells for ischemic myocardial repair. Nowadays we can obtain them from induced pluripotent stem cells (iPS). Our objective is to compare the safety and efficacy of "conventional" MSC and iPS-derived MSC in a large animal model of myocardial ischemia.

Methods: Phase I/II preclinical randomized, placebo-controlled trial, with 30 large white pigs included. Acute myocardial infarction (AMI) was created after 90-min occlusion of the LAD. The 3 groups were: injection of 20x10⁶ MSC from human adipose tissue (n=10); injection of 20x10⁶ MSC from human iPS (n=10); injection of saline (n=10). Injections were performed in the scar border with the NOGA XP platform, 7 days after AMI. Safety endpoints include MACE, malignant arrhythmias and lab parameters (intraprocedural and for 5 weeks). Efficacy endpoints include scar size and LV parameters (MRI) and myocardial repair by histology (fibrosis and capillary density, staining with human mitochondrial antibodies) at 5 weeks.

Results: Thirty pigs were included, weight 37.4±6.2 kg. Troponin I values (mg/L) raised from 0.24±0.35 to 0.32±0.23 postinjection (p=0.02). Cell injection was successful in all cases, with 1 episode of ventricular fibrillation successfully cardioverted and 1 case of non-cardiac death (vascular complication). Both types of MSC reduced infarct size compared to controls to a similar extent (fig). Development of cardiomyocytic and vascular structures from human origin were identified in pathological studies (preliminary results, fig).

Conclusions: MSC NOGA-guided injections 7 days after AMI were safe. Cardiac repair potentiality was similar between adipose and iPS-derived MSC.

Scar size and pathological studies

Safety and efficacy of first in-human use of muscle-derived stem cells transfected with connexin-43 gene for chronic heart failure

A Adrian Gwizdzala¹; T Kolanowski²; N Rozwadowska²; A Malcher²; A Cieplucha¹; B Perek³; E Straburzynska-Migaj¹; W Cholewinski⁴; S Grajek¹; M Kurpisz²

¹Poznan University of Medical Sciences, 1st Department of Cardiology, Poznan, Poland; ²Institute of Human Genetics, Poznan, Poland; ³Poznan University of Medical Sciences, Department of Cardiac Surgery, Poznan, Poland; ⁴Greater Poland Cancer Centre, Nuclear Medicine Department, Poznan, Poland

Background: Patients with advanced heart failure (HF) have still poor prognosis despite number of available treatments, including implantable and assist devices. Therefore, the use of stem cells is still a promising approach to treatment of this clinical entity. Among various cell types, skeletal myoblasts (SkMb) were first studied. Although there were some encouraging results, significant amount of malignant

ventricular arrhythmias (VA) decreased the volume of clinical research involving those cells. However, the latest studies showed that overexpression of connexin-43 (Cx43) led to improvement of electromechanical coupling and engraftment of SkMb into the myocardium in animal models and in vitro human cardiomyocytes.

Objectives: To evaluate the safety and efficacy of transcatheter delivery of muscle-derived stem/progenitor cells (MDS/PC) with connexin-43 overexpression in patients with advanced HF.

Methods: Thirteen subjects with advanced HF, NYHA class II-III, with implanted cardioverter-defibrillator, ineligible/disagreeing to other interventions, including transplantation ("no option group") were enrolled. For safety and efficacy assessment patients were followed-up for at least 6 months (physical exam, cardiopulmonary exercise test, rhythm monitoring, ECHO/SPECT imaging, electroanatomical mapping [12/13 patients]).

Results: The mean total number of cultured MDS/PCs was 552.3±282.6x10⁶ and the mean number of injected Cx-43 MDS/PC was 161±115x10⁶ per patient. Cx43 overexpression (Cx43+) was significantly higher in all but one subject (Cx43-: due to transfection error).

Efficacy analysis: Injection of MDS/PC was associated with a significant improvement of exercise capacity: NYHA (3±0 vs. 1.8±0.7, p=0.003), exercise duration (388.69±141.83 vs. 462.08±176.69 s, p=0.025), peak oxygen consumption (14.38±3.97 vs. 15.83±3.74 ml/kg/min, p=0.022) and oxygen pulse (10.58±2.89 vs. 18.88±22.63, p=0.012). BNP levels, LV ejection fraction and end-diastolic volumes tended to improve, however no significant differences were documented. There was a significant decrease in scar size expressed by increase in mean total unipolar voltages (8.83±2.80 vs. 10.22±3.41 mV, p=0.041).

Safety analysis: No deaths were documented. Cx43+ patients (n=12) had no VA. Cx43-neg (n=1) subject suffered from recurrent VT (2xICD interventions 2 and 3 months of implantation, IV/PO. amiodarone, good effect).

Conclusions: Our pilot study demonstrated for the first time that injection of Cx-43+ MDS/PCs in patients with severe HF led to significant improvement of exercise capacity and myocardial viability while inducing no significant ventricular arrhythmia. It may be due to improved electrical coupling of the injected cells and injured myocardium and thus better in-situ mechanical cooperation of both cell types. Therefore, further clinical studies with Cx43+ MDS/PCs are warranted.

P1811

A combined cellular and surgical ventricular reconstruction therapeutic approach produces attenuation of remodeling in infarcted rats

M Bonios¹; M Nana²; S Vakrou²; CJ Kapelios²; D Perrea¹; J John Nanas¹; K Malliaras²

¹University of Athens, Athens, Greece; ²University of Athens, School of Medicine, 3rd Cardiology Dept., Athens, Greece

Background: Left ventricular reconstruction surgery (LVR) has been shown to provide transient improvement in LV function in infarcted hearts; however long-term results have been disappointing, as LVR-induced benefits are typically not sustained. We hypothesized that administration of cardiomyocyte-derived cells (CDCs), which have been shown to promote myocardial repair and regeneration of infarcted hearts, may result in long-term preservation of the beneficial effects of LVR in ischemic cardiomyopathy.

Purpose: To investigate the effects of a combined biological and surgical therapeutic approach comprising cell therapy with CDCs and LVR on LV remodeling in infarcted rats

Methods: In female Wistar Kyoto rats myocardial infarction (MI) was induced by permanent ligation of the left descending coronary artery after left thoracotomy. Two weeks later, after a second thoracotomy, animals were randomly allocated to 3 groups: in Group 1 (n=9) the infarcted apex was plicated and 3*10⁶ CDCs were injected in the border zone of the LV plication, while Group 2 animals (n=9) received vehicle solution in the border zone of the plication. Group 3 animals (n=10) received intramyocardial injections of vehicle solution in the infarct border zone, without plication of the apex. Echocardiograms (conventional and 2D speckle-tracking) were performed at baseline (prior to the second thoracotomy), 4 days post-apex plication, and 3 months post-MI. LV ejection fraction (EF), LV volumes, LV circumferential strain (CS) and peak systolic LV torsion were assessed.

Results: At baseline, all animal groups had comparable LVEF, LV end-diastolic volume (EDV) and LV end-systolic volume (ESV). Four days post-LV apex plication, Group 1 and Group 2 animals exhibited comparable significant improvement in EF and comparable significant reduction in LVEDV. Three months post-MI, Group 1 animals had decreased LVEDV (274±9 uL vs 357±29 uL vs 369±19 uL, p=0.003, in Groups 1, 2 and 3 respectively, p<0.003), decreased LVESV (149±8 uL vs 216±26 uL vs 232±13 uL, p=0.002), less impaired CS (-14.2±0.4% vs -10.9±0.6% vs -10.9±0.7%, p=0.001), increased peak systolic torsion (7.8±0.6 °/cm vs 4.7±0.7 °/cm vs 4.4±0.8 °/cm, p=0.006) and increased EF (48±4% vs 36±4% vs 35±3%, p=0.005) compared to animals in Groups 2 and 3.

Conclusion: In infarcted rat hearts, intramyocardial delivery of CDCs in conjunction with LVR resulted in significant and sustained amelioration of LV remodeling and improvement in global and regional LV function, compared to LVR alone.

³Pathology Unit, Siena, Italy

Background: Recent studies have challenged the dogma that the adult heart is a postmitotic organ and raise the possibility of the existence of resident cardiac stem cells (CSCs). Our study aimed at exploring if the isolation of colonies of CSCs from "ventricular tip" obtained from patients with end-stage heart failure (HF) undergoing left ventricular assist device (LVAD) implantation was possible and how it correlated with LV dysfunctional area extent.

Methods: Four consecutive patients with ischemic cardiomyopathy and end-stage HF submitted to LVAD implantation were studied. The explanted "ventricular tip" was used as a sample of apical myocardial tissue for the pathological exam. Patients underwent clinical and echocardiographic examination, both standard transthoracic echocardiography (TTE) and speckle tracking echocardiography (STE) before LVAD implantation.

Results: All patients presented severe apical dysfunction, with apical akinesis/dyskinesis and very low levels of apical longitudinal strain ($-3.5 \pm 2.9\%$). Despite this, it was demonstrated the presence of CSCs in pathological myocardial samples of "ventricular tip" in all the 4 patients. It was found 6 c-kit cells in 10 fields magnification 40x.

Conclusions: Multipotent cells can be isolated in the LV apical segment of patients undergone LVAD implantation despite LV apical fibrosis.

Stem cells from LV apical tip

Candesartan cilexetil and extract of Polygonum sp. influence on the number of stem cells in vitro

A Aliaksandra Beliaeva¹

¹National Academy of Science, Institute of Bioorganic Chemistry, Minsk, Belarus

Purpose: To conduct analysis of the influence of candesartan cilexetil (angiotensin II type 1 receptor blocker) and extract of Polygonum sp. in different dosages on variations in the number of endothelial progenitor cells CD117+ in vitro.

Methods: Bone marrow cells of C57Bl/6 mice were sampled for further experiments. The cells were grown in flasks containing DMEM supplemented with 10% of fetal bovine serum with addition of 0.1 % antibiotics in CO₂-incubator (5% CO₂, 37°C). Candesartan cilexetil and extract of Polygonum sp. were supplied to the cell culture. Flow cytometric method was applied for the analysis.

Results: Nowadays cardiovascular diseases are one of the most widespread scourges in economically developed countries and the majority of the population all over the world suffers from these pathologies. Stem cell technologies are used for treatment of various diseases, including cardiovascular diseases. It is shown that mobilized stem cells and endothelial progenitor cells have the capacity to migrate into the heart muscle and endothelium with the subsequent positive therapeutic effect.

It was found during this study that candesartan cilexetil at 1.5 µg/ml dose and 3 µg/ml dose decreased the number of CD117+ stem cells in vitro in comparison with the control. Extract of Polygonum sp. at low doses (under 30 µg/ml) didn't cause statistically significant changes. High doses of Polygonum sp. extract (over 30 µg/ml) increased the amount of CD117+ stem cells in vitro ($p < 0.05$).

Combination of candesartan cilexetil at 1.5 µg/ml dose and extract of Polygonum sp. at 10 µg/ml dose didn't raise the number of CD117+ cells in vitro in comparison with the control. Mixed application of candesartan cilexetil at 1.5 µg/ml dose and extract of Polygonum sp. at 30 µg/ml dose and 50 µg/ml dose increased the ratio of CD117+ stem cells ($p < 0.05$). This substances didn't influence cell cycle and change the number of apoptotic cells.

Conclusions: It was found that candesartan cilexetil alone didn't increase the number of CD117+ stem cells in vitro, whereas the first evidence was recorded that concerted use of candesartan cilexetil and extract of Polygonum sp. in different dosages stimulated formation of examined stem cells. The obtained results may lay the basis for further studies aimed at elaboration of novel complex drug for treatment of cardiovascular diseases capable to mobilize endothelial progenitor cells.

Epigenetically reprogrammed mesenchymal stem cells improve myocardial remodeling and cardiac function after myocardial infarction by modulating post-infarct inflammation and neoangiogenesis

J J Jin Jin Kim¹; KY Lee¹; TH Kim¹; HJ Park¹; BH Hwang¹; SM Seo¹; CJ Kim¹; SW Jang¹; EJ Cho¹; K Chang¹

¹Catholic University Hospital, Seoul, Korea Republic of

Background: The efficacy of transplantation of default mesenchymal stem cells (MSCs) is controversial because of their limited plasticity and decreased function in elderly patients with myocardial infarction (MI). We investigated whether epigenetically reprogrammed-MSCs ameliorate myocardial remodeling in a mouse model of MI.

Methods: Bone marrow-derived MSCs were sequentially treated with 5 mM/L of valproic acid and 100 nM/L of 5-azacytidine for 24 hours, respectively. Quantitative RT-PCR was performed to evaluate the effect of epigenetic modifiers on the gene expression of MSCs. 2 x 10⁵ default MSCs, 2 x 10⁵ epigenetically reprogrammed-MSCs, or phosphate-buffered saline were injected into peri-infarct zone immediately after ligating proximal portion of left anterior descending artery. On days 28 after MI, in vivo cardiac magnetic resonance (CMR) and harvest of heart tissue was sequentially performed.

Results: Epigenetic modification of MSCs significantly induced gene expression of anti-inflammatory markers such as transforming growth factor- β , indoleamine 2,3-dioxygenase. Basic fibroblast growth factor increased 1.6 fold and GATA4 increased 1.7 fold at the mRNA level. Transplantation of modified-MSCs showed improved ejection fraction on CMR. In histopathologic analysis, infarct size was significantly decreased in modified-MSCs transplanted mice ($p = 0.002$). When assessing capillary density of peri-infarct zone, larger number of CD31+ staining vascular structures was observed in modified-MSCs transplanted mice. Immunofluorescence stain showed marked increase of CD4+CD25+Foxp3+ regulatory T cells as well as CD68+MR+ M2 macrophage and decrease of CD68+iNOS+ M1 macrophage in modified-MSCs transplanted mice.

Conclusions: Transplantation of epigenetically reprogrammed-MSCs significantly improves cardiac function by modulating post-infarct inflammation and neoangiogenesis in a preclinical model of AMI.

Understanding the metabolism of cardiac progenitor cells: a first step towards controlling their proliferation and differentiation?

E Andre¹; A De Pauw¹; P Porporato¹; C Bouzin¹; N Draoui¹; P Sonveaux¹; J-L Balligand¹

¹Institute of Experimental and Clinical Research (IREC), Brussels, Belgium

Cardiac regenerative approaches using progenitor cells (CPC) may be limited by their low survival and differentiation when injected at the border zone of an infarct. We investigated the bioenergetic transition underlying CPC differentiation in order to identify key metabolic regulators that could be modulated to promote their repair capacity.

Sca1+ CPC were isolated from adult mouse hearts by MACS separation. Under normoxic conditions, glucose consumption and lactate release were significantly higher in CPC than in neonatal rat cardiac myocytes (NRCM) with a ratio of 2 moles of lactate released per mole of glucose supporting a high glycolytic metabolism. Glucose consumption and lactate release were increased in hypoxia (1%O₂), together with increased abundance of the monocarboxylic transporter MCT4 (lactate efflux mediator), of Glut-1 and of PFKFB3 (key regulator of glycolytic rate). BrdU incorporation in CPC was critically dependent on pyruvate, glucose and glutamine availability (but not lactate) under normoxia and hypoxia. Oxygen consumption analysis indicated that CPC and NRCM display active mitochondrial ATP production. Notably, basal and maximal respiration were higher in NRCM compared to CPC. Consistently, mitochondrial populations were differentially active in both cell types, as reflected by a 40% decrease in tetramethylrhodamine methyl ester staining intensity (flow cytometry) in CPC compared to NRCM. Moreover, the expression of TOM20 (translocase of outer mitochondrial membrane) was also 50% lower in CPC compared to NRCM and MitoTracker Green reveals by imaging small sphere-shaped mitochondria in CPC whereas they form a branched network in NRCM, reflecting differential dynamic organelles in both cell types. This CPC phenotype dramatically changed upon differentiation (azacytidine/TGF β /ascorbic acid; 4 weeks in normoxia), with a reduction by third of glucose consumption and lactate release compared to proliferative cells. In conclusion, despite active mitochondrial ATP production, undifferentiated CPC exhibit lower respiratory reserve than CM, which correlates with a less mature mitochondrial network. However, they exhibit aerobic glycolysis and lactate production, which further increased under hypoxia together with (HIF-1 α dependent) PFKFB3, Glut-1 and MCT4. Such glycolytic activity, together with glutamine metabolism supports their proliferation but is dramatically downregulated upon differentiation. This may open the way for pharmacological modulation of the survival/differentiation of CPC for cell therapeutic repair through their mitochondrial fusion and biogenesis.

Enhancement of the paracrine potential of human adipose derived stem cells when cultured as spheroid bodies

Montreal Heart Institute. Chaire Desgroseillers.
C Celia Sid-Otmane¹; HQ Ly¹

¹Montreal Heart Institute affiliated with the University of Montreal, Montreal, Canada

Background: Ischemic heart disease remains a leading cause of mortality and morbidity worldwide. Cardiac cell therapy (CCT) is a promising therapeutic strategy to help in cardiac repair. Adipose tissue constitutes an important reservoir for the stem cells. Both preclinical and clinical data have shown that adipose derived stem cells (ASCs) could improve cardiac function and volumes, mostly through a paracrine mechanism.

Study Aim: The objective of our in vitro study is to characterize and compare the secretion profile of ASCs, when cultured under standard conditions (i.e. as a monolayer (ML)) versus in a three-dimension (3-D) structure (i.e. as a spheroid body (SB)).

Methods: Human ASCs (hASCs) were expanded in standard culture conditions in a monolayer form. ASCs were characterized according to both surface markers expression (assessed by immunofluorescence) and their ability to maintain multi-lineage differentiation. Alternatively, ASCs were also cultured as 3-D structure as spheroid bodies (SBs), by using the hanging drop technique. Luminex and ELISA assays were conducted to quantify key anti-inflammatory and angiogenic mediators to compare the two study groups.

Results: hASCs expressed similar surface markers as those documented for bone marrow MSCs including CD44, CD105 and CD90. Their ability to differentiate into adipogenic, chondrogenic and osteogenic lineage were unaltered. Paracrine activity of hASCs was enhanced when cultured as hASC-SBs. SBs secreted higher levels of anti-inflammatory cytokines such as MCP-1, IL-6 and IL-10, in a time dependent manner (Figure). Similarly, hASC-SBs exhibited greater pro-angiogenic potential as VEGF levels were increased also compared to hASC-MLs.

Conclusion: hASC represent a promising cell source for CCT and cardiac repair. Their paracrine, therapeutic potential can be optimized. Our findings clearly showed that hASCs cultured as 3D structures (i.e. as SBs) exhibit an improvement in both anti-inflammatory and angiogenic properties. Spheroid body formation thus represents an effective alternative to enhance the therapeutic potential of hASCs.

Bone marrow cell transplantation in acute myocardial infarction and left ventricular dysfunction: lack of long term beneficial effects

U Corvi¹; A Malagoli¹; A Verde¹; S Binno¹; L Surdi¹; MC Murru¹;
C Armentano¹; GQ Villani¹; M F Massimo Francesco Piepoli¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Purpose: Bone marrow progenitor cells may improve cardiac function and outcome in patients after acute myocardial infarction (AMI). In a single-centre randomised controlled trial we observed a beneficial effect of intracoronary transfer of autologous bone-marrow cells on global left ventricular (LV) function, autonomic control, and exercise tolerance at 12 months' follow-up. In a mean 37 \pm 5 month follow-up we aimed to assess the persistence of the beneficial effect on cardiac parameters

(Echocardiography) Methods- After successful percutaneous coronary intervention (PCI) for acute ST-segment elevation myocardial infarction and residual LV dysfunction, 41 patients were randomly assigned to either a control group (CTR, n=20, on optimum postinfarction treatment) or a bone-marrow-cell group (BMC, n=21, optimum treatment plus intracoronary transfer of autologous bone-marrow cells 5 \pm 1 days after successful PCI). Test analyses were done by two investigators blinded for treatment assignment. Results- No differences in clinical characteristics or therapy between the two groups. Global LVEF at baseline (determined 4 \pm 1 days after PCI) was 38.4 \pm 1.5 in BMC, and 38.9 \pm 1.4 in the CTR group (P=NS). After 12 months, mean global LVEF increased by 14.4 \pm 3.8 % in the BMC group vs. 6.8 \pm 3.4 % in the CTR group (P0.05) with an anti-remodeling effect in the former: LVEDV was -14.3 \pm 1.5 % in BMC vs. 3.9 \pm 3.5 % in CTR, while LVESV was -14.7 \pm 5.9 % in BMC vs. 4.0 \pm 4.2 % in CTR (P < 0.05). After an average 37 \pm 5 month follow-up, no significant difference between the two groups in any of the evaluated parameters including LVEF (+2.0 \pm 9.4% vs. +5.0 \pm 10.2%, p=NS), LVESV (+2.6 \pm 33.9 ml vs. +4.0 \pm 55.8 ml, p=NS) and LVEDV (+2.6 \pm 52.6 ml vs. 20.2 \pm 58.9 ml, p=NS). Furthermore, no differences were observed in any relevant clinical parameters such as adverse clinical events, in-stent stenosis or pro-arrhythmic events between treated and control groups.

Conclusions: A potential beneficial effect of intracoronary transfer of autologous bone-marrow-cells on haemodynamic indices in post AMI patients with depressed left ventricular function present on the short but not long term analysis is consistent with other larger studies where intra- coronary application of BMCs did not promote a sustained improvement of LV

BASIC SCIENCE: ISCHEMIA / REPERFUSION / PRECONDITIONING / POSTCONDITIONING

Comparative assessment of left ventricular remodeling in patients after coronary artery bypass grafting, depending on the method of operation

G Guzel Abzalova¹; GF Abzalova¹; SD Mayanskaya²

¹Interregional Clinico-Diagnostic Center, Kazan, Russian Federation; ²Kazan State Medical University, Kazan, Russian Federation

Aim: To study and compare rates' changes of inotropic function of the heart of patients with ischemic heart disease after coronary artery bypass surgery (CABG) in early postoperative period. Methods of research. 105 patients suffering from ischemic heart disease (IHD) were examined (45 women and 60 men), aged from 39 to 76 years, who have two (5 people), three (30 people) and more than four (70 people) coronary arteries (CA) damaged. Hemodynamically significant artery stenosis were diagnosed at all patients, at that 95 patients had vascular occlusion of different localization, 10 patients had stenosis of the trunk of the left coronary artery for more than 80%, 53% of patients had myocardial infarction. All patients had coronary artery bypass surgery (CABG) or mammo-coronary bypass surgery (MCBS) with the imposition of two (5 people), three (55 people) and more than four (45 people) shunts. In the 1-st group of patients (70 people) CABG was done in the conditions of cardiopulmonary bypass (CPB) and pharmaco-cold cardioplegia (PCC). In the 2-d it was done on the beating heart (off — pump coronary artery bypass, OPCAB). We assessed parameters of cardiovascular hemodynamics by volume compression oscillometry before and 7 days after CABG.

Results: The analysis of hemodynamic parameters showed that in the 1-st group in 7 days after the surgery cardiac output (CO) decreased for 11%, heart index (HI) — for 6,1%, stroke volume (SV) — for 23%, stroke volume index (SVI) — for 25%, volume rate of output (VRO) — for 26,5%, power of contraction of the left ventricle (LV) — for 30,2%. In the 2-d group by the 7-th day after the surgery CO vice versa increased more than in 1,5 time, HI — for 11,3%, VRO — for 26%, power of contraction of the left ventricle (LV) — for 24,4%.

Conclusions: Thus, preliminary analysis of cardiovascular hemodynamic parameters that were obtained by VCO method in dynamics of CABG showed that patients with IHD already in 7 days after the off — pump coronary artery bypass had an improvement of inotropic function of the heart, while those patients who had CABG in the conditions of CPB and PCC in early postoperative period had a decrease almost of all parameters; this probably may testify to cardio depressive effect of this surgical intervention for recovery of cardiovascular hemodynamics in total.

P1819

Pre-hospital delay in patients with ST-elevation-myocardial infarction: clinical characteristics and outcomes

A Andre Correia¹; B Silva¹; M Neto¹; J Monteiro¹; AC Alves¹; D Pereira¹

¹Hospital Funchal, Funchal, Portugal

Introduction: Pre-hospital delay results in impaired outcome after ST-Elevation-Myocardial Infarction (STEMI). The time between the onset of pain to first medical contact (FMC) depends on the recognition of symptoms by the patient and the celerity to seek medical help.

Purpose: Identify the factors associated with late diagnosis of STEMI.

Methods: Pain-to-FMC and long-term outcomes were documented in 534 individuals presenting with STEMI from 2010 to 2014. The baseline parameters of patients with pain-to-FMC \leq 60 minutes ("early presenters" (EP)) were compared to patients with pain-to-FMC $>$ 60 minutes ("late presenters" (LP)). Groups were also compared regarding mortality rate and a primary composite endpoint (re-MI, stroke, and cardiovascular mortality) at one year follow-up.

Results: Late presenters were older (EP=59.89 \pm 1.33 vs LP=63.98 \pm 0.66 years; $p < 0.05$), had a higher prevalence of arterial hypertension (EP=48% vs. LP=56.4%, $p < 0.05$) and Diabetes Mellitus (EP=13.3% vs. LP=25.9%, $p < 0.01$) in the univariate analysis. No differences were found regarding prior dyslipidemia, angina, acute myocardial infarction, peripheral artery disease or family history.

EP were more submitted to primary percutaneous coronary intervention (EP=92.7% vs LP = 77.9%, $p < 0.01$).

LP had more Killip Class $>$ 1 at admission (EP=9.6% vs LP=22.0%, $p < 0.01$) and at 72h (EP=20.2% vs LP=31.5%, $p < 0.02$) and higher levels of BNP (EP=373.6 \pm 69.5 vs LP=559.9 \pm 38.5, $p < 0.01$). They were more medicated with loop diuretics (EP=23.5% vs LP=32.6%, $p < 0.05$) and aldosterone receptor antagonists (EP=5.1% vs LP=12.6% $p < 0.05$).

At 1-year follow-up there were no significant statistical differences regarding mortality (EP=8.3% vs LP=14.5, $p = 0.098$) and primary composite endpoint (EP = 11.5% vs LP = 17.7%, $p = 0.121$).

After multivariable adjustment, Diabetes Mellitus (OR 2.221; CI 1.277–3.861) was independently associated with delayed FMC.

Conclusion: In this real world cohort, Diabetes Mellitus was associated with later diagnostic of ST-Elevation-Myocardial Infarction. Patients presenting to first medical contact after 60 minutes of pain onset showed a trend towards higher mortality. Special attention should be paid to avoid diagnostic delays in these patients.

P1820

The association between percutaneous coronary intervention and abdominal or thoracic drainage of congestive heart failure with reduced ejection fraction patients

K Khaled Salem¹; S Khaled¹; O Elkhateeb¹

¹ King Abdullah Medical City, Cardiology Departement. Heart failure program, Makkah, Saudi Arabia

Background/Introduction: The correlation between percutaneous coronary intervention (PCI) and abdominal ascites or pleural effusion drainage of heart failure with reduced ejection fraction (HFrEF) patients, is not well studied.

Purpose: We aimed to identify the association between PCI and abdominal ascites or thoracic drainage incidence of HFrEF patients enrolled in a Middle Eastern single centre heart failure registry.

Methods: We performed subgroup analysis of prospectively collected data of 174 consecutive HFrEF patients hospitalized over 12-month period.

Results: Ultrasound guided drainage was performed more frequently in ischemic compared to non-ischemic cardiomyopathy patients (8% vs. 0.9%; $P = 0.024$). Among the 23 (13%) PCI patients, there was no need for abdominal or thoracic drainage, compared to 151 (67%) non-PCI patients ($P = < 0.0001$). Females had higher statistically insignificant drainage incidence compared to males (10% vs. 4%; $P = 0.261$).

Conclusion: PCI is associated with significant reduction of drainage requirement of HFrEF patients. Ischemic cardiomyopathy, female gender and non-PCI feasible subgroups were at high risk for abdominal or thoracic drainage requirement.

Subgroup characteristics				
Gender characteristics	Males (n = 135)	Females (n = 39)	P value	CI

The influence of remodeling of left ventricle on results of surgical treatment of ischemic heart disease

G Guzel Abzalova¹; GF Abzalova¹; SD Mayanskaya²

¹ Interregional Clinico-Diagnostic Center, Kazan, Russian Federation; ² Kazan State Medical University, Kazan, Russian Federation

Aim: To examine the intracardiac hemodynamics in patients with coronary artery disease (CAD) before and 4 months after coronary artery bypass grafting.

Materials and methods: We examined a total of 105 patients (45 women and 60 men) with coronary artery disease from 39 to 76 years, with obstruction of two (5 patients), three (25 patients), more than four (75 patients) coronary arteries (CA). All patients had hemodynamically significant CA obstruction; 77 patients had obstruction of different CA, 8 - had more than 80% obstruction of left main CA, 53% of patients had a myocardial infarction (MI). All patients underwent coronary artery surgery (CABG) or mammary coronary artery bypass surgery (MCABG) resulted in two (5 patients), three (25 patients) and more than 4 grafts (75 patients). We performed a 4 months observation of 105 patients with (CAD) who underwent (CABG). Patients were divided into two groups: group 1 included 45 people with CAD without a history (MI) and the 2-nd group consisted of 60 patients with postinfarction cardiosclerosis (PICS). The groups matched by age and sex. We assessed parameters of cardiovascular hemodynamics by volume compression oscillometry before and 4 months after CABG.

Results: Analysis of hemodynamic parameters showed that patients from the first group had increased all the examined parameters: cardiac output (CO) (13.6%), cardiac index (CI) - 13.1%, stroke volume (SV) - 8, 5%, stroke index (SI) - 8.6%, the volume rate of cardiac output - 4.5% LV contracting power - 12% after 4 months of CABG. The second group, after 4 months after the operation, on the contrary, demonstrated a decrease of CO (5.2%), CI - 5.32%, CV - 10.7%, the volume rate of cardiac output - 22.6%, LV contracting power - 22.1%.

Conclusion: Thus, the analysis of cardiovascular hemodynamic parameters obtained by the volume compression oscillometry showed that CABG in patients without a history of MI, leded to an improvement in ventricular function after 4 months after surgery. Whereas in the group of patients with PICS even after successful surgical myocardial revascularization in the first 4 months there has been a deterioration in hemodynamic parameters caused more pronounced initially negative remodeling of the heart and symptoms of heart failure.

P1822

Serum uric acid levels and heart failure in acute myocardial infarction

A Djokovic¹; T Jakimov¹; T Vukasin¹; S Hinić¹; M Zdravkovic¹

¹ University Hospital Medical Center Bezanijska Kosa, Belgrade, Serbia

Background: Serum uric acid (SUA) levels are associated with poor outcomes in patients with stable and unstable coronary heart disease.

Purpose: We investigated the relationship between SUA and heart failure (HF) in subjects with acute myocardial infarction (AMI) and the impact of hyperuricemia on prognosis of AMI patients.

Methods: A total of 184 patients (aged 63.7 \pm 12.4 years, 64.1% men) diagnosed with AMI (56.5% with ST elevation AMI (STEMI) and 43.5% with non ST elevation AMI (NSTEMI)) were evaluated. Uric acid levels were assessed at the admission and all patients have undergone coronary arteriography. The composite of major adverse cardiac events (MACE) including cardiovascular death, HF, revascularization (percutaneous coronary intervention or CABG), new AMI, stroke or transient ischemic attack has been evaluated for a 30 days and 6 months follow up period.

Results: There were 27.2% AMI patients with acute HF. Average value of ejection fraction of LV was 41.7 \pm 9.3%. Average value of SUA in STEMI was 348.33 \pm 101.5 mmol/l and 377.5 \pm 116.5 mmol/l in NSTEMI. There was significant difference between SUA levels regarding HF presence ($p = 0.041$), and negative correlation between LVEF and SUA (Pearson -0.205, $p = 0.05$). Hyperuricemia in AMI patients was related to extent of coronary artery disease in the means of number of coronary arteries with significant lesions detected ($p = 0.034$). SUA level was independent predictor of 6 months MACE, including HF occurrence, in AMI patients (OR 4.766, CI 95% 0.988-0.999, $p = 0.029$), predominantly in STEMI patients (OR 4.962, CI 95% 0.976-0.999, $p = 0.026$).

Conclusion: Elevated SUA is associated with HF in AMI and has prognostic impact on outcome. This low-cost routinely available biomarker, could improve risk stratification of patients with AMI, especially in patients with STEMI.

P1823

Favorable effect of remote ischemic preconditioning on postischemic-reperfusion function of the myocardium

VEGA 2/0133/15, 2/0201/15; APVV-0102-11

M Miroslav Ferko¹; M Jasova¹; I Kancirova¹; I Waczulikova²; V Farkasova¹; J Kucharska³; A Chytilova⁴; M Murarikova¹; T Ravingerova¹; A Ziegelhoffer¹

¹ Slovak Academy of Sciences, Institute for Heart Research, Bratislava, Slovak Republic; ² Comenius University, Faculty of Mathematics, Physics & Informatics,

Department of Nuclear Physics, Bratislava, Slovak Republic; ³Comenius University, Laboratory of Pharmacobiochemistry, Third Department of Internal Medicine, Faculty of Medicine, Bratislava, Slovak Republic; ⁴Academy of Sciences of the Czech Republic, Institute of Physiology, Prague, Czech Republic

Background: Remote ischemic preconditioning (RIP) represent a suitable model for investigation of adaptive mechanisms leading to reduction of extent of ischemia-reperfusion injury in the myocardium. RIP represented the impulse, which was not induced directly in rat myocardium, but in distant place by short-term occlusion of the artery supplying the lower limb.

Purpose: We studied the role of mitochondria in mechanisms of increasing ischemic tolerance by RIP induction.

Methods: The protocol of RIP consisted of 3 cycles of 5 minute ischemia and 5 minute reperfusion. Subsequently, the hearts were perfused in the Langendorff mode. Heart mitochondria were isolated and forwarded to biochemical and biophysical investigation performed after 15 minute stabilised perfusion, 30 minute global ischemia and 40 minute post-ischemic reperfusion. Levels of interleukin 10 (IL-10) were determined using the elisa kit (RAT IL-10 Platinum ELISA). Fluidity of mitochondrial membrane were assessed by estimating fluorescence anisotropy of 1,6-diphenyl-1,3,5-hexatriene (DPH). Content of oxidised isoforms of coenzyme Q (CoQ9ox a CoQ10ox) was measured in isolated mitochondria by HPLC method.

Results: We noticed the significant ($p < 0.05$) decrease in anisotropy reflecting the increase in mitochondrial membrane fluidity of RIP group in comparison with the control group after reperfusion. The nonsignificant increase in oxidised isoforms of coenzyme Q (CoQ9ox, CoQ10ox) during stabilisation induced by RIP reflects the moderate increase of free radicals having just a signal character and initiates the protective mechanisms. Downward trend of the coenzyme Q concentrations (CoQ9ox, CoQ10ox) in RIP group after ischemic-reperfusion injury confirmed the positive role of RIP to huge formation of free radicals. In RIP group after ischemic-reperfusion load, the content of oxidized isoforms CoQ9ox was nonsignificantly reduced by 5.62% compared to control group after reperfusion phase of myocardium.

Conclusions: The observed trend of increased concentration of IL-10 after IR injury in the group subjected RIP suggests the involvement of inflammatory processes in the mechanisms of endogenous myocardial protection. RIP induced endogenous protective mechanisms by increasing the membrane fluidity, thereby improved the energy demand during ischemia. The process of short-term adaptation, such as the RIP induced positive signal is sufficient enough to start the process of myocardial protection against ischemia-reperfusion injury.

P1824

Glutathione as possible mediator of the paradoxical synergy between inhibition and stimulation of H₂S synthesis in terms of cardioprotection

Y Yulia Goshovska¹; TV Shimanskaya¹; RA Dobrovol'ska¹; VF Sagach¹

¹Bogomoletz Institute of Physiology, Kiev, Ukraine

Glutathione is an essential molecule for antioxidant defense. It is synthesized by glutamate-cysteine ligase enzyme (GCL) from L-cysteine which alternatively might be used for production of hydrogen sulfide (H₂S) by cystathionine-gamma-lyase (CSE). In this work we used CSE and GCL inhibitors (D,L-propargylglycine (PAG) and D,L-buthionine-(S,R)-sulfoximine (BSO) correspondingly) in order to modulate the metabolic pathways of L-cysteine in cardiac ischemia/reperfusion model.

Wistar rats were divided into five groups of 6-8 animals each (control, PAG (11.3 mg/kg), L-cysteine (121 mg/kg), PAG+L-cysteine, BSO(22.2 mg/kg)+PAG+L-cysteine). The aorta was cannulated, and then the heart was mounted on a Langendorff apparatus. Next, a balloon was inserted into the left ventricle and the left ventricular developed pressure (LVDP), the first derivative (dp/dt) were registered by Global Lab software. Coronary flow (CF), heart rate and oxygen cost of myocardial work (OCMW) in pre-ischemia and reperfusion period were calculated. All groups underwent a 20-minute global ischemia followed by a 40-minute reperfusion. Mitochondrial membrane permeability in situ was evaluated by UV-spectra absorbance of effluent probes collected from the pulmonary catheter during first minute of reperfusion and tested at 230-260 nm. The heart tissue was examined for superoxide radical, hydroxyl radical, and diene conjugates content by spectrophotometrical method.

PAG as well as L-cysteine slightly improved heart function recovery during reperfusion. Simultaneous application of both, PAG+L-cysteine, manifested in strong cardioprotective effect in terms of 95% recovery of the LVDP and the dp/dt throughout the whole period of reperfusion. PAG+L-cysteine significantly decreased reactive oxygen species production and diene conjugates due to I/R, thus, preventing oxidative stress and non-effective oxygen utilization by ischemized myocardium. The OCMW was increased only by 34% at 10th min of reperfusion in PAG+L-cysteine group. In control group, the OCMW was increased by 139% ($p < 0.05$). Notably, there was no ischemic contracture in PAG+L-cysteine group comparing to 45 mmHg in control hearts. In addition, coronary effluents demonstrated lower UV-absorbance spectra than in control indicating lesser damaging effect of I/R on cardiomyocytes membranes. Pre-treatment of rats with BSO completely abolished cardioprotective effect of PAG+L-cysteine suggesting the role of glutathione as a main trigger in PAG+L-cysteine induced cardioprotection. Thus, PAG and L-cysteine might be promising as the cardioprotective combination for endogenous glutathione stimulation.

3-month survival of the improvement of functional capacity after in-hospital short courses of leg neuromuscular electric stimulation in patients with decompensated chronic heart failure

MG Poltavskaya¹; VP Sviridenko¹; IB Kozlovskaya²; YUA Koriak²; IYU Giverts¹; AA Doletsky¹; IV Patchenskaya¹; AL Syrkin¹

¹I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; ²Institute of Biomedical Problems of Russian Academy of Science, Moscow, Russian Federation

Background: In stable chronic heart failure (CHF) long-term neuromuscular electric stimulation (NMES) of leg muscles is beneficial for aerobic capacity and muscle force.

Aim of the study: To evaluate the impact of short-term NMES on functional capacity, well-being and quality of life in patients hospitalized with decompensated CHF and the survival of the effect after discharge in the randomized sham-controlled trial.

Methods: 45 patients with decompensated CHF (58,2% male, mean age 66,4 ± 10,2 years) were randomized for NMES (n = 22) or sham NMES (n = 23) starting from the 2-3d day after admission to the hospital in addition to standard medical treatment. Anterior and posterior thigh and calf muscles were stimulated simultaneously, using symmetric biphasic rectangular electric impulses with pulse duration = 1 ± 0,5 ms, current frequency = 25 ± 1 Hz and the duty cycle 1 ± 0,1s - on and 2 ± 0,1s - off. In the group of effective NMES the amplitude of stimulation was adjusted up to maximally tolerated muscle contraction, in the group of sham stimulation the amplitude was minimal and caused only skin sensation. Mean session time in two groups was 58,7 ± 18,6 and 54,54 ± 10,4min (=0,003), number of sessions - 8,8 ± 2,9 in effective and 8,0 ± 2,0 in the sham group (ns). General well-being by visual-analogue scale (VAS), 6-minute walk test (6-mwt), Duke Activity Status Index (DASI) and Minnesota Living with Heart Failure Questionnaire (MLHFQ) were assessed at baseline, at discharge from the hospital, after 1 and 3 months after discharge.

Results: At discharge MLHFQ score improved from 55,6 ± 8,5 to 34,2 ± 9,0 (p < 0,05) in effective NMES and from 56,5 ± 7,1 to 48,7 ± 8,1 (p < 0,05) in the sham group, DASI from 12,1 ± 5,6 to 18,3 ± 7,2 (p = 0,017) and from 11,6 ± 3,8 to 13,4 ± 4,3 (ns), 6mwt from 206,1 ± 61,3 to 299,5 ± 91,1m (p = 0,005) and from 211,4 ± 51,6 to 236,8 ± 54,7m (p = 0,056) respectively. All measures at discharge were significantly better in the effective NMES group than in the sham group. Well-being improved equally in both groups: from 3,0 ± 0,6 to 7,0 ± 0,8 in effective NMES and from 3,4 ± 0,8 to 7,0 ± 0,7 points in the sham group. 3 months after discharge there were no changes of MLHFQ (37,8 ± 5,8 in NMES vs 47,6 ± 6,4 in sham, p < 0,05) and 6mwt (282,1 ± 83,2 vs 220,4 ± 46,1m, p < 0,05), DASI further improved (21,0 ± 7,8 vs 15,4 ± 3,9, p = 0,01), and VAS improved only in NMES group (8,1 ± 1,0 vs 6,3 ± 1,1, < 0,05).

Conclusion: In patients hospitalized with decompensated CHF short-term leg neuromuscular electric stimulation in addition to usual treatment improves exercise capacity, activity and quality of life. The effect survives at least 3 months and facilitates further increase of daily activity after discharge. NMES can be used as initial rehabilitation modality for patients unable to exercise.

1844

Prognostic value of right ventricular systolic function in cardiac amyloidosis AIRECAR

D Diane Bodez¹; J Ternacle¹; A Guellich¹; S Guendouz¹; JP Couetil²; L Hittinger¹; JL Dubois-Rande¹; V Plante-Bordeneuve³; JF Deux⁴; T Damy¹

¹University Hospital Henri Mondor, Department of Cardiology, Creteil, France;

²University Hospital Henri Mondor, Department of Cardiac Surgery, Créteil, France;

³University Hospital Henri Mondor, Department of Neurology, Creteil, France;

⁴University Hospital Henri Mondor, Department of Radiology, Creteil, France

Background: Right ventricular (RV) dysfunction is a strong predictor of poor outcomes in heart failure. Its prognosis meaning in cardiac amyloidosis (CA) is unclear.

Purpose: To assess RV structure and function in CA using standard echocardiography, strain imaging, MRI, and pathological studies; to evaluate the prognostic value of RV parameters, as well as of left ventricular (LV), clinical and biological parameters.

Methods: 129 patients with suspected CA and an interventricular septum thickness (IVST) ≥ 12mm underwent echocardiography with measurement of LV and RV longitudinal strain (LS), late gadolinium enhancement (LGE) cardiac MRI, and standard evaluation.

Results: Among 82 confirmed CA, types were immunoglobulin light chain (AL, n = 26), hereditary transthyretin (m-TTR, n = 37) and senile (WT-TTR, n = 19). Compared to those without, CA patients had significantly lower RV fractional shortening (RV-FS), tricuspid annular plane systolic excursion (TAPSE), tissue Doppler systolic velocity, and global RV-LS, without difference between CA types. RV-LGE, observed in 62% of CA patients, was associated with lower global and basal RV-FS. Median follow-up was 8(2;16) months. Using multivariate analysis, NYHA-class and low TAPSE independently predicted major adverse cardiac events defined as death, heart transplantation, and acute heart failure. Independent determinants of TAPSE < 14mm, the best identified cut-off value, were LV ejection fraction, estimated filling pressure (E/e'), and pulmonary artery pressure, but not RV-LGE.

Conclusions: RV dysfunction is common in CA, and might be linked to LV involvement rather than RV amyloid burden. Its routine evaluation by a simple TAPSE may be an aid in assessing the prognosis of CA patients.

1845

Estimated glomerular filtration rate formulas and acute heart failure: does it worth to complicate?

M Madeira¹; R Teixeira¹; I Almeida¹; F Caetano¹; L Reis¹; P Dinis¹; A Fernandes¹; M Costa¹; L Goncalves¹

¹Hospital and University Center of Coimbra; Faculty of Medicine, University of Coimbra, Department of Cardiology, Coimbra, Portugal

Purpose: Chronic kidney disease has an undisputable prognostic influence in acute decompensated heart failure (ADHF) patients. Classically, glomerular filtration rate (GFR) is estimated with the Modification of Diet in Renal Disease (MDRD) formula. Three new glomerular filtration rate (GFR) estimating equations recently emerged, based on serum creatinine (CKD-EPI Cr), serum cystatin C (CKD-EPI Cyst) or a combination of both (CKD-EPI Cr/cyst). These formulas are validated in kidney disease screening, however, the clinical impact in ADHF is unknown. Our aim was to evaluate the prognostic value of these new estimated GFR (eGFR) formulas and to compare its discriminatory capacity regarding mortality after an episode of ADHF.

Methods: Observational and longitudinal study of 112 consecutive patients (69 ± 14 years old, 79% male gender) with ADHF, admitted along 5 years. Serum creatinine and cystatin C were evaluated at admission and a clinical follow-up of 13 ± 13 months was performed targeting all cause mortality. The variables with independent predictive value for mortality in our sample were determined through a logistic binary regression (stepwise).

Results: The mean eGFR according to the different formulas were: MDRD: 57 ± 32, CKD-EPI Cr: 53 ± 28, CKD-EPI Cyst: 51 ± 30, CKD-EPI Cr/Cyst: 51 ± 27 ml/min/m²; and the percentage of patients with a eGFR < 30 ml/min/m² according to the 4 formulas were: MDRD – 22%, CKD-EPI Cr – 27%, CKD-EPI Cyst – 33% e CKD-EPI Cr/cyst – 27%. Mortality during follow-up after an episode of ADHF was 38%. All formulas were significantly associated with mortality during follow-up (MDRD: area under the curve [AUC] 0.61, P = 0.046; CKD-EPI Cr: AUC 0.62, P = 0.03; CKD-EPI Cyst: AUC 0.65, P < 0.01; CKD-EPI Cr/cyst: AUC 0.66; P < 0.01). There was no difference in the discriminatory power of the four formulas to predict, in an isolate way, mortality during follow-up (P > 0.05 for the comparison of the AUC). The age plus serum levels of sodium and alkaline phosphatases were considered independent predictors of mortality, with a good calibration and discriminatory capacity (AUC 0.80, P < 0.01, Hosmer-Lemeshow 0.72). The introduction of the above mentioned

formulas to the previous model, did not significantly improve the accuracy of the model (figure 1).

Conclusion: The four eGFR formulas had the same accuracy to predict mortality after an admission for ADHF, either on an individual basis or when adjusted for other variables. Thereby, in ADHF clinical setting the new eGFR did not add an additional clinical or prognostic value.

Figure 1

Ergoreflex overactivity in mitochondrial disease: linking skeletal myopathy to exercise intolerance, dysautonomia, and cardiac damage

A Alberto Aimò¹; A Giannoni²; MF Piepoli³; M Mancuso⁴; G Siciliano⁴; C Passino²; M Emdin²

¹Sant'Anna School of Advanced Studies, Pisa, Italy; ²Gabriele Monasterio Foundation, Pisa, Italy; ³Guglielmo da Saliceto Hospital, Piacenza, Italy; ⁴University of Pisa, Pisa, Italy

Background: Mitochondrial disease (MD) is a neuromuscular disorder. MD patients often complain of exercise limitation because of dyspnoea and muscle fatigue; autonomic imbalance with sympathetic predominance is a recurrent finding in these patients.

Purpose: We aimed to clarify the mechanisms through which muscle depletion leads to intolerance to effort and dysautonomia in MD.

Methods: Twenty-five adult patients with MD and previously demonstrated skeletal myopathy, aged 48 ± 3 years, underwent a cardiorespiratory screening composed of cardiac magnetic resonance (CMR), cardiopulmonary exercise testing (CPET), Holter monitoring, norepinephrine (NE) dosage, ergoreflex and baroreflex assessment. Thirteen patients were matched with respect to age and sex to healthy, sedentary controls.

Results: Two patients had cardiac hypertrophy, and eight had myocardial fibrosis. At CPET, maximal workload and peak oxygen consumption/kg were significantly lower in patients than controls (both $P < 0.001$). The ergoreflex is a neural mechanism regulating ventilation and autonomic function during muscle activation. Its sensitivity, measured through post-exercise circulatory occlusion, is increased in chronic heart failure-related skeletal myopathy, promoting dyspnoea and muscle fatigue on exertion. In our MD patients ergoreflex sensitivity was markedly higher than controls ($P < 0.001$). It correlated with the fat-to-water ratio at proton muscle spectroscopy (Spearman's $Rho = 0.779$, $P = 0.042$), suggesting a link between muscle damage and ergoreflex overactivity. Ergoreflex sensitivity displayed an inverse correlation with peak workload ($Rho = 0.711$, $P < 0.001$) and peak oxygen consumption/kg ($Rho = 0.648$, $P < 0.001$); increased ergoreflex sensitivity might then contribute to reduced exercise tolerance. Ergoreflex overactivity could also account for adrenergic activation and vagal withdrawal, demonstrated by lower baroreflex sensitivity and higher NE levels (both $P < 0.001$), and reduced heart rate variability. Indeed, ergoreflex sensitivity correlated directly with NE ($Rho = 0.322$, $P = 0.020$), and inversely with the standard deviation of RR intervals ($Rho = 0.530$, $P = 0.013$). At univariate analysis, NE levels were the only predictors of myocardial fibrosis at CMR. NE levels were higher in patients with fibrosis than those without ($P = 0.034$); a 692 ng/L cut-off was selected (area under the curve 0.800, sensitivity 90%, specificity 75%).

Conclusion: In MD, skeletal myopathy can increase ergoreflex sensitivity, causing exercise intolerance and sympathetic-vagal imbalance. Sustained sympathetic overactivity may contribute to cardiac damage.

Efficacy and safety of dipeptidyl peptidase 4 inhibitors in patients with type 2 diabetes mellitus: a meta-analysis of 116 trials

G Savarese¹; C D'Amore¹; F De Martino¹; GMC Rosano²; B Trimarco¹; P Perrone-Filardi¹

¹Department of Advanced Biomedical Sciences; Federico II University, Naples, Italy, Naples, Italy; ²St George's University of London, Cardiovascular and Cell Sciences Research Institute, London, United Kingdom

Background: Dipeptidyl Peptidase 4 Inhibitors (DPP4-I) are widely used to improve glycemic control in type 2 diabetes mellitus (DM) patients. However, although cardiovascular (CV) outcome studies conducted to assess the safety of these drugs demonstrated no effects on major CV events and mortality, concerns were raised on the association between DPP4-I use and increased incidence of heart failure (HF) hospitalization reported in one phase III trial.

Purpose: To evaluate the effects of DPP4-I on HF hospitalization, major CV events and mortality in type 2 DM patients by a meta-analysis.

Methods: Randomized trials enrolling more than 200 patients, comparing DPP4-I versus placebo or active treatments in patients with DM and reporting at least one event among all-cause and CV mortality, stroke, myocardial infarction (MI) and HF hospitalization, were searched. Meta-analysis was performed to assess the influence of treatment on pre-specified end points. The assumption of homogeneity between the treatment effects in different trials was tested by Q statistic and further quantified by I^2 statistic.

Results: 116 randomized clinical trials enrolling 108,405 patients (60,077 on DPP4-I and 48,328 on control/placebo), with a follow-up ranging from 4 to 209 weeks, were included in the analysis. Compared to control, treatment with DPP4-I did not affect all-cause (RR: 1.011; 95% CI 0.936 to 1.092; $p = 0.784$; $pQ = 0.995$; $i^2 = 0\%$) and CV (RR: 0.975; 95% CI: 0.887 to 1.072; $p = 0.603$; $pQ = 0.979$; $i^2 = 0\%$) mortality, as well as risk of MI (RR: 0.919; 95% CI: 0.839 to 1.007; $p = 0.070$; $pQ = 0.968$; $i^2 = 0\%$), stroke (RR: 0.935; 95% CI: 0.821 to 1.064; $p = 0.307$; $pQ = 0.994$; $i^2 = 0\%$) and HF (RR: 1.84; 95% CI: 0.975 to 1.207; $p = 0.137$; $pQ = 0.956$; $i^2 = 0\%$). Analyses were then repeated according the different control arm used (placebo or active treatments). Compared to active treatments, DPP4-I significantly reduced the risk of MI (RR: 0.524; 95% CI: 0.356 to 0.771; $p = 0.001$; $pQ = 0.962$; $i^2 = 0\%$) and stroke (RR: 0.604; 95% CI: 0.382 to 0.954; $p = 0.031$; $pQ = 0.905$; $i^2 = 0\%$), without any effect on all-cause (RR: 0.761; 95% CI: 0.517 to 1.121; $p = 0.166$; $pQ = 0.964$; $i^2 = 0\%$) and CV (RR: 0.669; 95% CI: 0.363 to 1.233; $p = 0.197$; $pQ = 0.921$; $i^2 = 0\%$) mortality and risk of HF (RR: 0.665; 95% CI: 0.394 to 1.123; $p = 0.127$; $pQ = 0.747$; $i^2 = 0\%$). Compared to placebo, DPP4-I did not affect all-cause (RR: 1.027; 95% CI: 0.949 to 1.111; $p = 0.511$; $pQ = 0.975$; $i^2 = 0\%$) and CV (RR: 0.989; 95% CI: 0.898 to 1.090; $p = 0.828$; $pQ = 0.955$; $i^2 = 0\%$) mortality, as well as the risk of MI (RR: 0.954; 95% CI: 0.868 to 1.049; $p = 0.334$; $pQ = 0.956$; $i^2 = 0\%$), stroke (RR: 0.977; 95% CI: 0.851 to 1.121; $p = 0.739$; $pQ = 0.968$; $i^2 = 0\%$) and HF (RR: 1.112; 95% CI: 0.996 to 1.242; $p = 0.059$; $pQ = 0.948$; $i^2 = 0\%$).

Conclusions: Use of DPP4-I in type 2 diabetic patients is safe and is not associated with unfavorable effects on incidence of new HF, major CV end points or mortality.

¹Sapienza University of Rome, Department of clinical and molecular medicine, Rome, Italy; ²San Camillo Forlanini Hospital, Cardiology Division, Cardiac Arrhythmia Center and Cardiomyopathies Unit, Rome, Italy; ³University of Milan, Department of clinical sciences and community health, Milan, Italy; ⁴Second University of Naples, Cardiology SUN, Monaldi Hospital, Naples, Italy; ⁵University of Foggia, Department of cardiology, Foggia, Italy

Background: Major advances have been made in pharmacological and non-pharmacological approaches in patients with hypertrophic cardiomyopathy (HCM). The challenge is now to identify early those patients at high risk of cardiovascular (CV) events and of heart failure (HF) development/progression.

Methods: A total of 620 consecutive stable HCM outpatients were enrolled and prospectively followed in five tertiary HCM Italian centers between September 2007 and October 2015. Each HCM patient underwent a de-novo full clinical assessment, including a maximal CPET with a personalized ramp exercise protocol. All patients had planned clinical reviews every 6–12 months or earlier. The primary end-point was represented by: death to HF or stroke, cardiac transplantation, progression to a stable NYHA class III or IV, hospitalization due to HF worsening, cerebro-vascular non-fatal events and new onset of atrial fibrillation.

Results: Median follow-up was 3.9 years with a total of 2,755 patient-year. During the follow-up period, 138 (22%) reached at least one of the events considered. Multivariate analysis showed that left atrial diameter (LAd), abnormal blood pressure response at exercise (ABPRE), ventilatory efficiency (VE/CO₂ slope) and peak oxygen uptake (pVO₂) were independently associated to the study end-point. The ROC analysis showed a pVO₂ < 70% of maximum predicted as well as a VE/CO₂

slope>32 as the cut-off values with the best accuracy in predicting the study end-point (AUCs: 80% and 85%, respectively). Conclusion. The present study provides evidence of the CPET prognostic role in patients with HCM, particularly with respect to CV events.

Characteristics of overall population

General data	Overall Sample [n: 620]	Primary End-Point	
		Yes [n: 138]	No [n: 482]
Age, years	49 ± 16	50.7 ± 16.8	48.5 ± 15.7
Male, n (%)	425 (69%)	82 (60%)	343 (71%) [†]

Heart failure following myocardial infarction: a cohort study of incidence and prognostic factors in 24 745 patients using linked electronic records

JMHH Gho¹; AF Schmidt²; S Koudstaal¹; M Pujades-Rodriguez³; S Denaxas³; CP Gale⁴; AW Hoes⁵; JG Cleland⁶; H Hemingway³; FW Asselbergs³

¹University Medical Center Utrecht, Department of Cardiology, Division Heart and Lungs, Utrecht, Netherlands; ²University College London, Institute of Cardiovascular Science, Faculty of Population Health Sciences, London, United Kingdom; ³University College London, Farr Institute of Health Informatics Research, UCL Institute of Health Informatics, London, United Kingdom; ⁴University of Leeds, Leeds, United Kingdom; ⁵University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands; ⁶Imperial College London, London, United Kingdom

Background/Introduction: Linked electronic health records (EHR) from primary and secondary care offer the opportunity to investigate the contemporary incidence of and risk factors for heart failure (HF) after a first myocardial infarction (MI).

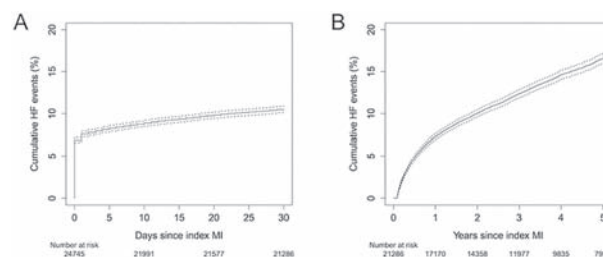

Purpose: To investigate the incidence of and risk factors for HF after a first MI.

Methods: The UK based CALIBER (CARDiovascular research using Linked Bespoke studies and Electronic health Records) programme, linking primary care data to hospital admissions and national MI and mortality registries was used to identify all patients aged 18 years or older who experienced a first MI between 1 January 1998 and 25 March 2010 and had no prior HF history. Time to HF was modeled using Cox proportional hazard models, with HF defined as the first recorded HF diagnosis in any of the CALIBER sources.

Results: 24,745 patients without a prior history of HF experienced a first MI. During a median follow-up of 3.7 years, 6005 (24.3%) patients developed HF, crude incidence rate of 66.1 cases (95% CI: 64.4–67.8) per 1000 person-years. During the first 30 days from index MI, 2581 (10.4%) patients developed HF (Fig. 1A). Among event free patients during the first 30 days, 2779/21286 (13.1%) subsequently developed HF over the following 5 years (Fig. 1B). Of the patients with an index MI between 1998–2001 938/5229 (17.9%) developed HF during a 3-year follow-up compared with 1496/6939 (21.6%) patients with a first MI between 2004–2007. Baseline characteristics independently associated with HF development were:

age [HR per 10 years increase: 1.45 (95%CI 1.41–1.49)], greater socioeconomic deprivation (5th [HR 1.27 (95%CI 1.13–1.42)] vs. 1st quintile), a history of hypertension [HR 1.16 (95%CI 1.09–1.23)], diabetes [HR 1.44 (95%CI 1.34–1.55)], atrial fibrillation [HR 1.63 (95%CI 1.51–1.75)], peripheral arterial disease [HR 1.38 (95%CI 1.26–1.51)], COPD [HR 1.28 (95%CI 1.17–1.40)] and ST-elevation MI [HR 1.21 (95%CI 1.11–1.32)]. Results did not change after imputing missing covariate data, or accounting for competing risks.

Conclusion: One in 4 people developed HF within 4 years of experiencing a first MI. Key clinical characteristics identify patients at greater risk of HF following MI, some of which are modifiable.

Crude incidence of HF after index MI

The role of conventional mitral surgery in patients with functional regurgitation and left ventricular dysfunction: a three-centers experience

L Botta¹; B De Chiara²; L Di Marco³; F Massi⁴; A Costetti¹; A Moreo²; C Giannattasio²; M Portoghese⁴; R Di Bartolomeo³; CF Russo¹

¹Niguarda Ca' Granda Hospital, Cardiac Surgery Unit, Milan, Italy; ²Niguarda Ca' Granda Hospital, Cardiology IV Unit, Milan, Italy; ³University Hospital Policlinic S. Orsola-Malpighi, Bologna, Italy; ⁴SS. Annunziata Hospital, Sassari, Italy

Background: Percutaneous trans-catheter approaches are being investigated as potential alternatives to conventional open interventions for the management of functional mitral regurgitation (FMR). The optimal strategy in patients with FMR and moderate-severe left ventricular dysfunction is still debated. Purpose We retrospectively evaluated the outcomes of patients with FMR and left ventricular dysfunction at three different hospitals to assess the current role of conventional open surgery and predictors of poor results.

Methods: From 2001 to 2015, 202 patients (136 males, mean age 69 years) with ischemic (139 pts) and non-ischemic (63 pts) FMR and an ejection fraction (EF) less than or equal to 45% underwent conventional mitral valve surgery. Mean preoperative EF was 35.3 ± 6.5%. Mean PASP was 47 ± 15 mmHg. Fifty-two patients had diabetes, 31 peripheral vasculopathy and 27 cerebro-vascular accidents. Variables with a P value < 0.10 at univariate analysis entered the multivariate logistic regression to determine predictors of deaths. Kaplan-Meier estimates were calculated and compared using a log-rank. Results Mitral valve repair was performed in 83 pts (41%). A biological or mechanical prosthesis was implanted in 85 and 34 patients respectively. CABG was performed in 109 pts. Cardiopulmonary-bypass and cross-clamp times were 164 ± 57 and 115 ± 40 minutes. Perioperative IABP was necessary in 26% of patients. In-hospital mortality was 7.4%. Postoperative low cardiac output occurred in 46 patients while neurological complications in 17. Twelve patients required a continuous veno-venous hemofiltration or dialysis. Overall survival rates were 87, 82, and 75% at 1, 5 and 10 years. Mortality was significantly higher in patients with diabetes (log rank 0.03) and renal failure (log rank 0.006). No differences were observed when considering etiology of FMR (ischemic vs. non-ischemic), type of surgery (replacement vs. repair), lower EF (<30% vs. >30%). At multivariate analysis, diabetes (P=0.05; HR 4.4; C.I. 1–21), peripheral vasculopathy (P=0.01; HR 6.3; C.I. 1.35–29.7) and CPB time (P=0.01; HR 1.012; C.I. 1.002–1.022) were independent predictors of 30-days mortality.

Conclusions: Conventional mitral surgery still represents a satisfactory option in very complex patients with FMR and moderate/severe myocardial dysfunction. Diabetes, peripheral vasculopathy, and cardiopulmonary bypass time are independent predictors of in-hospital deaths. Patients with a combined cardio-renal impairment, diabetes, and peripheral vasculopathy can probably better benefit from alternative/trans-catheter therapies.

Prevalence and prognostic impact of chronic obstructive pulmonary disease in patients with chronic heart failure. Data from the GISSI-Heart Failure trial.

AstraZeneca, Pfizer, Sigma-Tau, Società Prodotti Antibiotici Spa
M Canepa¹; PL Topporelli²; A Rossi³; A Rossi³; L Gonzini⁴; GL Nicolosi⁵;
L Staszewsky⁶; R Marchioli⁷; AP Maggioni⁴; L Tavazzi⁸

¹University of Genoa, Genoa, Italy; ²Fondazione Maugeri, Veruno, Italy; ³University of Verona, Verona, Italy; ⁴Associazione Nazionale Medici Cardiologi Ospedalieri Research Center, Florence, Italy; ⁵Santa Maria degli Angeli Hospital, Pordenone, Italy; ⁶IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy; ⁷Quintiles, Milan, Italy; ⁸Maria Cecilia Hospital, Cotignola, Italy

Background and aims: Chronic obstructive pulmonary disease (COPD) is a common comorbidity in patients with heart failure (HF), yet its prevalence, characterization and long-term prognostic impact remain controversial. Herein we aimed to assess the clinical characteristics and outcomes of COPD patients enrolled in the GISSI-HF trial.

Methods: The study randomized 6975 ambulatory patients with chronic HF to either n-3 polyunsaturated fatty acids or placebo and followed them up for a median of 3.9 years. We performed a retrospective analysis of clinical characteristics and outcomes of the 1533 patients diagnosed with COPD at study enrollment (22%).

Results: COPD was associated with a worse clinical presentation and an increased burden of comorbidities, including diabetes, hypertension, history of atrial fibrillation and peripheral vascular disease (all $p < 0.0001$). At unadjusted and at adjusted Cox proportional hazard analysis, COPD was found to be an independent predictor of both predefined primary study endpoints, including all-cause mortality (adjusted HR 1.28, 95%CI 1.15-1.43, $p < 0.0001$) and all-cause mortality or hospitalization for cardiovascular reasons (adjusted HR 1.19, 95%CI 1.10-1.30, $p < 0.0001$). Both cardiovascular (adjusted HR 1.20, 95%CI 1.05-1.36, $p = 0.007$) and non-cardiovascular mortality (adjusted HR 1.56, 95%CI 1.26-1.94, $p < 0.0001$) were significantly increased in COPD HF patients, as well as hospitalizations for any reason (adjusted HR 1.23, 95%CI 1.14-1.34, $p < 0.0001$), for cardiovascular reasons (adjusted HR 1.16, 95%CI 1.06-1.27, $p = 0.002$) and for HF (adjusted HR 1.27, 95%CI 1.14-1.43, $p < 0.0001$). Figure 1.A and figure 1.B show the Kaplan Meier survival curves for the two co-primary endpoints mentioned above, in patients with COPD and without COPD.

Conclusions: COPD is an independent predictor of mortality and hospitalizations in ambulatory HF patients evaluated over a 4-year period. Increased awareness and improved management of COPD may reduce the burden of this morbidity to patients with HF.

Is serum cortisol a predictor of left ventricular remodelling after an event of cardiac decompensation?

M Christa¹; S Brenner¹; C Malsch¹; G Gueder¹; D Berliner¹; C Morbach¹; C Angermann¹; S Stoerk¹

¹University of Würzburg, Comprehensive Heart Failure Center, Würzburg, Germany

Background and Purpose: Stress hormones like cortisol and aldosterone are associated with higher mortality risk in heart failure (HF). Cardiac decompensation

exerts stress on the failing heart and may influence cardiac recovery by altered cortisol levels. We investigated whether levels of corticosteroid hormones after an event of cardiac decompensation predict left ventricular (LV) remodelling after 6 months.

Methods: The Interdisciplinary Network for Heart Failure (INH) trial recruited 1022 patients hospitalized for cardiac decompensation with LVEF (echo) $\leq 40\%$ at discharge. Serum levels of cortisol and aldosterone were measured prior to discharge. $n = 533$ subjects with complete data incl. echocardiography 6 months after discharge were analysed in this post-hoc analysis. Specifically, use of mineralocorticoid receptor antagonists (MRA) was considered in analyses. Linear regression analyses were run considering the specific nature of skewed data (Tobit regression).

Results: The median age of the study cohort was 68 years (quartiles: 59;75), 76% of the patients were male and 46% took MRA. At baseline, median values of serum cortisol, aldosterone and LV end-diastolic diameter (LVEDD) were 14.7 (11.4;18.3) $\mu\text{g/dl}$, 56 (10;98) pg/ml and 62 (57;66) mm, respectively. After six months, a median change of LVEDD $-1(-8;+4)\text{mm}$ was observed. Baseline levels of serum cortisol but not aldosterone were related to the change in LVEDD: T-value for log cortisol 1.99; $p = 0.05$; T-Value for log aldosterone -1.55; $p = 0.12$. By contrast, change in LVEF was not predicted by any corticosteroid. After adjustment for potential confounders (selected from anthropometrics, echocardiography and laboratory) the predictive utility of cortisol was slightly attenuated (Table 1). Of note, not taking a MRA remained a decisive modulating factor in multivariable analyses.

Conclusion: In this post-hoc analysis, based on a modest sample size, we observed that higher levels of cortisol predict a larger increase in LVEDD 6 months after an event of acute cardiac decompensation. This association was particularly pronounced in subjects not taking MRA, but was abolished in subjects on MRA. Our findings indicate that cortisol is indeed involved in the mediation of remodelling after an event of acute cardiac decompensation. However, further contributing factors still need to be identified.

Table 1: Independent prediction of 6-month changes in LVEDD by serum cortisol (multivariable stepwise regression)

	Change LVEDD in mm	
	T	P value
Step 0: Log serum cortisol at baseline	1.99	0.047
Step 1: Baseline LVEDD	1.73	0.085
Step 2: Age, sex, NYHA class, baseline LVEDD	1.54	0.125
MRA yes	0.41	0.683
MRA no	1.61	0.108
Step 3: Age, sex, NYHA class, baseline LVEDD, Log GFR, Log hs-CRP, Log NT-proBNP	1.87	0.062
MRA yes	0.52	0.604
MRA no	1.88	0.062

Stepwise increasing levels of adjustment (linear regression). For step 3, independent predictors for cortisol were forced into the analysis, and repeated for patients with or without MRA intake.

Major cardiovascular events in long-term survivor of childhood cancer

FJ Francisco Javier Irazusta Cordoba¹; J Caro Codon¹; O Gonzalez Fernandez¹; P Meras Colunga¹; V Rial Baston¹; SO Rosillo Rodriguez¹; E Refoyo Salicio¹; M Moreno Yanguela¹; JL Lopez-Sendon¹; T Lopez Fernandez¹

¹University Hospital La Paz, Cardiology, Madrid, Spain

Introduction: Anticancer therapies have led to a long life expectancy for many patients; however, treatment-related comorbidities, and mainly cardiac toxicity, have become an issue for long-term cancer survivors.

Clinical case: A 38-year-old woman presented to the emergency department of our hospital after one week of low respiratory tract infection symptoms and a 20-minute episode of acute oppressive chest pain.

Her medical history was remarkable for a diagnosis of Wilms tumor at 12 years old. She was treated with surgery and anthracycline-based chemotherapy (ABCT). Ten years later she received a diagnosis of femur osteosarcoma, being treated with surgery and adjuvant ABCT. Subsequently, at 34 years old, she developed chemotherapy-related left ventricular dysfunction (CRLVD) and, therefore, was receiving regular follow-up in the cardiology outpatient clinic.

On physical examination stood out a systolic murmur with no other remarkable findings. A 12-lead ECG was performed, without encountering signs suggestive of myocardial ischemia. Laboratory tests revealed mild elevation of C-reactive and significant elevation of Troponin I (23.55 ng/mL, normal range <0.04 ng/mL) and NT-proBNP (3750 pg/mL, normal range <125 pg/mL). The patient underwent transthoracic echocardiography, which revealed moderate-to-severe left ventricular dysfunction, inferior and posterior wall akinesia, and severe mitral regurgitation. Given the history of CRLVD, the presence of cold symptoms and an increase in troponin level, a differential diagnosis of myocarditis was raised. Subsequent coronary computed tomography angiography (CCTA) revealed normal coronary arteries. The patient remained asymptomatic during the hospitalization and a cardiac magnetic resonance (CMR) was scheduled to continue the diagnostic process. CMR showed an image suggestive of mural thrombus in the right side of the interventricular septum, adjacent to an akinetic region with transmural late gadolinium enhancement. Finally, a diagnosis of septal acute myocardial infarction (AMI) with normal coronary arteries, presumably embolic, was performed in a young woman with CRLVD.

Discussion: Cardiac toxicity is one of most feared side-effects of anticancer agents so that the gain in life expectancy due to anticancer therapy might be countered by increased mortality due to cardiac problems. In our patient CRLVD diagnosis was performed belatedly, and even with focused treatment for heart failure, left ventricular ejection fraction did not improve. Later she suffered an AMI regarding an embolic event, but differential diagnosis with viral myocarditis was really difficult. Final diagnosis was performed by the CMR.

Conclusion: This particular case illustrates the importance of the development of programs directed towards the early diagnosis and treatment of CRLV. Cardiac imaging evaluation is the cornerstone in the diagnosis and decision-making process of these patients.

Embolic AMI diagnosed by CMR

Beyond heart failure in an oncological patient

R Rocio Eiros¹; I Baraibar²; G Bastarrika³; A De La Fuente¹; I Eguren²; M Artaiz¹; JP Fusco²; J Barba¹; JJ Gavira¹; S Martin-Algarra²

¹University Clinic of Navarra, Cardiology, Navarra, Spain; ²University Clinic of Navarra, Oncology, Navarra, Spain; ³University Clinic of Navarra, Radiology, Navarra, Spain

We present the case of a 43-year-old man with a previous history of dyslipidemia and hyperuricemia. In April 2015, he consulted for progressive dyspnea and left pleural effusion. Three months later he referred worsening of symptoms and a 25 cm pleural mass were seen in July 2015. Left pleuropneumectomy was performed, with anatomopathological result of synovial sarcoma. The surgery got complicated with massive intrasurgical haemorrhage that required massive transfusion. After adjuvant chemotherapy with adriamycin and ifosfamide, a reevaluation with PET was done, showing no residual disease. Then, adjuvant radiotherapy to the left chest wall with concurrent gemcitabine was administered (Fig1).

He was referred to our department in December 2015 because of shortness of breath (NYHA III) and edema in lower extremities. On examination, hypotension and elevated jugular venous pressure was noted. EKG showed sinus tachycardia and QRS low voltages. An echocardiogram demonstrated moderate pericardial effusion that conditioned collapse of the right atrium and right ventricle with inferior vena cava plethora and normal systolic function.

Because of cardiac tamponade, a pericardial window draining into right pleural space was made. The pericardial fluid cytology was negative for malignancy. However, no clinical improvement was noted and he was readmitted 10 days later with right heart failure (HF). The echocardiogram dismissed cardiac tamponade, and showed dilated inferior cava with no other complains. Intravenous diuretic treatment was started, with slight improvement.

A week later he developed symptomatic atrial fibrillation with rapid ventricular rate and hypotension, so intravenous amiodarone was given restoring sinus rhythm. Posterior evolution was torpid and the patient developed a low cardiac output syndrome. The echocardiogram showed signs of heart constriction, but the acoustic window was suboptimal so a cardiac magnetic resonance (CMR) was performed. The CMR showed pericardial thickening (5 mm maximum) with lobulated pericardial effusion (29 mm of maximum thickness) (Fig2) and paradoxical movement of the septum with limitation of left ventricular relaxation. No collapse was observed. All these data suggested constrictive pericarditis, probably induced by radiation. After hemodynamic stabilization, pericardiectomy was performed. Pathological diagnosis was fibrous pericardium with no signs of malignancy. Right HF remained even after the procedure, and he is still on treatment for HF, being NYHA II now. Radiation-induced pericardial disease should be a differential diagnosis in oncological patients suffering from symptoms related to chronic HF and pericardial thickening or effusion. Examination should be done with appropriate noninvasive (echocardiography, CMR) and invasive techniques (cardiac catheterization). Early pericardiectomy has been advocated immediately after confirming the diagnosis. Otherwise, surgical outcome is not always favorable.

Radiation map and CMR

1855

Right ventricle heart failure in pulmonary embolism caused by neoplastic infiltration of the vena cava superior and the right atriumM Zechowicz¹; M Rucinska¹¹University of Warmia and Mazury, Department of Oncology, Olsztyn, Poland

Introduction: The risk of venous thromboembolism (VTE) is significantly higher in cancer patients than in the general population and its diagnosis deteriorates the overall prognosis. It can present as the first manifestation of a neoplasm, its progression or recurrence. It appears usually as a deep vein thrombosis (DVT), rarely it manifests as an isolated pulmonary embolism (PE).

Case study: A 53-year-old female patient, who was treated with chemotherapy (ChTH) and radiotherapy (RTH) due to metastatic mediastinal cancer of unknown primary location (FPI) in the past, was admitted due to increasing dyspnoea, tachycardia and cervical veins distension. Transthoracic echocardiography (TTE) showed indirect signs of pulmonary hypertension and a movable structure in the right atrium (RA) suggesting a thrombotic process. Computed Tomography (CT) confirmed the presence of PE and revealed cancer recurrence in the mediastinum. No DVT was present in ultrasonography of the lower limbs. As there was no clinical improvement after unfractionated heparin treatment, another cause of PE was suspected. Further CT scans reconstructions with magnetic resonance (MRI) revealed neoplastic infiltration of vena cava superior, penetrating to its lumen and to the atrial cavity. The PE material in segmental arteries seemed to be both thrombotic and of neoplastic origin. The patient was qualified for oncological treatment with palliative RTH followed by ChTH, and dalteparin (200 UI/kg/day) was recommended as anticoagulant treatment. In the follow-up, the right ventricle heart failure signs diminished and the patient covered a greater distance (444 and 420 meters respectively) in 6-minutes walking test. Decrease in size of the structure in RA was observed in TTE and 3D-Echocardiography and the right ventricle systolic pressure normalized.

Discussion: Risk of VTE coexisting with neoplasm is the highest (4–13 times) in patients suffering from metastatic pancreas, stomach and lung cancer. Such patients have also a higher risk of VTE recurrence as well as a higher risk of bleeding during anticoagulation. With the anticancer treatment the risk of VTE increases additionally about 7-fold. The presented case showed the occurrence of PE as the first manifestation of the neoplastic disease progression, which can also represent its higher aggressiveness. Additionally, the co-occurrence of VTE and the structure in the RA pretending a thrombus resulted in delay of the right diagnosis, as the symptoms of right ventricle heart failure fitted the primary diagnosis of PE and simultaneously masked the neoplastic infiltration of responsible vessels. It was found necessary to combine TTE, CT and MRI for the final accurate diagnosis and the simultaneous cardio-oncological treatment was implemented.

Conclusions: A symptomatic right ventricle heart failure in patients with a history of cancer needs diagnosing towards PE. An isolated PE in metastatic cancer can be both thrombotic and of neoplastic origin.

1856

Rapidly progressive aortic and tricuspid regurgitation after radiotherapy for breast cancerAl Ana Isabel Azevedo¹; A Dias¹; J Ribeiro¹; M Fonseca¹; N Ferreira¹; L Vouga¹; V Gama Ribeiro¹¹Hospital Center Vila Nova Gaia, Porto, Portugal

Introduction: Radiation therapy has improved survival in early stage breast cancer. However, heart irradiation can damage virtually any cardiac structure. Clinical manifestations of cardiotoxicity can appear after a long follow-up and there is not a minimum radiation dose considered to be entirely safe.

Case report: A 66-year-old woman presented with syncope and atypical chest pain. She had history of left breast cancer at 42 years-old, submitted to left mastectomy and adjunctive chemotherapy and radiotherapy (RT). Physical examination was unremarkable. Electrocardiogram revealed second degree atrioventricular (AV) block (Mobitz II), left anterior fascicular block and right bundle branch block. Transthoracic echocardiography (TTE) showed mild aortic valve regurgitation (AVR) and normal left ventricle systolic function (LVSF). Cardiac magnetic resonance confirmed mild AVR and no signs of ischemia or fibrosis. A dual chamber pacemaker was implanted. One-year later, atypical chest pain persisted and progressive worsening fatigue, facial and lower limb oedema developed. TTE showed moderate AVR (A), mild mitral regurgitation and mild to moderate tricuspid regurgitation (TR), with normal pulmonary artery systolic pressure (PASP) and LVSF. Optimal medical therapy was adopted. Four months later, TTE showed moderate to severe AVR (B) and moderate TR (C), with normal PASP and LVSF. Cardiac catheterization showed no coronary artery disease and severe AVR. Two months later, on transoesophageal echocardiography, AVR was quantitative assessed as moderate (D) and severe TR with pulmonary hypertension and signs of right ventricle pressure overload were seen. Pulmonary angioCT excluded embolism or parenchymal abnormalities. The patient underwent surgical replacement of the aortic valve with a mechanical prosthesis and tricuspid annuloplasty. On TTE one-month after surgery, severe TR

persisted and mild right ventricle dysfunction was present. The patient remained clinically stable.

Discussion: Incidental radiation of the heart is associated with cardiovascular disease. There is a dose-dependent relation and cardiotoxicity is greater for RT of left-sided breast cancer. Conduction abnormalities include left or right bundle branch block and different degrees of AV block. Syncope is the most common symptom. Aortic valve regurgitation is the most common valvular abnormality and patients can develop symptoms of heart failure several years after RT. Valve replacement is the mainstay of treatment for severe valvulopathy and echocardiographic screening for valvular heart disease is advisable 10 years after RT.

Conclusion: RT-induced cardiotoxicity affects any heart structure in a dose-dependent relation. AVR is the most common valvulopathy and can manifest several years after RT. Multidisciplinary involvement (cardio-oncology) in the planning of thoracic RT and long term follow-up are essential for preventing and/or early detecting radiation-induced cardiotoxicity.

1857

Phantom tumor of the lung in a patient with mitral valve infective endocarditisS Matic¹; K Kristina Andjelkovic¹; D Kalimanovska Ostric¹; V Karadzic¹; B Orbovic¹¹School of Medicine, University of Belgrade, Cardiology Clinic, CCS, Belgrade, Serbia

Infective endocarditis is still a deadly disease, despite management improvement achieved. Heart failure is common complication and frequently the reason for early surgery.

We present a 58-yr-old female patient was admitted on orthopedic department of the local hospital with symptom of severe back pain. There was no evidence of vertebral lesion, but inflammation markers were increased. Few days later she became 39,9 C febrile and felt poor. Antibiotics were administrated and she became afebrile. One week after she was admitted to the hospital, she felt short breath and pulmonary embolism was suspected. At the same time echocardiography finding was severe mitral regurgitation (MR) in enlarged left atrium and 2,5 x 1,7 cm large mitral valve vegetation. Hence, mitral valve endocarditis was diagnosed. She was transferred to cardiology clinic. Laboratory and microbiology tests were performed. BNP and inflammatory parameters levels were increased. Three blood cultures were negative. Chest radiography was unspecific. Echocardiography finding was the same as the first done. Antibiotics were given empirically. All the time the patient was hypotensive, in sinus rhythm but tachycardic, with hypoproteinemic leg edema and small bilateral pleural effusion. Suddenly, she got hemoptysis. At the same time we have noticed inguinal lymphadenopathy. D-dimer was not significantly increased. The control chest radiography showed in her right pulmonary hilum tumor-like phenomena. She was observed by pulmonologist. Chest CT-scan showed suspected tumorous process. Bronchoscopy and biopsy were performed. Neither malignant process, nor pulmonary embolism was diagnosed. The histopathological finding of biopsied enlarged lymphoid nodus showed inflammatory reaction. After the high doses of furosemide administered, our patient has stabilized. Hemoptysis and tumor-like phenomena disappeared. They were just uncommon acute heart failure manifestations. BNP level was lower, too. The control five samples of blood cultures were sterile. Surgical treatment has been indicated. The latest echocardiographic finding before the operation showed enlarged diastolic dimension of left ventricle, rupture of degenerative changed posterior mitral cusp and severe MR in enlarged left atrium. It was

three months of intensive conservative treatment since the first manifestation of her illness occurred, needed to be adequately prepared for surgery. Artificial mitral valve was implanted. One month after the operation, she was completely healed and went home. The control echocardiography showed normal sized left ventricle with good ejection fraction (54%).

Heart failure with atypical manifestation, such as phantom tumor of the lung, can delay surgery treatment that is necessary in patients with infective endocarditis, due to unnecessary additional diagnostic. Therefore, practitioners should be cautious in such clinical pitfalls.

1858

Acute heart failure due to reversible cardiomyopathy in patient under b-raf inhibitor for metastatic melanoma.

M Masciarucci¹; F Bruni¹; M Maio²; R Danielli²; G Bova¹

¹Polyclinic Santa Maria alle Scotte, Emergency department, Siena, Italy; ²Polyclinic Santa Maria alle Scotte, Oncology, Siena, Italy

Vemurafenib is an orally administered drug that inhibits BRAF kinase and blocks tumor growth by hindering cellular proliferation. It is indicated for the treatment of BRAF-mutated unresectable and metastatic melanoma. The most commonly reported adverse events includes joint pain, rash, alopecia, photosensitivity and fatigue. The main cardiac side effect is a QT prolongation which may cause life threatening cardiac arrhythmias such as torsades de pointes. For this reason a close monitoring with electrocardiogram for the entire duration of the treatment is necessary. We report a severe acute heart failure due to a reversible cardiomyopathy in a patient treated with Vemurafenib. A 40 years old woman with a metastatic melanoma was sent to cardiologic evaluation for shortness of breath (NYHA III), ankle swelling and heart murmur developed after the ninth administration course. No previous history of cardiovascular disease was reported except for a border line not treated hypertension and smoking history. Electrocardiogram showed non-specific ST alteration with T-wave inversion in chest leads (V4-V5-V6) meanwhile the echocardiographic assessment revealed a severe left ventricular function impairment (LVEF 35%). There was a left ventricle (LVED 62mm) and atrium enlargement, mild to severe mitral regurgitation and pulmonary hypertension (PAPs 55mmHg). In the effort to treat the cardiomyopathy, we started a therapy with ACE inhibitors, beta blockers, diuretics and digoxin. The first diagnosis was a multi-factorial disease due to hypertension and valvular insufficiency. However in the hypothesis of a iatrogenic damage, Vemurafenib has been suspended. The symptoms and ECG alterations improved in 2 months. The left ventricular function totally recovered in the latter 4 months as well as the pulmonary pressure. Little information is known about the cardio toxicity of the tyrosine kinase inhibitor, however, in these case, the fast recovery after Vemurafenib holding seems to exclude an immune-mediated mechanism. The reversible nature of Vemurafenib-induced cardio toxicity suggests a cellular mechanism of the dysfunction. The interaction of BRAF inhibitors with ionic channels and kinase (ATP or calcium related), may induce the loss of capacity to produce energy. This mechanism can explain the association with QT-alteration and myocardial dysfunction. In Vemurafenib administer protocol, time depending ECG controls are mandatory to detect early QT-elongation. In our case not specific ECG alteration anticipated myocardial dysfunction despite not clinical related. We suggest that all patients under B-Raf inhibitor therapy should receive a particular attention for ECG little modifications, that can show early signs of myocardial toxicity which are to be confirmed by echocardiographic assessment (LVEF).

Cardiogenic shock during first infusion of chemotherapy in a patient with Hodgkin's lymphoma: an unusual evenience

G Giulio Binaghi¹; S Cossa²; S Massidda³; D Pasqualucci¹; F Pilo³; F Sanna¹; E Angelucci³; M Porcu¹

¹G. Brotzu Hospital, Department of Cardiology, Cagliari, Italy; ²G. Brotzu Hospital, Department of Radiology, Cagliari, Italy; ³Businco" Oncology Hospital, Department of Haematology, Cagliari, Italy

Hodgkin's lymphoma (HL) is a common type of cancer of the lymphatic system. The outcomes of HL have improved due to advances in treatment (Tx). However, survivors have an increased risk for cardiovascular morbidity and mortality related to cardiotoxicity (CTX) of Tx, also because of use of anthracycline (AXA). Typically, CTX happens in mid- or long-term follow-up, but it can rarely occur also in an acute phase.

A classical HL was diagnosed in a 60 years-old male, ex smoker and with a previous cerebral TIA. The haematological scheduled plan consisted in 2 cycles of ABVD (Adriamycin; Bleomycin; Vinblastine; Dacarbazine) followed by a new staging. The pre-Tx cardiac evaluation was normal, showing no clinical, ECG and echocardiographic alterations. Near the end of the first ABVD-cycle, during the infusion of dacarbazine, the patient presented a cardiogenic shock characterized by pulmonary oedema, treated with infusion of inotropes (dobutamine followed by epinephrine) and diuretics. Transferred to our Cardiac Care Unit, the ECG showed no ST-abnormalities and echocardiography (TTE) revealed a severe left ventricular

dysfunction (EF 25%). In the following days, the patient was also treated with levosimendan with an improvement of haemodynamic and clinical status. In order to realize the cause of myocardial dysfunction, a coronary CT scan was performed, showing a coronary artery disease (CAD). Thus, an angiography was planned revealing a not significant two-vessel disease. The cardiac MRI, executed in the same days, demonstrated the recovery of systolic function, no oedema and no early or late gadolinium-enhancement. After 15 days the patient was discharged with a normal EF (56%) at the TTE. In the following weeks, he underwent a different haematological Tx with bendamustine, without any cardiac complication and with a discrete haematological response. Unfortunately, some months later, he was re-hospitalized because of a septic shock in absence of cardiac involvement, with a lethal outcome. In this case the acute and reversible ventricular dysfunction was probably due to the AXA-infusion, as other possible concomitant causes, such as significant CAD or myocarditis, have been excluded. The risk to develop a heart failure (HF) after AXA-containing Tx is well known. However, the CTX leading to HF, usually, develops after some weeks or months from the start of Tx, because of it is dose-dependent and produced by an oxidative stress. Indeed, a hyper-acute CTX, responsible for the critical scenario observed in our case, is very rare. Moreover, we attended to a full recovery of cardiac function, sign of a non-irreversible injury. To our knowledge, in literature there is only another similar case, describing an acute HF developed, however, 30 hours after an AXA-Tx, with a total recovery in some days. In these rare cases, the pathophysiology is still unknown. Further in-vitro and clinical studies are needed to understand and prevent the events of hyper-acute AXA-CT.

1860

Acute heart failure in patient with giant left atrial mass

M Marta Menna¹; A Posteraro¹; A Granatelli¹; P Crisci¹; S Leombruni¹

¹S. Giovanni Evangelista Hospital-Tivoli, Cardiology Unit, Rome, Italy

1. A 49-year-old man was evaluated for hacking cough and exertional dyspnea for a few months and palpitations and orthopnea for two weeks especially at night, in supine position. A recent chest x-ray showed an enlarged cardiac shadow.

2. The outpatient evaluation revealed a blood pressure of 105/70 mmHg, irregular heartbeats and an elevated heart rate. The electrocardiogram showed an high heart rate atrial fibrillation (150 bpm) and widespread alterations of ventricular repolarization.

The transthoracic echocardiogram revealed a large atrial mass inhabiting the majority of the left atrium volume. The mass had round shape, irregular profile, inhomogeneous echogenicity and large planting base on the atrial septum. Its low mobility during cardiac cycle was due to its dimensions: longitudinal diameter was of 82 mm and a transverse diameter of 62 mm, resulting in almost complete occlusion of the left atrium, that was severely dilated. The Doppler analysis of mitral valve function revealed a moderate mitral functional regurgitation. Left ventricle dimensions were normal, but ejection fraction, estimated according the Simpsons' rule, was severely reduced (20%), due to diffuse hypokinesia.

3. The echocardiographic characteristics of the mass (localization in left atrium, planting base on the atrial septum, round shape, irregular profile, inhomogeneous echogenicity), lead the diagnosis of myxoma. On the other hand it could not be excluded the diagnosis of a thrombotic mass (the patient's rhythm was atrial fibrillation) or another tumoral mass.

4. After an initial treatment with low doses of beta-blockers and digoxin to obtain the rate control, heparin sc and diuretics, the patient was referred to the Cardiac Surgery Unit. A chest TAC-PET examination excluded an extracardiac diffusion of the mass. After the surgical removal of the mass, the post-operative histological examination confirmed the diagnosis of myxoma. The post-operative period ran without complications. Two months after the surgical intervention the echocardiographic control showed an improvement of left ventricle function (ejection fraction of 40%).

5. This case is particularly interesting for the unusually dimensions of the mass and the clinical presentation with increasing symptoms of heart failure.

Left atrial myxomas, are the most common benign primary heart tumors. Because of nonspecific symptoms, early diagnosis can be difficult. Symptoms may occur at any time, but often they occur according to changes of body position and may include shortness of breath, palpitations, syncope and chest pain. The echocardiographic diagnosis should be integrated by a transesophageal examination to better define the characteristic of the mass and to exclude multiple masses. The surgical treatment is indicated for the high risk of embolization related with the mass.

Early manifestation of restrictive cardiomyopathy in young patient with light chain deposition disease

S Sofiya Lypovetska¹; M Hrytsenko¹; I Hrytsenko¹

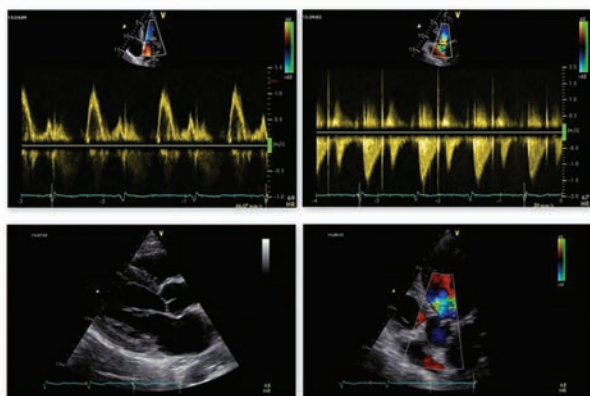

¹Terнопil State Medical University, Ternopil, Ukraine

A 30 years old male presented with exertional shortness of breath and general fatigue which extremely progressed over the past 2 weeks in February 2016. In September 2015 he was diagnosed with light chain deposition disease (LCDD), identified as paraproteinemia with pathological kappa/lambda ratio and renal

dysfunction. There were no significant clinical changes of respiratory and cardiovascular systems, except arterial hypertension, at first occurred in March 2015. Physical exam: BMI- 23.5, BP 155/90 mm Hg, HR 72, paleness of skin, no other changes. Light chain's diagnostics: free kappa light chain – 164 mg/l, lambda – 10.9 mg/dl, kappa/lambda ratio 15.05. Bone marrow biopsies suggested an underlying plasmocytoma: presence of 18 % of pathological plasma cells. ECG – regular sinus rhythm with HR 75, no significant changes. Thoracic echo: moderate enlargement of left atrium (46 mm), minimal mitral insufficiency, normal large left ventricle (LVEDD 47 mm), PW -14 mm, IVS -15 mm, EF - 65 %. Restrictive diastolic dysfunction. Pulmonary hypertension – 46 mm Hg. These echocardiographic findings suggested development of restrictive cardiomyopathy in patient with LCDD, primarily manifested with nephropathy. During last 5 months renal disorder has been progressively increased: eGFR falls down from 60 to 30 ml/min/1.73m².

LCDD is a monoclonal proliferative plasma cell disorder characterized by tissue deposition of light chain immunoglobulins, predominately in the tubular basement membranes of the kidneys. This case shows that cardiac involvement can present early in the course of disease as a pattern of restrictive cardiomyopathy. The differential diagnosis includes idiopathic hypertrophic cardiomyopathy, amyloid heart disease, Fabry's disease, Loeffler's endomyocardial fibrosis etc. Endomyocardial biopsy is the gold standard to differentiate between specific histopathologic entities in all cardiomyopathies. In myocardial LCDD light chain fragments mostly kappa chains do not organize into amyloid fibrils, but form granular deposits. In contrast in primary AL amyloidosis mostly lambda chains organize into fibrillar structure that are deposited predominantly perimycytic in patchy pattern. Light chain deposits are amorphous, Congo red negative, but positive to light chains on immunofluorescence examination on snap frozen biopsies. Our patient had renal biopsy, which approved LCDD. There is no specific treatment of cardiac involvement of LCDD, in particular conventional chemotherapy regimens for multiply myeloma, combined with classic heart failure therapy. Our patient has finished course of chemotherapy, now he receives Privigen, Valsartan 160 mg, Concor 2,5 mg.

LCDD of the myocardium is a rare cause of restrictive cardiomyopathy, associated with impaired renal function and underlying plasma cell dyscrasia. In the majority of cases cardiac involvement is very detrimental, reducing therapeutic options and survival.

Cardiogenic shock developed 24 hours after initiation of capecitabine therapy

A E Aura Elena Vijiia¹; A G Nestoruc¹; C A Teodorescu¹; S Iancovici¹; R Onut¹; G Tamasescu¹; E Weiss¹; M Dorobantu¹

¹Emergency Clinical Hospital Floreasca, Cardiology and Internal Medicine, Bucharest, Romania

Capecitabine is a chemotherapeutic agent widely used to treat gastrointestinal and breast malignancies. It is the oral pro-drug of 5-fluorouracil, with similar cardiac toxicity. We present the case of a patient who developed cardiogenic shock shortly

after capecitabine administration, with rapid resolution and complete normalization of left ventricular function.

A 48 year-old patient was admitted to our unit with signs and symptoms of acute heart failure and hemodynamic instability, 24 hours after the initiation of capecitabine therapy, which had been prescribed for gastrointestinal cancer. He had no history of heart disease and he had a normal echocardiogram during a routine check-up before starting chemotherapy. The physical examination revealed signs of shock with a blood pressure of 70/40 mm Hg. The initial evaluation showed nonspecific ST-T wave changes on his ECG and normal levels of cardiac biomarkers. His transthoracic echocardiogram revealed a dilated, globally hypokinetic left ventricle (LV), with a severely impaired systolic function (EF=23%). Over the course of 7 days of treatment, inotropic support included, his clinical status came back to normal, with complete normalization of his LV systolic function.

The spectrum of cardiac toxic effects of capecitabine varies from coronary thrombosis and coronary vasospasm to toxic myocarditis, arrhythmias, cardiogenic shock and sudden cardiac death. The cardinal symptom associated with capecitabine administration is chest pain, while acute heart failure and cardiac arrest are less frequently reported. Several mechanisms have been proposed for capecitabine cardiotoxicity, including direct myocardial injury, autoimmune phenomena and coronary vasospasm. Predisposing factors for the risk of cardiac toxicity are not clear.

Our patient presented with cardiogenic shock, requiring ICU admission and inotropic support. He had no clinical or electrocardiographic evidence of coronary vasospasm, while his cardiac biomarkers' dynamic wasn't consistent with acute myocarditis. We think that the underlying mechanism was mainly direct toxicity to the myocardium. His follow-up echocardiogram performed 7 days after admission revealed normal systolic function (EF=56%) without evidence of wall motion abnormalities.

Capecitabine-induced cardiotoxicity is a rare but potentially fatal complication; all patients should undergo echocardiographic evaluation before starting chemotherapy and close follow-up is needed in order to avoid severe complications. Oncologists as well as cardiologists should be highly aware of this phenomenon and collaborate closely in order to ensure patients' safety.

Reverse takotsubo cardiomyopathy and cardiogenic shock with polyuria

NIL

N Naveen Velaga¹; CK Tan¹; HA Ong¹

¹Ng Teng Fong General Hospital, Singapore, Singapore

A middle aged Malay gentleman who is a known case of COPD (Chronic obstructive pulmonary disease), presented with worsening shortness of breath for 2 days and chest tightness. He presented late to the emergency. On admission he was in severe Respiratory acidosis with pCO₂ (partial pressure of CO₂) of 109.8 mmHg and pH of 7.010. He was hypotensive with blood pressure of 75/47 mm Hg, and polyuria (> 3.5 litres/day). High sensitivity troponin T was elevated at 843 ng/L (normal value is <15ng/L). NTproBNP is 4125 pg/mL. (Cutoff levels 900 pg/mL for ages 50-75 yrs with Positive prediction of 83%). His inflammatory markers were normal. His Electrocardiogram showed sinus rhythm with anterior Q waves in leads V2 and V3 and ST segment elevation in anterior precordial leads. Other blood tests are within normal parameters. Transthoracic echocardiogram revealed multiple regional wall motion abnormalities corresponding to multiple territories, basal, mid LV hypokinesis with apical hyperkinesis and LV ejection fraction of 45% (image). He was treated for the acute exacerbation of COPD. His hypotension is supported by a single vasopressor which was weaned off. Coronary angiogram showed minor coronary artery disease without any significant obstruction. He was diagnosed to have inverse (Reverse) variant Takotsubo cardiomyopathy based on the proposed Mayo clinic criteria. His polyuria in this setting of cardiogenic shock which could be secondary and attributed to the release of natriuretic peptides from stress cardiomyopathy which could be higher in basal variant since the myocardium involved is larger. The patient significantly improved with vasopressors and was discharged home in 3 days. This acute episode of heart failure is likely precipitated by COPD exacerbation for which he was given education and preventive measures. This case highlights the importance of recognition of basal variant of stress cardiomyopathy and its clinical implications. Many patients often require supportive measures till the acute stressor is dealt with.

Feasibility of a fast-track pathway of care of the patients with acute dyspnea using handheld echocardiography

C Cristian Podoleanu¹; I Coman¹; ZS Jeremias²; C Tarta¹; A Serdean¹;

I Grancea²; E Carasca²

¹Clinic Medical 4, Targu Mures, Romania; ²University of Medicine and Pharmacy, Targu Mures, Romania

Purpose: to evaluate the feasibility and diagnostic accuracy of a "fast-track" pathway of care of the patients with acute dyspnea requiring urgent cardiac evaluation with a handheld echocardiography (HHE) device compared to classic echocardiographic evaluation.

Methods: a prospective study was performed on 65 patients (41 females, mean age 68 ± 12 years) with acute dyspnea referred for urgent cardiac evaluation in a multidisciplinary hospital, in whom bedside ECG and HHE were performed, followed by classic echocardiographic evaluation.

Results: The mean waiting time till ultrasound examination was performed was 16 ± 6 minutes when using HHE compared with 45 ± 19 (p < 0.01) minutes by using classic ultrasound machine and the duration of the examination was shorter when using HHE: 15 ± 2 minutes vs. 21 ± 13 minutes (p < 0.1). The degree of correlation of the results was excellent in the case of left ventricular dilatation (kappa coefficient of agreement=0.85) and LV dysfunction (k=0.82) and good when valvular abnormalities were found (k=0.67)

Conclusion: handheld echocardiography can speed up the diagnostic pathway in patients with acute dyspnea and to provide reliable data to assess the severity of the underlying mechanism of acute dyspnea.

Heart failure in women and men during acute coronary syndrome: interaction for long-term cardiovascular mortality (The ABC-4 Study on Heart Disease)

G Giuseppe Berton¹; R Cordiano²; F Cavuto³; F Bagato¹; S Mastrosimone¹

¹Conegliano General Hospital, Conegliano, Italy; ²Adria General Hospital, Adria, Italy; ³Bassano General Hospital, Bassano, Italy

Background: Natural history studies have suggested important differences in survival between men and women in a broad spectrum of heart failure (HF) severity. Nonetheless, the relationship between gender and HF for adverse prognosis after acute coronary syndrome (ACS) has not been thoroughly examined, especially in the long term. We investigated the gender-based differences in the association between HF during ACS and post-discharge, long-term cardiovascular (CV) mortality.

Methods: The present study included 557 patients enrolled in three intensive coronary care units and discharged alive. HF during ACS was evaluated by Killip class and left ventricular ejection fraction (LVEF). Interaction between gender and HF after 15 years of follow up was studied using Cox models including a formal interaction term.

Results: Median age was 67 (interquartile range [IQR], (59–75) years, 29% were females, 37% had non-ST elevation myocardial infarction and 32% Killip class>1, and median LVEF was 53% (IQR 46–61). All but five patients were followed up to 15 years, representing 5332 person-years. Of these, 40.2% died of CV-related causes. Crude CV mortality rate was higher among women (52.2%) than men (35.3%; P<0.0001). At a univariable level, a negative interaction between female gender and Killip class for CV mortality was found [hazard ratio (HR)=0.51 (0.34–0.77), P=0.002]. In five multivariable models after controlling for age, main CV risk factors, clinical features, post-discharge medical treatment, and mechanical coronary reperfusion, the interaction was significant across all models [HR=0.63 (0.42–0.95), P=0.02 in the fully adjusted model]. LVEF showed no significant hazard associated with female gender on univariable analysis [HR=1.4 (0.9–2.0), P=0.11] but did so in all adjusted models [HR=1.7 (1.2–2.5), P=0.005 in the fully adjusted model].

Conclusions: Gender is a consistent, independent effect modifier in the association between HF and long-term CV mortality after ACS.

P1872

Prognostic value of plasma renin concentration (PRC) in patients with acute heart failure (AHF)

IK Ioannis Tsorlalis¹; CE Jackson¹; EM Freel¹; C Haig²; R Spooner³; I Ford²; R Fraser¹; E Davies¹; JM Connell⁴; JJV McMurray¹

¹University of Glasgow, BHF Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom; ²University of Glasgow, Robertson Centre for Biostatistics, Glasgow, United Kingdom; ³Gartnavel General Hospital, Department of Biochemistry, Glasgow, United Kingdom; ⁴University of Dundee, School of Medicine, Ninewells Hospital and Medical School, Dundee, United Kingdom

Purpose: PRC is an independent prognostic factor and superior to plasma renin activity in predicting outcome in patients with chronic heart failure. The prognostic significance of PRC in patients with AHF is unknown. We examined the prognostic utility of PRC, in conjunction with other prognostic factors, in patients with AHF.

Methods: Consecutive patients admitted with suspected AHF were invited to participate in an observational study. A confirmed diagnosis of AHF required typical clinical findings and a BNP >100pg/ml. Exploratory data analysis revealed PRC was positively skewed and was analysed as log(PRC) in a continuous fashion, or as \leq median/ >median (binary). The prognostic importance of PRC was analysed in a univariate Cox proportional hazard model and then in a multivariate model including independent markers of all-cause mortality (age, systolic blood pressure, history of chronic obstructive pulmonary disease, serum urea [BUN], troponin, log(BNP) and haemoglobin). These prognostic variables were identified by backwards selection in a multivariate model with predetermined variables not including PRC.

Results: 722 patients were enrolled in the study. The median (IQR) follow-up was 998 (365-1217) days. A PRC measured during hospital admission was available in 689 patients. The median (IQR) PRC was 47.3 (13.0-177.3) mIU/L. Univariate analysis demonstrated that higher log(PRC) and PRC >median predicted higher mortality (Table). In multivariate analysis both PRC variables remained predictive of mortality.

Conclusion: PRC adds independent predictive information to that obtained using established prognostic variables in AHF, including BNP. This finding raises questions about the contribution of incomplete renin-angiotensin system (RAAS) blockade or RAAS escape to the high mortality after hospitalization for AHF.

Table

Variable	HR (95% CI)	P-value
Univariate analysis		
\leq median PRC (vs > median)	0.62 (0.50 - 0.76)	<0.001
Log(PRC)	1.11 (1.06 - 1.15)	<0.001
Multivariate analysis		
\leq median PRC (vs > median)	0.72 (0.56 - 0.94)	0.015
Log(PRC)	1.08 (1.03 - 1.13)	0.003

Hip fracture and heart failure

A M Garrido Castro¹; P Losada Mora¹; JL Carrillo Linares¹; M Jimenez¹; J M Garcia Pinilla¹

¹University Hospital Virgen de la Victoria, Cardiology, Internal Medicine, Malaga, Spain

Introduction: The proximal femoral fracture or hip fracture is one of the major health problems of the elderly population. Lead to an increase in morbidity, mortality, functional impairment, costs and increases the degree of dependency and institutionalization of these patients a year of the fracture. Medical complications during hospitalization are usual. Episodes of heart failure are among the most frequent complications.

Objectives: Analyze the prevalence of episodes of heart failure among patients admitted for hip fracture and a history of heart failure based on whether they were monitored by Internal Medicine or Cardiology before decompensation.

Material and methods: A descriptive analysis of patients admitted for hip fracture in the Trauma and Orthopedic Unit that had a history of heart failure decompensation and performed an episode during hospitalization. Those patients who had a previous monitoring by Internal Medicine and Cardiology, with those cases were Internal Medicine and Cardiology were asked for dyspnea or edema, with the final diagnosis of decompensated heart failure: two groups were compared.

Results: From June 2008 to December 2014, 990 patients admitted for hip fracture were presented to Internal Medicine and Cardiology. Of these patients, 79 (7.9%) had a documented history of heart failure. 34.1% (27p) developed heart failure during admission, of which 44.4% (12p) were in prior to the episode monitoring and 55.6% (16p) developed in the acute phase.

Conclusions: There is a slight decrease in the prevalence of cardiac decompensation in patients admitted for hip fracture and a history of heart failure if a previous follow up is performed by Internal Medicine and Cardiology.

P1874

Prognostic value of procalcitonin in a heart failure cohort

I Torres-Courchoud¹; C Josa-Laorden¹; I Gimenez-Lopez²; A Sola³; J Rubio-Gracia¹; J Puente-Lanzarote¹; M Sanchez-Martel¹; F Ruiz-Laiglesia¹; M Martinez-Marin¹; JI Perez-Calvo¹

¹Clinical University Hospital Lozano Blesa, Zaragoza, Spain; ²University of Zaragoza, Zaragoza, Spain; ³University Hospital of Bellvitge, Barcelona, Spain

Introduction: Recent studies have shown that Procalcitonin (PCT) rises in some noninfectious inflammatory conditions such as Heart Failure (HF). Proinflammatory cytokines and endotoxins are released from congestive bowel and stimulate PCT synthesis, hence higher levels could be related to severity of HF.

Purpose: To analyse prognostic value of PCT concentrations measured during acute heart failure (AHF) and after stabilization.

Methods: Prospective study including patients consecutively admitted for an AHF. PCT was measured during first 24 hours of admission and one month after discharge. Patients were followed-up for unless 12 months. We assessed prognosis (one year mortality and readmission rate) according to concentrations of PCT during acute and stable phase of HF. SPSS 20.0 version was used for statistic analysis.

Results: One hundred and fourteen patients (47.4% men), mean age 78.32 years (CI 95% 77-80) were included. PCT was similar between patients admitted for decompensated AHF, either due to infectious or non-infectious disease (0.19 vs. 0.08, p 0.212). Total mortality at one-year was 10%. A concentration of PCT at admission above the median significantly correlated with mortality (19.2% vs 3.4%, p 0.012). Among patients whose PCT levels remained above the median one-month after discharge, there was a non-significant higher mortality (5.4% vs 16.4%, p 0.07), but significant mortality rate in the third tertile of PCT (20% in the 3rd tertile vs. 2.6% in the 1st tertile, p 0.018). A cut-off concentration of PCT at admission of 0.062 ng/ml had the best sensitivity (75%) and specificity (62%) in predicting short-term mortality.

Conclusions: Procalcitonin concentration measured during AHF, but not after stabilization, correlates with higher risk of death at one year. PCT may help stratify the risk of death after an acute decompensation of HF.

Acute PCT Survival

P1875

Cardiogenic shock: what to expect?

A S Ana Sofia Lazaro Mendes¹; J Moura Ferreira¹; R Ferreira¹; S Costa¹; F Franco¹; D Ramos¹; M Pego¹

¹Coimbra University Hospital, Coimbra, Portugal

Purpose: Cardiogenic shock (CS) is a state of end-organ hypoperfusion due to cardiac failure. The definition of CS includes hemodynamic parameters: persistent hypotension (systolic blood pressure < 80 to 90 mm Hg or mean arterial pressure 30 mm Hg lower than baseline) with severe reduction in cardiac index (< 1.8 L/min/m² without support or < 2.0 to 2.2 L/min/m² with support) and adequate or elevated filling pressure (eg, left ventricular [LV] end-diastolic pressure > 18 mm Hg or right ventricular [RV] end-diastolic pressure > 10 to 15 mm Hg). The incidence of CS according to the registries is between 4-11%. The leading cause is acute coronary syndromes (ACS). The purpose of our study was to describe the characteristics of patients from a single center with the diagnosis of cardiogenic shock.

61687. Patients characteristics and evolution

Case	Sex / Age	BMI (m2)	Duration of support (days)/ Number of devices	Diagnosis	LVEF (%)	Preimplantation support	Lactate (mmol/l)	Creatinine (mmol/l)	GPT (mg/dL)	Complications	Final situation

7	Male / 32	1.6	4 / 1	Idiopathic DCM	18	DB	2.2	1.5	356	None	HT

BSA: Body surface area; RCM: Restrictive cardiomyopathy; STEMI: ST-segment elevation myocardial infarction; DCM: Dilated cardiomyopathy; LVEF: Left ventricular ejection fraction; NA: Noradrenaline; DB: Dobutamine; IABP: intra-aortic balloon pump; HT: Heart transplantation; IH: Intracranial hemorrhage

Methods: We reviewed retrospectively the medical records of 28 patients with CS who were hospitalized for heart failure in a single advanced heart failure unit between June 2009 and August 2013. Data regarding demographic, clinical, blood tests and echocardiograph parameters were collected in all patients. We measured the incidence of heart transplantation and cardiac death. Median follow-up time was 730 months.

Results: We retrospectively analyzed 30 patients (20 (66.7%) males) with a mean age of 64 ± 15.8 years old. At admission, 25% of the patients had ACS, 14.3% ventricular arrhythmias and 14.3% valvular disease. The mean ejection fraction was $32 \pm 13.7\%$ and atrial natriuretic peptide was 2457 ± 666 pg/mL. The mean hospitalization time was 12 ± 11 days. During the follow-up time, 8 patients (29%) with CS received a heart transplant. The long-term mortality was about 43%.

Conclusions: Despite improvements in reperfusion strategies and more frequent use of ventricular assist devices, mortality from CS remains high (around 50%). The heart transplantation can be a powerful tool in selected patients to reduce such catastrophic results.

P1876

"Should I stay should I go" is determined by beta blockers

H Hakki Kaya¹; MB Yilmaz¹

¹Cumhuriyet University, Cardiology, Sivas, Turkey

Background: Length of stay (LOS) remains as an important driver of heart failure (HF) hospitalization costs. The longer LOS also relates to higher rates of subsequent readmission and mortality. Therefore, it is important to determine those patients who will have longer LOS.

Methods: A total of 172 acutely decompensated, biventricular HF patients (33% females) were evaluated. Usage of Angiotensinogen Converting Enzyme Inhibitor/Angiotensin Receptor Blocker, Beta blocker, Mineralocorticoid Receptor Antagonist, diuretic before decompensation was recorded. The median LOS was six days, and the patients were classified into two groups: those with LOS ≤ 6 days and those with LOS > 6 days

Results: The mean age was 69 ± 11 years. Patients with longer LOS were older (72 ± 9 vs 67 ± 12 , $p=0.004$) had significantly higher BUN [35 (6-97) vs 27 (8-92), $p=0.018$], higher creatinine (1.6 ± 0.8 vs 1.3 ± 0.7 , $p=0.014$), higher systolic pulmonary artery pressure (48 ± 15 vs 42 ± 13 , $p=0.015$), and had significantly lower total cholesterol [115 (70-259) vs 151 (53-262), $p=0.004$], lower triglyceride [70 (33-298) vs 91 (32-379), $p=0.006$], lower hemoglobin and sodium levels (131 ± 3 vs 132 ± 4 , $p=0.001$; 12 ± 2 vs 13 ± 2 , $p=0.047$ respectively). Furthermore, the ratio of Atrial Fibrillation (AF) (60% vs 20%, $p<0.001$) and moderate-severe Tricuspid regurgitation (74% vs 57%, $p=0.041$) were higher in patients with longer LOS. Although the other medications prior to hospitalization were similar, the ratio of prior Beta Blocker (BB) usage were lower in patients with longer LOS than patients with shorter LOS (72% vs 89% , $p=0.008$). In the multivariate logistic regression with forward stepwise model; older age (OR: 1.051, 95%CI: 1.009-1.096, $p=0.017$), presence of AF (OR: 6.919, 95%CI: 2.867-16.696, $p<0.001$), lower sodium (OR: 0.855, 95%CI: 0.758-0.964, $p=0.010$) and lower hemoglobin levels (OR: 0.812, 95%CI: 0.669-0.986, $p=0.036$) associated with increased risk of longer LOS, but prior usage of BB (OR: 0.245, 95%CI: 0.087-0.688, $p=0.008$) associated with decreased risk of longer LOS in patient with biventricular HF after adjustment for variables found to be statistically significant in univariate analysis.

Conclusion: It would appear that in a cohort of acutely decompensated biventricular HF patients, prior usage of BBs independently predicted shorter LOS.

P1877

Early experience with percutaneous ventricular assist device Impella CP in cardiogenic shock

MA Maria Alejandra Restrepo Cordoba¹; FJ Hernandez Perez¹; J Segovia Cubero¹; M Gomez Bueno¹; JF Oteo Dominguez¹; J Goicolea Ruigomez¹; L Alonso Pulpon¹

¹University Hospital Puerta de Hierro Majadahonda, Cardiology, Madrid, Spain

Introduction: Cardiogenic shock (CS) is a therapeutic challenge with high mortality. Percutaneous ventricular assist devices (PVAD) are less invasive devices that could provide adequate hemodynamic support in these patients. The Impella CPTM is a new axial flow PVAD capable of providing up to 4L/min flow. The results of Impella CPTM support in CS are not disclosed.

Methods: We describe our initial experience with Impella CPTM in CS: Degree of support obtained, complications and final outcome of patients.

Results: From June 2014 to August 2015, 9 Impella CPTM were implanted in 7 patients with refractory CS (Average age 40 years [18-65]; 71% male). All patients were receiving combinations of catecholamine (71% noradrenaline) and 2 had intra-aortic balloon pump. The flow provided by the device was 2.9 ± 0.4 L/min (range 2-3.2). The mean duration of support was 7 days. Hemodynamic stabilization was achieved in 5 cases (71%) (patients with low body surface area [BSA], 1.4 to 1.7 m²), with mean arterial pressure between 65 and 94 mmHg two days post-implant, without increasing catecholamines. There was a device failure in two cases: One case presented acute arterial ischemia forcing its urgent withdrawal and in the second one the hemodynamic support provided was not enough (urgent heart transplant).

Complications were: hemolysis (5 cases), retroperitoneal bleeding (1), arterial ischemia (1), system dysfunction (1) and intracranial hemorrhage (1). Six patients got a heart transplant, they are all alive and without medium-term sequelae.

Conclusion: The Impella CPTM device provided sufficient hemodynamic support in 5 of 7 patients with CS of various etiologies, all with low BSA. The incidence of complications was significant. Larger series are necessary to establish the role of this PVAD.

P1878

Non invasive evaluation of hemodynamic effects of continuous positive airway pressure in patients with cardiogenic shock.

I Ilaria Battistoni¹; M Marini¹; L Angelini¹; M Shkoka¹; M Francioni¹; A Gili¹; S Moretti¹; GP Perna¹

¹University Hospital Riuniti, G.M.Lancisi Hospital, Department of Cardiology, Ancona, Italy

Background: beneficial effects of continuous positive airway pressure (CPAP) in patients (pts) with acute pulmonary edema (APE) have been already demonstrated. However, few it is known regarding the effects of CPAP on pts with cardiogenic shock (CS). This lack of data is mainly due to concerns about possible harmful hemodynamic effects in this subgroup of pts. The purpose of our study is to evaluate the hemodynamic effects of CPAP, measured by echocardiography, in pts with CS.

Methods: we evaluated 10 pts with acute CS to our ICU department of which. Acute HF was defined as a left ventricular ejection fraction < 0.45 associated with at least one criteria between dyspnea at rest, pulmonary rales or radiological signs of pulmonary congestion. CS defined as presence of almost three criteria: urine output < 0.5 ml/Kg/h, mean blood pressure < 65 mmHg,

cardiac index <1.8 L/min/m² without pharmacological support or <2.2 L/min/m² with support; LV filling pressures >15-18 mmHg, arterial lactates >2 mmol/L, central venous oxygen saturation <65%. Echocardiographic hemodynamic assessment was performed at presentation (T0) and at 30 minutes (T1), 24 h (T2) and 48 h (T3) after C-PAP beginning. Patients were treated with a different level of positive end expiratory pressure (PEEP 5-7, 5-10 mmHg) chosen according to clinical needs.

Results: mean cardiac output (CO) significantly increased during CPAP therapy (3.5 l/min at T0 vs. 4.16 l/min at T2; $p=0.02$) as well as mean stroke volume index (19.1 ml at T0 vs. 26.2 ml at T2; $p=0.04$), while the mean cardiac index (CI) increased but not significantly (2.05 l/min/m² at T0 vs. 2.48 l/min/m² at T2; $p=0.07$). There were no significant variation of systolic, diastolic and mean systemic blood pressure during the two days of treatment while mean ejection fraction improved at 48 h (26.1 % vs. 31.6%, $p=0.04$). The WP is reduced already at 30 min but not significantly (21.8 vs 16.0 at T2 $p=0.02$). Right ventricular function did not deteriorate after application of PEEP (TAPSE 14.6 ± 3.1 at T0 compared to 15.2 ± 1 to T1) and central venous pressure (CVP) has increased but not significantly (mean 8.6 ± 4.6 at T0 compared to 9.8 ± 4.8 to T1). Systolic pulmonary pressure did not vary significantly after C-PAP (38.72 ± 13.66 vs 37.31 ± 13.15 $p=0.8$). We have not had adverse cardiovascular events. All patients were discharged alive.

Conclusion: C-pap is safe in pts with CS and provides significant hemodynamic support even in this subgroup of patients. These encouraging results should be confirmed with larger numbers or maybe dedicated trials.

P1879

Urinary composition predicts diuretic efficiency of hypertonic saline solution with low-dose furosemide in patients with heart failure

T Tomotaka Ando¹; S Hirofumi¹; A Matsumoto¹; K Masai¹; Y Orihara¹; Y Okuhara¹; H Kondo¹; T Mano¹; M Ishihara¹; T Masuyama¹

¹Hyogo College of Medicine, Internal Medicine, Cardiovascular Division, Nishinomiya, Japan

Background: We have reported that combination of hypertonic saline solution with furosemide enhances diuretic effect of furosemide in patients with acute decompensated heart failure (ADHF). However, it is not yet clear that which factors determine the diuretic efficiency of the combination therapy.

Purpose: The purpose of this study was to identify predictive factors for diuretic efficiency of the combination therapy.

Methods: This study was a prospective, observational. Consecutive 29 patients with ADHF were enrolled. At baseline, patients were underwent biochemical tests and echocardiography. 500ml of 1.7% hypertonic saline containing 40 mg of furosemide were administered at speed of 20 ml/hour along with oral standard heart failure medication. We explored the associations between 24-hour urinary volume (24-h UV) and the baseline examination data. Patients were divided into 2 groups according to the median value of 24-h UV (median: 3300 ml).

Result: Mean 24-h UVs were 4081 ± 602 ml and 1539 ± 696 ml for group over the median and group the median and below, respectively. There were no significant differences in baseline, demographic data, serum creatinine levels, serum and urinary sodium levels, plasma osmolality, and echocardiographic parameters between 2 groups. There was a significant difference in urinary urea nitrogen-to-creatinine ratio (UUN/Cr) (7.2 ± 2.2 , 4.9 ± 1.7 respectively, $p < 0.05$). Receiver operating characteristics analysis identified UUN/Cr 5.1 as the optimal cut-off point for the prediction of 24-h UV more than the median (AUC 0.80 with sensitivity of 0.57 and specificity of 0.93).

Conclusion: This study suggested that UUN/Cr at baseline can be a predictive factor for the diuretic efficiency of hypertonic saline solution with furosemide therapy in patients with ADHF.

P1880

Defining the upper limits of "normal for their NT-proBNP" troponin T levels in acute decompensated heart failure patients

S Susan Stienen¹; T Tarvasmaki²; JP Lassus²; P Meregalli¹; YM Pinto¹; VP Harjola²; WE Kok¹

¹Academic Medical Center, University of Amsterdam, Department of Cardiology, Amsterdam, Netherlands; ²Helsinki University Central Hospital, Emergency medicine, Helsinki, Finland

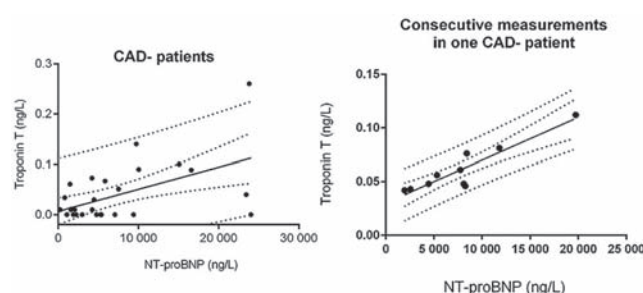

Background: Troponin T release is frequently observed in acute decompensated heart failure (ADHF) patients, and may be interpreted as the result of increased end-diastolic wall stress (EDWS), supply or demand ischemia, and/or the result of obstructive coronary artery disease (CAD). As increased EDWS is the main determinant of natriuretic peptide release, troponin release that is only dependent on increased EDWS should correlate with NT-proBNP. If corrected for the level of

NT-proBNP, the level of troponin release may thus be better interpreted as 'being normal for the level of natriuretic peptide' or as indicative of the presence of CAD. We investigated this question in ADHF patients without obstructive epicardial CAD.

Methods: Our study population was assembled from 2 European cohorts with ADHF patients. Patients were selected with both troponin T and NT-proBNP measured at admission, and in whom in-hospital coronary angiography (CAG) was performed ($n=80$). We assessed the association between troponin T (4th generation and high sensitive) and NT-proBNP in patients without CAD (CAD-) using linear regression analysis. CAD was defined as >70% stenosis in at least one vessel on CAG.

Results: A total of 29 CAD- patients (median age 60 (51-70), 59% male) was studied. Median troponin T and NT-proBNP levels were 0.029 ng/L (0.03-0.06) and 4776 ng/L (1765-9562) respectively. In CAD- patients, troponin T and NT-proBNP were correlated ($r^2 = 0.3$, $p = 0.003$) and troponin T levels did not exceed 0.24 ng/L up to an NT-proBNP level of 25000 ng/ml (Figure). In one CAD- patient with 10 admissions over 5 years, troponin T (up to 0.11) and NT-proBNP (up to 20000) were highly correlated ($r^2 = 0.84$, $p < 0.001$).

Conclusion: In ADHF patients without obstructive epicardial CAD, there is a significant correlation between admission troponin T and NT-proBNP. Using upper troponin T limits that are 'normal for their NT-proBNP' may increase the diagnostic yield of CAD in ADHF patients suspected for CAD.

Troponin T & NT-proBNP in CAD- ADHF pts

Serial measurement of ST-2 concentration in patients with decompensated acute heart failure (AHF)

A Slagman¹; J Searle¹; S Willun¹; F Holert²; M Mockel³

¹Charité - Universitätsmedizin Berlin, Division of Emergency Medicine (CVK, CCM); Department of Cardiology (CVK), Berlin, Germany; ²Charité - Universitätsmedizin Berlin, Department of Laboratory Medicine, Berlin, Germany; ³Charité - Universitätsmedizin Berlin, Division of Emergency Medicine (CVK, CCM), Berlin, Germany

Background: Sulfotransferase 2 (ST-2) is an evolving marker for risk stratification in patients with cardiovascular disease. As a marker of cardiac stress and cardiomyocyte fibrosis it seems to yield benefits in risk stratification and may also be useful for therapy guidance in patients with heart failure.

Methods: Prospectively, 99 patients who attended the Emergency Department of the Charité Virchow Klinikum with acute decompensated heart failure were enrolled in this study. Blood samples were taken at admission and, if applicable, after 1, 2, 3, 5, 10 days and on the day of discharge if thereafter. ST-2 was measured in August 2015 in EDTA-Plasma using a monoclonal sandwich ELISA assay (Presage® Critical Diagnostics, San Diego, CA). A follow-up was conducted at discharge and after 1 year.

Results: Patients had a mean age of 74 years (± 10) and the majority was male (54.5%; $n=54$). Within 1 year, 20.0% of all patients died ($n=17$) and 68.4% were rehospitalized ($n=54$). Median ST-2 values were higher in non-survivors (median 53.17 ng/ml; IQR: 32.68-80.97) as compared to survivors (76.91 ng/ml; IQR: 59.94-194.22) at admission and in following blood draws. ST-2 showed a falling pattern with an increase on day 10 in non-survivors while survivors had in median constant ST-2 values (see figure 1).

Conclusion: ST-2 might be helpful in early risk-stratification of patients presenting to the Emergency Department with acute decompensated heart failure. Additionally ST-2 might add to current diagnostic criteria used for therapy guidance in these patients (BNP, LVEF) and serial measurements might support therapeutic decision making and identification of patients with a poor prognosis.

Figure 1: serial ST-2 concentrations in

P1882

The effect of enhanced patient education and post discharge follow up on 30 day readmission rates after a heart failure admission.

A Dadosky¹; H Overbeck¹; GF Egnaczyk¹; S Menon¹; TM O'brien¹; EC Chung¹
¹The Christ Hospital, Cincinnati, United States of America

Background: Readmissions within 30 days after a heart failure (HF) discharge are associated with negative patient outcomes, increased hospital costs and likelihood of reimbursement penalties. With the goal of achieving greater patient engagement and knowledge, we implemented the HeartLink program; in this report, we analyzed the program's effect on the 30 day readmission rate.

Methods: Patients with the primary admission diagnosis of HF were identified through daily screening of the electronic medical record (EMR) or via consult order to the HeartLink nurses (1 registered nurse, 1 nurse practitioner). Patients discharged to care facilities or hospice were excluded. Between April and August 2015, 303 patients met the above criteria and received the standard HF care (written discharge instructions on core HF topics, daily HF education by staff nurses, 72-hour telephone follow up, and office follow up within 7 days of discharge). Of these patients, 75 were identified as being at higher risk of readmission based on chart review and a proprietary risk calculator that classifies patients as being low, medium, high and very high risk of readmission. These patients were personally seen by the HeartLink nurses for enhanced evaluation and treatment and formed the HeartLink group: 1) 15-60 minute one-on-one education session, featuring the teach-back method to focus on self-care. 2) screening for financial/social barriers to treatment plan (no scale, inadequate transportation, inability to fill medications, inability to read a food label), and 3) were referred to other disciplines (social work, dietician) as needed. All cause 30 day-readmissions to The our hospital were recorded for the control and intervention (HeartLink) groups.

Results: The 30 day readmission rates for the control (n = 228) and HeartLink (n = 75) groups were 18% and 12%, respectively. This reduction in readmissions is realized despite higher estimated risk in the HeartLink group: the proportion of patients assigned to high or very high risk of readmission was 21% for the control group and 41% for HeartLink.

Conclusion: In addition to existing best practice HF education and follow-up, incremental HF education provided prior to discharge by a certified HF RN/NP, is effective in reducing all-cause 30-day readmission rates.

P1883

MAGGIC score in heart failure: does left ventricular ejection fraction matter?

J G Julio Gil Goncalves Pereira¹; B Marmelo¹; A Delgado¹; H Antunes¹;
 L Abreu¹; L Goncalves¹; D Moreira¹; L Ferreira Dos Santos¹; J Costa Cabral¹
¹Hospital Sao Teotonio, Cardiology, Viseu, Portugal

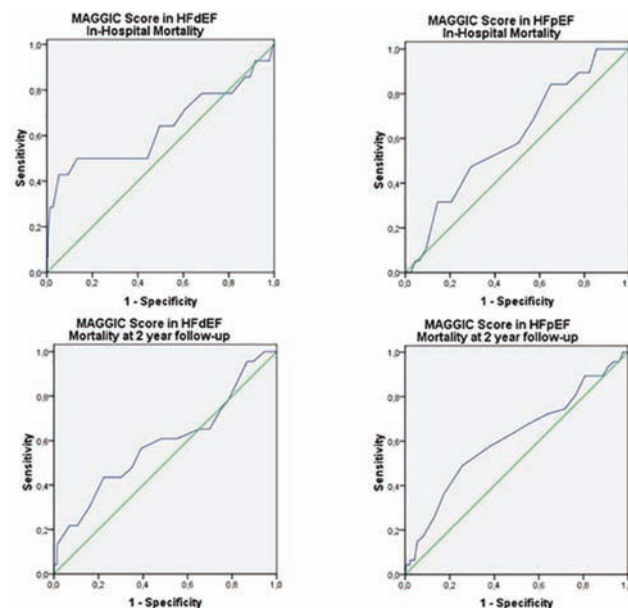

Introduction: In the MAGGIC meta-analysis[†], Pocock et al proposed the application of a risk score capable of predicting which patients with heart failure (HF) would have a worse prognosis.

Purposes: Application of the MAGGIC score in a population of patients hospitalized for HF. Correlation of the results with in-hospital mortality and after 2 years follow-up. Comparison of the accuracy of the score in patients with HF with preserved ejection fraction (HFpEF) and depressed ejection fraction (HFdEF).

Methods: The MAGGIC Score was calculated in patients hospitalized for heart failure. Clinical, analytical, and echocardiographic parameters were evaluated. The patients were divided into two groups: Group A with HFdEF vs Group B with HFpEF. A cut-off value for ejection fraction of 40% was used, which was the reference value used in the meta-analysis.

Results: Total sample of 1007 patients, 50.8% male, mean age 77 ± 10 years. When considering in-hospital mortality, the following ROC curves were ascertained: in the group with HFdEF, a AUC of 0.635 and $p=0.091$ and in the group with HFpEF, a AUC of 0.607 and $p=0.112$. Regarding mortality at 2 years follow-up, the ROC curves reveal a AUC of 0.586 and $p=0.180$ in the HFdEF and a AUC of 0.611 and $p=0.013$ in the group with HFpEF.

Conclusion: In this population of patients with HF, the score proposed in the MAGGIC meta-analysis did not reveal statistical power in predicting poor prognosis in both HF groups. It is extremely difficult to create risk scores, particularly in patients with HF, since it is a very heterogeneous group. More studies are needed to develop scores with actual utility in the real world.

P1884

Mechanical support by intra-aortic balloon pump in non-ischemic cardiogenic shock

G Giorgia Galli¹; LSD Jewbali¹; CA Den Uil¹; K Caliskan¹; O Manintveld¹; JJ Brugts¹; NMDA Van Mieghem¹; E Boersma¹; AA Constantinescu¹
¹Erasmus Medical Center, Cardiology, Rotterdam, Netherlands

Background: Intra-aortic balloon pump (IABP) did not improve survival in cardiogenic shock complicating acute myocardial infarction (AMI) in the IABP-SHOCK II trial. However, the effect of IABP in other settings of drug-refractory heart failure deteriorating to cardiogenic shock has been less investigated.

Purpose: Our aim was to evaluate haemodynamic changes and clinical outcomes of patients supported by IABP for non-ischemic cardiogenic shock.

Methods: We reviewed the charts of patients treated by IABP as the initial mechanical circulatory support between 2011 and 2015, excluding patients who had AMI or cardiac surgery in the past 30 days. We compared the patients who were successfully weaned or bridged to left ventricle assist device (LVAD) or heart transplantation (group 1) with those who died within 30 days or needed extracorporeal membrane oxygenation (ECMO; group 2). Continuous outcomes were evaluated by Mann Whitney U tests.

Results: We identified 27 patients supported by IABP for 5 days (interquartile range [IQR] 3-7). Lactate decreased from 3.2 (IQR 2.1-7.8) to 1.6 (IQR 1.2-3.5) mmol/L ($p<0.001$) at 12 hours and hyponatremia was resolved at 48 hours. In group 1, 17 patients (63%) were bridged to either recovery ($n=7$), LVAD ($n=4$) or transplant ($n=6$). In group 2, 10 patients (37%) died <30 days ($n=8$) or needed support by ECMO ($n=2$). The hemodynamic profile improved in group 1, as compared to group 2, already at 24 hours: lactate and heart rate were lower ($p=0.009$ and 0.006 , respectively), and fluid balance was more negative ($p=0.003$).

Conclusion: In severe heart failure sliding to cardiogenic shock, IABP can be used to improve the haemodynamic profile of patients, thus bridging them to recovery, advanced mechanical support or heart transplantation.

Fluid balance after IABP insertion

P1885

The effects of urapidil and nitroglycerin in acute heart failure patients with hypertension: a randomized multi-center parallel-control study.JINGYU He¹; Q Qi Hua¹; JIAN Qin¹; JING Li¹; YUJIE Zhou²; YAN Fu³; SHU Qin⁴; XM Chen⁵; JC Guo⁶; DEZHAO Wang⁷¹Xuan Wu Hospital, Capital Medical University, Department of Cardiology, Beijing, China People's Republic of; ²Beijing Anzhen Hospital, Department of Cardiology, Beijing, China People's Republic of; ³Tong Ren Hospital, Capital Medical University, Emergency Department, Beijing, China People's Republic of; ⁴First Affiliated Hospital, Chongqing University, Department of Cardiology, Chongqing, China People's Republic of; ⁵Ningbo First Hospital, Department of Cardiology, Ningbo, China People's Republic of; ⁶Luhe Hospital of Beijing Tongzhou District, Department of Cardiology, Beijing, China People's Republic of; ⁷Mentougou District Hospital, Department of Cardiology, Beijing, China People's Republic of**Background:** Acute heart failure (AHF) is a common cause of hospitalization with high morbidity and mortality. Evidence based treatment of AHF is less and Urapidil improves cardiac function in heart failure (AHF) by reducing cardiac load.**Objective:** To compare the hemodynamic responses, efficacy and safety of urapidil and nitroglycerin (NG) in acute heart failure patients with hypertension.**Methods:** 248 patients with New York Heart Association class from II to IV were consecutively enrolled in 10 study centers from January 2012 to December 2013. The patients were randomized to receive urapidil(mrco-pump velocity: $99.77 \pm 73.99 \mu\text{g}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$, n=123) or nitroglycerin(micro-pump velocity: $10.18 \pm 5.35 \mu\text{g}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$, n=125) within 48 hours. All patients were monitored for blood pressure (BP), heart rate, NT-pro BNP levels and ultrasonic cardiogram at baseline, 48 hours and 7 days; and major adverse cardiovascular events (MACE) at 7-day and 30-day following-up were recorded.**Results:** Baseline characteristics of patients were similar between groups. (1) NT-proBNP decreased following the treatment of urapidil or nitroglycerin, although the difference of NT-proBNP level was't significant between the two groups(P=0.85); Urapidil group had higher left ventricular ejection fraction (EF) and end-diastolic volume (EDV) than the nitroglycerin group at 48 hours and 7 days(all P<0.05), the end-systolic volume (ESV) also decreased significantly (P=0.039) in urapidil group at 7 days. (2)The changes in total cholesterol (TCHO) and Low density lipoprotein (LDL) level were significant between the two groups at 48 hours and 7 days.(ΔTCHO: 48h, P=0.016; 7day, P=0.010; ΔLDL 48h, P=0.031). (3) The creatinine level was significantly higher in urapidil patients at baseline (P=0.024), while the changes in creatinine at 48 hours and 7 days was similar among these two groups(Δcreatinine: 48h, P=0.69; 7day, P=0.74). (4) Within 30 days follow-up, the incidence of cardiac function deterioration and re-hospitalization was lower in urapidil group than in nitroglycerin group (P<0.001).**Conclusions:** Urapidil was as safe and effective as Nitroglycerin on the treatment of acute heart failure patients with hypertension. Urapidil demonstrated better efficacy than nitroglycerin on improving cardiac function, and decreasing the rate of heart failure deterioration and re-hospitalization after 30 days follow-up. While urapidil also had the trend to better the lipid metabolism and renal function during the treatment. This contribution of urapidil may due to its attenuating cardiac pre-/after-load.

P1886

Heart failure with preserved ejection fraction: patient characteristics, outcome and prognostic factors.R N Leao¹; R Pocinho¹; S Faustinho¹; J Ribeiro¹; J Almeida¹¹Hospital de São José, Internal Medicine Department, Lisbon, Portugal**Introduction:** Heart failure (HF) represents a major health concern. Classically associated with cardiac dilatation and impaired cardiac contractility, this clinical syndrome has been widely recognized to occur even when systolic function is preserved - HF with preserved ejection fraction (HFpEF). HFpEF is now known to be as frequent as HF with reduced ejection fraction (HFrEF) and is responsible for high morbidity and mortality. However, data on the prevalence, clinical characteristics, outcomes and risk factors of patients hospitalized with HFpEF are limited.**Purpose:** This study was performed to analyze epidemiological features and outcomes of patients with HFpEF, comparing to those with HFrEF and to identify prognostic factors.**Methods:** An observational study was conducted with data prospectively collected from an internal medicine department. All consecutive patients hospitalized with acute HF during the year 2014 were included. Demographic, clinical, laboratorial and transthoracic echocardiograms data were collected. To determine outcomes (rehospitalization, emergency admission, death), patients were followed for one-year. HFrEF was defined as ejection fraction $\leq 50\%$ and HFpEF as ejection fraction $> 50\%$, $E/e' > 15$ or $E/e' > 8$ and $\text{BNP} > 220 \text{ pg/ml}$.**Results:** 255 patients included, with 81 ± 8 years, 146 women. 61% had ejection fraction $> 50\%$. Patients with HFpEF were more likely to be older and female (p<0.01), to have history of coronary heart disease (CHD) (p=0.03), hypertension (p=0.05) or dyslipidemia (p=0.03) and to have an infectious disease as precipitating factor (p=0.01). Mortality and rehospitalization rates for patients with HFpEF (27.5% and 61.2%) weren't significantly different from those with HFrEF. The hospital length of stay was similar between the 2 groups. Patients with HFpEF had more episodes of decompensated HF requiring treatment at the emergency department (p=0.05). Univariate statistical analysis determined that dyslipidemia (p=0.03) and CHD (p=0.05) were associated with need of rehospitalization and chronic kidney disease (CKD) was also associated with mortality (p=0.02). Multivariate statistical analysis with logistic regression showed that mortality was related with CKD (OR(95% CI)=2.7 [1.1-6.5], p=0.03).**Conclusions:** Preserved systolic function was found in the majority of patients. Those were more likely to be older and female, with coronary heart disease, hypertension or dyslipidemia and to have an infectious disease. One-year readmissions and mortality were high both in HFpEF and HFrEF groups but patients with HFpEF required more often emergency care. In this population CKD, CHD and dyslipidemia were related with poor prognosis.

P1887

The association between cystatin c and in-hospital mortality in acute decompensated heart failure: 3-years follow-up studyH Selcuk¹; H Selcuk¹; O Maden¹; KG Balci¹; MM Balci¹; S Tekeli¹; EH Cetin¹; M Balci¹; N Karabiber¹; A Temizhan¹¹Türkiye Yüksek İhtisas Hospital, Cardiology Clinic, Ankara, Turkey**Objectives:** HF is often accompanied by impaired renal function, and the co-existence of both conditions is associated with an increase in cardiovascular risk and mortality. Cystatin C, an inhibitor of cysteine proteases of the cathepsin family has received considerable attention in recent years as a more accurate measure of renal function than serum creatinine based estimations. The present study aimed to investigate the relationship between in-hospital mortality in patients with ADHF and both cystatin C and N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels. Another aim was to assess if the out hospital mortality was related to in-hospital levels of cystatin C at a regular follow-up period (36 months).**Methods:** Cystatin- C and NT-proBNP levels were measured in 57 consecutive patients hospitalized with acute decompensated heart failure (ADHF) with a glomerular filtration rate $> 30 \text{ ml/min/1.73m}^2$ admission. Every patient was clinically followed for 3 years, and the primary clinical endpoint for this study was defined as the combination of any death from heart failure readmission and/or other reasons.**Results:** During hospitalization 7 patients (12.3%) died. Patients who died during the in-hospital follow-up were more likely to be younger (47.4 ± 17.5 vs. 60.8 ± 15.8 , p=0.043) and more likely to have a prior cerebrovascular accident (28.6% vs. 6.0%, p=0.048). Moreover, those patients who died had lower sodium concentrations ($128.9 \pm 7.6 \text{ mmol/L}$ vs. $135.5 \pm 5.1 \text{ mmol/L}$, p=0.003), higher cystatin C ($1.62 \pm 0.62 \text{ mg/L}$ vs. $1.22 \pm 0.39 \text{ mg/L}$, p=0.023) and NT-proBNP levels ($1101.6 \pm 228.7 \text{ pmg/L}$ vs. $577.2 \pm 585.5 \text{ pmg/L}$, p=0.001) compared to survivors. In multivariate logistic regression analysis, no significant association was found between in-hospital mortality and NT-proBNP and sodium (p>0.05). However, cystatin C (OR: 12.311, 95% CI: 1.616- 93.764; p=0.015) and age (OR: 0.925, 95% CI 0.866- 0.990; p=0.023) were identified as independent predictors of mortality.

In correlation analysis, plasma cystatin C levels were correlated significantly with NT-proBNP ($r=0.324$, $p=0.014$) and GFR ($r=-0.638$, $p<0.001$) but not with age ($p>0.05$). During a constant follow-up period (36 months), 38 patients died. In-hospital cystatin C levels were compared between the survivors and the patients who died. At 12-, 24- and 36-months follow-up the baseline cystatin C levels did not differ according to the survival ($p>0.05$).

Conclusions: In patients with ADHF, assessment of in-hospital cystatin C levels may provide a better prediction of mortality compared to eGFR or NT-proBNP estimation. Although, higher cystatin C levels rendered relevant prognostic information in the setting of in-hospital adverse events, the prognostic significance of this marker did not persist during the post-discharge follow-up.

Predictors of in-hospital mortality in a population of acutely decompensated heart failure patients

I Ilir Sharka¹; S Myftiu¹; A Quka²; A Duka¹; L Kresto¹; A Kristo¹; G Sulo³; M Xhafaj¹; J Seiti¹; I Balla¹

¹University Hospital Center Mother Theresa, Department of Cardiology & Cardiac Surgery, Tirana, Albania; ²University Hospital Center Mother Theresa, Tirana, Albania; ³Norwegian Institute of Public Health, Department of Global Public Health and Primary Care, Bergen, Norway

Background: despite current therapeutic strategies organ (pulmonary, renal, hepatic) dysfunctions (AODs) are commonly encountered in the settings of ADHF patients (pts) leading to serious adverse implications on in-hospital clinical course and prognosis.

Purpose: the aim of our study was to investigate the levels of AODs in ADHF pts in a tertiary cardiology center; the main predictors of their in-hospital mortality and the influence of AODs in the complicated clinical course.

Methods: we prospectively analyzed in-hospital clinical and laboratory data on 937 ADHF pts from 2012 to November 2015: monitoring for cardio-renal syndrome type I (CRS), cardio-hepatic syndrome (CHS), diuretic resistance (DR), MELD score, dyspnea severity scale (DSS) was performed on a daily basis. Patients were stratified into four levels: 1 (absence of AODs), 2 (CRS present), 3 (CRS and CHS present); 4 (CRS & CHS & DR present). A composite endpoint (use of intravenous inotropes, DR, a prolonged in-hospital treatment-a week, pulmonary edema (PE), cardiac death) was defined a complicated clinical course; Cox proportional hazards models were used to define the role of AODs on the complicated clinical course and in-hospital mortality.

Results: between dead and alive groups there were significant differences in: age (69.7±0.6 vs 57.4±0.9, $p<0.05$); CHS (70.1% vs 43.2%, $p<0.0001$); cardiac index <1.5 l/min/m² (63.6% vs 21.7%, $p<0.0001$); MELD score (39.6±7.5 vs 17.3±8.5, $p<0.0001$); DR (47.3% vs 12.4%, $p<0.0001$); PE (81.6% vs 48.3%, $p<0.0001$); no significant differences in sex (males) (65.7% vs 62.4%, $p>0.05$); diabetes (32.7% vs 29.4%, $p>0.05$); hypertension (18.7% vs 21.3%, $p>0.05$); ischemic cardiomyopathy (67.2% vs 69.3%, $p>0.05$). In Cox regression independent predictors of in-hospital mortality were: age HR 1.87 (95%CI: 1.15-2.34), hypotension on admission HR 2.3 (95%CI: 1.4-2.89), CRS HR 1.95 (95%CI: 1.3-3.04), CHS HR 2.1 (95%CI: 1.34-2.76), DR HR 2.43 (95%CI: 1.5-3.89), cardiac index <1.5 l/min/m² HR 2.64 (95%CI: 1.67-4.1). Comparing complicated clinical course HR (95%CI) of level

2 to 1 of ADHF pts was 1.57 (1.14-1.96), level 3 to 1 was 2.26 (1.62-3.78), and level 4 to 1 was 3.12 (1.89-4.37).

Conclusions: In our study main predictors of in-hospital mortality in ADHF patients were advanced age, hypotension on admission, cardio-renal syndrome and cardio-hepatic syndrome, diuretic resistance and low cardiac index. Presence of organ dysfunctions denotes an increased risk for complicated clinical course and should prompt adequate efforts to reduce costs, imposed by prolonged hospitalization and to improve survival.

Profile of patients admitted in emergency department with decompensated heart failure in a tertiary care centre in South India

A Abraham Oomman¹; R Narasimhan¹; I Sathyamurthy¹; B Suryaprabha¹

¹Apollo Hospitals, Greaves Lane, Chennai, TN, India- 600006., • Department of Cardiology and Internal Medicine, Chennai, India

Objectives: India is fast becoming the diabetes capital of the world. With clustering of multiple risk factors, noncommunicable diseases is a major cause of morbidity, mortality and health burden in India. Heart failure (HF) is the converging point of many cardiovascular diseases and constitute a major public health problem. This study aims at analysing the profile of HF in patients coming to the emergency room (ER) with HF in a tertiary care centre in India.

Materials and methods: This is a prospective study conducted between April 2013 to March 2014 in an Hospital in India. Patients coming to the ER with complaints of breathlessness and having history and clinical examination suggestive of HF were included. Four sets of parameters - history, physical examination, laboratory investigations and imaging were collected. Patients with primary pulmonary, hepatic and renal cause of dyspnoea and those with glomerular filtration rate less than 30 ml/min were excluded.

Results: 153 patients were admitted during this period of which 132 were enrolled and 21 were excluded. 68(51.5%) were more than 65 years and 92(69.7%) were male. 76.55% had hypertension, 59.8% had diabetes, 73.5% had coronary artery disease (CAD) and 31.8% were smokers. 86.4% had pedal edema on presentation. 69.7% had desaturation on admission and 22% presented with cardiogenic shock. Anemia was found in 40.25%, hyponatremia in 35.6% and hyperurecemia in 56.1% cases. Mean value of NT Pro BNP was 27786±/-8258 in expired patients and 10838±/-1616 in survivors. 28% had LV ejection fraction (EF) less than 30%. 95.5% had LV systolic dysfunction (EF <50%). 28.7% had biventricular dysfunction. 22(16.7%) patients died. Length of hospital stay was 20.4days in expired patients and 7.9 days for the discharged patients.

Conclusions: In India diabetes and hypertension are the important comorbidities and CAD is much more frequent than dilated cardiomyopathy in patients presenting to ER with HF. NT Pro BNP values were very high and in-hospital mortality was also high. This may indicate that patients may present late in the course of their illness.

P1890

The blood pressure paradox in acute heart failure

nil

W M Wei Ming Huang¹; SH Sung¹; HM Cheng¹; DY Lu¹; CW Lee¹; PF Hsu¹; WC Yu¹; CH Chen¹

¹Taipei Veterans General Hospital, Cardiology, Taipei, Taiwan ROC

Background: The lower blood pressure (BP) has been associated with poor outcome in patients with chronic heart failure, especially reduced ejection fraction (EF) and described as the "BP paradox". Whether that paradox is present in acute heart failure (AHF) remains changeable. We therefore investigated the rule of BP in patients hospitalized for AHF with both reduced and preserved EF.

Methods and Results: Our registry enrolled patients hospitalized for AHF. Hemographic and biochemistry data, echocardiographic characteristics, and BP on arrival were collected. Among a total of 2099 subjects (age 77±12 years, 66% men), 848 patients died during follow up. The group with higher BP had higher proportion of hypertension and diabetes, lower levels of hemoglobin and estimated glomerular filtration rate (eGFR), and higher left ventricular EF. As the systolic BP level was increased, the risk of mortality was decreased in those with reduced EF [HR and 95% CI per-1SD, 0.881 (0.778-0.998)] but not in those with preserved EF [0.951(0.860-1.051)]. The relation between systolic BP and mortality in the patients with preserved EF may be non-linear and U-shaped. (Figure 1)

Conclusions: The effect of systolic BP for mortality were different between those with reduced and preserved EF. The BP paradox might be absent in those patients hospitalized for AHF with preserved EF.

³Konstantopoulou General Hospital, Cardiology Department, Athens, Greece;

⁴Harefield Hospital, London, United Kingdom

Introduction: Early risk stratification of patients admitted with acute heart failure (AHF) is important. As the prognostic value of admission BNP is limited, there is a need for an admission score to early risk stratify AHF patients.

Purpose: To develop a risk score to early risk stratify patients admitted with AHF.

Methods-Design: 104 consecutive patients (age, 73.5 ± 12.0 years; male gender, 55.8%; LVEF $38.9 \pm 14.7\%$) admitted with AHF between January 2014 and July 2014 were enrolled in the study. Clinical, echocardiography and laboratory assessment were performed at admission. The endpoint of the study was the composite of death from any cause and/or rehospitalization for HF during 1-year of follow up.

Results: The independent prognostic factors of 1-year survival or rehospitalization are listed in the Table. Based on the odds ratios of the multivariable logistic regression we developed a model assigning 2 points for the absence of hypertension (HTN), 1 point for history of coronary artery disease or myocardial infarction (CAD/MI), and 1 point for an admission red cell distribution width (RDW) value ≥ 15.0 (median value). This simple score predicted the study end-point with an area under the curve of 0.80 (Figure).

Conclusions: These preliminary findings suggest that a simple admission score, consisting of HTN history, CAD/MI history, and RDW, may accurately risk stratify AHF patients. Further prospective validation of this score is necessary.

Variable	Odds Ratio (95% CI)	P Value
Hypertension	0.14 (0.05, 0.39)	< 0.0001
CAD/MI	3.88 (1.47, 10.24)	0.006
RDW ≥ 15.0	3.09 (1.22, 7.83)	0.02

Multivariable logistic regression

Background and aim: Leukocytes and their subpopulation have an important role in the progression of the heart failure (HF). Recent data show that the lymphocyte-to-monocyte ratio (LMR) have a prognostic value in patients with acute decompensated heart failure (ADHF). Our aim is to correlate LMR with the severity of disease in patients with HF.

Methods: We included 423 consecutive heart failure patients admitted to our clinic. LMR was analyzed in relation to NYHA class, NT-proBNP levels, ejection fraction (EF) and length of hospital stay (LOS), as markers of heart failure severity.

Results: The mean age was 69.47 ± 11.06 years. LMR was correlated with NYHA class ($r = -0.451$, $p < 0.0001$), NT-proBNP ($r = 0.485$, $p < 0.0001$), EF ($r = 0.307$, $p < 0.0001$) and LOS ($r = -0.372$, $p < 0.0001$).

In ROC curve analysis, LMR predicted ADHF with an AUC of 0.714 (95% CI 0.668–0.757, $p < 0.0001$), NYHA 4 class with an AUC of 0.745 (95% CI 0.700–0.784, $p < 0.0001$) and EF $< 35\%$ with an AUC of 0.646 (95% CI 0.597–0.692, $p = 0.0001$) with a cut-off value calculated by the Youden index of LMR < 2.79 , < 2.59 and < 2.41 , respectively. In multivariate logistic regression LMR < 2.5 was an independent predictor of ADHF (OR 4.14, $p < 0.0001$), and NYHA 4 class (OR 4.64, $p < 0.0001$).

Conclusion: LMR, a cost-effective and easily-accessible biomarker, is an independent predictor of ADHF and NYHA IV class in patients with HF.

P1893

Uric acid confers additive prognostic information in patients with acute heart failure

A D'antonio¹; E Erberto Carluccio¹; P Biagioli¹; S Coiro¹; A Murrone¹; G Bardelli¹; R Lauciello¹; C Riccini¹; G Alunni¹; G Ambrosio¹

¹Division of Cardiology, University of Perugia, Perugia, Italy

Background: Serum uric acid (UA) has been described as an important prognostic marker and useful for metabolic, and functional staging in both chronic and acute heart failure (HF). However, the predictive ability of serum UA when added to known predictors of HF mortality in the setting of acute HF is not well known.

Methods and Results: One-hundred and ninety-six patients (age 75 ± 11 years, 80% with ejection fraction $\leq 45\%$) admitted for acute HF were followed-up for a mean time of 20 ± 16 months after discharge. The primary end-point was a combination of all-cause death and/or admission for HF. Median UA values was 7.2 mg/dl (interquartile range 5.6 – 9.5). Serum UA was independently associate to the primary end-point (hazard ratio: 1.11, 95%CI: 1.05–1.18; $p = 0.001$). Using Cox regression analysis, by adopting an interactive stepwise procedure, the prognostic value of serum UA was incremental to that of clinical features (age, gender, congestion score, mean arterial pressure, copd, anemia, chronic renal insufficiency, previous HF admission), laboratory data (oxygen arterial saturation, glycaemia, azotemia at discharge, serum sodium concentration, BNP at discharge), and therapy (use of inotropes, nitroprusside, diuretic dose, absence of beta-blockers and ace-inhibitors) (Figure).

Conclusions: High serum UA levels confirms to be strong and independent marker of poor prognosis in patients with acute HF. More importantly, the addition of uric acid to well established prognostic marker in this setting seems to confer incremental prognostic power.

Additive prognosi power of uric acid

P1894**A case series of takotsubo cardiomyopathy from a southeast asian perspective**HS Hong Sang Chua¹; I Jaafar²; DM Periasamy²; T Ganesan²; E Sim²¹Ripras Hospital, Department of Surgery, Bandar Seri Begawan, Brunei Darussalam;²Gleneagles JPMC Sdn Bhd, Bandar Seri Begawan, Brunei Darussalam**Objectives:** Our retrospective study looks at all patients who were diagnosed with Takotsubo cardiomyopathy in our centre over a 6 year period from 2007 to 2013.**Materials and Methods:** Patients diagnosed with Takotsubo cardiomyopathy were identified through the hospital cardiovascular patient database prior to clinical data collection. The data was then tabulated into a spreadsheet for analysis with a statistics software package.**Results:** The patient selection process identified 12 patients comprising 10 female patients (83.3%) and 2 male patients (16.7%) with a mean age of 62.3 years (range 38-78 years). The most common presenting complaints were chest pain and dyspnoea (Both with 66.7%). All patients had risk factors for coronary disease with 66.7% of patients presenting with at least 2 risk factors for ischaemic heart disease. 7 patients (58.3%) had documented psychological stressors with the most common being issues related to the home (41.7%). 11 patients (91.7%) had electrocardiographic changes and elevated serum troponin levels. All patients underwent coronary angiography with 8 normal studies (66.7%), 3 patients (25%) with minor coronary artery disease involving less than 30% stenosis of a single coronary artery and 1 patient (8.3%) with significant coronary artery disease involving 2 coronary arteries. Left ventriculography in all patients (100%) showed a similar presentation of a dilated left ventricle with akinetic mid to apical left ventricular segments and a hyperkinetic basal segment in all patients. Echocardiographic studies at the point of admission showed poor left ventricular ejection fractions of 30-50% (median 35%). Subsequent echocardiography showed a median change of 78% (Standard Deviation 55.4%) with the mean time between echocardiographic studies being 88.1 days (Standard Deviation 123.8 days). 7 patients required inotropic support and out of these patients, 2 required further support with an intra-aortic balloon pump. Follow-up data was available for all 12 patients with a median follow up of 463.5 days (Range 17 to 1234 days) post-presentation to the centre.**Conclusion:** In our centre, we describe a condition that presents similarly to an acute myocardial infarction with some patients in cardiogenic shock. Investigations show typical echocardiography and left ventriculography findings at the time of admission that appear to be reversible following conservative management measures only.**CHRONIC HEART FAILURE****P1895****Disorders of neurohumoral indicators and their correction in patients with chronic heart failure**Z D Zulfiya Rasulova¹; UK Kamilova¹¹Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan**Purpose:** to study the dynamics of brain natriuretic peptide levels of Nt-proBNP (BNP), aldosterone (Al) and noradrenaline (NA) in the serum of patients with chronic heart failure (CHF) II and III functional class (FC) during the treatment.**Methods:** There were examined in 46 patients with CHF with FC II - III, who on top of standard therapy including β -blockers (bisoprolol) took - lisinopril or losartan. The first group consisted of 23 patients with II (12) and III (11) FC CHF, who took over 6 months with standard therapy (spiranolakton, β -blockers) - losartan (mean dose of this preparation was $69,0 \pm 27,6$ mg/day); the second group - 23 patients with II (12) and III (11) FC CHF, took on a background of standard therapy - lisinopril (mean dose of this preparation was $8,9 \pm 2,6$ mg/day).**Results:** Analysis of the neurohormonal factors in the dynamics of treatment showed a significant reduction in BNP, Al and NA in both groups. After 6 months of treatment, patients of the first group (n=23) had decreased levels of neurohormones (BNP, Al and NA) in patients with class II 43,7%, 21,2%, 22,5%, respectively; in patients with FC III by 31,7%, 42,6%, 9,9%, respectively. After 6 months of treatment, patients of the second group (n=23) had decreased levels of neurohormones (BNP, Al and NA) in patients with FC II by 36,5%, 21,2%, 22,5%, respectively; in patients with FC III by 35,2%, 31,2%, 8,3% respectively.**Conclusion:** The results showed that both groups had a significant decrease in BNP, Al and NA after 6 months of therapy. Combination therapy with β -blockers and ACE inhibitors or ARA has achieved no increase in activity studied neurohormones and significantly reduce BNP, Al, and NA 6 months of treatment. But at the same

time were no significant differences in the groups of patients treated with, losartan or lisinopril dynamics level of neurohormones.

P1896**Right ventricular dysfunction in heart failure with either reduced or preserved LV function**S Ghio¹; M Guazzi²; A Rossi³; FL Dini⁴; P Faggiano⁵; P L Pier Luigi Temporelli⁶¹Policlinic Foundation San Matteo IRCCS, Division of Cardiology, Pavia, Italy;²IRCCS, Policlinico San Donato, Heart Failure Unit, San Donato Milanese, Italy;³University of Verona, Department of Biomedical and Surgical Sciences,Cardiology Section, Verona, Italy; ⁴University of Pisa, Cardiac Thoracic andVascular Department, Pisa, Italy; ⁵U.O. Cardiologia, Spedali Civili e Cattedra diCardiologia, Università di Brescia, Brescia, Italy; ⁶Cardiac Rehabilitation Unit,

Salvatore Maugeri Foundation, IRCCS, Veruno, Italy

Aim: Aim of the present study was to evaluate the clinical and echocardiographic determinants of right ventricular (RV) dysfunction and its prognostic significance in a population of chronic heart failure (CHF) patients with either reduced (HFrEF) or preserved (HFpEF) left ventricular ejection fraction (LVEF).**Background:** The reasons why RV dysfunction develops in CHF are still largely unclear.**Methods:** The study included 1663 CHF patients due to ischemic, hypertensive heart disease or to idiopathic cardiomyopathy. LVEF was $\leq 40\%$ in 1130 patients (HFrEF), 41-49% in 149 patients and $\geq 50\%$ in 384 patients (HFpEF). Imaging of the right ventricle was performed by echocardiography; RV function was defined on transthoracic annular peak systolic excursion (TAPSE) and its normalization for pulmonary systolic pressure (PASP). All-cause mortality was the end point of survival analysis.**Results:** In the entire population, LVEF $\leq 40\%$, atrial fibrillation or ventricular stimulation, heart rate > 70 bpm, ischemic etiology and E wave deceleration time < 140 ms emerged as independent determinants of a reduced TAPSE at multivariate analysis. The same set of parameters was found to be statistically significant in HFrEF patients. Non sinus rhythm, heart rate > 70 bpm and in particular PASP > 40 mmHg which carried a sixfold increased risk, were the parameters associated with a reduced TAPSE in HFpEF patients. TAPSE/PASP proved to be a powerful predictor of prognosis both in HFrEF and in HFpEF patients.**Conclusions:** Non sinus rhythm and high heart rate are critical determinants of RV dysfunction in all CHF patients. In addition to these parameters, peculiar independent determinants in HFrEF are ischemic etiology and severity of the left ventricular disease, whereas in HFpEF pulmonary hypertension is strongly associated with reduced TAPSE. The normalization of TAPSE for PASP allows a powerful independent predictor of prognosis in all CHF patients, regardless of LVEF.**P1897****Circulatory power and exercise phenotypes: insights on disease severity in heart failure reduced ejection fraction**V Valentina Labate¹; PL Laforgia¹; V Donghi¹; G Generati¹; F Bandera¹;M Guazzi¹¹IRCCS Policlinico San Donato, heart failure unit, San Donato Milanese, Italy**Background:** Cardiopulmonary exercise testing (CPET) provides indexes of functional capacity. Circulatory power (CP=peak systolic BP X peak VO₂) shows additional prognostic value to peak VO₂. Ventilatory power (VP=peak systolic BP/VE/VO₂, cutoff 3,5) combined with CPET derived CP (cutoff 1750 mmHg*ml²*kg⁻¹*min⁻¹) allows to better stratify this population.**Aim:** To describe the relationship between peak exercise CP, VP and functional and echocardiographic phenotypes in HFrEF.**Methods:** 128 HFrEF patients (mean age 64.39 ± 11.88 ; male 71.1%; ischemic etiology 56%; NYHA class I, II, III, IV 33.3, 34.4, 29.0, 3.2; mean EF $32.4 \pm 7\%$) underwent maximal CPET on tiltable cycle-ergometer combined with exercise echocardiography.**Results:** we divided patients into three groups according to peak VP and CP using cutoff value of 3,5 and 1750 respectively: Group A=preserved VP and CP, B=impaired CP, C=both VP and CP impaired. Group C had worse bi-ventricular function already at rest. Group B showed lower right ventricular systolic function (peak TAPSE) and dynamic pulmonary hypertension (higher peak PASP) compared to group A patients, and more severe dynamic mitral regurgitation (MR). These echo-data corresponded to impaired exercise tolerance and ventilatory efficiency.**Conclusions:** Assessment of CP and VP, seems very useful to unmask different degree of impaired functional phenotypes. Patients exhibiting a combined CP and VP impairment are those with the worse phenotype of RV-pulmonary circulation uncoupling.

Pattern of endothelial progenitor cells and apoptotic endothelial cell-derived microparticles differentiates preserved from reduced left ventricular ejection fraction chronic heart failure

A Alexander E Berezin¹; A Kremzer¹; T Berezina²; T Samura¹; O Gromenko³

¹State Medical University, Zaporozhye, Ukraine; ²Private medical center VitaCenter, Zaporozhye, Ukraine; ³State Pathology Bureau, Zaporozhye, Ukraine

Background: Chronic heart failure (HF) remains a leading cause of cardiovascular (CV) mortality and morbidity worldwide. The aim of the study was to investigate whether the pattern of endothelial progenitor cells (EPCs) with angiogenic capacity and apoptotic endothelial cell-derived microparticles (EMPs) would be able to differentiate HF with reduced (HFpEF) and preserved (HFpEF) ejection fraction.

Methods: One hundred sixty four chronic HF subjects met inclusion criteria. Patients with global left ventricular ejection fraction 50-59% were categorised as the HFpEF group (n=79) and those with ≤45% as the HFpEF group (n=85). All biomarkers were measured at baseline. The flow cytometric technique was used for predictably distinguishing circulating cell subsets depending on expression of CD45, CD34, CD14, Tie-2, and CD309 antigens and determining endothelial cell-derived microparticles. CD31+/annexin V+ was defined as apoptotic endothelial cell-derived MPs, MPs labeled for CD105+ or CD62E+ were determined as MPs produced due to activation of endothelial cells.

Results: In multivariate logistic regression model T2DM (R²=0.26; P=0.001), obesity (R²=0.22; P=0.001), previous MI (R²=0.17; P=0.012), galectin-3 (R²=0.67; P=0.012), CD31+/annexin V+ EMPs to CD14+CD309+ cells ratio (R²=0.16; P=0.001), CD31+/annexin V+ EMPs (R²=0.11; P=0.001), NT-proBNP (R²=0.11; P=0.046), CD31+/annexin V+ EMPs to CD14+CD309+Tie-2+ cells ratio (R²=0.102; P=0.001), CD14+CD309+ cells (R²=0.058; P=0.001), and CD14+CD309+ Tie-2+ cells (R²=0.044; P=0.028) were found as independent predictors of HFpEF. Using multivariate Cox-regression analysis adjusted etiology (previous myocardial infarction), cardiovascular risk factors (obesity, type 2 diabetes mellitus) we found that NT-proBNP (OR 1.08; 95% CI=1.03 – 1.12; P=0.001) and CD31+/annexin V+ EMPs to CD14+CD309+ cells ratio (OR 1.06; 95% CI=1.02 – 1.11; P=0.02) remained independent predictors for HFpEF.

Conclusion: We found that CD31+/annexin V+ EMPs to CD14+CD309+ cells ratio added to NT-proBNP, clinical data, and cardiovascular risk factors has exhibited the best discriminate value and higher reliability to predict HFpEF compared with NT-proBNP and clinical data / cardiovascular risk factors alone

P1899

Reasons of under prescription in heart failure

J Marchand¹; K Solecki¹; B Mandoorah¹; D Vandenberghe¹; S Aguilhon¹; Y Audurier¹; C Breuker¹; S Cade¹; A Agullo¹; F Francois Roubille¹

¹University Hospital of Montpellier, Montpellier, France

Introduction: On 2014, 155 patients left our institute without recommended treatment for heart failure including converting enzyme inhibitor (CEI) and β -blocker. II.

Purpose: The objective of this study was to find reasons about those under prescriptions. III.

Material and Method: During the year 2014, 667 patients were admitted for HF. Among the 667, 121 patients left without CEI, and 64 left without β -blocker. We investigated likely reasons for no prescription of β -blocker or CEI. IV.

Results: On the 121 patients who left without CEI, 103 of them (85 %) had valid reasons: - Renal Failure (DFG < 30 ml/min: 43; DFG < 60 ml/min: 53; DFG defined by Cockcroft and Gault equation), - Renal Stenosis (1), - Hypotension (4), - Palliative treatment (1), - Bad hemodynamic tolerance (1). 17 patients (14%) didn't show any reason, and one (1%) showed an invalid reason. A CEI intolerance was reported but a Sartan could have been used which was not the case here. On the 64 patients who left without β -blocker, only 34 (53%) had valid reasons: - Bradycardia (19), - Severe Asthma (> 3) or severe chronic obstructive pulmonary disease, and β -mimetic treatment (6), - Severe Atrio Ventricular Block (4), - Under amines treatment (2), - Bad hemodynamic tolerance (1), - Under β -mimetic treatment (1), - Cardiogenic shock (1), - Palliative treatment (1). 16 patients (25 %) didn't show any reason and 14 (22%) showed invalid reasons: - 8 suffer from no severe asthma or no severe chronic obstructive pulmonary disease, - 3 suffered a cardiac decompensation, but β -blocker could have been used after the decompensation, (1 β -blocker at the admission not reintroduced when leaving; the others hadn't got β -blocker at the admission), - 2 suffer from no severe constrictive ventilatory disorders, - 1 had an allergic effect under β -blocker, but the effect was not detailed as minor or major. A minor effect could have been in favour of continuing the treatment. Accountability was not proven, allergy test or pharmacovigilance declaration hadn't been realised. We were interested to know if patients who left without β -blocker, could have left with Ivabradine instead. On 34 patients with valid reasons, 11 could take Ivabradine but only 1 get it. On 14 patients without valid reasons, 7 could take Ivabradine but only 2 get it. On 16 patients with unknown reasons, 11 could take Ivabradine but only 3 get it. V.

Conclusion: Most of patients who left without CEI or Sartan had valid reasons to no prescribe them. But prescriptions can still be improved. β -blockers prescriptions are less efficient and could be improved, and prescription of Ivabradine, when β -blockers can't be used, could be more considered. This work points out several under prescriptions with lack of information that could induce poor outcomes for patients. Better understanding underprescription should help us with improving our practices.

P1900

Effect of levosimendan on cardiac output in stable chronic heart failure according to baseline cardiac output

Orion Pharma Inc., The Swedish Heart and Lung Foundation, The Swedish Research Council, Stockholm County Council.

E Emil Najjar¹; C Hage¹; M Stalberg¹; E Ottenblad¹; A Manouras¹; I Haugen Lofman¹; L Lund¹

¹Karolinska University Hospital, Department of Cardiology, Stockholm, Sweden

Background: The intravenous inodilator agent levosimendan improves hemodynamics in acute decompensated heart failure. However, it is increasingly used for repetitive or intermittent infusions in advanced but stable chronic heart failure; without clear indication, selection criteria or effect. We tested the hypotheses that (1) levosimendan improves hemodynamics also in stable heart failure and (2) that the response is dependent on baseline cardiac output.

Methods: Twenty-three stable ambulatory patients (median age 56 [49-64] years, 4 women) with New York Heart association (NYHA) III or IV heart failure and reduced ejection fraction received a single 24-hour levosimendan infusion. Noninvasive hemodynamics with gas re-breathing technique, estimated glomerular filtration rate and N-terminal pro-brain natriuretic peptide (NT-proBNP) were measured before and after infusion.

Results: Levosimendan had the following effects overall: a significant increase in cardiac output (CO) ($+9.8\% \pm 21.6\%$; $p=0.026$) and decrease in NT-proBNP ($-28.1\% \pm 16.3\%$, $p<0.001$), total peripheral resistance (eTPR) ($-16.9\% \pm 18.3\%$, $p=0.005$) and mean arterial pressure (MAP) ($-5.9\% \pm 8.2\%$, $p=0.007$) but no change in eGFR ($+0.89\% \pm 14.0\%$, $p=0.955$). In patients with baseline CO below median, there was an increase in CO ($+15.8 \pm 20.2\%$, $p=0.025$) and a decrease in NT-proBNP, MAP and TPR but no change in eGFR. In patients with baseline CO above median, there was a reduction in NT-proBNP but no change in CO, MAP, eTPR or eGFR.

Conclusions: In patients with stable advanced heart failure, levosimendan improves hemodynamics, but the effect may depend on baseline hemodynamics. Patients who started with CO below median showed a more favorable change in different variables compared to those who started with CO above median suggesting that the effect may be greater in patients with lower baseline CO. This has implications for patient selection and trial design for intermittent or recurrent levosimendan treatment.

P1901

Ivabradine in the treatment of heart failure: effectiveness in heart rate

V Vanessa Carvalho¹; PM Sarmento¹; J Sa¹

¹Hospital Luz, Internal Medicine, Lisbon, Portugal

Few drugs have demonstrated benefits on survival of patients with heart failure (HF) in the last decade, when added to standard therapy with ACE inhibitor, beta blocker (BB) and aldosterone antagonist. Ivabradine, to decrease heart rate (HR) acting on the sinus node If channels, significantly reduces morbidity and mortality in HF patients with systolic dysfunction of the left ventricle (LVSD) in sinus rhythm (SR) and HR > 70 bpm, and in Coronary Heart Disease.

Objective: To evaluate the early introduction of ivabradine in relocation and HR reduction at follow up. Population and

Methods: A retrospective observational study of patients consecutively admitted with HF LVSD, RS and HR > 70 bpm between February 2012 and December 2013 were studied demographic variables, cardiovascular risk factors and therapy at admission, discharge and follow up.

Results: 19 patients were identified with HF and LVSD, with RS and HR > 70 bpm, including 4 women (22%) and 15 men (78%) with a mean age of 71.5 ± 5 years. In the pre-admission, 15.8% patients had already been treated with ivabradine BB +; 42% only with BB and 10% only with ivabradine. During hospitalization, 42% of patients taking BB started ivabradine and 31.6% patients started treatment with ivabradine BB +. At follow up, 5 patients (26%) remained Ivabradine+BB and there was a 28% decrease in CF; 4 (21%) with only ivabradine, HR decreased by 13%; only one patient remained only at BB, with a decrease of 15% HR. 2 patients discontinued the medication for bradycardia. Lost to follow up in 7 patients.

Conclusions: The data presented demonstrate that early introduction of ivabradine in hospital is safe and is an adjuvant drug to the beta blocker in HR reduction effectiveness. International recommendations advocating the addition of ivabradine to conventional therapy of IC to reduce the morbidity and mortality are discussed.

P1902

Advantage of "nitrate centered" over "diuretic centered" treatment of acute decompensated heart failure on clinical congestion, NT-pro-BNP and renal function markers

I Gorda¹; A Bezrodnij¹

¹O. O. Bogomolets National Medical University, Kiev, Ukraine

Background: Our purpose was to compare effects of prolonged optimal-dosed nitrate infusion plus low doses of iv diuretics ('nitrate centered strategy' - NC) and moderate doses of iv diuretics plus short intermittent nitrate infusion ('diuretic-centered strategy' - DS) on congestion symptoms, NT-proBNP and renal function markers (Cystatin C) in pts with acute decompensated heart failure (ADHF).

Methods: In single-blind parallel-group randomized study we assigned pts with 'wet-warm' ADHF to receive either optimal-dosed GNT infusion ≥ 72 hrs plus low doses of iv diuretic (≤ 80 mg pd for furosemide, NC group, $n=21$ per protocol, age 58.7 ± 1.1 yrs or moderate doses of iv diuretic (41-120 mg pd plus short intermittent (<0 hrs pd, ≤ 3 days) GNT (DC group, $n=54$ per protocol, age 63.2 ± 1.6 yrs). Primary endpoints were CVP at D4-6, NT-pro-BNP (ELISA) and serum Cystatin C at D4-6 and Dsc.

Results: Total 1st week furosemide dose in NC group was 194 ± 20.7 mg, in DC group - 393 ± 14.3 mg, duration of NTG infusion - 3.2 ± 0.3 vs 0.76 ± 0.07 days ($p<0.001$). Symptomatic hypotension occurred in 3 (23%) and 2 (3.4%) pts, correspondingly, and transfer to p.o. diuretics in 7.2 ± 1.3 and 8.6 ± 1.7 days ($p<0.05$). At 1-st day NT-pro-BNP was comparable increased in both groups (1238 ± 342 and 1172 ± 304 pg/ml, $p>0.05$, between NC and DC groups respectively) but its on-treatment decrease was more significant in NC group (at D4-6 - 871 ± 244 vs 1061 ± 271 pg/ml, $p<0.04$, and at Dsc - 747 ± 128 vs 871 ± 249 pg/ml, $p<0.05$). The same was true for CVP lowering from D1 (correspondingly, 198 ± 14.7 and 188 ± 12.9 mm H₂O, $p>0.05$) to D4-6 (77 ± 5.2 vs 96 ± 5.8 mm H₂O, $p<0.05$ between NC and DC groups). Similar trend had changes of serum Cystatin C.

Conclusion: In ADHF patients 'nitrate centered' strategy compared to 'diuretic centered' one is associated with more pronounced and more early clinical decongestion, NT-pro-BNP lowering and better dynamics of serum Cystatin C.

P1903

The association between the prognostic value and the Controlling nutritional status (CONUT) in elderly patients repeating hospitalization for decompensated heart failure.

J Jun Iwasaki¹; S Sakuragi²; K Enkoh¹; T Takamura¹; H Kobayashi¹

¹Onomichi municipal hospital, cardiology, Onomichi, Japan; ²Iwakuni Clinical Center, Cardiology, Iwakuni, Japan

The association between the prognostic value and the nutritional CONUT scores in elderly patients repeating hospitalization for decompensated heart failure.

Background: Malnutrition is associated with poor prognosis in various setting of patients. Recently, controlling nutritional status (CONUT) score is emerging as a simple method for assessing nutritional status of a variety of disease. However, the association between CONUT score and outcome in patients with heart failure (HF) has not been clarified.

Purpose: This study aimed to investigate the clinical significance of CONUT score in predicting outcome in elderly patients with HF.

Methods: 53 consecutive patients (mean 85 years) admitted to our hospital with acute HF aged 75 or older were examined. All patients were evaluated nutritional status using CONUT score at discharge. Patients were classified into two groups according to the CONUT score at discharge: Low-CONUT score (<5) group ($n=31$) and High-CONUT score (≥ 5) group ($n=22$). Clinical variables as well as cardiac outcomes after discharge, including cardiac death, admission for HF, was compared between the two groups.

Results: In all patients, LVEF on admission was $51 \pm 16\%$. BNP on admission level was 804 ± 620 pg /ml, which was decreased to 471 ± 68 pg /ml at discharge ($p=0.0008$). BNP at discharge was negatively correlated with the time to re-admission for HF ($r=-0.30$, $p=0.04$). Of this patients, 49 patients (92%) were identified as having mild to severe nutritional disturbances. There were no significant differences between Low-CONUT score group and High-CONUT score group in setting of age, duration of hospitalization, and LVEF. Kaplan-Meier analysis revealed that the cardiac event free rate in Low-CONUT score group was significantly higher than in High-CONUT score group (log rank $p=0.006$).

Conclusions: The results of this study suggested that the CONUT score at discharge is associated with cardiac outcome in elderly patients with HF.

P1904

Preferences and therapeutic targets in patients with heart failure. an physicians survey in mexico

E Chuquiere-Valenzuela¹; A Mendez-Ortiz¹; G Vieyra Herrera¹; M Chuquiere-Gil²; M Paola Vieyra-Hernandez³; J Mena Madrazo⁴; E Arrieta Maturino⁴

¹Instituto Nacional de Cardiología "Ignacio Chavez", Mexico City, Mexico; ²Instituto Tecnológico de Estudios Superiores de Monterrey, Escuela de Medicina, Monterrey, Mexico; ³Universidad Panamericana, Escuela de Medicina, Mexico, Mexico; ⁴Novartis, Mexico, Mexico

Heart failure (HF) is a multifactorial disease with high prevalence and morbidity and mortality, there is diversity in drug treatment, as well as therapeutic targets.

Objective: To determine therapeutic preferences and goals to achieve in HF patients in Mexico.

Groups	NT-pro-BNP, M \pm m, pg/ml	CVP, M \pm m, mmH ₂ O	Cystatin C, M \pm m ng/ml						
D1	D4-6	Dsc	D1	D4-6	Dsc	D1	D4-6	Dsc	
NC	1238 \pm 342	871 \pm 244**#	747 \pm 128**#	194 \pm 14,7	78 \pm 5,28**#	-	3271 \pm 517	3528 \pm 624 **#	2714 \pm 478 **#
DC	1172 \pm 304	1061 \pm 271	871 \pm 249**	186 \pm 12,9	97 \pm 5,89**	-	3314 \pm 578	3895 \pm 683 **	3071 \pm 614 **

* - $p<0.05$, ** - $p<0.01$ compared to D1; # - $p<0.05$, ## - $p<0.01$ compared to Group DC

Material and Method: A survey in different cities in Mexico, was attended by physicians from various specialties General Practitioners (GP), Internists (IM), Cardiologists (CA) and Others (Ot). All agreed voluntarily to their participation. Trained personnel interviewed personally to each physician. Questionnaire had closed and open questions. Interrogated: Monthly amount and proportion of patients with HF, patients with reduced Ejection Fraction (EF), Functional Class (NYHA), Their personal preference in: drugs and treatment target objectives. We declare any commercial bias. Data analysis made with SPSS statistical programme. Alpha error less than 0.05

Results: Interviewed 2053 physicians, in various Mexico cities. Their specialties were: GP 858 (41.8%), IM 461(22.5%), CA 439 (21.4%) Ot 295(14.4%). Monthly consultations average 178±2.64. observed in various pathologies. Most of respondents (98.1%) attended 75 patients with HF monthly, reported 42.9% of HF patients had reduced EF, 52.16% observed in cardiologists compared with other specialties (GP 40%, IM:43.8% and Ot:38.3%, $p < 0.005$). NYHA Functional class were: Class I 383(18.7%) Class II 755(36.8%); Class III: 620(30.2%) and CF IV 295 (14.3%). 1758 patients (85.7%) were functional class I-III. The mostly used drug was Diuretics(DIU) followed by ARB's, Digital (DIG), ACE and Betablockers (BB). In dual combination was: ARB + ACE; ACE + DIU; ARB + Calcium Channel Blocker (CaCB). In triple combination ARB+CaCB+DIU. The objective of the treatment was: Quality of Life (28%) Improvement in NYHA Class (25%), Symptom Control (17.4%), Survival (8.5%). The Reduction of (Re)Hospitalizations (4.8%) and Improvement of EF (5.2%)

Conclusions: In this first survey in a Latin Country American, we observe that therapeutic behavior of cardiologists is different in the different specialties, there is similarity in the therapeutic objective.

P1905

Influence of telemedicine support to CHF patients on hospitalisation

United4Health

M Pusnik-Vrcovnik¹; CSP Slemenik-Pusnik¹

¹General hospital, Internal medicine, Slovenj Gradec, Slovenia

Several international studies have confirmed that telemedicine- (TM) support to patients with Congestive Heart Failure (CHF) at home have positive effects for the patients and for a hospital providing the service. A telemedicine support service provided by a regional hospital was set-up in 2014 offering it to a population of 140.000 inhabitants in a rural region. Before inclusion into TM support services the patients in the intervention group were re-educated on their self-management possibilities. 134 CHF patients (intervention group) were receiving a TM support service for one year, in average for 402 days. The comparator group to them was the observed group itself, but in the period of one year prior to inclusion into the service. In the observed two-years period the patients received the recommended heart failure treatment. The TM services consisted of TM data capturing of blood pressure, heart rate, weight and oxygenation. Data were transferred to the hospital by a mobile phone without any intervention from the patient. Based on daily measurements the patients received, when needed, an advice or suggestion to change their therapy at home or to come for an unscheduled visit to a CHF clinic. Number of admissions (readmissions) to the hospital related to CHF and duration of hospitalisation (hospital days) was the primary clinical outcome observed. In the period of two years (one year prior to enrolment into TM support service and one year of using TM service) the observed cohort was hospitalised for 390.5 days with CHF as the primary diagnose, of which 316.7 were in the control period and 73.8 days in the intervention period. Number of admissions was 46 in the control and 13 in the intervention period. The results demonstrate a substantial reduction in number of admissions (readmissions) to the hospital (from 0.34 per year per patient to 0.1 ($p < 0.001$)) and a reduction in duration of hospitalisation for the patients in the intervention period (from 2.36 days/year/patient to 0.55 days ($p < 0.001$)). The results were achieved by early reactions to the worsening of the health condition detected through processing of TM service.

P1906

Low-dose anti-cytokine treatment impacts on heart failure with preserved ejection fraction in active rheumatoid arthritis

AR Aida Babaeva¹; MN Usachyova¹; KS Solodenkova²; MA Osadchuk²

¹Volgograd State Medical University, Volgograd, Russian Federation; ²I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Recent data suggest that anti-cytokines can improve cardiovascular outcomes in RA. Heart failure with preserved ejection fraction (HF-P EF) is common cardiovascular condition in patients with rheumatoid arthritis (RA). In our previous studies we revealed the correlation between RA severity and functional class of HF. The purpose of this study was to assess the efficacy of combined anti-cytokine therapy with preparation arthrofoon (extra-low dose of antibodies against TNF- α) and anaféron (extra-low dose of antibodies against IFN- γ) in RA pts regarding to clinical manifestation of HF-P EF.

Methods: 86 pts (67 female and 19 male aged 34-58 years) with determined active RA and HF-P EF had been randomized on two groups. The 1st group (46 pts) was

treated with arthrofoon+anaféron in addition to standard therapy of RA. The 2nd one (40 pts) received only standard anti-rheumatic drugs. We compared the symptoms and signs of RA activity and HF manifestation/deterioration in both group before and after 1 year course of the treatment.

Results: Baseline clinical and laboratory data were similar in compared groups. According to DAS28 index more prominent decrease of RA activity associated with decreased levels of TNF- α , IL-1, IL-6 had been revealed in the 1st group than in 2nd. 42 pts (91.3%) from the 1st group and 5 pts (12.5%) from the 2nd one demonstrated mild or moderate improvement of HF symptoms and life quality. The dynamics of mean distance in six-min walk test was from 232.6 m to 398.7m in the 1st group, from 233.7 m to 245.1m in the 2nd group. During 1 year period of monitoring none serious cardiovascular events were registered in the 1st group while in the 2nd one 3 pts (7.5%) were hospitalized due to complicated hypertensive crisis and deterioration of HF.

Conclusion: Combination of two preparations (arthrofoon+anaféron) with anti-cytokine properties can improve the course of HF-P EF in pts with active RA. The possible mechanism of this phenomenon may be associated with decreased activity of RA.

Development of bioartificial myocardium and ventricular support bioprostheses using nanobiotechnologies

J C Juan Carlos Chachques¹; A Bayes Genis²; N Lila¹; C Soler²; N Mirochnik¹; G Autret¹; C Semino³

¹AP-HP - European Hospital Georges Pompidou, Paris, France; ²University Hospital Germans Trias i Pujol, Barcelona, Spain; ³University Ramon Llull, Barcelona, Spain

Background: Post ischemic ventricular dilatation and adverse remodeling raises the need to assist the heart to decrease ventricular wall deterioration. In this way myocardial tissue engineering should play a key therapeutic role due to its capacity to reinforce or replace extracellular matrix.

Purpose: To develop biomimetic: 1) Cardiopatch, to reduce fibrosis and reinforce infarct scars, and, 2) Cardiac wrap bioprostheses, for ventricular support and myocardial regeneration in chronic heart failure (HF). This will be done using semidegradable scaffolds manufactured with polymers and Nano biomaterials.

Methods: Cardiopatch and ventricular support bioprostheses were evaluated in a sheep ischemic HF model. Biohybrid templates were created using semidegradable elastomers and self-assembling peptide nanofibers. Adipose Progenitor Cells (APC) was introduced inside the porous 3D membranes. Channeled scaffolds were proposed to guide the capillary network of the host tissue, a suitable microenvironment that mimics the extracellular matrix.

Results: Late gadolinium enhancement (LGE) on MRI was used to assess the volume of infarct scars related to ventricular mass. Results at 6 months showed in cardiopatch vs control group a significant reduction of the infarct volume size.

Histopathology: APC positive for red fluorescent protein were found inside the patch, into the infarct scars and healthy myocardium in treated group. Hence, APC were able to migrate from the cardiopatch to the nearby tissue. Integration of APC into the vessel structures was also observed in the patch, interconnected with myocardium. Thus, APC contributed to the formation of a capillary network between patch and myocardium.

Ultrasound studies of the treated group showed significant improvements in Stroke Volume, E/A ratio, EDT, E/E' ratio, LV VTI, and longitudinal strain compared with control group.

Conclusions: This study was designed for the creation of bioartificial myocardium. Firstly we have developed "cardiopatch" to reinforce or replace ischemic areas, and eventually repair congenital heart defects. Secondly we developed "bioprostheses" for ventricular support and myocardial regeneration. Mechanical, chemical and biological characteristics of biomimetic scaffolds are adapted for the LV or RV geometry, physiology and pathology, designed with the concept of "helical myocardial bands". Bioprostheses should limit ventricular dilatation and restore elliptical shape, reducing the risk of HF progression and the indication for heart transplantation

P1908

Comparison of angioedema in heart failure patients treated with sacubitril/valsartan or enalapril in PARADIGM-HF

M Packer¹; H Streefkerk²; C Thorburn²; V Shi³; W Zhou³; H Heike Schwende⁴; A Kaplan⁵

¹Baylor University Medical Center, Dallas, United States of America; ²Novartis Pharma AG, Drug Safety and Epidemiology, Basel, Switzerland; ³Novartis Pharmaceuticals Corporation, East Hanover, United States of America; ⁴Novartis Pharma AG, Basel, Switzerland; ⁵Medical University of South Carolina, Charleston, United States of America

Background: The PARADIGM-HF study showed that sacubitril/valsartan (LCZ696) is beneficial in heart failure (HF) patients with reduced ejection fraction. Inhibition of neprilysin, angiotensin-converting enzyme (ACE) or aminopeptidase may lead to

bradykinin elevation and increased risk of angioedema. Therefore, this was considered an adverse event of special interest in the PARADIGM-HF study.

Methods: PARADIGM-HF included 10513 eligible class II-IV HF patients (ejection fraction $\leq 40\%$, and mildly elevated NT-proBNP/BNP) in the enalapril run-in phase. After a 36h wash-out, 9419 patients entered the LCZ696 run-in phase and 8442 patients were, after a further 36h wash-out, randomized to blinded twice-daily treatment with LCZ696 200mg or enalapril 10mg. Suspected angioedema or angioedema-like events were reported by the investigators or identified by the sponsor and were adjudicated by an independent angioedema adjudication committee (AAC).

Results: Prior to run-in 77.3% of patients used ACE-inhibitors and 22.9% ARBs. Investigators reported 25 angioedema events during the enalapril run-in period (18.6 ± 6.3 days) and 29 events during the LCZ696 run-in period (30.3 ± 9.2 days). During the double-blind period (27 ± 11 months), 45 events were reported for enalapril and 48 for LCZ696. Of all 147 reported events, 54 were confirmed by the AAC as angioedema (run-in period 25/54, double-blind period 29/93), with 25 confirmed events for enalapril and 29 for LCZ696. The incidence of confirmed angioedema was higher in black patients than in non-black patients (Table). The majority of events were of mild severity, requiring no treatment or antihistamines only. In 5 patients (enalapril: 2, LCZ696: 3) angioedema required hospitalization, including 1 black patient, but no patient required mechanical airway support.

Conclusion: In PARADIGM-HF, the incidence of confirmed angioedema was low, with no severe cases. Black patients were at higher risk of angioedema events with both treatments. A wash-out period when switching treatment is considered important to avoid the risk of overlapping ACE- and neprilysin inhibition.

	Run-in Enalapril n = 10513	Double-blind LCZ696 n = 9419	Enalapril n = 4229	LCZ696 n = 4203
Confirmed angioedema: n (%) patients	15 (0.14)	10 (0.11)	10 (0.24)	19 (0.45)

Continuous flow left ventricular assist device for end-stage heart failure: mild-term outcome and quality of life.

M Bugetti¹; G Harmelin¹; E Bellanti¹; R Bessi¹; A Gambacciani¹; G Sani¹; M Bonacchi¹

¹University of Florence, Cardiac Surgery Unit - Dept of Experimental and Clinical Medicine, Florence, Italy

Introduction: Heart transplantation is actually the gold standard therapy for patients with end stage heart failure; unfortunately, the demands is much greater than the number of donors. The introduction of ventricular assist devices has changed the therapeutic possibilities for these patients. In this study, we evaluate the effectiveness and mild-term results of a continuous flow left ventricular assist device as definitive therapy.

Methods: We evaluate 178 patients who received a Jarvik 2000 FlowMaker between June 2008 and december 2015 as "destination therapy". Concerning the etiology of heart failure, 90 patients (50,4 %) had a post-ischemic heart disease, 69 patients (38,8 %) had an idiopathic dilated cardiomyopathy and 19 (10,7 %) other pathologies such as hypertrophic cardiomyopathy and muscular dystrophy. At LVAD implantation time, the average INTERMACS level was 3 ± 1.2 . Post-operative clinical and instrumental evaluation of each patient was made every 3 month after implantation. The assessment of quality of life was carried out with the Short Form-36 Health Survey questionnaire, administered at 3, 6 and 9 months after LVAD implantation.

Results: In 49 patients (27,8 %) the device has been implanted in a minimally invasive approach; in 100 patients (56,8 %), the device has been implanted without the extra-corporeal circulation. In 160 patients (90,9 %) a retroauricular connection to driveline was used. The average time on system was 441 days and the average

support time of patients discharged out of hospital was 599 days. The cumulative support time was greater than 210 years. Concerning the survival rate, at 1 year is 82%, 60% at 2 years and 54 % at 3 years. Results show a significant progressive improvement in functional and mental status with results, at 9 months from LVAD implantation, similar to those of a healthy population.

Conclusions: Clinical data suggest that technological evolution and an interdisciplinary approach to the patient could propose in the next years VAD therapy as a "gold standard" for end-stage heart failure.

P1910

Influence of the high blood pressure on the resistance to overload hypoxia

N Maksimovich¹; Y Maksimovich¹

¹Grodno State Medical University, Grodno, Belarus

The aim of the study was to evaluate the effect of high blood pressure on the performance of Serkin's sample.

Methods: Studies were conducted on 74 students, 56 of them where girls with systolic arterial pressure (APsyst) values recorded not more than 120 mmHg. The effect of increasing systolic blood pressure to 130 mmHg (n = 11) and up to 140 mmHg (n = 7) was studied. In students determination of the duration of breath holding on inspiratory (Stange's sample) or the first phase sample Serkin, the duration of breath holding immediately after 20 squats (second phase) and the duration of breath holding on inspiration after 1 minute of rest (third phase of Serkin's sample). Results. In girls with elevated systolic blood pressure up to 130 mmHg we observed shortening of the first phase to $47 \pm 11,0$ min, the duration of the second phase was $19 \pm 3,3$ min (39% of the first phase and the duration of the third phase was $-34 \pm 12,9$ min (76%). In students with increased systolic blood pressure (140 mmHg), we observed shortening of the first phase of the sample until $44 \pm 8,8$ min, the second phase - until $15 \pm 2,7$ min (34%), the third phase - until $27 \pm 6,7$ min (60%), $p < 0,05$.

Conclusions: The increasing of APsyst, contributes to poor Serkin's sample indicators characterizing the state of the respiratory and cardiovascular systems, which suggests that a correction of arterial hypertension, play a role in increasing the body's sensitivity to hypoxic load and promotes the development of heart failure.

Pharmacotherapy of the heart failure - what is the reality in the clinical practice in Slovakia.

J Gajdosik¹; A Dukat¹; T Szadocka¹; L Serugova¹; P Sabaka¹; F Simko²

¹Comenius University, 2nd.Dept.of Internal Medicine, Bratislava, Slovak Republic;

²Comenius University, 3rd.Dept.of Internal Medicine, Bratislava, Slovak Republic

Background: Despite the possibilities of the current pharmacotherapeutic measures of the heart failure patients and the current national guidelines for the complex management of these patients the morbidity and mortality is still extremely high.

Aim of the study was to study the pharmacotherapeutic approaches of the followed patients in their daily clinical practice in the country, as well as the adherence to the therapy compared to the current clinical guidelines.

Patients and methods: 6584 heart failure patients have been followed-up for the period of one year (2014-2015). 5692 (83%) pts were older 60 years, 1162 (17%) were younger 60 yrs.

Results: 6463 pts (94%) took the drugs affecting the renin-angiotensin-aldosterone system, From this sample 3882 (60%) took ACE-inhibitors, (majority were the pts younger 60 yrs of age in 69%, 54% were older than 60 yrs). 2581 pts (40%) took ARBs. Therapy of beta-blockers were in 6584 pts (77%), with 84% using them among younger 60 yrs. Mineralocorticoid antagonists took 1568 pts (23%). 4324 pts (63%) were on diuretic treatment, with the majority among older 60 yrs (85%). 1012 pts (15%) took digoxin (90% among pts older 60 yrs). 1012 pts took vasodilators (isosorbide-dinitrate) and only 218 pts were on ivabradine treatment.

Conclusion: the gap between the international and national clinical guidelines and the current clinical practice was seen from the daily care physicians.

P1912

Patients with non-ischemic heart failure in waiting list of heart transplant

PA Fedotov¹; MYU Sitnikova¹; MA Bortsova¹; YV Sazonova²; MA Simonenko²; TA Lelyavina¹; MA Karpenko²

¹Federal Almazov North-West Medical Research Centre, Heart Failure, Saint-Petersburg, Russian Federation; ²Federal Almazov North-West Medical Research Centre, Saint-Petersburg, Russian Federation

Purpose: to estimate predictors of death in patients with non-ischemic etiology of heart failure in waiting list of heart transplant (WLHTx).

Methods: From 2010 to 2015 in a Medical Research Centre in WLHTx included 128 patients. WLHTx 67 patients with non-ischemic heart failure: DCM - 74,6% (n=50), non-compact myocardium - 13,4% (n=9), the other CM - 12% (n=8); men - 58,2% (n=39), CHF 4 [3;4] FC, LVEF 22 ± 10%, VO2peak < 12 ml/kg/min, PCWP 19 [12;24] mmHg, TPG 9 [7;14] mmHg, the CI 1,9 ± 0,5 l/min/m², PVR 2,8 [2,3;3,8] units Wood. Duration in WLHTx 87 [31;163] days, 38 patients (56,7%) performed HTx, 17 patients (25,4%) died, 7 patients (10,4%) had stabilized and was excluded from WLHTx. In WLHTx received therapy: combined diuretic therapy - 100%, spironolactone - 100%, beta-blockers - 82,1% (n=55), ACEI/ARA - 52,2% (n=35), ivabradine - 15% Amiodaron - 60%, dopamine or dobutamine - 49,3% (n=33), 7 patients (10,4%) implanted CRT-D, 16 patients (23,9%) - ICD, extracorporeal circulatory support EXCOR - 8 patients (11,9%), physical therapy - 100%. All patients were divided into 2 groups: 1 group (n=50) patients survived in WLHTx, 2 group (n=17) - patients who died.

Results: patients died compared with the surviving patients at the time of inclusion in WLHTx had higher CHF FC (4 [4;4], and 3 [3;4] FC, respectively, p=0,004), low GFR (64 ± 19 and 81 ± 24 ml/min/1,73m² respectively, p=0,008) greater frequency of use of inotropic support (70,6% (n=12) and 42% (n=21), respectively, p=0,04), high bilirubin level (34 [23;47] and 17 [14;28] mmol/L respectively, p=0,01), ALT (52 [22;502] and 22 [14;31] U/L respectively, p=0,008), low sodium (129 ± 8 and 139 ± 5 mmol/L respectively, p=0,03), shorter duration to outcome (29 [10;45] and 106 [63;204] days, respectively; p=0,0001). From the selected predictors (HF FC, GFR, RLA, hemoglobin, bilirubin, ALT, AST, sodium, inotropes, days WLHTx) in the patient's death WLHTx greatest force an outcome (death) were: bilirubin (r=0,49; p=0,01), HF FC (r=0,47; p=0,0001), Sodium (r=-0,43; p=0,03), ALT (r=0,37; p=0,006), GFR (r=-0,36; p=0,006).

Conclusions: WLHTx mortality in patients with CHF noncoronary pathology 25,4%. Predictor of death in patients WLHTx are symptoms of right heart failure (hepatic, renal dysfunction) and FC CHF. To increase the percentage of survival to HTx require increasing the frequency of implantation of mechanical circulatory support.

P1913

Chronic Heart Failure acutely decompensated by a hypertensive urgency in an elderly population

E Emma Weiss¹; D Penes¹; E Badila¹; D Bartos¹

¹Clinical Emergency Hospital Bucharest, Internal Medicine Department, Bucharest, Romania

Purpose: To describe and compare comorbidities of the elderly (80+ yrs) chronic heart failure (HF) patient with and without reduced ejection fraction admitted for an acute decompensation secondary to a hypertensive urgency in the clinical setting of an emergency hospital.

Methods: We included consecutive elderly chronic HF patients admitted to the Internal Medicine Clinic for an acute decompensation secondary to a hypertensive urgency from January through December 2015. We separated them in two groups - HF with reduced ejection fraction (HF-REF) and HF with preserved ejection fraction (HF-PEF) and compared the two groups in terms of presence of cardiovascular risk factors (smoking, obesity) and comorbidities - diabetes, dyslipidemia, coronary heart disease, atrial fibrillation (AF), chronic kidney disease stage>3, COPD, previous stroke, dementia.

Results: Coronary heart disease, AF and COPD were more frequent in the HF-REF group, however there were no significant differences between the two groups in terms of other CV risk factors and comorbidities. For other results see table.

Conclusions: Hypertension is a major risk factor for HF both with REF and PEF. Elderly patients admitted for chronic HF acutely decompensated by a hypertensive urgency had in 80% of the cases HF-PEF. However, in terms of CV risk factors and comorbidities there were very few differences between the groups.

	HF-REF	HF-PEF	Total	HF-REF vs HF-PEF		
No pts	53 (19.63%)	217 (80.37%)	270			
Males	24	45%	60	28%	84	p < 0.05

Factors associated with heart failure readmissions from skilled nursing facilities

F Folashade Akande¹

¹Stony Brook University Medical Center, Stony Brook, United States of America

Background: Despite guideline-driven pharmacological therapies and careful transitional care, the rates of preventable hospital re-admission of heart failure patients and associated costs remain unacceptably high in the SNF populations. Transfer to SNF is one strategy to limit hospitalisations. As such, 25% of patients are still symptomatic at time of discharge.

Purpose: The objective of this study is to identify patient factors affecting re-admissions of HF patients residing in SNF within 30-days.

Methods: A retrospective electronic chart review was completed on patients > 65 years with HF who were admitted into large medical center between 2012 and 2014. Descriptive statistics and univariate analyses using the chi-square test, Fisher's test and Mann-Whitney test was used to compare patients readmitted within 30 days vs. those who were not readmitted within 30 days. Significant factors associated with readmission in the univariate analysis (p < 0.10) were included for a multivariate logistic regression model.

Results: Fifteen variables: creatinine, weight difference, CKD, Angina, Arrhythmia, VHD, Tobacco, ADL, independent in bathing, independent in the toilet, S3 Heart sounds present, HJR, AF, Nitrates, and Hydralazine, were identified for the multivariate logistic regression as potential risk factors associated with "readmission within 30 days". Based on 23 readmissions within 30 days, our final model included only 2 predictor variables. Creatinine and ADLs were included in the final model as this subset of predictors was found to be the best for prediction of "readmission within 30 days". Creatinine (p < 0.0087) and ADLs (p < 0.0077) were both significantly associated with readmission within 30 days in the final logistic regression model. Every 1-unit increase in creatinine is associated with an 87% increase in the odds of being readmitted within 30 days (OR = 1.87). Those patients who require assistance with ADLs are over 9 times more likely to be readmitted within 30 days (OR = 9.25) as compared to patients who are independent.

Parameter	Estimate	Standard Error	Odds Ratio	95% Confidence Interval	Pr > ChiSq
Intercept	-1.69	0.57			0.0029
Cr	0.63	0.24	1.87	1.17	2.99
ADL	1.11	0.42	9.25	1.80	47.49

P1915

RAAS genetic polymorphism association with clinical features of CHF

SU Volkova¹; KA Tomashevich²; AU Efanov¹

¹Tyumen State Medical Academy, Tyumen, Russian Federation; ²"Neftyanic" hospital, Tyumen, Russian Federation

Aim: To estimate renin angiotensin aldosterone system (RAAS) genetic polymorphism association with clinical features of chronic heart failure (CHF).

Materials and methods: The 51 patients with heart failure (27 women, 24 men, mean age – 73.1 ± 11.3 years old), who had 3-4 functional classes (NYHA). Having analyzed genomic DNA with PCR – analysis (PCR-express) followed by electrophoresis detection we estimated type I angiotensin II (AGTR1) A1166C receptor polymorphism, polymorphism of T174M and M235T AGT gen of ACE. Results are presented as genotype (homozygote in allele 1, allele 2 or heterozygote) detection for AGTR1 genes and AGT and in detection allele D-deletion or allele I – insertion Alu – consequences in intron ACE gen. Data were statistically processed with standard methods.

Results: RAAS genotype distribution analysis in dependence of CHF clinical features taking into account stage and NYHA class together with left ventricular systolic dysfunction, estimated as ejection fraction less than 40%, found no 174M AGT and Cgenetic polymorphisms association with CHF clinical features. We also found no association of genetic polymorphisms with left ventricular systolic dysfunction. We found association tendency of 1166 allele (AA and AC genotypes) with lower CHF NYHA class (93.3% in 3-class NYHA Vs 66.7% in 4 class NYHA, $\chi^2=4.26$, $p=0.099$). The same association was found in Met235 allele (84.4% in 3-class NYHA Vs 50% in 4 class NYHA, $\chi^2=43.99$, $p=0.081$). This was concordant with less N-proBNP level in patients having Met235 allele (2086,6 [658,9;2996,5] Vs 3482,0 [1563,3;4487,3] in its absence, $p=0.06$). The lowest N-proBNP level was found in heterozygotes, who had N-proBNP level 19882,0 [475,7; 2460,8] ($=0.045$ compared to TT genotype and $=0.092$ compared to genotype MM).

Conclusion: During our investigation we found relatively small frequency of RAAS genes polymorphisms, which is responsible, according to literature data, for IHD and AH association. Quite an interesting fact was that in our research we found no genetic polymorphism candidates, associated with systolic dysfunction of left ventricular. Together with that there was a tendency to lower CHF NYHA class in patients having 1166 AGTR1 allele and Met235 AGT allele in genome. Although N-proBNP lower level was found in Met235 heterozygotes. Considering that modern literature data often give controversy information about genome influence on CVD development, especially in the researches that involved not very large population, further analysis of RAAS polymorphisms functional significance in CHF patients it is very actual.

¹ICREC research group, Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Spain; ²Germans Trias i Pujol Health Science Research Institute, Flow Cytometry Facility, Badalona, Spain; ³Germans Trias i Pujol Hospital, Cardiology Service, Badalona (Barcelona), Spain

Introduction: Systemic monocyte subset counts are valuable as predicting factors in heart failure. Additionally, telomere length and telomere attrition are linked to genetic instability, pathogenesis and disease progression. Current analytical techniques, including Southern blot, qPCR, flow cytometry and Fluorescence In Situ Hybridisation (FISH), have limitations such as sample volume waste, number of available reagents, difficulty to conjugate antibodies and accuracy.

Purpose: The aim of this study was to develop a novel and timely method for assessing simultaneously monocyte heterogeneity and ageing in patients with heart failure.

Methods: Ninety-six consecutive patients diagnosed with heart failure and attended in the Cardiac Insufficiency Unit of our hospital were enrolled. Referral criteria were heart failure irrespective of the origin, at least 1 hospitalisation and/or reduced left ventricular ejection fraction of <40%. Methodologically, the study included standard procedures of peripheral blood extraction and Flow-FISH staining. The samples were incubated previously to telomere probe hybridisation with monoclonal antibodies conjugated with Brilliant Violet dyes (BV421, BV605 and BV786) against monocyte surface antigens CD86, CD14 and CD16, respectively. Data were acquired using a BD LSR Fortessa flow cytometer and analysed in BD FACSDiva software (v.6.0.2). Telomere length was expressed as Relative Telomere Length (RTL). The RTL value was calculated as the ratio between the telomere signal of each subset and the control cell (1301 cell line) with correction for the DNA index of G0/1 cells.

Results: Percentage of monocyte subsets expressed as mean ± SD were CD14+CD16- (Classical Subset; 50.38 ± 17.29), CD14+CD16+ (Intermediate Subset; 42.02 ± 17.26) and CD14lowCD16++ (Non Classical Subset;

8.13 ± 4.21). In addition, RTL of monocyte subsets were CD14+CD16- (Classical Subset; 9.64 ± 2.51), CD14+CD16+ (Intermediate Subset; 9.68 ± 2.58) and CD14lowCD16++ (Non Classical Subset; 10.00 ± 2.43).

Conclusions: The use of Brilliant Violet dyes in FISH hybridisation protocol provides accurate measure of specific monocyte subpopulations and their respective telomere length done at the same time. Importantly, this novel methodology may be easily applied in broad patient populations to establish clinical associations between heart failure categories and/or progression and monocyte heterogeneity and ageing.

P1917

Risk factor for Heart failure admissions in adults with congenital heart disease in monocentric tertiary center

N Ben Moussa¹; F Pontnau¹; V Salles¹; Y Boudjemline²; A Legendre²; L Iserin¹; D Bonnet²; M Ladouceur¹

¹Hôpital Européen Georges Pompidou, Université Paris Descartes, congenital heart disease department, Paris, France; ²Hospital Necker, Paris, France

Background: Adult with congenital heart disease (ACHD) are now more important than children with heart malformation, and this population is rapidly growing. Heart failure (HF) is a serious complication in the long-term follow-up of ACHD, and is one of the main causes of death in these patients. Therefore, a substantial increase in hospitalizations because of heart failure in ACHD is observed, requiring specialized care and making this problem an important public health issue.

Aims: we aimed to characterize HF in ACHD and its management in a tertiary center. We also wanted to identify risk factors of first HF-admission.

Methods: We retrospectively assessed the medical records of 408 consecutive admissions of adults with CHD in our center. Risk factors for HF-admission were assessed using regression logistic models.

Results: 408 patients were admitted in our center during a median follow up period of 14 months. HF criteria were met by 29 patients (7.1%). ACHD with HF were significantly older than other ACHD patients admitted (median age was 43 years vs 33 years, $p=0.001$). They had more complex congenital heart disease (62%), they were mainly patients with history of right ventricle outflow tract surgery, single ventricle and pulmonary artery hypertension ($p=0.007$). The aetiologies of HF were myocardial dysfunction ($n=15$), valvular disease ($n=5$), pulmonary hypertension ($n=4$), arrhythmia ($n=3$) and infective endocarditis ($n=2$). Mean hospital stay of ACHD patients with HF was longer (13 days vs 5 days, $p<0.0001$). Ten percent (3/29) died at a mean period of 23 days after their admission, one patient required circulatory support, and 2 patients were listed for heart transplantation. Independent risk factors for HF-admission were history of stroke (OR: 7.6 95%CI[2.4- 23.8], p), abnormal rhythm conduction (OR: 4.2 95%CI[1.5- 11.6], heart failure (OR = 4.7 95%CI[1.6-13.7], $p<0.01$), and atrial arrhythmia (OR: 3.5 95%CI[1.4 to 9.2). Number of cardiac surgeries was not a risk factor of HF. At admission systemic ventricle ejection fraction was the factor the most strongly associated with HF

Conclusions: Mortality risk is substantially increased after HF-admission, which emphasizes the importance to identify patients at high risk of HF-admission. These patients might benefit from closer follow-up and earlier medical interventions. This may add in care of patients with ACHD in the community and streamline care at tertiary centers.

P1918

Epidemiology of chronic heart failure in Germany: a retrospective study of the health risk institute healthcare claims database

Novartis Pharma AG, Basel, Switzerland

F Calado¹; S Stork²; S Klebs³; R Lahoz¹; R Handrock³; J Jacob⁴; J Walker⁴; S Hupfer³

¹Novartis Pharma AG, Basel, Switzerland; ²University of Wuerzburg, Department of Internal Medicine I, Cardiology, Wuerzburg, Germany; ³Novartis Pharma GmbH, Nuernberg, Germany; ⁴Elsevier, Berlin, Germany

Background: Chronic heart failure (CHF) is associated with significant healthcare expenditure, morbidity and mortality. Nationwide CHF registries in Germany are lacking. Therefore, a retrospective study of healthcare claims data from the Health Risk Institute (HRI) was conducted.

Purpose: We aimed to estimate the incidence and prevalence of CHF in Germany and associated frequency of hospitalization, and morbidity and mortality.

Methods: The HRI database contains anonymized data from approximately 7 million individuals with statutory health insurance in Germany. From this data set an age- and sex-stratified subset of 4 million people was drawn. Eligible patients for the present analysis had uninterrupted data from 1 Jan 2009 to 31 Dec 2013. Data from patients with at least two recorded CHF-related diagnoses based on ICD-10 German Modification codes for CHF in a hospital or ambulatory setting in 2011 were analysed. Furthermore, a subgroup of patients with newly diagnosed CHF was identified based on the absence of a CHF diagnosis in the year before first diagnosis in 2011. All patients were followed for 2 years after first CHF diagnosis in 2011.

Results: Of 3 132 337 eligible patients, 3.96% ($n=123\ 925$; mean age 76.2 years,

55.2% women) had CHF in 2011 and were included in the study, corresponding to an estimated prevalence of 3.87% in Germany. Out of those, a subgroup of 26 368 patients had newly diagnosed CHF, corresponding to an incidence of 655 per 100 000 persons at risk in Germany. The number of new CHF cases increased with age, and was similar in women and men. In the 2-year follow-up period, there were 48 159 hospitalizations among patients with newly diagnosed CHF; heart failure was the most common reason specified for hospitalization (7.5%). The most common comorbidities in the newly diagnosed CHF subgroup were primary hypertension (81.7%), dyslipidaemia (50.4%) and chronic ischaemic heart disease (44.4%). In the 2-year follow-up period, 16.3% (n=20 148) of all patients with CHF had died. In the same period, there were 5983 deaths in the newly diagnosed CHF subgroup (22.7%). Mortality was similar in women (22.6%) and men (22.8%), and increased with New York Heart Association class (14.6%, 16.9%, 30.8% and 53.3% for classes I, II, III and IV, respectively).

Conclusions: The high prevalence and incidence of CHF observed in this study underline the burden of CHF in Germany. Substantial mortality and hospitalization rates highlight the need for earlier diagnosis and appropriate treatment.

P1919

Congestive heart failure quality markers: measures of gender-specific economic indicators (middle eastern population): data from a single centre heart failure registry

K Salem¹; D Fallata¹; O Elkhateeb¹

¹King Abdullah Medical City, Cardiology Departement. Heart failure program, Makkah, Saudi Arabia

Background/Introduction: Identifying economic characteristics of congestive heart failure (CHF) measures is a vital component of resource allocation and clinical decision making.

Purpose: We aimed to identify the significant factors of economic and gender variability of CHF patients with a reduced ejection fraction (HFrEF).

Methods: We performed gender comparison of HFrEF patients hospitalised over a 12-month period.

Results: Of 174 consecutive patients, 78% were males and 22% were females. Compared to males, females had a statistically significant older age (64 vs. 58; $P < 0.001$). After one year, both males and females had similar all-cause and heart failure hospitalisation and re-hospitalisation rates. Females showed no differences in re-hospitalisation rates. Males were more likely to require defibrillator device implantation (34% vs. 12%; $P = 0.008$) and had higher gender-adjusted average annual expenses for single hospitalisation per patient (\$8,509 vs. \$6,232; $P = 0.035$), direct daily costs (\$967 vs. \$708; $P = 0.038$) and higher device implantation costs (\$3,714 vs. \$1,477; $P = 0.002$) than females. The total annual cost of \$2,142,186 was \$1,697,557 and \$444,629 from males and females, respectively.

Conclusion: Our findings showed that female HFrEF patients had similar annual costs; LOS; in-house mortality, hospitalisation and rehospitalisation rates; less resource utilisation for implantable devices and lower direct cost per patient per day in comparison to male patients.

Gender-specific economic indicators

Characteristics	Males (n = 135)	Females (n = 39)	P-value	95% CI for difference
Age	58, (13.5)	64, (9.04)	< 0.001	(-10.4, -3)
EF	23, (9.2)	28.2, (12.8)	0.02	(-9.6, -0.7)

Eradication therapy for Helicobacter Pylori, an important tool to improve the heart function in patients with coronary heart disease.

A I Andra Iulia Suceveanu¹; AP Suceveanu¹; RI Parepa¹; L Mazilu¹; D Catrinioiu¹; F Voinea¹

¹Ovidius University of Constanta, Faculty of General Medicine, Constanta, Romania

Background: The pro-inflammatory and pro-coagulant status of Helicobacter Pylori (HP) and its involvement in ischemic coronary heart disease was studied largely in the last 20 years, but the literature data regarding the benefit of the curative treatment for HP and its repercussions on heart function was not explored sufficiently.

Aim: We aimed to investigate the benefit of eradication therapy for HP according to Maastricht IV/Florence Consensus 2010 in patients with different stages of heart insufficiency (HI) and coronary heart disease (CHD).

Material and Methods: During one year, between 2014 and 2015, 240 patients with CHD admitted in Cardiology and Gastroenterology Departments were explored according the HP infection status and found positive. The infection was determined by one of the most sensitive methods, including HP-Ag from faces, urea breath test or endoscopic biopsy. The CHD was assessed by electrocardiography (ECG) and HI was staged according to NYHA classification. According to the implementation of eradication therapy for HP, we divided the patients in two equal groups, matched by age, gender and severity of HI: one group of 120 patients with treatment and the other group of 120 patients without eradication therapy. We compared the heart function improvement after treatment for HP in both groups. We also compared the evolution of PCR, fibrinogen, IL-6 and other inflammatory cytokine.

Results: The eradication therapy for HP with one PPI and two antibiotics associated with cardiac treatment, improved the clinical status based on NYHA criteria in 96 patients with at least 1 stage decrease in NYHA staging compared with only 45 patients from the group with cardiac treatment but without eradication therapy ($p = 0.03$). The laboratory finding also revealed a favorable course of pro-inflammatory tests in treated patients compared with untreated patients, regarding protein C-reactive, leucocytes, IL-6 and fibrinogen ($p = 0.023$, $p = 0.041$, $p = 0.03$, respectively $p = 0.017$, ss).

Conclusion: Our study results demonstrate that eradication therapy for HP should be one of the treatment targets when managing infected patients with CHD in order to improve their cardiac function.

Low hemoglobin, diabetes and renal impairment: the perfect cocktail for death in advanced heart failure patients.

C Catarina Ruivo¹; F Sa¹; L Ginja¹; J Correia¹; J Morais¹

¹Hospital Santo Andre, Cardiology, Leiria, Portugal

Introduction: Patients with heart failure with reduced ejection fraction (HF-REF) are at higher risk of death. In the last decade, the progress made in the therapeutic approach has greatly improved the prognosis of HF-REF patients. However, there're baseline patient characteristics which are associated with higher rates of mortality and adverse events.

Objective: The aim of the study was to find independent variables with impact on death in stable HF-REF patients followed in an outpatient clinic.

Methods: Retrospective analysis of patients with advanced HF-REF. Clinical, laboratory and therapeutic variables were considered. A logistic regression model was performed to find the predictors of death in stable HF-REF patients.

Results: We evaluated 130 patients [99 (76.2%) men] with stable HF-REF whose mean age was 65.9 ± 14.8 years and mean follow up duration was 42 ± 7.7 months. The 16 patients (12.3%) who died had more previous emergency department's admissions. They were older, showed higher prevalence of diabetes, dyslipidemia, hypertension, coronary revascularization (percutaneous or surgery) and pulmonary disease. At laboratory findings, they had lower hemoglobin values and higher creatinine and urea values, leading to a lower GFR (MDRD calc). There were no statistically significant differences in therapeutic approach considering medical treatment and devices. Multivariate analysis showed diabetes, low hemoglobin value and renal impairment (MDRD calc) as independent predictors of death (Table). Despite its low specificity (22.2%), this adjusted model has high sensitivity (97.3%) and a good discriminating ability ($AUC = 0.78$; $p < 0.001$).

Conclusions: In spite of great achievements in the medical treatment, baseline characteristics still remain highly valuable in predicting death in HF-REF. According to the current data low hemoglobin, diabetes and renal impairment are independent predictor of death in patients with stable heart failure with reduced ejection fraction.

	OR	IC 95%	p-value
Diabetes	11.04	1.04 - 117.69	0.047
Low hemoglobin	1.77	1.08 - 2.92	0.025
Renal impairment	1.06	1.01 - 1.11	0.016

Chronic heart failure management

Heewad complex hospital (private) bust Helmand hospital (governmental)
D Diwa Yaqin¹

¹Cheragh medical college, Kabul, Afghanistan

Heart failure is a common syndrome that is increasing in incidence and prevalence. Optimal management of chronic heart failure includes combination medical therapies such as ACE inhibitors, aldosterone antagonist, and B blocker. The treatment of heart failure is aimed at relieving symptoms, improving function status and preventing death and hospitalization. 1. diuretic therapy :- diuretic are most effective means of providing symptomatic relief to patients with moderate to severe heart failure. 2. ACE inhibitors reduce mortality by approximately 20% in patients with symptomatic heart failure and have been shown also to prevent hospitalization, increase exercise tolerance, and reduce symptoms in patients. 3. ARBs:- thus ARBs specifically candesartan or valsartan, provide important benefits as an alternative and in addition to ACE inhibitors in chronic heart failure with reduced LV EF. 4. B blockers : this has led to a strong recommendation that stable patients with mild moderate and even severe heart failure should be treated with a B blocker unless there is noncardiac contraindication. 5. Digitalis glycosides : based on these results digoxin should be used for patients who remain symptomatic when taking diuretics and ACE inhibitors as well as for patients with heart failure.

Prognostic markers of myocardial electric instability

T Tatyana Vaikhanskaya¹; AV Frolov¹; LM Gul¹; OP Melnikova¹; AP Vorobiev¹
¹Republican Scientific and Practical Center "Cardiology", Minsk, Belarus

Purpose of this study was assessment of the diagnostic significance of the complex of markers of myocardial electric instability: microvolt T-wave alternation (mTWA), HRT (TOVTS), intervals QTd and JTd dispersion, deceleration (DC) and acceleration (AC) indexes of heart rate to predict ventricular tachyarrhythmias (VTAs).

Material and methods: The study included 183 patients with systolic dysfunction (NYHA III) of different genesis (aged 51.2 ± 12.3 years, male 77.6%; LVEF 36.7 ± 10.8%); follow-up 35.3 ± 9.6 months. All patients were examined: echocardiography; Holter monitoring (HM) ECG; 7-min ECG (Intekard-7) and telemetry of the implanted device (DDD, VVI, CRT, CRT-D, ICD) if in presence.

Results: In 86 (47%) patients according to the HM-ECG and devices telemetry the ventricular tachyarrhythmia (VTA) events (sustained and nonsustained ventricular tachycardias) have been registered. Correlative analysis revealed a positive correlation VTA events with a pathological test mTWA (p of pathological mTWA and average value mTWA; p = 0.00001), the daily number of premature ventricular beats (PVEs\ 24h; p = 0.00001), LVEF (p = 0.0001), the index of DC (p = 0.003), HRT (TO; p = 0.004) and interval JT dispersion (p = 0.01). By the step discriminant analysis (F = 5.58; p < 0.0001) were confirmed the predictive value of LVEF (Wilks' Lambda 0.90; p = 0.00018), the percentage of pathological mTWA (Wilks' Lambda 0.87; p = 0.006), and PVEs\ 24h (Wilks' Lambda 0.87; p = 0.008). Data analysis and classification coefficients of the equations are presented in table.

Conclusions: The applying of classification matrix including markers of electric instability of myocardium (mTWA, PVEs\ 24h) and LVEF enabled to predict VTA events in patients with reduced ejection fraction (sensitivity 65%, specificity 70%).

Results of discriminant analysis

Predictors	Wilks' Lambda	Partial Lambda	F-remove (1,58)	p-level	Coefficients of the equations

Influence of pacemaker implantation in patients with heart rhythm disorders and heart failure without indications to cardiac resynchronization

R Mlynarski¹; A Mlynarska²; KS Golba²

¹Upper-Silesian Cardiology Center, Katowice, Poland; ²Medical University of Silesia, Katowice, Poland

There is a group of patients in different stages of heart failure and heart rhythm disorders which are qualified for standard right heart pacing without classic indications to cardiac resynchronization (CRT). Question, how pacemaker implantation influence the quality of life is still actual. Aim of this study was to evaluate the way on which pacemaker implantation influences the quality of life (QoL) in patients with heart rhythm disorders and heart failure without indications to cardiac resynchronization after six months of follow up.

Methods: 182 patients with heart rhythm disorders and heart failure (NYHA I - IV) qualified for pacemaker implantation (without indications to CRT) were included into this prospective single center study. A DDD pacemaker was implanted in each patient. The ventricular lead was positioned in the right ventricle outflow tract. QoL and was evaluated twice: 3-5 days before implantation and 6 months later using an MLWHF (Minnesota Living With Heart Failure) questionnaire - less points mean better QL.

Results: An overall statistical improvement in QoL was found in the global score (before 42.36 ± 9.58, after 25.54 ± 7.02; p = 0.000), emotional components (before 9.56 ± 4.15, after 7.75 ± 3.41; p = 0.000) and physical components (before 19.13 ± 4.73, after 9.99 ± 3.54; p = 0.000) 6 months after implantation. QoL results according NYHA class are presented in the table below. Highly statistical improvements QoL was observed in all its components and in all NYHA classes.

Conclusions: Implantation of a pacemaker improves the quality of life in patients with heart rhythm disorders and heart failure.

Left cardiac sympathetic denervation done by a video-assisted thoracoscopic approach (VATS) led to terminate electrical storm in ICD patients with ischemic cardiomyopathy.

E Hatzinikolaou-Kotsakou¹; K Tsakiridis²; M Konstantinidou¹; A Mpakas²; G Ioannidis³; M Kotsakou¹; P Latsios¹; A Koletas²

¹Saint Lukes Private Hospital, Electrophysiology Department, Thessaloniki, Greece; ²Saint Luke's Private Hospital, Cardiothoracic Surgery, Thessaloniki, Greece; ³Saint Lukes Private Hospital, Cardiac Care Unit, Thessaloniki, Greece

Introduction: Electrical storm is a life threatening experience for the patients and it is a great therapeutic challenge for the physician. An electrical storm is usually associated with catecholaminergic hyperactivation and requiring frequent shocks in patients with implantable cardioverter defibrillators. Deactivating repeated shocks induces myocardial damage and further worsens the arrhythmias, which are resistant to the antiarrhythmic drugs. Thus the management of an electrical storm by sympatholytic measures, other than the conventional pharmacologic beta adrenergic blockade, is of very significance.

Methods: We treated the electrical storm in 5 patients (4 men), aged 42-58 years with ischemic cardiomyopathy. In all patients the conventional therapy failed. Cardiac sympathetic blockade was assessed by Left cardiac sympathetic denervation (LCSD). LCSD was done by video-assisted thoracoscopic approach (VATS). The pleural cavity was entered through three small incisions in the left subaxillary area; a double lumen endotracheal tube allowed ventilation of the contralateral lung while the ipsilateral lung was deflated and not ventilated to facilitate access to the sympathetic chain. The blockade was succeeded using 20ml of 2% xylocaine followed by an extra infusion of 20ml ropivacaine in the selected ganglion area.

Results: The effects of xylocaine and ropivacaine on hemodynamic parameters are minimal. The arrhythmia was tolerated by electrical storm termination. A partial Horner's syndrome was developed in 3 patients which is remained for one week. The patients remained symptom-free without any incident of ventricular arrhythmias since 13-18 months now.

Conclusions: Sympathetic hyperactivity seems to play an important role during electrical storm in ischemic cardiomyopathy patients. Therefore neuroaxial modulation is an attractive option for the arrhythmia management. These treatment modalities can be considered when standard treatments fail. Large prospective randomized studies are needed to further define the clinical role of these therapeutic strategies in the future.

Arrhythmic risk and genetic variations in dilated cardiomyopathy patients

PTDC/BIM-MEC/0650/2012

A Sousa¹; P Canedo²; M Campelo³; B Moura⁴;
S Leite⁵; A Belo⁵; F Rocha Goncalves¹; JC Machado²; J Silva Cardoso³;
E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Institute of Molecular Pathology and Immunology at the University of Porto, Porto, Portugal; ³Sao Joao Hospital, Porto, Portugal; ⁴Regional Military Hospital n°1, Porto, Portugal; ⁵Portuguese Society of Cardiology, Lisbon, Portugal

Introduction: Dilated cardiomyopathy (DCM), characterized by left ventricle (LV) enlargement and contractile dysfunction, is associated with high risk of arrhythmic sudden cardiac death (SCD) in a subgroup of patients. Until now, risk stratification has been based on the individual arrhythmic profile and LV ejection fraction (EF), even though SD may occur with EF > 35%. Family history of unexplained SD, especially in the young, is a raising concern, taking into account potential inheritable risk factors. Currently, with rare exceptions of lamina A/C mutations carriers, it remains unknown how genetic factors and respective tests can be used in clinical practice for SD prediction.

Purpose: We intend to assess the relation between the arrhythmic risk and genetic variations in dilated cardiomyopathy patients, to evaluate the potential role of genetic tests in clinical practice.

Methods: In this work we included idiopathic DCM patients (age ≤ 50 years) and familial DCM patients (irrespective of the age), and compared the presence of genetic variants between two subgroups with a priori distinct SD risk: those with family history of SD and/or previous implantable cardioverter-defibrillator (ICD) for primary or secondary prevention, versus those without any of the conditions. Molecular analysis included the search of mutations in LMNA/C, MYH7, MYBPC3, TNNT2, ACTC1, TPM1, CSRP3, TCAP, SGCD, PLN, MYL2, MYL3, TNNI3, TAZ and LBD3 genes using PCR technique with direct-sequencing (next-generation sequencing with at least a 30- fold coverage combined with Sanger sequencing). Pathogenicity was assessed by comparisons with mutations previously described, functional tests and segregations studies.

Results: We studied 112 patients, 46.4% with familial DCM; 58.3% males, mean age 47 ± 12 years, with mean age at diagnosis of 38 ± 13 years. Mean left ventricle ejection fraction was 32 ± 12% and LV end-diastolic diameter 64 ± 9 mm, and 37.4% of them presented left bundle branch block. Twelve (10.7%) patients had family history of unexplained SCD, 21 (18.8%) patients had implanted an ICD device and 3 patients (2.7%) presented both conditions. A total of 35 genetic variants were found in 29 (25.6%) patients. These mutations occurred in different genes: 10 in MYBPC3, 6 in TNNT2 and in LMNA, 3 in MYH7, in PLN, in TCAP and in LBD3, and one in TPM1 gene, with their relative distributions being similar between both groups (30.6% versus 23.7% in patients with and without family history of SCD/ICD, respectively; p = 0.438).

Conclusion: In our DCM patients, family history and previous ICD implantation decision could not predict the genetic results. Follow-up of DCM patients with distinct genetic mutations is necessary to clarify how the genetic profile can be integrated in algorithms for SCD primary prevention.

Incidence, associated factors and patient outcomes of heart failure complicated by ventricular arrhythmia in saudi arabia: from heart function assessment registry trial in saudi arabia.

B Alenazy¹; KF Alhabib²; AA Elafar³; H Alfaleh²; T Kashour²; A Hersi²; H Albackr²; F Alshaer²; K Alnemer⁴; W Alhabeeb²

¹King Saud University, College of Medicine, Riyadh, Saudi Arabia; ²King Saud University, King Fahad Cardiac Center, Department of Cardiac Sciences, College of Medicine, Riyadh, Saudi Arabia; ³King Fahad Medical City, King Salman Heart Center, Riyadh, Saudi Arabia; ⁴Security forces Hospital, Riyadh, Saudi Arabia

Introduction: Arrhythmia is a common finding in heart failure (HF) patients. It has a greater impact on prognosis in those patients, especially ventricular arrhythmia type. Although there are some studies about premature ventricular contractions (PVCs) and non-sustained ventricular tachycardia (NSVT) in heart failure, few data

are available regarding sustained ventricular tachycardia (VT)/ ventricular fibrillation (VF) in heart failure.

Purpose: In this study, our aim was to investigate the incidence of sustained VT/VF, the factors associated with its occurrence and prognosis in hospitalized heart failure patients.

Methods: This is sub-study of prospective study of 2610 patients admitted in 18 government hospitals with HF between October 2009 and December 2010. Patients were categorized as having ventricular arrhythmia (VA) if they experienced either sustained VT or VF or both during hospitalization.

Results: Of 2610 patients with HF enrolled in Heart Function Assessment Registry Trial in Saudi Arabia (HEARTS), 110 (4.2%) were diagnosed with VA. The vast majority (97%) occurred in patients with heart failure with reduced ejection fraction (HFrEF). Factors associated with an increased risk of developing VA during hospitalization for HF are arrhythmia (OR 7; 95% CI 2.4-19.3), STEMI (OR 4.7; 95% CI 1.6-14), infection (OR 3; 95% CI 2.4-19.3) as precipitating factors for HF, and low SBP (<90 mm Hg) at presentation (OR 3.6; 95% CI 1.2-11). Adverse in-hospital outcomes including recurrent HF, hemodialysis, shock, sepsis, major bleeding, intra-aortic balloon pump (IABP) and pacing were higher for patients with VA (P ≤ .001 for all comparisons) and signified a poor prognosis. The in-hospital, 30-days, 1-year, 2-year, and 3-year mortality rates were significantly higher in VA patients compared with non-VA patients (P ≤ .001 for all comparisons).

Conclusions: VA was found in a small percentage of hospitalized heart failure patients. However, it was associated with remarkably high rates of adverse events and increased mortality rate. Information from patient's medical history and clinical presentation parameters can predict VA development in HF patients. Evaluating those associated factors would help in identifying patients at high risk for VA.

Factors associated with in-hospital VA

Associated Factor	Odds ratio	95% CI	P value
Arrhythmia	7	2.4-19.3	<.001
STEMI	4.7	1.6-14	0.006
Infection	3	1.2-7.6	0.024
SBP < 90 mmHg	3.6	1.2-11	0.023

P1928

The relation between digoxin and appropriate shocks in patients with ischemic heart failure and implantable cardioverter defibrillator

K Kevser Balci¹; MK Balci¹; F Sen¹; MK Akboga¹; O Maden¹; H Selcuk¹; T Selcuk¹; Y Balbay¹; A Temizhan¹; S Aydogdu¹

¹Turkiye Yuksek Ihtisas Hospital, Cardiology Clinic, Ankara, Turkey

Objective: Although digoxin improves heart failure symptoms, its potential proarrhythmic effects on ischemic myocardium has been debated. In this cross-sectional study, we investigated the relation between appropriate shocks in patients with ischemic heart failure (HF) and implantable cardioverter defibrillator (ICD).

Material and Method: In between January 2014 and August 2015, patients who were admitted to our hospital for routine ICD controls were evaluated according to the presence of appropriate ICD therapy. All patients included into the study provided ventricular pacing <5%.

Results: A total of 139 patients were included in the present study. Of these 35 patients (25.1%) experienced appropriate ICD shocks. In patients with ICD shocks, baseline left ventricular ejection fraction (LVEF) was significantly lower (p = 0.009). When patients were compared according to the medications used, the number of the patients using aspirin and diuretic was significantly higher in the shock-received group whereas, statin usage was significantly lower in the shock-received group (p = 0.030, p = 0.046, p = 0.044; respectively). Digoxin usage did not differ between the groups (p = 0.388). In logistic regression analysis, aspirin usage and LVEF were found as independent predictors of ICD shocks (p = 0.032 and p = 0.045).

Conclusions: Baseline LVEF independently predicts ICD shocks. However, digoxin has no effect on ICD shocks in patients with ischemic HF and ICD. Moreover,

patients with ICD shocks require more diuretic therapy and were less treated with statins compared to patients without shocks.

Permanent junctional reciprocating tachycardia: a cause of heart failure during pregnancy

SN Naccache¹; FH Halimi¹

¹Hôpital privé de Parly II, le chesnay, France

Permanent junctional reciprocating tachycardia (PJRT) is a rare form of supraventricular arrhythmia, more common in the pediatric than in the adult population. This type of accessory-pathway-mediated tachycardia is usually incessant and can lead to tachycardia-induced cardiomyopathy. We describe the case of a 38-year old woman, consulting during the 17th week of pregnancy for dyspnea and progressive fatigue. Physical examination was unremarkable. A long RP narrow complex supraventricular tachycardia with inverted P waves in inferior leads was noted on her ECG. Transthoracic echocardiography revealed a dilated cardiomyopathy with depressed left ventricular ejection fraction. Since this arrhythmia became life-threatening for both mother and fetus, ablation was discussed. This was a challenging task because fluoroscopy at this stage of pregnancy is associated with a considerable risk of congenital malformation. In the electrophysiology laboratory, initiation of the clinical tachycardia occurred after sinus rhythm acceleration. Catheters were placed in the right atrium, without using Fluoroscopy, guided by Carto 3D system. The earliest retrograde atrial activation during tachycardia was present at the proximal-to-mid coronary sinus. Paced ventricular extrastimuli, timed to His bundle refractoriness, advanced the atrial electrogram approximately 20 ms and reset the tachycardia. On the basis of these findings, diagnosis of orthodromic reciprocating tachycardia utilizing a slowly conducting posteroseptal accessory pathway, or PJRT, was made. A mapping of the right atrium was performed. Radiofrequency ablation of the right posteroseptal pathway was accomplished and stopped definitely the tachycardia. Radiofrequency ablation of the accessory pathway is the only real curative treatment in PJRT. It prevents side effects of such incessant tachycardia and allows total cardiac recovery after ablation. During pregnancy, zero fluoroscopy ablation represents an advantageous technique that must be considered.

Appropriate therapies in patients with implantable cardioverter-defibrillator for primary prevention of sudden death: how to identify patients who benefit the most?

S Sofia Alegria¹; O Simoes¹; AR Almeida¹; R Miranda¹; S Almeida¹; G Morgado¹; I Rosario Cruz¹; L Brandao¹; H Pereira¹

¹Hospital Garcia de Orta, Cardiology, Almada, Portugal

Introduction: Left ventricular (LV) ejection fraction (EF) $\leq 35\%$ is a major determinant for implantable cardioverter-defibrillator (ICD) therapy for primary prevention of sudden death, in patients with ischemic cardiomyopathy or dilated non-ischemic cardiomyopathy. However, LVEF presents limited sensitivity and specificity as a risk marker of sudden death, since a significant amount of patients with poor LV function never present malignant ventricular arrhythmias.

Purpose: Characterization of a population submitted to ICD implantation for primary prevention of sudden death; analysis of the occurrence of appropriate therapies and its predictors.

Methods: Retrospective analyses including patients with ischemic cardiomyopathy and non-ischemic dilated cardiomyopathy who implanted ICD, with associated

cardiac resynchronization therapy (CRT) or not, for primary prevention of sudden death, between 2011 and 2014.

Results: 59 patients were included (mean age 61 ± 10 years, 68% male sex), 66% with ischemic cardiomyopathy and 29% with associated CRT. The mean baseline EF was $28 \pm 6\%$, 48% of patients were on NYHA class II and 44% on NYHA class III. During a mean follow-up of 825 ± 412 days, 17% of patients had appropriate therapies (3.4% shocks, 10.2% ATP and 3.4% both) and the mortality rate was 15%. Among the 43 patients in whom a follow-up transthoracic echocardiogram (TTE) was available, 34.9% recovered LV function (defined as improvement of EF $\geq 5\%$, with final value $> 35\%$). The occurrence of appropriate therapies was not associated with the etiology (ischemic vs. non-ischemic), baseline EF, functional class, presence of CRT-D, evidence of delayed enhancement in the cardiac MR and aneurysm in the TTE. However, there was a trend to the increase in appropriate shocks in patients with severe compromise of LV function (11% vs. 0% in patients with moderate compromise, $p=0.098$). In this population the only variable associated with the occurrence of appropriate therapies was the EF post-implantation; patients who maintained EF $< 30\%$ had an increased risk of dysrhythmic events (29% vs. 4%, $p=0.028$; OR=9.17). In addition, the occurrence of appropriate therapies was associated with higher mortality during follow-up (40% vs. 10%, $p=0.017$; OR 5.9 95% CI 1.2-28.1).

Conclusion: In this population of patients with compromised LV function submitted to ICD implantation for primary prevention of sudden death, appropriate therapies, although not common, were associated with higher mortality. Since the etiology, EF or functional class were not associated with the occurrence of appropriate therapies, our results reinforce the need to identify new risk markers of sudden death in this population. Taking into consideration that the only variable associated with appropriate therapies was the EF post-implantation, the identification of predictors of function recovery might contribute for a better risk stratification of these patients.

ATRIAL FIBRILLATION

Influence of metoprolol and diltiazem on diastolic function in patients with recurrent atrial fibrillation and heart failure with preserved ejection fraction

IM Irina Balabanenko¹; AA Shavarov¹; GK Kiyakbaev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Objective: Heart failure with preserved ejection fraction (HF-PEF) is presumed to be due to diastolic dysfunction (DD) and is an independent predictor of atrial fibrillation (AF) in the elderly. Positive impact of beta-blockers has been studied and proven, but data for the effects of diltiazem on DD are limited.

Aim: The purpose of this study was to compare parameters of echocardiography and DD in AF patients with HF-PEF under metoprolol (M) and diltiazem (D) treatment.

Methods: The study included 55 patients (40% men) aged 66 (62; 73) years with mild-to-moderate AH, recurrent AF and HF-PEF ($>50\%$). Clinical characteristics of M group patients ($n=31$) and D group patients ($n=24$) were similar. Average duration of AF was 11 (9; 13) months. All patients underwent echocardiography before and 3 months after treatment.

Results: Forty one patient (75%) had diastolic dysfunction, in 76% of these cases it was impaired relaxation. There were no significant differences in e' and E/e' medians in M and D groups, but comparison of delta showed significant opposite changes of these parameters. $\Delta e'$ increased by 0,01 m/s in M group and reduced by -0,2 m/s in D group ($p=0,002$); $\Delta E/e'$ increased by 0,01 in M group and decreased by -0,8 in D group ($p=0,04$). E/e' had significant direct correlations with left ventricular myocardial mass index (LVMMI) ($r=0,34$) and left atrial (LA) volume index ($r=0,24$), and indirect correlations with LA emptying fraction ($r=-0,31$) and LA expansion index ($r=-0,31$). Changes of LVMMI and LA structural and functional parameters, as well as AF recurrent rate, were not significant in both groups during follow-up.

Conclusion: E/e' was correlated with structural and functional LA parameters in patients with AF and HF-PEF. Diltiazem improved cardiac diastolic function in comparison with metoprolol but it didn't lead to difference in AF recurrence rate.

P1932

Relation of the severity of mitral regurgitation to thromboembolic risk in patients with atrial fibrillation

A Metwally¹

¹Al-Azhar University, cardiovascular department, Cairo, Egypt

Atrial fibrillation (AF) is the commonest sustained cardiac rhythm disorder and is responsible for substantial mortality and morbidity due to stroke, thromboembolism, heart failure, reduced quality of life and impaired cognitive function. This arrhythmia is commonly seen in everyday practice. The most important threats patients with atrial fibrillation face are stroke and heart failure. Furthermore, quality of life

grades of MR			
	mild	moderate	severe
specific signs	vena contracta width <0.3 cm, with small central jet (<4 cm ² or <10% of LA), no or minimum flow convergence.	MR more than mild, without any criteria for severe MR.	Vena contracta width ≥0.7 cm, with large central MR jet (area > 40% of LA) or with a wall-impinging jet of any size; large flow convergence; systolic reversal in pulmonary veins; prominent flail leaflet or ruptured papillary muscle.
supportive signs	Systolic dominant flow in pulmonary veins; A-wave dominant mitral inflow; low-density doppler MR signal; normal left ventricle (LV) size.	MR more than mild, but no criteria for severe MR.	Dense, triangular doppler MR signal; E-wave dominant mitral inflow (> 1.2 m/s); enlarged LV and left atrium (LA), particularly with normal LV function.
quantitative variables Rvol (mL per beat) RF ERO area (cm ²)	<30 <30% <0.20	30–44; 45–59 30–39; 40–49% 0.20–0.29; 0.30–0.39	≥60 ≥50% ≥0.40

is diminished due to AF symptoms as well as frequently associated cardiovascular diseases like hypertension, heart failure, coronary artery and valvular diseases. In the present study, the relationship between severity of mitral regurgitation (MR) and thrombo embolic risk in patient with AF was studied. Forty five patients (21M/24F) 30 patients with AF and MR referred to our cardio. dep., and 15 patients with atrial fibrillation without MR between Oct. 2012 and April 2013. Patients were subjected to full history taking, clinical evaluation, ECG., Transthoracic and transesophageal Echocardiographic (TEE) assessment was done. The severity of MR was assessed based on American Society of Echocardiography (ASE) guidelines (listed in a table down). Multiple standard tomographic planes were imaged by (TEE) for assessment of left atrium, spontaneous echo contrast (SEC), left atrial appendage (LAA) emptying velocities and LAA thrombi. Data were coded & entered using the statistical demo version of the graph Pad InStat, P value < 0.05 was considered statistically significant. It was found that thrombo embolic risk has been shown to increase significantly in patients with AF without MR compared to patients with AF with MR. SEC is increased significantly in patients with mild MR than patients with moderate and severe MR and no significant changes between SEC grade in moderate and severe MR. The prevalence of LAA thrombus is increased in patients with mild MR than patients with severe MR. LAA emptying velocity is decreased in patients without MR than patients with MR and decreased in patients with mild MR compared to patients with severe MR.

P1933

Clinical characteristics of patients treating heart failure with and without atrial fibrillation under oral anticoagulant therapy.

PR Paulo Roberto Chizzola¹; VS Issa¹; SM Ayub-Ferreira¹; GEC Souza¹; VCM Salemi¹; LS Alves¹; GV Guimaraes¹; EA Bocchi¹

¹Heart Institute (InCor) - University of Sao Paulo Faculty of Medicine, Department of Heart Failure, Sao Paulo, Brazil

Background: Oral anticoagulant (OAC) therapy is usual in patients with heart failure (HF), and atrial fibrillation (AF) is a common indication to prevent embolic complications. Clinical characteristics may influence therapeutical choices and modulate treatment response.

Purpose: To evaluate clinical characteristics of patients treating HF using OAC and to explore clinical differences between patients with AF and without AF (No-AF).

Method: A cross-section observational study analyzed 50 patients randomly selected from 417 treating HF and using OAC in referral service for cardiology in Brazil (29 AF and 21 No-AF). Variables as age, gender, weight, height, heart rate, heart disease etiology, functional class, history of hypertension, diabetes mellitus, use of alcohol, tobacco, previous occurrence of intracardiac thrombus, pulmonary embolism, stroke, presence of coronary artery disease confirmed by coronary angiography, echocardiography data, blood count, serum urea, creatinine, sodium, potassium, thyroid hormone level and BNP, dose of medication, time of follow-up, number of visits, hospitalizations, and free time for complications were compared between the groups. Statistical analysis: the t-test was applied to the continuous variables and the chi-square in categorical variables. P value less than 0.05 was considered significant.

Results: Among patients treating HF and using OAC, males were more prevalent in AF than No-AF (93% vs. 57%, $p < 0.0001$). Heart disease etiology showed more prevalence of hypertension and alcoholic cardiomyopathy in AF group and more prevalence of heart Chagas disease and ischemic cardiomyopathy in No-AF group (see the table below, $p = 0.02$). In AF group were more prevalent previous alcohol use (34.5% vs 14.3%, $p = 0.03$) and history of hypertension (69% vs 52.4%, $p = 0.04$).

In No-AF group were more prevalent previous occurrence of intra-cardiac thrombus (23.8% vs. 0%; $p = 0.04$) and pulmonary embolism (9% vs 0%, $p = 0.03$). The mean of left atrial diameter was higher in AF group (50.8 ± 7.0 vs 46.6 ± 7.3 mm, $p = 0.047$). There was no significant difference in the other variables analyzed.

Conclusion: Despite of the same condition of HF and OAC therapy, AF and No-AF groups shows some clinical differences. These distinct characteristics should be considered in therapeutic decision.

P1934

Pulmonary vein isolation with cryoablation versus ablation with radiofrequency in the treatment of atrial fibrillation: a comparative analysis

Al Ana Isabel Azevedo¹; J Primo¹; L Adao¹; H Goncalves¹; M Oliveira¹; M Fonseca¹; N Ferreira¹; J Ribeiro¹; A Dias¹; V Gama Ribeiro¹

¹Hospital Center Vila Nova Gaia, Porto, Portugal

Introduction: Atrial fibrillation (AF) is the most frequent sustained arrhythmia and is associated with a poor quality of life. Electric isolation of the pulmonary veins aims to prevent the occurrence of AF and represents a treatment option for symptomatic patients, refractory to antiarrhythmic drug therapy. Radiofrequency and cryoenergy are two used sources of energy; however, there is no consensus on which is the best choice. The authors present the initial experience of the Centre in pulmonary veins isolation (PVI) using cryoablation, analysing its efficacy and safety compared to ablation with radiofrequency.

Methods: Retrospective analysis of the PVI procedures using cryoablation and ablation with radiofrequency (ARF), based on review of clinical and interventional data of the procedures undertaken between August 2014 and October 2015. Follow-up was done by telephonic interview and clinical files consultation.

Results: 119 procedures, 42 (35.3%) with cryoablation and 77 (64.7%) with ARF, were performed in 118 patients (mean age 54.4 ± 11.2 years-old, 71.2% men). In the ARF group, 4 procedures included cavotricuspid isthmus ablation. There were no significant differences in age, comorbidities, left atrium diameter, ejection fraction, type of AF (paroxysmal or persistent), duration of AF, antiarrhythmic drug therapy or CHA2DS2-VASc score between the groups. Isolation of the 4 pulmonary veins was achieved in 73 (94.8%) of the procedures in the ARF group and in 38 (90.5%) in the cryoablation group, with similar acute complication rates (one small pericardial effusion in the ARF group and one transient phrenic nerve palsy in the cryoablation group). Procedural time was significantly inferior in the cryoablation group (98.5 ± 17.8 vs 109.1 ± 23.3 minutes, $p = 0.01$) and fluoroscopy time was higher (22.7 ± 10.2 vs 15.2 ± 6.1 minutes, $p < 0.001$). After a mean follow-up of 7.4 ± 4.2 months, AF recurred in 5 patients (11.9%) in the cryoablation group and 18 (23.4%) in the ARF group ($p = 0.12$), in a mean of 3.2 ± 2.5 vs 3.3 ± 3.5 months after the PVI procedure ($p = 0.45$), respectively. After multivariate logistic regression (adjusted for age, cardiovascular risk factors, echocardiographic parameters, type and duration of AF), the type of energy source used in the PVI was not a predictor of recurrence of the AF. There was a significant improvement in the palpitations, dyspnea, dizziness and fatigue symptoms in both groups, after the intervention.

Conclusion: The cryoablation and ARF methods in PVI showed comparable results in acute success and complication rates. Procedural time was significantly shorter in the cryoablation group and fluoroscopy time was longer. At short-term follow-up, recurrence rate was similar in both groups, mostly occurring during the blanking period. Patients experienced a significant improvement in the arrhythmia-related symptoms, irrespective of the method used.

P1935

Risk factors of the atrial fibrillation progression in patients with recurrent atrial fibrillationTZ Tohir Ganiyev¹; NU Zakirov¹; RD Kurbanov¹; DB Irslov¹¹Specialized Cardiology Center of the Republic of Uzbekistan, Cardiac arrhythmia, Tashkent, Uzbekistan

Background: HATCH score - acronym for hypertension, age>75, TIA or stroke, chronic obstructive pulmonary disease and heart failure are stratifies patients with paroxysmal AF according to their risk for AF progression during 1 year.

Purpose: to evaluate the accuracy of the HATCH score to predict progression and to identify some other possible factors leading to permanent AF within 1 year in patients with recurrent AF.

Methods: We retrospectively studied 203 patients (mean age 55 ± 13 years; 143 of men, 137 of them had paroxysmal AF (>2 onset per 3 months) and 66 had persistent AF (mean AF duration 81 ± 9 days) after cardioversion. Antiarrhythmic drugs administered to 88% patients in addition to upstream therapy. Progression of AF was defined, if paroxysmal or persistent AF at baseline becoming permanent AF. The primary end point was rhythm status at 1 year. We constructed a receiver operating characteristic (ROC) curve and calculated the area under the curve to estimate the HATCH score's accuracy of predicting AF progression.

Results: Among 203 patients 43(22%) had progression to permanent AF (8.8% for paroxysmal and 47% for persistent AF). The mean HATCH score was 1.79 ± 1.58 and was significantly higher in patients whose AF progressed than who had no AF progression (2.95 ± 1.8 vs 1.48 ± 1.4 , $P=0.0001$). According to HATCH score 50 (24%) patients had 0 points, 63 (31%) patients had score = 1, and 78 (38%) patients had score 2-4. Only 12 (6%) patients had score>5 (4 patients had 6 points and no patients with score 7). High risk patients in paroxysmal AF subgroup were 8 and 4(50%) of them had progression versus 4 patients (100%) in persistent AF subgroup (n/s). According to logistic regression analysis, only 2 items of the HATCH score was associated with a risk of AF progression: HF (OR: 3.89, 95% CI: 1.46-10.35, $P=0.006$) and history of stroke or TIA (OR: 3.32, 95% CI: 1.45-7.62, $P=0.004$). In addition to HF and previous stroke or TIA, the history of persistent AF (OR: 11.84, 95% CI: 4.68-29.91, $p<0.0001$), and the presence of obesity or overweight at baseline (OR: 8.01, 95% CI: 1.49-43.08, $p=0.015$) were independently associated with AF progression. The HATCH score's ROC area under the curve was 0.732 (95% CI, 0.64-0.83, $p<0.0001$).

Conclusions: At baseline, the HATCH score was a significant, but predictive accuracy was modest. Only 4 patients had a HATCH score>5 points and this recommended tool wasn't useful in identifying high-risk patients in this cohort. Independent predictors were the presence of HF, previous stroke or TIA and obesity or overweight and history of persistent AF.

P1936

Change in peak left atrial longitudinal strain predicted atrial fibrillation recurrence after cardioversionAA Andrey Shavarov¹; GK Kiyakbaev¹; VS Moiseev¹¹Peoples' Friendship University of Russia, Moscow, Russian Federation

Background: Several echocardiographic studies have demonstrated that left atrial (LA) strain and strain rate imaging is a very useful to assessing atrial function before and after cardiovascular procedures. We hypothesized that speckle tracking imaging could be superior to traditional echocardiography in predicting atrial fibrillation (AF) recurrence after electrical cardioversion (CV).

Purpose: To compare the predictive value of baseline echocardiographic parameters and its changes after CV for AF recurrence at 3 months.

Methods: Thirty one patients [mean age 64 (60; 72) yrs, 48% men] with paroxysmal and persistent non-valvular AF were included in study comparing echocardiographic measurements before and 10 days after CV. All pts underwent conventional and speckle tracking echocardiography and received III class antiarrhythmic drugs after CV. Apical four- and two-chamber views images of 6 myocardial segments in the filling phase were obtained to assess global peak left atrial longitudinal strain (PALS) and strain rate (PALSR) in the reservoir (r) and contractile (c) phase.

Results: Sinus rhythm maintenance was observed in 13 (42%) patients (group 1) throughout follow-up period whereas 18 (58%) patients (group 2) experienced at least one AF recurrence. Baseline echocardiographic and speckle tracking parameters were comparable between the 2 groups excluding PALSRc that was higher in group 1 than in group 2 (-1.87 vs -1.49 1/s, $p=0.03$, respectively). Change (Δ) in PALSr and PALSc 10 days after CV were significantly higher in group 1 to compare with group 2 (1.9 vs 0.5% , $p=0.01$, and -1.8 vs -0.7% , $p=0.001$, respectively). Regression analysis showed that Δ PALSc was associated with AF recurrence ($\beta=-0.67$, $=0.011$). The AUC of Δ PALSc in discriminating AF recurrence was 0.85 (95% CI 0.71-0.99, $=0.001$). An optimal cut-off value for Δ PALSc of -1.96% predicted AF recurrence with sensitivity of 88.9% and a specificity of 61.5%.

Conclusions: Improvement of PALSc within 10 days after CV was independently associated with AF recurrence. Baseline echocardiographic measurements did not reveal predictive ability regarding recurrent AF.

P1937

Effect of chronic kidney diseases on mortality among digoxin users treated for non-valvular atrial fibrillation: a nationwide register-based retrospective population-based cohort study.M Sessa¹; A Mascolo¹; MP Andersen²; G Rosano³; F Rossi¹; A Capuano¹; C Torp-Pedersen²¹Second University of Naples, Department of Experimental Medicine, Naples, Italy;²Aalborg University, Department of Health, Science and Technology, Aalborg,Denmark; ³San Raffaele Pisana Hospital IRCCS, Rome, Italy

Introduction: After the post-DIG trial era, digoxin is commonly used worldwide as heart rate control agent for the treatment of atrial fibrillation. Current clinical practice guidelines recommend administering digoxin to patients with or without chronic kidney disease, if the clinical condition permits the treatment. However, no single study have directly evaluated the effect of chronic kidney disease on mortality in patients receiving only digoxin as the treatment for atrial fibrillation. Taking into account that patients with chronic kidney disease typically were excluded from clinical trials, register-based observational studies could potentially improve knowledge on this topic.

Purpose: The objective of this study was to investigate the impact of chronic kidney disease on mortality across non-valvular atrial fibrillation patients treatment-naïve with digoxin.

Methods: All patients with non-valvular atrial fibrillation and/or atrial flutter as hospitalization diagnosis from January 1, 1997 to December 31, 2012 were extracted through Danish nationwide administrative registries. Among these patients we selected only digoxin treatment-naïve users who have initiated pharmacological treatment for non-valvular atrial fibrillation in the period. A "new user" design was applied, to remove bias due to the inclusion of prevalent drug users. Patients were excluded if they started digoxin in co-administration with other antiarrhythmic drugs. Treatment initiation date of digoxin was used as the index date for each patient, as all patients should be diagnosed with non-valvular atrial fibrillation within this index date. The study population was divided into two cohorts: patients with or without chronic kidney disease. Cox proportional hazard model was used to estimate the adjusted risk of all-causes and cardiovascular mortality between the cohorts.

Results: We identified 37981 patients treated for non-valvular atrial fibrillation receiving digoxin. Of these, 1884 patients had the diagnosis of chronic kidney disease. The study population of 37981 patients was followed up in the Patient Register for 10294 person-year (median = 99 days; range = 0-180), 22536 (59.3%) patients died. Among these, 14862 (39.1%) patients died for cardiovascular disease. Kaplan-Meier survival curves differed between the two cohorts for all-causes and cardiovascular mortality (log-rank test, p -value < 0.05). However, Cox regression analysis showed no statistically significant differences in all-causes (p -value = 0.110) and cardiovascular mortality (p -value = 0.146) among patients with chronic kidney disease compared to those without within both 180 days and 2 years from the index date.

Conclusions: This study suggesting no effect of chronic kidney disease on all-causes and cardiovascular mortality within both 180 days and 2 years from the first prescription of digoxin in patients treatment-naïve with digoxin for non-valvular atrial fibrillation.

CARDIOMYOPATHY

Long-term outcome of patients with virus-negative inflammatory cardiomyopathy after immunosuppressive therapyF Felicitas Escher¹; U Kuehl¹; D Lassner²; D Westermann³; B Pieske¹; C Tschöpe¹; HP Schultheiss²¹Charité - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Institute of CardiacDiagnostics and Therapy (IKDT), Berlin, Germany; ³University Heart Center

Hamburg, Hamburg, Germany

Aim: To analyse the long-term outcome after immunosuppressive treatment of patients with virus-negative inflammatory cardiomyopathy (CMI).

Methods and Results: We investigated 114 patients with endomyocardial biopsy (EMB)-proven virus-negative CMI, who were treated with prednisone and azathioprine for 6 months. Myocardial inflammation was assessed by quantitative immunohistology (IH). We examined hemodynamic measurements after 6 month and long-term follow-up periods of up to 10 years (mean 35.4 ± 127.9 months).

At follow-up, the patients altogether showed a significant improvement of left ventricular ejection fraction (LVEF) compared to baseline after 6 month and in the long-term follow-up ($p=0.006$). Simultaneously, EMB-analysis revealed significant reduction of quantified inflammatory infiltrates (CD3+, CD2+, perforin+ cells), and cell-adhesion molecule HLA-1.

In a subgroup analysis, Patients with initial LVEF $\leq 45\%$ ($n=74$) significantly increased with LVEF at follow-up ($29.3 \pm 8.8\%$ to $41.7 \pm 13.2\%$ to $42.1 \pm 13.1\%$, $p<0.0001$). Patients with initial LVEF $>45\%$ - 60% ($n=25$) significantly improved further (hemodynamically) or recovered completely, regarding LVEF ($53.0 \pm 3.6\%$ to $59.0 \pm 9.4\%$ to $59.8 \pm 10.0\%$, $p=0.03$). Patients with initial LVEF $>60\%$ ($n=15$) remained stabilized and did not deteriorated over long-term follow-up ($68.8 \pm 6.7\%$

to $67.5 \pm 10.9\%$ to $68.8 \pm 10.7\%$, $p=0.5$). Our data imply, that all patients can benefit from an immunomodulatory treatment, even in cases where initially only a slightly impaired LV function is present.

Conclusions: In patients with CMI we could show the effectiveness and beneficial effects of immunosuppressive treatment. This LVEF improvement is lasting for a long-term period of time.

P1939

Benefit of heart failure treatment in left ventricular non-compaction of the myocardium

M Cortes Garcia¹; J Palfy¹; MR Oliva²; M Orejas¹; MA Navas¹; M Taibo¹; R Rabago¹; M Rey¹; ME Martinez¹; J Farre¹

¹Foundation Jimenez Diaz, Madrid, Spain; ²Hospital Rey Juan Carlos, Cardiology, Mostoles, Spain

Introduction: Up until now there is no specific therapy for patients diagnosed with left ventricular non-compaction of the myocardium (LVNC). In the clinical practice if these patients present systolic dysfunction, standard heart failure treatment is initiated, however, its efficacy and clinical benefit is not studied among this group of patients.

Methods: We have included in our study all patients (pts) who fulfilled criteria for LVNC of the myocardium with decreased ejection fraction (EF < 50%) measured by echocardiography and magnetic resonance in the non-invasive cardiology laboratory of our tertiary hospital between January 2012 and February 2014. All of them received medical therapy for heart failure, including anti-remodeling agents according to the last recommendations. Clinical follow-up and control echocardiography study was carried out in order to determine the benefit of standard heart failure therapy in this patient population.

Results: We identified 11 pts fulfilling current criteria for LVNC and presenting decreased EF. Seven of them (63.6%) were males. Our study population had a mean age of 54.4 ± 14.9 years and a mean ejection fraction of $32.9\% \pm 10.4$. Five pts (45.5%) had a previous heart failure episode. Two pts were in NYHA class \geq II, and the resting 9 patients were in NYHA class I. Ten pts (91%) received beta-blockers, 10 pts (91%) angiotensin converting enzyme inhibitors or angiotensin receptor blockers (91%), and 6 pts anti-aldosterone agents (54.5%). A resynchronization device was implanted in 1 patient. After a mean follow-up of 29.6 ± 8.4 months, the mean ejection fraction was $37\% \pm 18.2$ in the study population. Five patients presented a significant increase (>10%) of the EF after initiating the anti-remodeling treatment and 3 of them achieved a complete normalization of the EF (>55%). All these patients were alive and asymptomatic at the end of the follow-up. All 6 patients who did not present improvement of the EF were alive, and 50% of them was in NYHA class II at the end of the follow-up.

Conclusions: A significant percentage of our patients on anti-remodeling therapy presented increase of the left ventricular EF and in some of them the LVEF normalized. Anti-remodeling therapy can be beneficial in patients with LVNC and left ventricular systolic dysfunction.

P1940

Effect of combined treatment with ozonotherapy on the structural and geometric parameters of the myocardium in patients with hypertension and metabolic syndrome

D Oliynyk¹; VN Bondar¹; NV Chumachenko¹

¹Odessa National Medical University, Propaedeutics of internal disease and therapy, Odessa, Ukraine

Hypertensive heart disease is the most common diseases of the cardiovascular system, being one of the causes of disability, morbidity and mortality. Also, the attention of clinicians focused on metabolic syndrome.

The aim of the study was to investigate the influence of complex medical treatment with the inclusion of ozonotherapy (OT) on the structural, geometric and functional parameters of left ventricular myocardium in hypertensive patients with metabolic syndrome.

The study involved 90 patients (44.2% men, 55.8% women) with essential hypertension II degree, concentric left ventricular hypertrophy, heart failure of 0-I and metabolic syndrome. The average age of the patients was (55.98 ± 2.29) years. The control group consisted of patients (30 persons), receiving standard medical therapy. The study group included 60 patients who in addition to standard medical therapy conducted in drip ozonated physiological sodium chloride solution with a concentration of ozone in the solution 3000 mg / l, 200 ml infusion lasting 60 minutes every other day, 10-12 procedures a course of treatment.

After treatment, there was a significant decrease of End Diastolic Volume (EDV) in all subgroups. Left Ventricular Ejection Fraction (LVEF) in the control and basic groups after treatment has not changed much. Increased Stroke Volume (SV) in the study group compared with the results before the treatment and was statistically significant. An increase in Minute Volume (MV) in the main group compared with the results before the treatment and was more pronounced, statistically significant nature than in the control group.

Thus, for the intergroup comparison showed a trend to improved left ventricular systolic function.

In analyzing the structure and geometric parameters of the left ventricle, found that after treatment the dynamics of changes in these indicators in the control groups and the main character was one-way with a tendency to their normalization. Also, significantly decreased indicators such as Interventricular Septal Thickness (IVST), the thickness of the posterior wall of the left ventricle (PWT), the index of left ventricular mass (LVM).

Based on the above, we can conclude that the effect of ozonotherapy has its own character, which is not dependent on the use of antihypertensive drug base to optimize medical treatment of these patients.

Thus, comprehensive medical treatment including ozonotherapy improves the pumping function and reduces diastolic dysfunction of the left ventricle in hypertensive patients with metabolic syndrome.

P1941

Acute heart failure complicating takotsubo syndrome

C Carina Arantes¹; S Rocha¹; C Braga¹; J Martins¹; P Azevedo¹; A Gaspar¹; S Fonseca¹; C Quina-Rodrigues¹; G Abreu¹; J Marques¹

¹Hospital de Braga, BRAGA, Portugal

Introduction: Takotsubo syndrome (TS) has generally been regarded as a relatively benign disease; however growing evidence suggests it is a more serious acute cardiac disorder with a high incidence of acute heart failure (HF).

Purpose: To characterize a population with TS and acute HF and to determine the predictors of HF.

Methods: Retrospective study of 57 patients (pts) consecutively admitted for TS in a cardiology department over a period of 5 years. We define HF as Killip class ≥ 2 . We analyzed the demographic and clinical characteristics, biomarkers and electrocardiographic and echocardiographic parameters.

Results: The mean age of the pts was 67.3 ± 11.6 years and there were 46 (80.7%) female pts. The prevalence of HF was 43.9% and 8.8% of the pts developed cardiogenic shock. There were no differences in the demographic characteristics and cardiovascular risk profile of these pts. The presence of atrial fibrillation/flutter on admission was more common in pts with HF (28 vs 3.1%, $p=0.007$). There was no difference in other electrocardiographic parameters. Pts with HF had, at admission, higher levels of creatinine (1.1 ± 0.4 vs 0.8 ± 0.3 mg/dl, $p=0.01$) and NT-proBNP (12750 ± 14869 vs 3827 ± 2767 pg/ml, $p=0.007$), as well as lower glomerular filtration rate (70.1 ± 29.5 vs 89.1 ± 33.3 ml/min/1.73m², $p=0.03$). The peak troponin I was also superior in these pts (6.0 ± 5.1 vs 3.6 ± 3.3 ng/ml, $p=0.03$). In echocardiographic evaluation, the pts with HF had a higher prevalence of severe depression of left ventricular systolic function (LVSF) (36% vs 12.9%, $p=0.04$), left ventricular outflow tract obstruction ≥ 40 mmHg (12% vs 0%, $p=0.04$) and mitral regurgitation (grade > II/IV) (25% vs 3.1%, $p=0.01$). The mean left ventricular ejection fraction was lower in these pts ($34.2 \pm 7.4\%$ vs $38.5 \pm 7.2\%$, $p=0.03$). Most had the apical variant, with no difference between groups regarding anatomical variant. After multivariate analysis, we established as independent predictors of heart failure: atrial fibrillation/flutter at admission ($p=0.03$, OR = 15.2 95% CI 1.3-186) and severe depression of LVSF ($p=0.04$, OR = 6.5 95% CI 1.2-39.2).

Conclusion: In our population, HF is a frequent in-hospital complication, with a cardiogenic shock prevalence of 8.8%. Severe depression of LVSF and the presence of atrial fibrillation/flutter were found to be independent predictors of HF.

Clinical features of peripartum cardiomyopathy

TA Abdullaev¹; ST Mirzarakhimova¹; NA Kurbanov¹; YUK Yuldasheva¹; I A Igor Tsoy¹; SHSH Davirova¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

Objective: To study the clinical features and prognosis of patients with peripartum cardiomyopathy (PCM).

Materials and Methods: The study involved 50 patients with PCM in the age from 20 to 41 years (mean age 28.2 ± 0.8 years). All patients underwent ECG, HMECG, echocardiogram, a 6-minute walking test with definition of functional class (FC) of heart failure (HF) by NYHA, and also studied life prognosis. The study of the dynamics of the disease lasted from 3 to 175 months (average, 5.4 ± 6.7 months), the mortality was 17 cases (34%). Patients were divided into 2 groups: I-Group amounted 17 patients died in the period from 3 to 131 months of observation (36.6 ± 7.2 months). II group of patients – 33 patients, survivors in the process from 31 to 175 months (average 83.1 ± 5.7 months; $p < 0.001$) surveillance. Therapy in these groups did not differ.

Results: A group of patients with lethal outcome, compared with patients surviving in the reference period was characterized by significantly higher FC of the CHF: 3.6 ± 0.1 and 3.2 ± 0.1 ($p=0.01$), and disease duration was 7.8 ± 1.8 and 6.2 ± 1.2 months., respectively ($p > 0.05$). The walk distance (WD) in the reference period

in the I group was 25.6% lower than in the II group, and amounted 170.3 ± 15.7 m and 214 ± 12.1 m ($p=0.02$). When comparing the parameters of intracardiac hemodynamics revealed that the I group of patients have decrease of ejection fraction (EF) of LV ($32.6 \pm 1.7\%$ and $37.6 \pm 1.8\%$; $p=0.01$) was associated with significant differences in the linear dimensions of the heart; EDV 6.8 ± 0.2 6.4 ± 0.09 sm ($p=0.04$), ESD 5.9 ± 0.1 5.5 ± 0.3 sm ($p=0.01$). In the analysis of ECG, a worst performance recorded in I group; violation of AV conduction of I degree found in 5 (29.4%) and 4 (12.1%) patients, atrial fibrillation in 3 (17.6%) and 1 (3.03%), pseudo - Q wave at 3 (17.6%) and 1 (3.03%), respectively, in I and II groups, but which did not have a statistically significant character. Analysis of the HMECG results showed that comparative aspect, high grade of VE; pair 12 (70.6%) and 12 (36.4%), Groups 6 (35.3%) and 3 (9.1%) significantly more frequently recorded in the group of died patients (both $p < 0.05$), unstable ventricular tachycardia (less than 30 sec) are set at 2 (11.8%) and 4 (12.1%), sustained at 1 (5.9%) (30 sec).

Conclusions: Results of the study patients' life expectancy PCM with prolonged follow-up (average 67.4 ± 5.4 months) revealed that mortality rates amounted to 17 (34%) cases. In case of death, heart failure is characterized by relatively severe, accompanied by a deterioration in the basic parameters of intracardiac hemodynamics and accompanied by a significant increase in the incidence of ventricular arrhythmias high gradation.

P1943

Incidence, risk factors, and clinical characteristics of peripartum cardiomyopathy in south korea

SK Sunki Lee¹; GJ Cho²; GU Park³; EJ Kim¹

¹Korea University Guro Hospital, Cardiovascular Center, Korea University Guro Hospital, Seoul, Korea Republic of; ²Korea University Guro Hospital, Department of Obstetrics and Gynecology, Seoul, Korea Republic of; ³Chung-Ang University Hospital, Department of applied statistics, Seoul, Korea Republic of

Background: Peripartum cardiomyopathy (PPCM) is a rare disorder associated with pregnancy that can lead to a life threatening conditions. Because of its rarity, the incidence and the clinical characteristics of this condition remain poorly understood.

Objective and methods: The purpose of this study was to produce the first population-based study for PPCM in South Korea using the Korea National Health Insurance Claims Database of the Health Insurance Review and Assessment Service. Patients were identified from International Classification of Diseases, tenth edition (ICD-10) who fulfilled diagnostic criteria of PPCM by searching for a pregnancy and heart failure related codes from 2009 to 2013. To discriminate the PPCM from other causes of heart failure (HF), we exclude who already have HF related ICD-10 codes in 2009 and performed investigations between 2010 and 2012.

Results: During 2010 and 2012, a total of 838 cases were identified as PPCM by discharge ICD-10 codes and there were 1,385,902 deliveries in South Korea. Thus, the overall incidence of PPCM was 1 in 1667 deliveries. Patients with PPCM were older ($p < 0.01$), had a higher prevalence of preeclampsia ($p < 0.01$) and gestational DM ($p < 0.01$), and more likely to occur in primiparous ($p=0.02$) and multiple pregnant women ($p < 0.01$) compared with control. Moreover, not only cesarean section ($p < 0.01$) was more common during delivery but related complications were also more common (Uterine arterial embolization, $p < 0.01$; peripartum hysterectomy, $p < 0.01$) in PPCM patients. Intriguingly, contrary to the classic criteria for the diagnosis of PPCM, quite large number of PPCM patients were still reported until 9 months (figure).

Conclusions: The incidence of PPCM was 1 per 1667 deliveries in South Korea. PPCM patients were older, more associated with primiparity and multiple pregnancy, and had more pregnancy related complications than control. In addition, the current traditional criteria of PPCM is too strict and that patients who develop HF after the 5 months of delivery might also be considered as a continuum of PPCM.

Time of diagnosis of PPCM

Meta-analysis on the clinical effects of colchicine in recurrent pericarditis

M Michel Noutsias¹; P Schlattmann²; P Aftanski³; JG Westphal³; T Bekfani³; PC Schulze³; L Seres-Sturm³

¹Charite - University Medicine, Campus Benjamin Franklin, Berlin, Germany;

²Institute of Medical Statistics, Friedrich-Schiller University Jena, Jena, Germany;

³University Hospital Jena, Department of Cardiology, KIM I, Jena, Germany

Background: Colchicine inhibits microtubule self-assembly by formation of tubulin-colchicine complexes, and thereby ultimately decreases leucocyte motility and phagocytosis, thereby reducing the inflammatory response. Recurrent pericarditis is partly responsive to colchicine treatment, as elucidated in several randomized controlled trials.

Purpose: Meta-analysis of RCTs on the clinical effects of colchicine treatment for recurrent pericarditis.

Results: We identified $n=7$ RCTs eligible for inclusion to this meta-analysis, with 1,832 patients (mean age: 57.1 years; range: 18-85 years; men: 56%), presenting with recurrent pericarditis under nonsteroidal anti-inflammatory drugs, (NSAID) and partly also corticosteroids. The mean follow-up period was 13.1 months (range: 3-22 months). The patients treated with colchicine were prescribed colchicine 1.0 to 2.0 mg on the first day, followed by a maintenance dosage of 0.5 to 1.0 mg/d for 3-6 months. Compared with the control group, colchicine treatment reduced the risk of recurrent pericarditis (OR: 0.42; 95% CI: 0.33-0.52; $p < 0.001$). Pericarditis-associated re-hospitalizations and persistence of symptoms at 72 hours were reported in 5 RCTs. The rate of symptom persistence at 72 hours (OR: 0.29; 95% CI: 0.21-0.41; $p < 0.001$), and pericarditis-associated re-hospitalizations (OR: 0.29; 95% CI: 0.16-0.53; $p < 0.001$) were significantly reduced by colchicine treatment compared with the control group, respectively. Compared with the control group, colchicine treatment was associated with a higher rate of adverse events (OR: 1.48; 95% CI: 1.06-2.07; $p=0.02$). The most frequent adverse event was gastrointestinal intolerance / diarrhea (mean incidence: 9%).

Conclusions: The results of this meta-analysis of RCTs confirm that colchicine treatment decreases significantly the rate of pericarditis recurrence, as well as the hospitalization rate resulting from recurrent pericarditis.

P1945

Advanced left ventricular diastolic dysfunction in uremic patients with type 2 diabetes on maintenance hemodialysis.

R Rania Hammami¹; LEILA Abid¹; FATEN Triki¹; SOUAD Mallek¹; SAMIR Kammoun¹

¹Hedi Cheker Hospital, Department of Cardiology, Sfax, Tunisia

Background: It is generally difficult to determine whether myocardial dysfunction in diabetic patients on hemodialysis is due to diabetes or kidney disease and whether the association of these two conditions will worsen again myocardial disease. The aim of the study is to identify the impact of diabetes on the left ventricular diastolic dysfunction in uremic patients on hemodialysis.

Methods: A total of 72 patients on maintenance hemodialysis with normal LV systolic function were studied. We compared the diastolic function in 2 groups: group1 = with diabetes (11 patients) and group 2 = without diabetes (61 patients).

Results: The conventional LV diastolic echocardiographic parameters did not differ between the 2 groups, except for the left atrial size ($p=0.02$) and volume index ($P < 0.001$). The ESRD patients with DM, however, had significantly decreased mitral annular early diastolic peak velocity (<0.001) and ratio of early to late diastolic mitral annular velocity (e'/a' ; $P < 0.016$). Additionally, diabetic patients had markedly higher estimated LV end-diastolic filling pressure (E/e' ; $p=0.03$).

Conclusions: In End stage renal disease patients with type 2 DM undergoing hemodialysis, TDI indicated more advanced LV diastolic dysfunction. Also, TDI offers a feasible means of evaluating subclinical alterations of LV function, possibly allowing for the early detection of diabetic heart disease in severe uremic patients.

P1946

Inflammatory cardiomyopathy detected by immunohistological methods - a meta-analysis

M Noutsias¹; J Katzmann¹; I Porokhovnikov²; E Noutsias³; PC Schulze¹; P Schlattmann²

¹University Hospital Jena, Department of Cardiology, KIM I, Jena, Germany;

²Institute of Medical Statistics, Friedrich-Schiller University Jena, Jena, Germany;

³Charite - University Medicine, Campus Benjamin Franklin, Berlin, Germany

Background: Chronic intramyocardial inflammation has been associated with the pathogenesis of dilated cardiomyopathy. Whereas the histological diagnosis of myocarditis according to the Dallas criteria has no prognostic and diagnostic value, the immunohistological diagnosis of inflammatory cardiomyopathy (DCMI) in endomyocardial biopsies (EMB) has endorsed a novel entity within the clinical presentation of DCM patients.

Purpose: Meta-analysis on the immunohistologic and histological diagnosis of intramyocardial inflammation in EMB.

Results: We identified $n=61$ investigations eligible for inclusion in this meta-analysis, with 10,491 patients (mean age: 47.1 years; men: 66%) who underwent EMB obtainment and immunohistological quantitative diagnostics for infiltrate density and endothelial cell adhesion molecule (CAM) expression. In these studies, $n=460$ control patients were reported. The mean detection rate of DCMi by immunohistology was 50.8 % (95 %-CI: 47.7–53.8%). A substantial publication bias was excluded by linear regression / Funnel Plot ($p=0.4264$). The positivity rate of the immunohistological proof of intramyocardial inflammation in patients with clinically suspected acute myocarditis (AMC: mean: 58.6%; 95 %-CI: 51.2–65.0%) was significantly ($p=0.0053$) higher compared with patients presenting with chronic DCM (mean: 47.0 %; 95%-CI: 42.3–51.7 %). This immunohistological detection rate was significantly ($p<0.0001$) higher compared to the mean detection rate of myocarditis according to the Dallas criteria (mean: 13.6 %; 95%-CI: 11.3–16.3%).

Conclusions: The results of this meta-analysis confirm that the immunohistological detection technique is significantly more sensitive in the detection of intramyocardial inflammation in patients presenting with AMC or DCM compared to the histological Dallas criteria. The proof of the adverse prognostic impact, and the suitability of the immunohistological approach for selection of candidates profiting from immunosuppression, as shown in 2 randomized trials, as opposed to the histological Dallas criteria, may be due to the observer-independent, methodologically determined higher detection robustness.

P1947

Reverse left ventricular remodeling after cardiac resynchronization in patients over 75 years.

S Briongos Figueroa¹; M Cortes²; JA Palfy²; M Martin²; M Lopez²; I Hernandez¹; A Sanchez¹; A Garcia²; R Munoz-Aguilera¹; J Farre²

¹University Hospital Infanta Leonor, Cardiology, Madrid, Spain; ²Foundation Jimenez Diaz, Cardiology, Madrid, Spain

Background: little data exist on the benefit of cardiac resynchronization therapy (CRT) in the elderly since the number of these patients was limited in large trials. We aimed to describe predictors of response to CRT in a group of elderly patients (≥ 75 years old).

Methods: A total of 41 patients undergoing CRT implantation between June 2006 and October 2014 were included. Left ventricular reverse remodelling was defined as reduction of $\geq 15\%$ in left ventricle end diastolic diameter (LVEDD).

Results: mean age was 79.2 ± 2.9 years and 20.4% were women. At the time of the implant left ventricle was dilated (mean LVEDD 60.4 ± 6.6 mm) and impaired (mean left ventricular ejection fraction (LVEF) $23.4 \pm 6.7\%$). Almost half of the patients suffered non-ischemic cardiomyopathy (51%) and mostly were in NYHA III-IV (54.2%). Medical treatment was optimized (Beta blockers: 87.5%; ACEI (angiotensin-converting enzyme inhibitors): 64.6% and aldosterone antagonists: 68.8%). Left bundle branch block (LBBB) was present in 67.3% of the overall population, and mean QRS duration was of 155.4 ± 25 ms. After a mean follow up of 37.2 ± 19.3 months, a reduction in LVEDD (57.3 ± 9.3 mm) and an improvement in LVEF ($30.8 \pm 13.7\%$) were observed. 60.5% of patients were in NYHA I-II. Significant reverse left ventricular remodelling (positive response) was observed in 11 patients (26.8%). Responders not only showed greater reduction in LVEDD (baseline LVEDD 61.3 ± 4.1 mm; final 47.6 ± 5.9 mm; $p=0.024$ in responders Vs baseline LVEDD 59.9 ± 7.1 mm; final 60.8 ± 7.8 mm; $p=0.286$ in non-responders) but also showed greater improvement in LVEF (baseline LVEF $23.4 \pm 7.1\%$; final $44.1 \pm 12.9\%$; $p=0.02$ in responders Vs baseline LVEF $22.9 \pm 6.7\%$; final $24.7 \pm 9.6\%$; $p=0.212$ in non-responders). A positive remodelling was associated with female sex (OR 50.5; IC 95%: 1.96-1296.03); QRS duration ((OR 1,1; IC 95%: 1.02-1,19).

Conclusion: left ventricular dilatation reversed in a 26.8% of elderly patients after CRT. Given the high costs of the implant, defining strategies to select elderly patients who are more suitable for CRT, is necessary. QRS duration and female sex were good predictors of reverse remodeling.

P1948

Assesment of bioelectrical impedance indicators among the patients with dilated cardiomyopathy

D Stettner-Leonkiewicz¹; A Glowinski¹; W Zaluska²; A Wysokinski¹

¹Medical University of Lublin, Department of Cardiology, Lublin, Poland; ²Cardinal Wyszyński Hospital, Department of Nephrology, Lublin, Poland

Introduction: Dilated cardiomyopathy is one of the cardiomyopathies a group of diseases that affect primarily the myocardium. In DCM, a portion of myocardium is dilated, often without any obvious cases. So far volemia has not been examined by BIA (bioelectrical impedance) parameters among the patients diagnosed with this disease.

Purpose: Assesment of selected bioelectrical impedance indicators among the patients affected with dilated cardiomyopathy.

Methods and materials: In the Cardiology Department in the Medical University of Lublin 106 patients with DCM and 103 healthy persons have been examined. For the assesment of bioimpedance parameters the WBIA method has been applied and used by means of bioelectrical impedance analysis measurements by BCM Body Composition Monitor (Fresenius Medical Care Deutsche and GmbH) with frequency from 5 to 500 kHz. The following correlations of parameters have been set: OH (overhydration), ECW (extracellular water), ECW/TBW indicator (extracellular water/total body water), ICW/TBW indicator (intracellular water/total body water).

Results: Parameters OH was significantly higher in patients with DCM than in the control group, 0,2 vs 0,1 ($p=0,02$). ECW was significantly higher in patients with DCM than in the control group, 16,6 vs 14,1 ($p<0,000001$). ECW/TBW was higher in patients with DCM, 0,47 vs 0,43 ($p<0,000001$). ICW/TBW was lower in patients with DCM, 0,53 vs 0,57 ($p<0,000001$).

Conclusions: The analysis of bioelectrical impedance indicators make signifant importance in volemia and potential overhydration among the patients with DCM.

Left ventricular dysfunction (burn-out phase) in hypertrophic cardiomyopathy: prevalence and associated factors

R A Rui Alexandre Pontes Dos Santos¹; I Cruz²; J Guedes³; B Marmelo⁴; L Reis⁵; K Domingues⁶; R Faria⁷; S Leao⁸; B Picarra⁹; O Azevedo¹⁰

¹Hospital Centre do Tamega e Sousa, Penafiel, Portugal; ²Hospital Garcia de Orta, Almada, Portugal; ³Faro Hospital, Faro, Portugal; ⁴Hospital Sao Teotónio, Viseu, Portugal; ⁵University Hospitals of Coimbra, Coimbra, Portugal; ⁶Hospital of Santarém, Santarém, Portugal; ⁷Medio Ave Hospital Centre, Famalicão, Portugal; ⁸Hospital Center of Tras-os-Montes and Alto Douro, Vila Real, Portugal; ⁹Hospital Espírito Santo de Évora, Évora, Portugal; ¹⁰Alto Ave Hospital Center, Guimarães, Portugal

Introduction: Left ventricular hypertrophy (LVH) in hypertrophic cardiomyopathy (HCM) is usually associated with a normal LV ejection fraction. However, a small minority of patients progress to a dilated stage with LV systolic dysfunction, known as “burnout phase”. The prevalence of this phase in HCM patients varies from 2.4% to 4.9%.

Purpose: Describe a HCM Portuguese population and determine the prevalence of “burn-out” phase among those patients. Define any clinical, genetic, eletrocardiographic or imagiologic factors related with advancement to “burnout phase”.

Methods: A multicentre Portuguese study involving 10 hospital centres and including all patients diagnosed with HCM. Clinical, genetic, eletrocardiographic, echocardiographic and magnetic resonance (MR) characteristics were evaluated. “Burnout phase” was defined as the presence of an ejection fraction $<50\%$.

Results: 476 patients with HCM were included (58% were male and mean age 62 ± 15 years). HCM was predominantly septal asymmetric (72%), but concentric symmetrical in 13% and apical in 15% of patients. The most common symptoms were dyspnoea (57%), angina (19%) and syncope (13%). Cardiac death occurred in 11 patients (2.3%) after a mean follow up of 6 years. Family history of HCM was identified 15% and of sudden death in 14%. Genetic study was done in 244 patients (51%), and 34% presented with pathogenic genetic mutations. 21% had a history of atrial fibrillation and 16% of non-sustained ventricular tachycardia. Pacemaker was implanted in 6% and ICD in 16% of this patients. The mean ejection fraction was $66 \pm 9\%$. MR late gadolinium enhancement was found in 58%. 2.9% of patients were in “burnout phase”. They had most frequently chronotropic incompetence in 24 hour Holter ($p<0,001$). There were no significant differences in the remaining clinical, genetic, eletrocardiographic, echocardiographic and MR characteristics.

Conclusion: In this Portuguese population, the prevalence of “burnout phase” was 2.9%, which is consistent with previous studies. Chronotropic incompetence was significantly associated with “burnout phase”.

P1950

Predictors of cardiopulmonary responses to exercise in hypertrophic cardiomyopathy

T Thomas Zegkos¹; D Parcharidou¹; G Efthimiadis¹; M Didagelos¹; D Ntelios¹; P Rouskas¹; G Giannakoulas¹; H Karvounis¹

¹Ahepa University Hospital, 1st Cardiology Department, Thessaloniki, Greece

Background: Inconclusive evidence exist about the main determinants of exercise intolerance, ventilatory inefficiency and chronotropic incompetence in hypertrophic cardiomyopathy (HCM). Aim of this study was to investigate the main demographic, clinical and echocardiographic predictors of cardiopulmonary responses to exercise in patients with HCM.

Methods: Exercise capacity (maximal oxygen consumption/predicted [%peakVO₂]), ventilatory efficiency (ventilation/carbon dioxide output [VE/VCO₂] slope) and chronotropic index (heart rate reserve/220-age-heart rate at rest [%HRR]) were evaluated in 154 consecutive HCM patients (age at first evaluation 43 ± 14 years; 72% male) that underwent cardiopulmonary exercise testing.

Results: A total of 78 (50.6%) of 154 patients had impaired exercise tolerance (%peakVO₂ $<80\%$ of predicted), 81 (52.6%) reduced chronotropic response

Predictors of cardiopulmonary responses

	Exercise capacity ($R^2 = 0.37$)	Ventilatory efficiency ($R^2 = 0.21$)	Chronotropic index ($R^2 = 0.21$)			
	B	p value	B	p value	B	p value
Female gender	-17.90	< 0.001	1.63	0.048	NA	NA
NYHA class > I	-13.01	< 0.001	2.17	0.005	-0.13	< 0.001
Age	0.39	0.001	NA	NA	NA	NA
Maximum wall thickness	-7.39	0.01	NA	NA	NA	NA
Obstructive phenotype	-8.80	0.01	NA	NA	NA	NA
B-blocker	NA	NA	NA	NA	-0.13	< 0.001
Left atrial diameter	NA	NA	2.13	< 0.001	NA	NA
NA:	not	applicable,	valid:	New	York	Heart
						Association

(%HRR <80% of predicted), and 17 (11%) ventilatory inefficiency (VE/VO₂ slope > 34). Forward stepwise multivariate regression analysis resulted in female gender, NYHA class > I, younger age, higher maximum wall thickness and obstructive phenotype as main independent determinants of reduced %peakVO₂ ($R^2 = 0.37$). Furthermore, independent predictors of higher VE/VO₂ slope were increased left atrial diameter, NYHA class > I and female gender ($R^2 = 0.21$), whereas of lower %HRR were NYHA class > I and b-blockers administration ($R^2 = 0.21$) (Table).

Conclusions: The prevalence of exercise intolerance, ventilatory inefficiency and chronotropic incompetence was high in our HCM population. Patients' functional status was the only common independent determinant. Female gender independently correlated with reduced %peakVO₂ and higher VE/VO₂ slope whereas younger age seem to have a negative effect on exercise capacity. Echocardiographically, obstructive phenotype and increased left atrial diameter were associated with lower %peakVO₂ and higher VE/VO₂ slope, respectively.

P1951

The risk factors of advanced heart failure in hypertrophic cardiomyopathy

SJ Sookjin Lee¹; IH Jung²; HJ Chang¹; SK Hong¹

¹Sejong General Hospital, Cardiology, Bucheon, Korea Republic of; ²Sanggye Paik Hospital, Cardiology, Seoul, Korea Republic of

Background: Hypertrophic cardiomyopathy (HCM) is the most common genetic cardiomyopathy worldwide of which diastolic heart failure is the dominant clinical manifestation. Proportion of patients progress into burnt out dilated cardiomyopathy (DCM), which have very poor prognosis. However, very little is known about its clinical risk factors, echocardiographic features and therapeutic strategies.

Purpose: The hypothesis is that subgroups of HCM depending on heart failure syndromes have heterogeneous prognosis. The prognostic markers of the subgroups are searched by comparing clinical and echocardiographic risk factors. Next, we searched for prognostic markers of clinical outcomes of total death, cardiac death, heart failure admission and VT in total HCM patients.

Methods: Medical record of 520 HCM patients in a large cardiovascular center in Korea from January 2000 to December 2013 are retrospectively reviewed. The total HCM patients are classified into three groups (1) systolic heart failure (2) diastolic heart failure (3) neither (1) nor (2). The risk factors and clinical outcomes of total death, cardiac death, heart failure and VT were compared with each group. Cox regression analysis was performed in regard to clinical outcomes of all the HCM patients.

Results: 520 patients are enrolled. 453 patients are followed up for more than 1 year. Average follow up period is 90 ± 60 months. Baseline characteristics of total HCM are as follows. Average age 58 ± 14 years-old, male is 289 (55.6%) patients. Apical hypertrophy is the most frequent (34%), followed by septal hypertrophy (21%), septal-anterior-lateral hypertrophy (18%), septal and apical(mixed) hypertrophy (22%). Maximal wall thickness is 20.5 ± 4 mm, obstructive HCM is in 21% of patients. Total death occurred in 89(17%) patients during follow up, cardiac death in 36(7%), heart failure admission in 61(12%), VT in 26(5%). Group 1 had significantly decreased survival rate for total death, cardiac death and heart failure. With multivariable logistic regression, LA volume, HCM types are significant risk factors for HCM progression to DCM. With Cox regression analysis, age, AF are significant risk factors for total death, cardiac death and heart failure admission. Age, maximal wall thickness and AF are significant for VT.

Conclusion: We retrospectively documented poor prognosis of HCM into DCM progression group and risk factors, which are LA volume, HCM type. In addition, age and AF are significant prognostic markers for total death, cardiac death, and heart failure admission.

P1952

Vascular endothelial growth factor is associated with the morphologic and functional parameters in patients with hypertrophic cardiomyopathy

R Radek Pudil¹; M Vasatova²; A Fucikova³; H Rehulka³; P Rehulka³; V Palicka²; J Stulik³

¹Charles University Prague, Faculty of Medicine in Hradec Kralove, 1st Department of Medicine, Hradec Kralove, Czech Republic; ²University Hospital Hradec Kralove, Institute of Clinical Biochemistry and Diagnostics, Hradec Kralove, Czech Republic; ³Faculty of Military Health Sciences, University of Defence, Department of Molecular Pathology and Biology, Hradec Kralove, Czech Republic

Purpose: Hypertrophic cardiomyopathy (HCM) is mostly autosomal dominant disease of the myocardium, which is characterized by myocardial hypertrophy. Vascular endothelial growth factor (VEGF) is involved in myocyte function, growth, and survival. The aim of study was to analyze the clinical significance of VEGF in structural and functional changes in patient with non-obstructive type of HCM.

Methods: In a group of 21 patients (58.4 ± 13.2 years, 6 female) with non-obstructive HCM, we assessed serum VEGF and analyzed its association with morphological and functional parameters.

Results: Compared to healthy controls, serum VEGF was increased: 199 (IQR: 120.4–260.8) ng/L versus 20 (IQR: 14.8–37.7) ng/L, $p < 0.001$. In patients with New York Heart Association (NYHA) functional classes I and II, serum VEGF values were lower compared to patients with NYHA classes III and IV: 146.4 (IQR: 113.6–235.2) ng/L versus 328.1 (IQR: 286.7–406.3) ng/L, $p < 0.01$. The mean left ventricle mass was 408.4 ± 11.8 g, and it exceeded reference values for two-dimensional method (female: 150 g, male: 200 g) in all patients. The mean left ventricle mass index was 202.4 ± 53.9 g·m⁻², and it exceeded reference values for two-dimensional method (female: 88 g·m⁻², male: 102 g·m⁻²) in all patients. The mean of the left ventricle ejection fraction was 65.4 ± 12.2%. The mean of the left ventricle fractional shortening was 0.32 ± 0.09, and it exceeded the reference values (female: 27–45, male: 25–43) in 3 (15%) patients. The mean peak tricuspid regurgitation gradient was 22.6 ± 11.8 mmHg. The inferior vena cava diameter was 18 ± 3.7 mm. None of the patients had left ventricle outflow tract obstruction. The peak left ventricle outflow tract gradients were 6 (IQR: 1–7.5) mmHg during at rest measurement and 15 (IQR: 2.2–29) mmHg during Valsalva maneuver. The median values for the peak LVOT pressure gradient were 3 (IQR: 2.2–5) mmHg for at rest measurements and 14 (IQR: 2–22) mmHg during Valsalva maneuver. VEGF levels were associated with left atrium diameter ($= 0.51$, $p = 0.01$), left ventricle ejection fraction ($= -0.56$, $p = 0.01$), fractional shortening ($= -0.54$, $p = 0.02$), left ventricular mass ($= 0.61$, $p = 0.03$), LV mass index ($= 0.46$, $p = 0.04$), vena cava inferior diameter ($= 0.65$, $p = 0.01$), and peak gradient of tricuspid regurgitation ($= 0.46$, $p = 0.03$).

Conclusions: Increased VEGF level is associated with structural and functional parameters in patients with HCM and serves as a potential tool for diagnostic process of these patients.

Elderly patients with heart failure, how do they go?

LS Secco¹; DAF Fernandez¹; MGM Masuelli¹; LL Lapadula¹; MB Baglioni¹; SM Mettini¹; SMPG Pereiro Gonzalez¹

¹Hospital Center Churrua-Visca, Buenos Aires, Argentina

Intro: Heart failure (HF) has been studied for many years, it has high incidence and it seems to be increasing. However, in every paper, elderly patients (p) are excluded.

Objective: 1- Describe characteristics and evolution of 75 years old or older p admitted for decompensated HF (DHF). 2- Compare these p with younger ones.

Method: It is a prospective analysis of 370 p admitted for DHF, consecutively, in our Cardiology Service, from June 2012 to November 2015, with a median follow-up of

23 months (Q1 13 - Q3 33). We divided p into 2 groups according to their age: G1 ≥ 75 years old (151 p) and G2 < 75 years old (219 p). Quantitative variables with normal distribution were expressed with mean and with standard deviation (analyzed by Fisher's Test); those with not normal distribution, were expressed with median (m) and quartiles (analyzed by Mann Whitney's Test). Dichotomous variables were analysed by Chi2.

Results: G1 showed a mean age of 82 years old, 48% were males (vs 77.7% in G2, $p < 0.001$), 83.4% had HTA, 29.1% were diabetics (vs 34.9%, $p = 0.01$), 24.5% smokers (vs 62.4%, $p < 0.0001$). Etiology was predominantly ischemic, but we only had statistically significant difference (SSD) in valvular etiology (G1 17.1% vs G2 10%, $p = 0.04$). In the echocardiography, elderly p had smaller left ventricular diameters (diastolic 52 mm vs 58 mm, $p < 0.0001$, systolic 35 mm vs 47 mm, $p < 0.0001$), and they present better ejection fraction (EF) than younger p (45% vs 34%, $p = 0.0003$). Older p also had more prevalence of moderate mitral regurgitation (37% vs 27.6%, $p = 0.04$). Clinically, both G had similar presentation, but G1 had more males (80.1% vs 68.5%, $p = 0.006$).

At labs, renal function was worse in G1, as well as with glomerular filtration rate by MDRD as by creatinine clearance in 24 hs. (44.5 ml/min/1.73 m² vs 57 ml/min/1.73 m², $p < 0.01$). We also noted lower values in T3, bilirubin, uric acid, proteins, albumin, hematocrit and hemoglobin (every one with SSD), but with no clinical significance. At the EKG, G2 had had more sinus rhythm (67.3% vs 39.3%, SSD), and G1 more atrial fibrillation/flutter or pacemaker rhythm (both SSD). Also width of QRS complex was longer in G2 (105 msec vs 80 msec, SSD), with more LBBB (32.7% vs 20.4%, SSD).

There were no differences in previous treatment, except for more diuretics in G1 (59.6% vs 41.5%, SSD).

G1 had more mortality (MRT) at hospital (7.9% vs 2.8%, $p < 0.0001$) as well as at the following up (52.2% vs 22.8%, $p < 0.0001$). Readmission were about 35% in both G ($p = 0.58$).

Conclusions: We see that our population had similar characteristics to those in international registries. Older p had worse evolution even they had better EF; we think this could be due to comorbidities. It would be interesting to analyze each one.

P1954

Variation in the clinical profile of women with acute myocardial infarction and an ejection fraction lesser than 40% over the last 10 years

C Catia Costa¹; D Durao¹; M Leal¹

¹Hospital of Santarem, Cardiology, Santarem, Portugal

Introduction: The clinical profile of women patients has varied greatly over the past few years, particularly with regard to demographic characteristics and comorbidities.

Aims: Assess the profile variation of women with acute myocardial infarction (AMI) and an ejection fraction (EF) lesser than 40% (EF $< 40\%$) over the past ten years.

Methods: Retrospective study, including 1138 women with AMI and an EF $< 40\%$, from 2006 to 2015. The population was divided in three groups: A, including patients with AMI between 2006 and 2009 ($n = 498$); B, including patients with AMI between 2010 and 2012 ($n = 388$); C, including patients with AMI between 2013 and 2015 ($n = 252$). Differences between groups were evaluated regarding the clinical profile.

Results: There has been an important reduction of time interval between onset of symptoms and hospital admission over time ($p < 0.001$). Smoking habits have become a more prevalent risk factor in the last years ($p = 0.042$). Previous history of AMI and the prevalence of AMI without ST elevation have declined ($p < 0.05$), with growing reperfusion therapy ($p < 0.001$). A severe EF (under 30%) and decompensated heart failure have become less prevalent ($p < 0.001$). There was not significant change in hospital mortality or mortality at 6 months follow-up.

Conclusions: The clinical profile of women with AMI and an EF lesser than 40% has changed over time. This is a result of a modification of lifestyle habits, with growing smoking habits, and an improvement of health care, which translates into improved diagnosis of ischemic heart disease and a better ability to optimize therapy in these patients.

P1955

Comorbidities and prognostic factors associated with 1-year mortality and hospital admission in heart failure outpatients based on ejection fraction findings.

MA Miguel Antonio Lopez Garrido¹; HN Orellana-Figueroa¹; A Robles-Mezcua¹; P Cardila-Cruz¹; L Jordan-Martinez¹; D Elena-Aldana¹; A Guijaro¹; N Abdeslam¹; L Morcillo-Hidalgo¹; JM Garcia-Pinilla¹

¹University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background/Introduction: The presence of comorbidities is very common in patients with heart failure, making more difficult the clinical management and being associated with poor prognosis. The prognostic factors should be stratified according to currently recommended ejection fraction (EF) findings. We conducted this study in order to know the prevalence and type of comorbidities in heart failure outpatients and to determine prognostic markers.

Methods: We studied all the heart failure outpatients included in the ESC Heart Failure Registry in our Hospital, recording their clinical characteristics, comorbidities, and mortality and hospital admissions during 1-year follow-up. Preserved EF was defined as $\geq 45\%$.

Results: Of the 245 patients (67 years, 31.4% women), 139 (56.7%) had reduced EF and 94 (38.4%) had preserved EF. The group of patients with preserved EF presented a significantly higher mean age (69 vs 65 years, $p < 0.024$), higher percentage of women (51.1% vs 19.4%, $p < 0.001$), and lower prevalence of ischemic heart disease (17% vs 37.4%, $p = 0.001$). The patients with reduced EF practiced less regular physical activity (39.3% vs 55%, $p = 0.041$) and had higher prevalence of prior admission for heart failure (43% vs 16.3%, $p < 0.001$). There were no significant differences in both groups with regard to comorbidities (Charlson index 4.86 of reduced EF patients vs 4.84 of preserved EF patients, $p = 0.929$). Older age and Charlson index were independent predictors of 1-year mortality for all study patients. Atrial fibrillation and high heart rate were associated with 1-year mortality and 1-year hospital admission in outpatients with reduced EF, and high heart rate and regular physical activity were associated in outpatients with preserved EF.

Conclusions:

1. Heart failure outpatients have high prevalence of comorbidities, independently of EF.
2. Older age and Charlson index were independent predictors of 1-year mortality for all study patients.
3. Atrial fibrillation and high heart rate were associated with 1-year mortality and 1-year hospital admission in outpatients with reduced EF, and high heart rate and regular physical activity were associated in outpatients with preserved EF.

Heart in the air piacenza project: correlation between air pollution and heart failure hospitalisation in the po valley

GQ Villani¹; F Pugliese¹; G Miserotti²; N Montanari³; G Biasini²; M F Massimo Francesco Piepoli¹

¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy;

²Guglielmo Da Saliceto Hospital, Piacenza, Italy; ³Associazione Ambiente Lavoro, Piacenza, Italy

Background: Air pollution is a heterogeneous, complex mixture of gases, liquids, and particulate matter. Epidemiological studies have demonstrated a consistent increased risk for cardiovascular events in relation to both short- and long-term exposure to present-day concentrations of ambient particulate matter. The Po valley located in the Northern Italy is one of the most polluted area in the world due to geographic and demographic characteristics.

Aim and Methods: In order to evaluate the impact of air pollution on the occurrence of cardiac morbidity in our region, we correlated the increment in air pollutant and admission to Emergency Dept. at our General District Hospital for acute coronary syndrome, supraventricular arrhythmias, heart failure, hypertension, syncope, in the years 2007-2008. Preliminary a test of homogeneity was performed by computing three coefficients of correlations (Pearson, Lin, Bland-Altman). Therefore a correlation analysis using the Poisson model for the disease frequency was used.

Results: The study population was represented by 2810 patients admitted for cardiac causes, (72.61 \pm 14.2 years, 1404 males (49.96%): arrhythmias 6.6%, acute coronary syndrome 23.7%, hypertension (27%), heart failure (35.8%), syncope (6.5%). A significant correlation was detected among the rate of admission for supraventricular arrhythmias, syncope and increases in the air concentration of benzene ($P < 0.05$), while a no-significant correlation were detected between increases in the air concentration of NO₂, SO₂ and O₃ and admission for acute coronary syndrome.

Conclusion: We confirm the evidence of a relationship between cardiac disease and increment in air pollution. Several plausible mechanistic pathways have been described, including enhanced coagulation/thrombosis, a propensity for arrhythmias, acute arterial vasoconstriction, systemic inflammatory responses, and the chronic promotion of atherosclerosis.

P1957

Hyperuricemia is a determinant of mortality in heart failure patients irrespectively of age, ejection fraction, or renal function

K Kazumasa Harada¹; T Sakai²; N Sato²; S Kohsaka²; Y Shiraishi²; K Iida²; T Miyamoto²; S Tanimoto²; K Nagao²; M Takayama²

¹Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan; ²Tokyo CCU Network Scientific Committee, Tokyo, Japan

Purpose: Serum uric acid is a predictor of cardiovascular mortality in heart failure with reduced ejection fraction (HFrEF). We studied the prognostic value of serum uric acid (sUA) in patients hospitalized for acute heart failure (AHF), with specific focus on age, ejection fraction, and renal function.

Methods: The CCU Network Database is an on-going emergency medical service registry supported by 71 hospitals. Among 7573 patients hospitalized for AHF in

2012 and 2013, data of sUA and serum creatinine (sCr) were available in 5193 patients (75.6 ± 13.6 years; men, 59%).

Results: In-hospital mortality rate during hospital stay was 7.0%. Mean sUA was 7.2 ± 2.9 mg/dl. sUA correlated with sCr, and very weakly correlated with BNP and LV ejection fraction. Logistic regression analysis with in-hospital mortality as a dependent variable showed that sUA, sCr, systolic blood pressure, body mass index (BMI), and hemoglobin concentration (Hb) at admission were independent factors after adjusting age and sex. We, then, subdivided the AHF patients dependent on the LV ejection fraction ($< \text{or} \geq 40\%$, median) or on the age ($< \text{or} \geq 78$ years old, median). After adjusting age, sex, and sCr, sUA was still an independent predictor of mortality both in patients with HFREF and in those with heart failure with preserved ejection fraction (HFpEF), as well as in younger patients (YOUNG) and older patients (OLD).

Conclusion: Hyperuricemia in AHF patients is one of the strongest predictors of mortality either in younger or older patients, or in patients with HFREF or those with HFpEF, irrespectively of renal function.

Logistic regression of mortality (p)

Respiratory drive in patients with chronic heart failure and central sleep apnea

M Michele Correale¹; R Sabato¹; ND Brunetti¹; L Forte¹; I Monaco¹; A Ferraretti¹; GE Carpagano¹; MP Foschino Barbaro¹; M Di Biase¹; D Lacedonia¹
¹University of Foggia, Foggia, Italy

Background: Patients with chronic heart failure (CHF) are characterized by exercise intolerance and ventilatory abnormalities that are related to poor prognosis. We hypothesized that CHF patients with Cheyne-Stokes Breathing (CSB) have increased respiratory drive. The aim of this study was to evaluate the respiratory drive in patients with CHF and CSB.

Methods: Outpatients with CHF underwent nocturnal poligraphy to evaluate the presence of sleep apnea and CSB. Then, the respiratory drive was evaluated in all patients, measuring by mouth occlusion pressure (P0.1) while breathing room air and during CO₂ rebreathing.

Results: 19 outpatient with CHF (60.6 ± 10.3 years; mean LVEF: $37.94 \pm 9.37\%$) were enrolled in the study. 12 subjects were classified as CSB negative (CSB-) while in 7 patients (36%) there was high percentage of central sleep apnea and CSB and were classified as CSB positive (CSB+). These two groups were not different for age, BMI and LVEF. Subjects with evidence of CSB were characterized by higher values of resting P0.1 than CSB- patients (4.42 ± 2.42 vs 2.32 ± 0.91 , $p=0.04$) and higher value of P01/PetCO₂ slope (0.65 ± 0.53 vs 0.29 ± 0.29 , $p=0.01$).

Conclusions: outpatients with CHF and CSB have increased activity of respiratory drive. This increased activity might greater tendency to develop central apnea and CSB, over the stage of heart failure.

P1959

Enhanced adaptive servo-ventilation improves echocardiographic parameters of diastolic and right ventricle function in patients with sleep apnea and heart failure with preserved ejection fraction

E D'elia¹; P Ferrero¹; C Vittori¹; P Baio¹; V Duino¹; A Grosu¹; A Iacovoni¹; S Perlini²; M Senni¹

¹Ospedale Papa Giovanni XXIII, Cardiovascular, Bergamo, Italy; ²Policlinic Foundation San Matteo IRCCS, Internal Medicine, Pavia, Italy

Background: Enhanced adaptive servo ventilation (eASV) is a ventilator device with a new feature-auto-adjustment of expiratory positive airway pressure used to normalize ventilation in patients with sleep disorders breathing (SDB) and central sleep apnea (CSA). Very limited data are available on heart failure with preserved ejection fraction (HFpEF) and use of eASV.

Purpose: To test eASV in HFpEF patients with SDB and CSA.

Methods: 10 consecutive acute HFpEF (LVEF > 45 %) subjects with moderate to severe SDB (apnea-hypopnoea index, AHI > 15/h with prevalence of CSA) were enrolled and randomly assigned to two groups: 5 patients treated for 7 days with eASV (group 1) on the top of standard care and 5 patients treated only with standard care for acute HF (group 2). Echocardiographic parameters of diastolic function and right ventricle (RV) function were assessed. Brain natriuretic peptide (BNP) was measured at baseline and after 7 days of treatment.

Results: eASV therapy markedly reduced AHI and CSA (36 ± 9 to 3 ± 1 , $p < 0.001$ and 32 ± 7 to 1 ± 1 , $p < 0.0001$ respectively). A beneficial effect on cardiac diastolic function was observed in group 1 versus group 2 (E/E': 17.5 to 9.6 , $p < 0.02$ vs 18.5 to 14.5 , $p = 0.4$; S wave: 0.19 to 0.34 m/sec, $p < 0.04$ vs 0.23 to 0.28 m/sec, $p < 0.4$; pulmonary artery pressure: 36 to 23 mmHg, $p < 0.05$ vs 35 to 29 mmHg, $p = 0.07$). In addition, BNP decreased significantly in group 1 compared to group 2 (298 to 84 pg/ml, $p < 0.02$ vs 280 to 120 pg/ml, $p > 0.05$). RV function, calculated with tricuspid annulus plane systolic excursion (TAPSE) and fractional area change (FAC) of the RV, improved in group 1 (15 to 17 mm, $p = 0.05$ and 39 to 43 %, $p = 0.03$), while in group 2 no significant differences were observed.

Conclusions: eASV device may improve cardiac diastolic parameters, RV function and BNP in acute HFpEF patients with SDB and prevalence of CSA, with respect to standard treatment. These early and encouraging findings suggest that long-term application of eASV in HFpEF patients with SDB should be evaluated in larger prospective studies.

P1960

Daytime oscillatory breathing patterns and sleep disordered breathing in patients with heart failure: are they related?

M T Maria Teresa La Rovere¹; R Maestri¹; E Robbi¹; A Caporotondi¹; GP Guazzotti¹; E Traversi¹; GD Pinna¹

¹Fondazione S. Maugeri, IRCCS, Montescano (Pavia), Italy

Background: Sleep disordered breathing (SDB) is a highly prevalent but under-recognized comorbidity in patients with heart failure (HF). Daytime oscillatory breathing patterns (DOBP) have also been frequently reported in HF patients. The relationship between SDB and DOBP has not been addressed in large series. Particularly it is not known whether DOBP and SDB represent a continuum and the presence of DOBP might be related to an increased SDB burden.

Methods: We studied 302 patients with clinically stable, optimally treated moderate-to-severe HF (age 58 ± 9 years, NYHA class 2.7 ± 0.5 , LVEF $33 \pm 10\%$) who were submitted to a 10-minute daytime supine respiratory recording and to a standard polysomnography (PSG) on the same or subsequent night. DOBP was defined as a repeated oscillation of instantaneous tidal volume with regularly recurring hyperventilation and apnea or hypopnoea, with a greater than 25% variation in peak to trough values of tidal volume occurring in more than 75% of the 10 min record. The severity of SDB was quantified by the apnea-hypopnea index (AHI).

Results: DOBP was observed in 140/302 (46%) patients, while SDB (AHI ≥ 5 /h) was present in 263/302 (87%). The AHI was significantly different according to the presence or absence of DOBP (25 ± 17 vs 18 ± 14 , $p < 0.001$). The presence of DOBP was significantly associated with the presence of SDB ($p = 0.0004$). As shown in the table, 90% of the patients with DOBP had SDB but SDB was also present in 85% of patients who did not show DOBP.

Conclusions: Although DOBP and SDB are significantly related, the presence or absence of DOBP cannot be used to infer the severity of SDB.

	AHI < 5	AHI ≥ 5 - < 15	AHI ≥ 15 - ≤ 30	AHI > 30
DOBP yes	10%	26%	27%	37%
DOBP no	15%	37%	32%	16%

P1961

The frequency of anemia among patients with heart failure

A Amina Rakisheva¹; S Berkinbayev¹; A Mussagaliyeva¹; G Usayeva¹; G Ishakbayeva¹; A Kabdulkayeva¹

¹Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan

Background: HF is a socially significant problem throughout the world, according to statistics, about 1-2% of the adult population in developed countries suffers from HF. More than 5 million Americans suffer from HF and, according to the AHA, annually identify 550,000 new cases of HF. The prevalence of anemia in patients with CHF is from 10 to 50% or more. Most often, (80%) it develops in patients with NYHA IV.

Purpose: to evaluate the prevalence of anemia among the HF patients which were hospitalized to our institution.

Methods: retrospective analyze of clinical cases of patients with CVD that were hospitalized to our Institution in 2014.

Results: 3,089 patients were hospitalized with CVD in 2014. Six hundred nineteen (20, 03%) of them were with LVEF below 50%. According to the WHO definition of anemia, (Hb concentration is below 130 g/l in men and below 120 g/l in women) there were 128 patients with HF, which amounted 20, 67%. The number of women and men with HF and anemia was 46 (25.55%) and 80 (18.22%), respectively. The amount of HF patients with anemia over 70 years occurred in 17 (20, 98%) cases among men and 20 (43, 47%) among women.

Furthermore, the number of patients with LVEF 40-50% was 116 (64,44%) among women and 240 (54,67%) among men, the frequency of anemia among these groups of patients was 24 (20,08%) cases among women and 41 (17,08%) cases among men. As for LVEF 30-39% - these number was 41 (22,77%) among women and 136 (30,98%) among men, the prevalence of anemia in these groups of patients was 16 (39,02%) and 24 (17,64%), respectively. The total amount of the patients with LVEF below 30 % was 23 (12,7%) among women and 63 (14,35%), the prevalence of anemia was 6 (26%) among woman and 15 (23,80%) among men. So, we can see that percentage of HF patients with anemia is depending on the severity of HF.

Conclusion: Thus, the retrospective analyze shows that the prevalence of anemia among the HF patients is high and depends on severity of HF.

P1962

Does anaemia in Heart Failure correlate with chronic anticoagulant and antiplatelet therapies?

F Flavia Nicoli¹; D Brusoni²; C Vignati²; M Contini²; P Palermo²; N Corrieri¹; A Del Torto¹; C Tedesco²; A Apostolo²; P Agostoni²

¹University of Milan, Milan, Italy; ²Cardiology Center Monzino IRCCS, Milan, Italy

Introduction: Anaemia is a frequently reported co-morbidity of Heart Failure (HF), it has a prognostic role and it is an independent risk factor for HF hospitalization and mortality. Several conditions are associated with anaemia in HF, such as iron deficiency, renal failure, chronic inflammation, hemodilution, bone marrow dysfunction and drug therapy including anticoagulant and antiplatelet therapies.

Purpose: It is known the prevalence of anaemia increases with HF severity and other co-morbidities (advanced age, female gender, renal disease, diabetes mellitus). We investigated a possible correlation between anaemia/iron deficiency in HF and chronic anticoagulant and/or antiplatelet therapies, either alone or in combination.

Methods: We retrospectively studied 280 patients hospitalized for HF. We collected values of haemoglobin, Mean Corpuscular Volume (MCV), iron status, creatinine, International Normalized Ratio (INR) and Brain Natriuretic Peptide (BNP) in different groups based on either anticoagulant or antiplatelet therapy or both. In details: group 1 (no therapy, n = 37), group 2 (Vitamin K Antagonists (VKAs), n = 105), group 3 (either a VKAs or a Novel Oral Anticoagulants (NOACs), plus antiplatelet therapy, n = 30), group 4 (NOACs alone, n = 13) and group 5 (antiplatelet therapy alone, n = 86). We used Ancova analysis corrected by confounding factors (creatinine, age, sex, left ventricular ejection fraction, diabetes mellitus and others) to obtain a comparison between all groups variables.

Results: BNP shows a trend representing the severity of HF, with the highest value of adjusted mean in group 4 (1186 pg/mL; C.I. 615.3-1756.1) and the lowest value in group 1 (961 pg/mL; C.I. 588-1334.6). There are no significant differences among the groups regarding haemoglobin, MCV, ferritin, transferrin and transferrin saturation. Instead, there are significant differences among the groups on INR ($p < 0.0001$) and blood iron ($p < 0.014$). Then we have also made a post hoc Anova analysis (adjusted for confounding factors) for blood iron and haemoglobin to check differences in multiple comparison. Blood iron shows statistically significant differences between group 1 and all the other groups (p values: group 2, 3, 4, 5 respectively 0.002, 0.013, 0.034, 0.0006). Haemoglobin has a significant difference only between group 3 and 4 (11.84 mg/dL and 13.32 mg/dL, $p < 0.023$).

Conclusion: Iron is an important co-factor in mitochondrial respiration complexes and so in physiologic cardiac function. We demonstrate that antiplatelet and anticoagulant therapies correlate with iron deficiency as independent factors. Haemoglobin in patients with NAOs therapy alone reaches the highest value compared to the other group (adjusted mean 13.32 mg/dL; C.I. 12.2-14.4).

P1963

Establishing a heart failure unit for decompensated HFrEF patients with CKD class IV and diuretic resistance or deteriorating kidney function : a pilot project.

PHT Philippe Timmermans¹

¹Jessa Hospital, Rehabilitation and Health Centre, Heart Centre, Hasselt, Belgium

Background: Patients with decompensated HFrEF and CKD are difficult to treat. A substantial portion of these patients deteriorate despite adequate medical treatment. Others have diuretic resistance. These patients are often referred for dialysis.

Purpose: Establishing a dedicated heart failure unit on the CCU with a pre-specified hemodynamics based protocol for the above mentioned patients, to provide recompensation with improvement of kidney function and avoid dialysis.

Methods: 7 patients with HFrEF and CKD stage 4 admitted to the conventional

ward for decompensation with deteriorating kidney function were enrolled in this program.

The protocol for recompensation was based on PAC measurements, which was inserted at the cath lab.

The protocol consisted of measurements of cardiac pressures and SvO₂. Diuretics were stopped and nitroprusside drip was started and stepwise uptitrated every 5 minutes till the MAP was 60-65. If SvO₂ <40% in presence of anemia (Hb <10), transfusion was given.

The maximum dose of nitroprusside was given for > 6 hours. If CVP still was > 8, diuretics in combination with nitroprusside drip was started. Once CVP was < 8, nitroprusside was changed to hydralazine and oral nitrates. Thereafter, patients were readmitted to the conventional ward.

Results: 7 patients were included. Mean age 78 years; 5/7 ischemic CMP; mean EF 30%; 7 on b-blokkers and diuretics, 2 on ACE-inhibition and 1 on spironolactone. None with ICD or CRT.

3 patients had transfusion. 2 patients were started on dialysis because of persistent congestion without improvement of kidney function. One of them died on the second session of dialysis.

In all patients, hemodynamic parameters improved; mean PCWP (27,4 to 20,1), mPAP (41,4 to 34,4) and CVP went down (17,7 to 10,1), while CI remained stable (2,5 to 2,5) with increased MAP (75 to 81).

In the 5 patients without dialysis, kidney function either improved (1) or were less congested (4) with the same baseline creatinine levels. One of these patients later developed septic shock during hospital stay and died.

5 patients were able to leave the hospital. 2 out of 5 patients died suddenly (d37 and d52 after discharge). The other 3 are currently in FU > 1 year after hospital discharge.

Conclusion: The heart failure unit for patients with HFrEF, CKD 4 and worsening kidney function during recompensation was a valuable and feasible pilot project. In 5 patients, initiation of long-term dialysis or ultrafiltration could be avoided. However, 4 patients died within 3 months after discharge. Future research in patients with HFrEF and preterminal kidney failure should probably not focus on improved mortality, but on quality of life and dialysis-free survival.

P1964

B-type natriuretic peptide, congestion, and acute kidney injury in heart failure: incidence and relationship to outcomes

A Palazzuoli¹; PA Mc Cullough²; G Ruocco¹; V Palumbo¹; E Aloia¹; B Franci¹; B Lucani¹; R Nuti¹

¹University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine, Siena, Italy; ²Baylor University Medical Center, Baylor Heart and Vascular Institute, Dallas, United States of America

Background: While baseline B-type natriuretic peptide (BNP) and its change over time and the presence of pulmonary/systemic congestion have been related to inpatient mortality, their relationships to acute kidney injury (AKI) and outcomes are not well understood.

Purpose: The aim of this study were: 1- to investigate the relationship among BNP, congestion, and AKI in AHF; 2- to evaluate the independent prognostic role of BNP, renal dysfunction, and congestion in this setting to longer term outcomes after discharge.

Methods: In this study, we enrolled 157 patients admitted to our department with diagnosis of acute HF (BNP levels more than 400 pg/ml, echocardiography and chest-ray). At admission and at discharge two clinicians performed a standardized congestion assessment giving one point for each of the following signs: pulmonary rales, jugular venous distention, third heart sound, peripheral edema, hepatomegaly (total 5 points). All the patients underwent to laboratory assessment to measure blood levels of the following markers: BNP, creatinine, estimated glomerular filtration rate (eGFR). AKI was defined as creatinine increase ≥ 0.3 mg/dL or reduction 20% in eGFR during hospitalization. All patients were followed for six months for death or re-hospitalization due to cardiovascular causes.

Results: Of 157 patients, 146 completed the follow-up. In our population, 110 patients displayed effective decongestion (discharge congestion score ≤ 2), 116 patients experienced BNP decrease $\geq 30\%$ and 28 patients developed in-hospital AKI. BNP decrease $\geq 30\%$ rate was significantly higher in patients who showed good decongestion compared to persistent congestion at discharge (63% vs 22%; $p < 0.001$); no significant differences were found in the rates of AKI according to the degree of decongestion (15% vs 4%; $p = 0.526$). BNP reduction in the overall sample was not associated with a difference in rehospitalization or death. In those with a BNP decrease $\geq 30\%$, Kaplan-Meier survival plots showed better survival in terms of freedom from rehospitalization or death in patients with good decongestion at discharge ($p = 0.03$). In the same subgroup, AKI was not associated with a difference in outcomes.

Conclusions: BNP reduction in AHF is associated with decongestion. It appears that both BNP reduction and decongestion in the same patients is a favourable sign for long term survival irrespective of transient AKI.

P1965

The prevalence of renal dysfunction and its influence on the prognosis of patients with heart failure

¹Tyumen Regional Hospital, Tyumen, Russian Federation; ²Tyumen State Medical University, Tyumen, Russian Federation

The aim was to evaluate the prevalence of renal dysfunction and a prognostic impact of estimated glomerular filtration rate (eGFR) in patients with heart failure (HF).

Methods: 85 patients (mean age 54.4 ± 0.91 years, 88.2% males) with impaired systolic function (LVEF < 40%) and symptomatic HF (NYHA class II–IV) were recruited. During the study patients were treated by optimal medical therapy according to the national guidelines. N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels were measured by CARDIAC proBNP assay. Renal function was classified into 6 categories (≥ 90 , 60–89, 45–59, 30–44, 15–29, and < 15 mL/min/1.73 m²) by eGFR using the CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) formula. Serial blood samples were obtained at baseline. The primary end point was defined as unplanned hospitalization due to HF or death related to HF decompensation.

Results: 51.7% patients had eGFR less 60 mL/min/1.73 m². During the follow-up time (follow-up median 18 months), 33 patients (38.8%) had primary end point (33 hospitalizations due to HF including 6 lethal cases). eGFR ($p < 0.001$), creatinine ($p < 0.001$), NT-proBNP ($p < 0.001$) levels differed significantly between groups. NT-proBNP levels increased with a decrease eGFR ($p = 0.04$). We analyzed the end point onset frequency depending on the eGFR and microalbuminuria. Analysis of the and eGFR in relation to clinical condition of patients revealed that 33 patients had primary end point. 25 patients had eGFR less than 45 mL/min/1.73 m² and frequency end points increased with a decrease eGFR ($p = 0.005$) and increase microalbuminuria ($p = 0.013$). We investigated the OR of adverse events depending on eGFR. eGFR from 45 to 59 mL/min/1.73 m² increases the OR of end point onset (OR 95% 2.6 (1.03 – 6.34), $p < 0.044$) and eGFR from 30 to 44 mL/min/1.73 m² increases the OR of end point onset several more (OR 95% 5.8 (1.09 – 30.6), $p < 0.004$). The development of acute kidney injury during hospitalization is associated with an increase in the frequency end points ($p = 0.010$).

Conclusion: Renal dysfunction is one of their most important comorbid conditions in HF. Reduced eGFR is an important predictor of cardiovascular morbidity and mortality. Renal dysfunction is associated with a higher incidence of cardiac events (unplanned hospitalization due to HF or death related).

P1966

The role of BUN changes and its influence on worsening renal function in patients hospitalized for heart failure

A Palazzuoli¹; G Ruocco¹; V Palumbo¹; E Aloia¹; R Favilli¹; E Incampo¹; C Di Tommaso¹; R Nuti¹; JG Cleland²

¹University of Siena, Cardiovascular Diseases Unit, Department of Internal Medicine, Siena, Italy; ²Harefield Hospital, National Heart & Lung Institute, Imperial College, London, United Kingdom

Background: Blood urea nitrogen (BUN) may not only be a measure of renal function but also neuro-hormonal activation and adverse events in decompensated heart failure (DHF). Worsening renal function (WRF) is conventionally considered an unfavourable prognostic factor but may also reflect the effectiveness of decongestive therapy.

Purpose: In patients with DHF we would evaluate the prognostic significance of isolated increases in BUN compared to an increase associated with respect to congestion score at discharge and prognosis

Methods: We enrolled patients admitted to our department with DHF and assessed

the severity of congestion by clinical and laboratory assessments (BNP, creatinine, BUN) at admission and at discharge. WRF was defined as an increase in creatinine by ≥ 0.3 mg/dL and increasing BUN as an increase by $> 20\%$ during hospitalization. Congestion score was defined by five traditional signs (peripheral oedema, pulmonary rales, jugular venous distention, third heart sound, hepatomegaly). Effective decongestion was considered when ≥ 3 signs disappeared by discharge. All patients were followed for six months for re-hospitalization due to cardiovascular causes or death.

Results: Of 161 patients, 149 completed the study and 77 (52%) had events during follow-up. Patients who had both an increase in BUN and WRF had a higher rate of events (77%; $p < 0.01$) compared to those with isolated WRF (43%), isolated BUN increase (67%) or neither (45%). Absolute changes in BUN predicted outcome (AUC: 0.65 [0.57–0.74] $p = 0.002$) but changes in creatinine did not (AUC 0.57 [0.48–0.67] $p = 0.12$). Increases in BUN were also associated with a lower likelihood of achieving decongestion (62%; $p = 0.004$) compared to those with WRF (72%) or those who had neither (78%). Univariate analysis showed that BUN increase and persisting congestion were the only variables related to worse prognosis (HR 1.85 [1.16–2.96] $p = 0.01$; HR 1.84 [1.18–2.85] $p = 0.007$). Multivariable analysis adjusted for chronic kidney disease, LVEF and aetiology showed similar findings.

Conclusions: Increasing BUN during hospitalization predicts greater difficulty in decongestion and a higher rate of cardiovascular events independently from WRF.

P1967

Acute cardiorenal syndrome in patients with IE

EO Kotova¹; T S Getiya²; PV Lazarev¹; V L Filatov²; ZH D Kobalava¹; V S Moiseev¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation; ²M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Goal. To study the features of acute kidney injury (AKI) in patients with infective endocarditis (IE).

Material and methods: 125 patients (77 men) with IE (Duke 2015) were included, median age was 50 [33–72] years. 70 (56.0%) patients had native valve IE, 37 (29.6%) had IE associated with heart valve disease, 16 (12.8%) had prosthetic valve IE and 2 (1.6%) had IE attendant on pacemaker implantation. We evaluated the anamnesis, echocardiogram, renal function (GFR, proteinuria, microscopic hematuria, serum Cystatin C, urinary KIM-1), heart failure (NYHA) rates and NT-proBNP levels, AKI (KDIGO 2012) and mortality rates. Early AKI was defined as AKI at the hospital admission, late AKI — as AKI developed during hospitalization.

Results: Median GFRCKD-EPI at hospital admission was 58.8 [40–90] mL/min/1.73 sq.m. GFR > 60 mL/min was presented in 62 (49.6%) patients, 59–30 mL/min — in 45 (36.0%), 29–15 mL/min — in 14 (11.0%), < 15 mL/min — in 4 (3.0%). AKI was diagnosed in 63 (50.4%) patients with IE. Early AKI was detected in 23 (36.5%) patients, late AKI — in 40 (63.5%) patients. Active IE increased the chances of both early [OR 5.33 (95% CI 3.61–7.88), $p < 0.001$] and late AKI [OR 2.8 (95% CI 2.03–3.87), $p < 0.001$]. The chances of late AKI was increased in the presence of HF [OR 1.58 (95% CI 1.05–2.38), $p = 0.03$], using of vancomycin [OR 1.53 (95% CI 1.03–2.27), $p < 0.05$] or gentamicin [OR 1.67 (95% CI 1.14–2.34), $p < 0.01$]. Patients with AKI more often had NYHA FC III/IV HF [36 (57.1%) vs. 20 (32.3%), $p < 0.05$] and higher NT-proBNP levels — 3804 [1895–4709] pg/mL vs. 875.5 [424.5–1989.5] pg/mL ($p < 0.05$); more frequently had urine laboratory changes [59 (93.7%) vs. 41 (66.1%), $p < 0.05$], proteinuria [53 (84.1%) vs. 38 (61.3%), $p < 0.05$], had higher values of KIM-1 [2.7 (2.5–2.8) ng/mL vs. 1.5 (1.4–1.7) ng/mL, $p < 0.05$] and serum Cystatin C [2.8 (1.5–3.2) mg/mL vs. 1.9 (1.3–2.2) mg/mL, $p < 0.05$]. In AKI group prevailed *S. aureus* [20 (31.7%) and 20 (32.3%), $p > 0.05$], more often occurred embolic syndrome [39 (61.9%) vs. 22 (35.5%), $p < 0.05$] and was revealed higher mortality rate [21 (33.3%) vs. 11 (17.7%), $p < 0.05$]. AKI increased the chances of death [OR 1.52 (95% CI 1.02–2.31), $p < 0.05$].

Conclusion: The AKI complicates IE in 50% of patients and is presented mainly by late AKI associated with the activity of IE, HF and use of nephrotoxic antibiotics. In the group of IE with AKI more often occur NYHA FC III/IV HF, urine laboratory changes, proteinuria. These patients have higher values of NT-proBNP, Cystatin C and KIM-1, higher incidence of embolic syndrome and mortality rate of 33.3%.

CYTOKINES AND INFLAMMATION

The relationship in blood levels of proinflammatory cytokines and antibodies to myocardial tissue in patients with dilated cardiomyopathy depending on the severity of heart failure

NA Kurbanov¹; TA Abdullayev¹; AA Ismailov¹; I A Igor Tsoy¹; SHSH Davirova¹

¹Specialized Cardiology Center of the Republic of Uzbekistan, heart failure, Tashkent, Uzbekistan

Objective: To assess the concentration of antibodies to the myocardial tissue, and proinflammatory cytokines (TNF- α and interleukin-6) in the blood and their

relationship with the severity of heart failure (HF) in patients with dilated cardiomyopathy (DCM).

Materials and Methods: The study included 100 pts with DCM at the age of 18 to 61 years (mean 37.7 ± 1.1). Preclinical stage was diagnosed in 8 (8%) pts, NYHA class II was put up at 15 (15%), III - 42 (42%), IV FC -35 (35%) pts. All pts had made Complex conventional studies, the concentration of antibodies (Abs) to myocardial tissue and inflammatory cytokines were measured by ELISA. Instrumental studies conducted ECG, echocardiography. Assessment of the severity of heart failure was performed using 6-MWT. A control group comprised 29 healthy subjects matched for sex and age. Levels of IL-6, TNF- α and antibodies to myocardial tissue in the serum of pts in the control gr were, respectively, 3.4 ± 0.2 pg / ml, 4.58 ± 0.8 pg / ml and 33.3 ± 2.6 pg / ml.

Results: Immunologic monitoring depending on the severity of NYHA classes revealed the following: compared with control gr, the titer of antibody to the tissues of the myocardium in DCM pts in preclinical stage showed a fourfold increase (150.8 ± 33.3 ; $p=0.001$), in pts with II and III - a threefold increase (92.6 ± 17.8 and 92.9 ± 21.3 ; $p=0.001$) with minimum values of this indicator in pts with IV NYHA classes (69.5 ± 12.4 ; $p>0.05$). Through analysis between the concentration of pro-inflammatory cytokines in the blood and the severity of heart failure found that pts with DCM NYHA class IV the level of TNF- to 64.5% (12.7 ± 1.9 pg / ml versus 4.5 ± 0.8 pg / ml; $p=0.01$), with a class III 32% (6.6 ± 0.3 pg / ml; $p=0.02$), with class II to 13.4% (5.2 ± 0.6 pg / ml; $p>0.05$) in the gr of preclinical stage exceeded by 21% (5.7 ± 1.4 pg / ml; $p<0.05$) higher than in control group. It revealed a dynamic increase in the level of IL-6 with an increase in the severity of heart failure, amounting to 4.5 ± 0.2 pg / ml ($p>0.05$); 5.5 ± 0.1 pg / ml ($p>0.05$); 7.4 ± 0.8 pg / ml and 10.5 ± 1.5 pg / ml (Both $P<0.01$), respectively, in pts with HF of NYHA class II, III and IV respectively.

Conclusion: The most high concentrations of antibodies to tissue have been reported in patients with DCM identified in preclinical stage, at the same time as the worsening of heart failure characterized by gradually reduced titer of antibodies to the myocardial tissue, and the level of proinflammatory cytokines progressively increased.

P1969

Predictive value of circulating ve-catherin in patients with symptomatic ischemic-induced moderate-to-severe chronic heart failure

A Alexander E Berezin¹; A Kremzer¹; T Samura¹; T Berezina²; E Gronenko³

¹State Medical University, Zaporozhye, Ukraine; ²Private medical center VitaCenter, Zaporozhye, Ukraine; ³State Pathology Bureau, Zaporozhye, Ukraine

Background: Chronic heart failure (CHF) is considered as a leading cause of morbidity and mortality worldwide. VE-catherin is a component of endothelial cell-to-cell adherens junctions, and it has a key role in the maintenance of vascular integrity appeared to be a marker of endothelial dysfunction.

Aim: To evaluate the prognostic value of circulating VE-catherin for cumulative survival in patients with ischemic-induced chronic heart failure (CHF).

Methods: A total of 154 patients with ischemic symptomatic moderate-to-severe CHF were enrolled in the study on discharge from the hospital. Observation period was up to 3 years. All the patients have given their written informed consent for participation in the study. Blood samples for biomarkers measurements were collected. ELISA method for measurements of circulating level of VE-catherin was used. Concentration of VE-catherin for cumulative survival cases due to advanced CHF was tested. Additionally, all-cause mortality, and CHF-related death were examined.

Results: During a median follow-up of 2.18 years, 21 participants died and CHF-related death was defined in 18 patients. Additionally, 106 subjects were hospitalized repetitively due to advance CHF (17 cases in died cohort and 89 cases in survival cohort). Medians of circulating levels of VE-catherin in survived and died patient cohort were 0.63 ng/ml (95% confidence interval [CI] = 0.55 - 0.64 ng/ml) and 1.03 ng/ml (95% CI = 0.97 - 1.07 ng/ml) ($P<0.001$). VE-catherin plasma levels were directly related to NYHA functional class of CHF ($r=0.474$, $P=0.006$), NT-pro-BNP ($r=0.344$, $P=0.001$), T2DM ($r=0.42$, $P=0.006$), gender ($r=0.366$, $P<0.001$ for male), multi-vessel lesion of coronary arteries ($r=0.362$, $P=0.001$), /m($r=0.362$, $P=0.001$), /Em($r=0.35$, $P=0.001$), TC ($r=0.32$, $P=0.001$), age ($r=0.28$, $P=0.001$), smoking ($r=0.26$, $P=0.001$) and inversely to LVEF ($r=-0.426$, $P=0.001$) and eGFR ($r=-0.416$, $P=0.002$). No significant association between the levels of circulating VE-catherin with fasting plasma glucose, HbA1c, mean systolic and diastolic BP, premature CAD in family anamnesis, and medications for both cohorts of the patients was found. ROC analysis has been shown that cutoff point of VE-catherin concentration for cumulative survival function was 0.755 ng/ml. It has been found a significantly divergence of Kaplan-Meier survival curves in patients with high (>0.755 ng/ml) and low (<0.755 ng/ml) concentrations of VE-catherin. Circulating VE-catherin independently predicted all-cause mortality (OR = 1.27 ; 95% CI = 1.08 - 1.59 ; $P=0.002$), CHF-related death (OR = 1.16 ; 95% CI 1.02 - 1.50 ; $P<0.001$), and also CHF-related rehospitalisation (OR = 1.12 ; 95%CI = 1.07 - 1.25 ; $P<0.001$) within 3 years of observation period.

Conclusion: Increased circulating VE-catherin associates with increased 3-year CHF-related death, all-cause mortality, and risk for recurrent hospitalization due to CHF

P1970

Anti-inflammatory effects of metformin in diabetic patients and non-diabetic heart failure patients

MRC, Diabetes UK RW

M Mohan¹; AR Cameron¹; D Levin¹; C Lang¹; G Rena¹

¹University of Dundee, Division of Cardiovascular & Diabetes Medicine, Ninewells Hospital, Dundee, United Kingdom

Background & Aim: Metformin has been shown to reduce cardiovascular events in randomized controlled trials; however, the underlying molecular mechanisms remain poorly understood. Accumulating evidence suggests that diabetes (DM), and heart failure (HF) share a metabolic milieu characterized by chronic sub-acute inflammation. In this bench-to-bedside study, we studied the anti-inflammatory effects of metformin on inflammatory biomarkers in animal tissues, followed up these findings in a population cohort analysis of treatment naïve DM patients and in a group of non-diabetic HF patients from a randomised controlled trial (RCT).

Methods: In the molecular study, anti-inflammatory effects of metformin were studied in hepatic (primary mouse hepatocytes) and extrahepatic tissues (bone marrow derived macrophage/BMDM) of C57/BL6 mice. In the clinical study, we identified treatment naïve diabetic patients from the GoDARTS diabetes registry who had been commenced on metformin ($n=498$) or sulphonylurea (SU; as control; $N=172$), and examined the impact of diabetic therapy on change in Neutrophil-to-lymphocyte ratio (NLR), a marker of inflammation after 12 months of metformin/SU therapy. We followed up these findings in an RCT of metformin in non-diabetic HF patients (Age 63 ± 7.0 years; 85% male; NYHA I/II/III/IV, 04/28/01/0) who were randomized to receive either 4 months of metformin ($n=20$, 2 g/day) or placebo ($n=13$).

Results: Molecular study: Metformin inhibited the expression of pro-inflammatory cytokines IL-6, IL-1 β , VEGF & CXCL2 in primary mouse hepatocytes and also reduced IL-12p40 and IL-6 secretion in macrophages (BMDM) suggesting that the effects of metformin on anti-inflammatory signalling pathways are separable from its actions on metabolism and are likely to be different from conventional non-steroidal anti-inflammatory drugs.

Clinical Study: In a large treatment naïve diabetes population cohort, we observed differences in NLR, following incident treatment with either metformin or SU monotherapy. Compared to SU exposure, metformin reduced the mean log-transformed NLR after 8-16 months by 0.09 units (95% CI = 0.02 - 0.17 , $p=0.013$), and increased the likelihood that NLR would be lower than baseline after 8-16 months (OR 1.83, 95% CI = 1.22 - 2.75 , $p=0.00364$). Following up these findings in a double blind placebo controlled trial in non-diabetic heart failure patients, metformin suppressed plasma inflammatory cytokines such as CCL11, IL-2, IL-4, CCL22 and CXCL12 ($p<0.01$).

Conclusion: Cross-species evidence from cells, plasma, patient records and a randomized placebo controlled study strongly suggest that metformin exerts anti-inflammatory effects, irrespective of diabetes status. This apparent anti-inflammatory effect of metformin including its utility in non-diabetic 'at risk' cardiovascular disease groups warrants further investigation.

P1971

The effects of tumour necrosis factor on bone metabolism in patients with chronic heart failure

VN Larina¹; DG Karpenko¹; TN Raspopova²; MP Mikhaylova¹

¹The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation; ²Diagnostic Clinical Center No.1, Moscow, Russian Federation

In recent years, there has been growing evidence that tumor necrosis factor is associated with the progression of chronic heart failure (CHF) and bone resorption.

Aim: To investigate if circulating markers of bone tissue and tumor necrosis factor are associated with severity of heart failure and hemodynamic in patients with CHF.

Methods: Seventy outpatients suffering from CHF (40 women and 30 men, age 56-88 years) due to coronary heart disease or arterial hypertension entered the study. Forty subjects with cardiovascular diseases but without CHF (30 women and 10 men, age 57-88 years) were selected as sex- and age-matched controls. Spine and femoral neck bone mineral density (BMD) (expressed as T-score), calciotropic hormones (parathyroid hormone, PTH; 25-hydroxycholecalciferol, 25(OH)D3) and biochemical markers of bone turnover (osteocalcin, OC; type I collagen C-terminal telopeptide, CTX; N-terminal pro-B-type natriuretic peptide (N-proBNP) and tumour necrosis factor- α (TNF) were evaluated.

Results: Spine and femur T-scores were higher in the CHF patients (spine: -1.2 (0.4 - 2.3); femur: -2.5 (1.6 - 2.7)) compared to subjects of control group (spine: -0.7 (0.1 - 1.3), $p=0.003$; femur: -1.6 (0.9 - 2.3); $p=0.060$). CTX and OC concentrations were not significantly different between patients with HF and control group, whilst 1,25(OH)D3 concentrations were significantly lower in HF patients [9.6 (5.0 - 14.4) ng/ml compared with controls [16.8 (10.7 - 22.3) ng/ml], <0.001 . PTH were significantly higher in HF patients [7.7 (4.5 - 9.4) pmol/l] compared with controls [4.5 (3.7 - 5.7) pmol/ml], <0.001 . TNF was increased in HF patients [18.7 (5.1) pg/ml] but not in controls [3.5 (0.8) pg/ml]. The significant correlation was established between serum TNF and BMD in femur ($p=0.016$, $r=-0.35$), N-proBNP ($=0.017$, $r=0.43$), low

concentration of 1,25(OH)D3 ($p < 0.001$, $r = 0.50$); LV EDD ($= 0.015$, $r = 0.36$), LV ESD ($= 0.022$, $r = 0.35$), left atrium ($= 0.031$, $r = 0.33$), right ventricular diameter ($= 0.013$, $r = 0.38$), LV EDV ($= 0.016$, $r = 0.37$), LV ESV ($= 0.016$, $r = 0.37$) and LV EF ($= 0.031$, $r = -0.33$).

Conclusion: These data show that HF patients have an osteopenia, the degree of which is different in controls; however, bone turnover is not significantly higher in HF patients. These findings confirm the association between the TNF and BMD and N-proBNP. TNF may serve as a marker of severity of disease in concomitant osteopenic syndrome among HF patients. Properly controlled long-term trials are needed to fully evaluate the impact of TNF on bone mineral density in heart failure.

P1972

Role of interleukin-18 in estimation of hospital complications in subjects with coronary artery disease who underwent coronary artery bypass grafting

K Kristina Shafranskaya¹; OKK Kuzmina¹; MVZ Zykov¹; VVK Kashtalap¹; OLB Barbarash¹

¹Research Institute for Complex Issues of Cardio. Dis. - Siberian Branch RAMS Institution Scientific, Kemerovo, Russian Federation

Purpose: To estimate the clinical significance of interleukin-18 (IL-18) in blood serum for predicting the risk of hospital complications development in subjects with coronary artery disease (CAD) who underwent coronary artery bypass grafting (CABG). **Materials and methods:** The study included 720 subjects who underwent CABG in RI for CICVD in the period since March 2011 till April 2012. All the subjects before performing CABG and on the 7th day after surgical interference were measured the blood serum creatinine concentration, glomerular filtration rate (GFR) by MDRD (Modification of Diet in Renal Disease) formula and also interleukin-18 concentration in blood serum. We evaluated the incidence of adverse outcomes of surgical interference (myocardial infarction, stroke or transient ischemic attack, acute or chronic renal disease progression, reoperation) during in-hospital period. All the subjects were measured a score by EuroSCORE-II additive risk scale.

Results: In the present study we didn't receive significant differences in blood serum creatinine level and GFR both as before surgery and on the 7th postoperative day among subjects of different risk groups by EuroSCORE-II, as well as in subjects with complicated and uncomplicated course of postoperative period. Whereas the IL-18 level in the blood serum before surgery and on the 7th postoperative day was significantly higher in subjects of high and medium risk groups by EuroSCORE-II scale, as compared to low-risk subjects. Detection of IL-18 in the blood serum in preoperative period proved to be useful for estimation the risk of certain cardiovascular complications development in postoperative period. It was found out that in subjects with development of myocardial infarction (MI) or stroke after CABG preoperative IL-18 values were definitely higher as compared to subjects without MI or stroke. IL-18 values in the blood serum of subjects with the development of acute renal failure were also higher as compared to subjects without acute renal failure (ARF). Analysis of IL-18 levels in subjects with the development of postoperative adverse outcomes also showed its statistically significant higher values, both in preoperative and in postoperative periods, while such indicators of renal dysfunction as creatinine and GFR didn't show any significant differences in subjects with favorable and adverse outcomes.

Conclusion: Thus preoperative quantitative estimation of IL-18 in the blood serum which is a preclinical marker of acute kidney injury, allows to predict more accurately the hospital risk of development of adverse cardiovascular and renal complications of CABG.

VALVULAR HEART DISEASE (DIAGNOSIS, MANAGEMENT AND INTERVENTIONAL THERAPIES)

Transcatheter aortic valve replacement: a new opportunity for elderly patients

J C Joana Catarina Duarte Rodrigues¹; RP Pinto¹; MTS Tavares Silva¹; JCS Carlos Silva¹; RR Rodrigues¹; DM Magalhaes¹; PBA Almeida¹; MC Campelo¹; PP Pinho²; MJM Julia Maciel²

¹Sao Joao Hospital, Department of Cardiology, Porto, Portugal; ²Sao Joao Hospital, Department of Cardiothoracic Surgery, Porto, Portugal

Background: Aortic stenosis is the most common acquired valve disease in elderly patients. Surgical aortic valve replacement remains the standard therapy to reduce symptoms and improve survival. However, in patients who are not suitable or are at very high surgical risk percutaneous transcatheter aortic valve implantation (TAVI) offers a new therapeutic option. We aim to assess the feasibility and safety of this technique and evaluate periprocedural, short and mid-term outcomes.

Methods: Clinical, echocardiographic and procedural data were analyzed from patients referred for TAVI in a single tertiary centre between November 2014 and November 2015.

Results: Forty eight patients were consecutively referred for TAVI at our hospital, after Heart Team evaluation. Two refused the procedure, 5 died in the meantime

and 41 underwent TAVI and only those were included in our analysis. Transfemoral approach was used in 90% of cases, 68.3% implanted third-generation percutaneous self-expanding CoreValve. The mean age of the patients was 80 ± 7.4 years, 41.5 % of them were men. The median EuroSCORE II 3.5% (1.25-15.75%). Of this high-risk patients, porcelain aorta was the indication for TAVI in 60% of patients. The mean aortic valve orifice area was 0.69 ± 0.19 cm² and the mean transvalvular gradient was 51.5 ± 13.9 mmHg before the intervention. The mean duration of the intervention was 80 ± 20 minutes and the screening time 18.8 ± 7.4 minutes. The procedure was technically successful in all patients. The post-interventional mean transvalvular gradient was 9.8 ± 5.8 mmHg ($p < 0.001$). Significant residual aortic regurgitation (more than grade II/IV) was present in only two cases. Contained aortic root rupture was diagnosed in 1 patient and one vascular complication was immediately treated by catheter angioplasty. Mean hospital stay was 10 ± 5 days. A permanent pacemaker was implanted in 9 of the patients. All patients were discharged alive from hospital. Median follow-up time was 1 month (1-12 months). During this period no deaths occurred and there was one re-hospitalization from cardiovascular cause. NYHA functional class at follow-up was significantly improved (NYHA > II 34.1% vs 7.3%; $p < 0.001$).

Conclusions: The burden of severe symptomatic aortic stenosis among the elderly patients with co-morbidities is substantial. Although challenging, TAVI is creating a window of opportunity that should be considered to add quality-of-life and improve functional status for those who have contraindications to surgical valve replacement. In this first year of experience we obtained excellent results during hospitalization and short-term follow-up which encourages our center for further development of this promising technique.

P1974

Percutaneous transvenous mitral commissurotomy in patients with calcific mitral stenosis: immediate and in-hospital clinical, echocardiographic and hemodynamic outcome

MT Md Toufiqueur Rahman¹; AASM Majumder¹

¹National institute of cardiovascular diseases, Dhaka, Bangladesh

Objectives: To see Immediate and In-hospital Clinical, Echocardiographic and Hemodynamic Outcome of Percutaneous Transvenous Mitral Commissurotomy in Patients of Mitral Stenosis with and without fluoroscopically visible mitral valve calcification.

Background: Rheumatic fever and rheumatic heart disease continue to be the major health problem in all developing countries including Bangladesh. Rheumatic mitral stenosis is a very common problem in our population having an incidence of 54 percent among rheumatic heart disease with a female preponderance of 2:1. Mitral valve calcification has been shown to be an important factor in determining immediate outcome of patients undergoing surgical mitral commissurotomy. Percutaneous balloon mitral commissurotomy is appealing because the mechanism of valve dilation closely parallels the mechanism of surgical mitral commissurotomy. The technique of balloon mitral commissurotomy has evolved rapidly, with improvements in balloons, guide wires, and the application of double-balloon techniques. Percutaneous transvenous mitral commissurotomy (PTMC) using an Inoue balloon catheter is of established efficacy and safety and is an alternative to surgical valvotomy in selected patients with rheumatic mitral stenosis.

Methods: A prospective study was done during the period of August 2003 to November 2015. Nineteen hundred and eighty (1980) patients with rheumatic mitral stenosis who underwent PTMC were evaluated clinically, by echocardiography and by catheter during and after procedure. Out of 1980 patients 80 patients had fluoroscopically visible mitral valve (MV) calcification (Group-1) and rest 1900 patients had no fluoroscopically visible mitral valve (MV) calcification (Group-2).

Results: Mean age of the study population was 44.25 ± 08.40 years in group-1 and 29.14 ± 12.31 years in Group-2. Most of the population are female, 72% in Group-1 and 75% in group-2. After PTMC mean mitral valve area increased from 0.70 ± 0.15 cm² to 1.46 ± 0.34 cm² as measured by echocardiography in group-1 and from 0.82 ± 0.22 cm² to 1.81 ± 0.33 cm² in group-2. Mitral valve gradient reduced to 12.73 ± 4.19 mm Hg from 33.56 ± 04.94 mm Hg after PTMC in group-1 and 11.75 ± 3.67 mm Hg from 27.34 ± 04.34 mm Hg after PTMC in group-2. Mean left atrial pressure as recorded by catheter before PTMC was 32.99 ± 08.58 mm Hg while after PTMC it was 22.72 ± 05.38 mm Hg in group-1 and in group -2, 29.72 ± 06.27 mm Hg before while after PTMC it was 22.76 ± 05.12 mm Hg in group-2. In Group-1 had higher NYHA class, higher atrial fibrillation, High Wilkins Echo score and higher age.

Conclusions: PTMC can be performed effectively and safely in patients had fluoroscopically visible mitral valve (MV) calcification with good immediate result but result is inferior to patients had no fluoroscopically visible mitral valve (MV) calcification.

P1975

Heart failure class at presentation: a predictor of prognosis in patients with infective endocarditis

I Ines Silveira¹; R Santos B¹; B Brochado¹; M Trepa¹; A Luz¹; S Torres¹

¹Hospital Center of Porto, Cardiology, Porto, Portugal

Purpose: Despite diagnostic and therapeutic advances infective endocarditis remains an important cause of morbidity and mortality worldwide. To recognise predictors of poor prognosis at presentation is crucial in the management of these patients.

Methods: Retrospective, single center study, of patients admitted for infective endocarditis (EI) in a tertiary hospital, during a ten years period. The patients were divided in two groups according to heart failure classification by New York Heart Association (NYHA) criteria at admission: Group 1 (NYHA class I/II) and Group 2 (NYHA class III/IV). For each group we analyse clinical, echocardiographic parameters and in-hospital and one year outcomes.

Results: 103 patients with EI were included, 62,1% men, mean age 65.8 ± 17.2 years. Native valve EI was present in 85% of cases with same prevalence of aortic and mitral valve involvement (40%). Perivalvular complication were reported in 17,6% (14,7% abscess and 2,9% fistulas). According to division in heart failure NYHA class at presentation Group 1 included 72 patients and Group 2 31 patients. There were no significant differences between groups regarding gender, type and location of EI or perivalvular complication, but with a higher proportion of severe valvular regurgitation in Group 2 (18.3 vs 28.7% $p=0.027$). Patients in Group 2 were older (62.6 ± 17.1 vs 73.2 ± 15.1 years $p=0.003$), had a lower creatinine clearance at admission (68.1 ± 29.4 vs 44.6 ± 23.9 $p<0.001$) and developed more frequent acute kidney injury (25.4 vs 51.6% $p=0.010$), with no significant differences in diabetes, immunosuppression or use of IV drugs. Group 2 had also a higher percentage of patients with atrial fibrillation (28.2% vs 44.8% $p=0.010$) and with moderate to severe left ventricular dysfunction (4.3% vs 20% $p=0.020$). We found same proportion of embolic events, but with higher rates of sepsis and cardiogenic shock in Group 2. In-hospital and one year mortality rate were higher in Group 2 (21.4% vs 45.2% $p=0.015$ and 6.0% vs 28.6% $p=0.036$, respectively). After multivariate analysis acute kidney injury and NYHA class remained as independent predictors of mortality (OR: 3,44; 95% CI: 1,22 to 9,66; $p=0.019$ and OR:2,37; 95% CI:0,72 to 7,83; $p=0.043$).

Conclusion: NYHA class at admission proved to be a strong predictor of prognosis in patients with EI. Presentation in class III/IV NYHA reflects a type of patients with higher comorbidities and in-hospital complications, with a consequent higher mortality rates.

Comparison of the effectiveness of transcatheter aortic valve implantation in patients with degenerated bioprosthetic surgical valves versus. aortic stenosis

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; AJ Dominguez-Franco³; MF Jimenez-Navarro³; JM Garcia-Pinilla³; JH Alonso-Briales³; JM Hernandez-Garcia³; E De Teresa-Galvan³

¹Department of Cardiology, Malaga, Spain; ²Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Reoperation, the current standard of care for failed bioprosthetic tissue valves, carries significant risk in terms of both morbidity and mortality. Implantation of a transcatheter valve inside a failed surgical valve (valve-in-valve) has recently emerged as an alternative, less-invasive option. The aim of this study was to evaluate the clinical results of this technique using the CoreValve prosthesis in patients with degenerated bioprosthesis surgical valves and comparing them with patients with aortic stenosis.

Methods: The CoreValve prosthesis (Medtronic, Minneapolis, MN, USA) was implanted in 18 patients with symptomatic degenerated surgical aortic valves (SAV) and in 482 patients with aortic stenosis (AS).

Results: The mean age was lower in SAV compared with AS 74.1 ± 16 vs. 79.3 ± 6 years, $p=0.002$ and logistic EuroSCORE was higher by SAV $27.5 \pm 17\%$ vs. 17 ± 11 , $p=0.001$. TAVI procedure was successful in all patients with degenerated bioprosthesis. In two patients required to implant a second valve prosthesis. After procedure and 1-year, the mean gradient was higher in patients with SAV than AS, 19.7 ± 14 mmHg vs. 8.8 ± 4 mmHg, and 15.1 ± 9 vs. 9 ± 4 mmHg, $p<0.001$, respectively. The aortic regurgitation grade post procedure in patients with SAV was: absent in 66.7%, middle in 22.2% and moderate in 11.1% and there were not complications after procedure including mortality at 30 days. There were more moderate and severe prosthesis-patient mismatch when compare with the rest of patients treated (73.3% vs. 38.3% , $p=0.024$ and 40% vs. 8.7% , $p=0.001$, respectively). There were tend to lower requiring pacemaker after procedure (13.3% vs. 24.8% , $p=0.310$). In the follow-up, after 34.3 ± 23 months, the total mortality was similar in both groups, 3.5 vs. 3.6% , $p=0.936$ and 80 % of patients was at an Association functional class I-II.

Conclusions: The valve-in-valve procedure is clinically effective in patients with degenerated bioprosthesis aortic valves. The procedure and outcomes are similar in some aspects to TAVI in the setting of native aortic valve stenosis.

Cardiac remodeling after percutaneous intervention for mitral regurgitation using the MitraClip system

Al Ana Isabel Azevedo¹; C Guerreiro¹; J Ribeiro¹; F Sampaio¹; R Fontes-Carvalho¹; B Melica¹; P Braga¹; M Fonseca¹; A Dias¹; V Gama Ribeiro¹
¹Hospital Center Vila Nova Gaia, Porto, Portugal

Introduction: Reverse remodeling of the cardiac chambers can be seen in most patients undergoing mitral valve repair surgery. Percutaneous mitral valve treatment with the MitraClip system is considered an alternative intervention for symptomatic patients with severe mitral regurgitation (MR) and high surgical risk and has shown favourable clinical results. However, data regarding cardiac remodeling after this percutaneous intervention are sparse.

Methods: Retrospective study including patients with moderate to severe MR and high surgical risk undergoing MitraClip implantation, between May 2014 and November 2015. Clinical and echocardiographic follow-up was achieved at discharge, 1, 6 and 12 months. The echocardiographic parameters analysed included: left atrium (LA) indexed volume, short axis/long axis ratio of LA, LA and right atrium area, left ventricle (LV) telesystolic and telediastolic indexed volumes, LV sphericity index, LV ejection fraction (EF), right ventricle (RV) basal and longitudinal diameters and RV systolic function evaluated by tricuspid annular plane systolic excursion (TAPSE).

Results: The studied population included 22 patients: 21 with functional MR and one with MR of a mixed etiology. 9 patients (40.9%) had an EF $<30\%$ and 10 (45.5%) were in sinus rhythm. Comparing to pre-procedural evaluation, there was a significant improvement in the degree of MR at discharge ($p<0.001$), after implantation of a median of 2 clips [IQR 1-2]. Comparing to discharge, at one month follow-up there were no significant differences in the echocardiographic parameters evaluated. At 6 months, there was a significant reduction in the short/long axis ratio of the LA (from 0.84 [IQR 0.79-0.88] to 0.78 [IQR 0.75-0.89]; $p=0.03$). At 12 months, a significant reduction in LV telediastolic indexed volume (from 108.0mL/m² [IQR 94.3-122.7] to 100.0mL/m² [IQR 91.6-114.0]; $p=0.04$) and a decrease in the LV telesystolic indexed volume (from 78.3 ± 31.6 mL/m² to 73.1 ± 10.6 mL/m²; $p=0.08$) were seen. There were no significant differences in the remaining evaluated parameters at 6 and 12 months.

Conclusion: In this population of patients, MitraClip implantation was associated with a reduction in the short/long axis ratio of the LA and LV telediastolic indexed volume at short term follow-up. There were no significant differences in the other echocardiographic parameters evaluated. The addition of a greater number of patients to this initial experience and a long term follow-up will be relevant in the re-evaluation of the impact of this intervention in cardiac chambers size and function.

P1978

Obstructive sleep apnea in continuous flow LVAD supported patients: incidence and therapeutic implications

D Murninkas¹; B Ben Abraham¹; I Mats¹; T Hasin²; B Medalion³; D Aravot⁴; R Kornowski¹; T Ben Gal¹

¹Rabin Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Dept. of Cardiology, Petah Tikva, Israel; ²Shaare Zedek Medical Center, Cardiology, Jerusalem, Israel; ³University Hospitals Case Medical Center, Thoracic Surgery, Cleveland, United States of America; ⁴Rabin Medical Center, Cardiac Surgery, Petah Tikva, Israel

Background: Obstructive Sleep apnea (OSA) and hypopnea result from complete or partial collapse of a narrowed pharynx. The reported prevalence of OSA in the healthy population is approximately 4% in women and 9% in men. In the heart failure (HF) populations, prevalence of OSA varies between 37% up to 54%. However, only a minority of the HF patients complain of excessive daytime sleepiness, suggesting that many patients with HF have relatively asymptomatic OSA. The incidence of sleep apnea in HF patients supported with continuous flow LVAD is unknown. The aim of this study was to assess the incidence and therapeutic implications of sleep apnea in LVAD supported patients.

Methods: Sleep study was performed in 12 continuous flow LVAD supported patients. The participating patients were 6 months post operation, stable with no changes planned in their medical management and had no OSA related symptoms.

Results: OSA was present in 11 patients (91%). According to the apnea-hypopnea index, OSA was mild (5 to 15) in 4, moderate (15 to 30) in 6 and severe (more than 30) in 1 patients. CPAP treatment was offered to the entire group with OSA but was tolerated in only 8 patients who used it for more than 3 months. After 3 months of CPAP therapy a mild improvement in kidney function (decrease in mean creatinine from 1.30 to 1.18 mmol/l), mean pulmonary pressures (from 22.75 to 18.5 mmHg) and mean cardiac index (from 2.05 to 2.70 l/min/m²) was observed.

Conclusion: OSA is very frequent in continuous flow LVAD supported patients. The use of CPAP in LVAD supported patients has a significant hemodynamic effect. Due to the low symptomatology of OSA in the LVAD supported patients and the benefits of CPAP therapy; we propose to perform sleep study in all LVAD patients.

Baseline characteristics (12 patients).

Age (years)	63
Sex (male)%	66
Etiology (ischemic)%	41
Creatinine (mg/dl)	1.3
Hemoglobin (mg/dl)	12.1
Doppler blood pressure (mmHg)	90
Pulmonary pressure (mmHg)	22.75
Cardiac index (l/min)	2.05

Improving long-term results of mechanical circulatory support in crash-and-burn patients

M Minoru Ono¹; K Nawata¹; H Yamauchi¹; O Kinoshita¹; T Imamura¹; E Amiya¹; M Hatano¹

¹University of Tokyo, Department of Cardiac Surgery and Cardiology, Tokyo, Japan

Purpose: Crash-and-burn patients are still challenging group of patients. We sought to find preimplant factors which may improve long-term results of mechanical circulatory support in this cohort.

Methods: Fifty-seven adult patients in crash-and-burn status (15 females, 40.2 years of age) were treated by paracorporeal VAD (Nipro-Toyobo) since 2003. Thirty-four patients were on ECMO support before VAD implant. DCM was seen in 21, AML in 14, and fulminant myocarditis in 9. Bridge strategy to continuous-flow VAD after stabilization of general condition was adopted in 2011. Actuarial survivals were analysed and compared.

Results: Survivals at 1, 3, 5 years were 68.4%, 55.0% and 42.9% in the whole population. Survival of recent cases (2010-2015) was superior to that of early cases (5-year survival: 70.3% vs 32.9%). Successful endpoints (weaning from the system and alive, bridged to continuous-flow VAD and alive and transplanted) were met in 22 cases in recent cases, whereas only 11 cases in the other. ECMO support before implant and BiVAD requirement were significant risk factors for unfavorable outcomes.

Conclusions: Long-term results of VAD implantation in crash-and-burn patients were improving in recent years thanks to our recent bridge strategy. Preimplant ECMO and BiVAD requirement were still big hurdles.

P1980

Right heart failure post LVAD therapy - timing of RVAD placement predicts survival

K Karen Booth¹; M Urban¹; N Robinson-Smith¹; A Woods¹; N Wrightson¹; S Scheuler¹; G Macgowan¹

¹Freeman Hospital, Newcastle upon Tyne, United Kingdom

Purpose: Right ventricular (RV) support in the case of RV failure after left ventricular assist device (LVAD) implantation is a well-established surgical therapeutic option and remains an important cause of mortality. We sought to review our practice of RVAD implantation post LVAD insertion and the association between time in hours from LVAD implantation until the need for RVAD and survival in hospital discharge or long term survival.

Methods: Retrospective analysis was performed of a prospectively collected database of all LVAD implantations between March 2011 and October 2015. The study cohort included patients who required post-operatively RVAD support post LVAD implantation. Demographic and clinical characteristics were compared in patients in survivors and non-survivors.

Results: Out of 171 adult patients with a heartware H-VAD implantation, 20 received RVAD support for post-operative right heart failure (12%). The median time on LVAD support was 28 days (1-1000). 10 (50%) patients had inpatient deaths, 2 were transplanted, 1 was successfully decommisioned and 7 remain on support. Univariate analysis of basic demographic and clinical data performed no significant differences for age, gender, height, weight, bilirubin at the time of LVAD insertion and measurement of central venous pressure, pulmonary artery systolic pressure. Out of the 20 supported patients, 14 had RVAD support instigated at the time of LVAD insertion. 30 day survival for those 14 patients was 55 +/- 15% versus 20 +/- 18% (p=0.031)

Conclusion: Our data supports the use of good pre-operative evaluation of right heart function with timely insertion of RVAD support leading to increased survival.

P1981

Impact of a new less invasive ventricular restoration system on ischemic mitral regurgitation

BioVentric Inc.

N Wunderlich¹; S Nodari²; P Neuzil³; S Brugaletta⁴

¹CardioVascular Center Darmstadt, Cardiology, Darmstadt, Germany; ²Civil Hospital of Brescia, Heart Failure, Brescia, Italy; ³Na Homolce Hospital, Cardiology and Electrophysiology, Prague, Czech Republic; ⁴Hospital Clinic de Barcelona, Interventional Cardiology, Barcelona, Spain

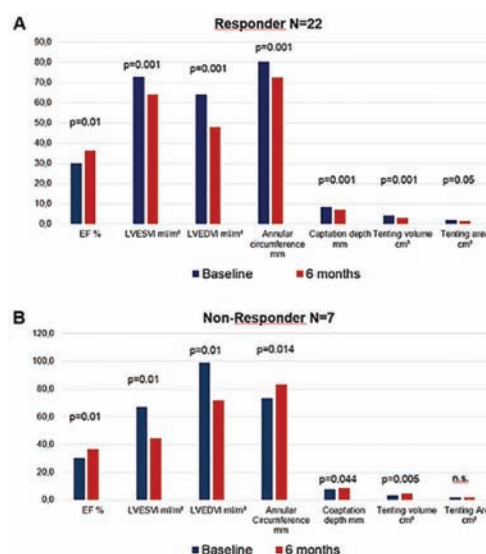

Background: The frequency of secondary mitral regurgitation (MR) which originates from LV dysfunction is up to 90% in a population with CHF. It could be demonstrated that associated secondary MR is an independent predictor of mortality. An altered LV geometry constitutes the main factor for the development of secondary MR. Left ventricular reconstruction (LVR) has the potential to improve MR. Compared to surgical LVR, this new system is a less invasive device which enables LV volume reduction through scar exclusion. This system excludes akinetic or dyskinetic scars located in the antero-septal LV. The device replicates the geometric reconfiguration achieved through surgical LVR, but on a beating heart.

Purpose: The aim of this multicenter study is to assess the impact on mitral valve geometry of a less invasive LV restoration therapy for ischemic heart failure. Multiple MV geometric parameters were assessed by the use of echocardiography.

Methods: Retrospective core laboratory analysis of 29 patients treated for ischemic cardiomyopathy following an anterior myocardial infarction. Patients underwent the LV volume reduction procedure using a series of micro-anchors. Patients with paired (before and after implant) echocardiographic acquisitions were included into analysis. MV geometric parameters were measured before and 6 months after implantation.

Results: Twenty-nine patients were included in the analysis. There was significant reduction in annular circumference (80.3±13.8 mm vs 72.6±10.6 mm; p=0.001) coaptation depth (8.5±1.9 mm vs 7.2 ±1.8 mm; p=0.001), tenting volume (4.3±2.1 cm³ vs 3.1±1.5 cm³; p=0.001) and tenting area (2.2±0.7cm² vs 1.6±0.5 cm²) in 22 patients (76%=Responders) at 6 months follow-up. Seven patients (24%=Non-Responders) showed no significant reduction (or even an increase) in annular circumference (73.4±12.4 mm vs 83.4±15.8 mm; p=0.014), coaptation depth (7.8±3.1 mm vs 8.6±2.7 mm; p=0.044), tenting volume (3.6±1.9 cm³ vs 4.8±2.3 cm³; p=0.005) and tenting area (1.8±0.8 cm² vs 2.1±0.8 cm²; n.s.) at 6 months follow-up. Ejection fraction (EF) and LV Volume indices improved significantly in both groups (Responders: EF 29.0±7.4% vs 32.2±5.1%, p=0.01; LVEDVI 89.3±22.9ml/m² vs 72.7±23.3ml/m², p=0.001; LVESVI 64.2±21.4 ml/m² vs 48.0±21.5ml/m², p=0.001/ Non-Responders: EF 30.2±7.4% vs 36.5±7.9%, p=0.01; LVEDVI 98.9±26.5 ml/m² vs 71.8±12.8 ml/m², p=0.01; LVESVI 67.1±19.8 ml/m² vs 44.7±6.5 ml/m², p=0.01).

Conclusions: This less invasive, off pump, ventricular restoration system shows a favorable impact on MV geometry. In 76% of patients at 6 months post implantation there were beneficial geometric changes to the mitral apparatus. The observed geometric changes have the potential to improve MR. This technology is unique in that it directly addresses the underlying ventricular origin of ischemic mitral regurgitation.

Mitral geometry after less invasive SVR

P1982

Preoperative severe mitral valve regurgitation resolves after continuous-flow left ventricular assist device implantation and is not associated with adverse outcomes

M Monica Dobrovič¹; RA Spampinato¹; AL Meyer¹; J Fischer¹; JG Da Rocha E Silva¹; F Bonamigo Thome¹; J Hahn¹; E Strottdrees¹; FW Mohr¹; J Garbade¹
¹Heart Center of Leipzig, Leipzig, Germany

Background: The presence of severe mitral valve regurgitation (MR) at the time of left ventricular assist device (LVAD) implantation is prevalent and its clinical importance remains still unclear.

Purpose: The impact of an untreated preoperative severe MR on outcomes after LVAD implantation should be evaluated.

Methods: Between November 2008 and October 2014 235 patients underwent first time implantation of a continuous-flow LVAD in our center. We excluded 11 patients with prior mitral valve replacement and 2 patients with mitral valve reconstruction during LVAD implantation. Based on availability of echocardiography with good image quality before and after LVAD implantation (n = 110 HVAD, n = 18 HeartMate II), 128 patients of our outpatient clinic were divided into 2 groups according to the presence of severe pre-operative MR: group A with severe MR (n = 65) and group B with none to moderate MR (n = 63; 28 of 63 with moderate MR). We evaluated the transthoracic echocardiography preoperative (mean \pm SD 24 \pm 33 days pre LVAD) and postoperative: first postoperative (19 \pm 15 days post LVAD), second postoperative (353 \pm 83 days post LVAD), and the last follow-up available (574 \pm 457 days (5-2213 days) post LVAD). We registered deaths, complications, and clinical status in the entire population.

Results: Patients in group A were more likely to have a dilated cardiomyopathy, increased left ventricle diameters, and higher pulmonary pressure before LVAD implantation. We observed a significant decrease in severity of MR after LVAD implantation (severe MR 51% pre vs 6% post, $p < 0.0001$). There was no difference between groups regarding right heart failure, rate of urgent heart transplantation due to any cause, pump thrombosis or ventricular arrhythmias. Finally there was no difference in 1- and 3-years survival (87.7% vs. 88.4% and 71.8% vs. 66.6% for group A and B respectively, $p = 0.97$)

Conclusions: Preoperative severe MR resolves in the majority of patients after LVAD implantation and is not associated with worse clinical status, increased risk for right heart failure or long-term survival.

P1983

Minimally invasive LVAD implantation - initial two years single centre experience

V Vladimir Horvath¹; P Nemec¹; J Ondrasek¹; P Fila¹; H Bedanova¹; J Slavik¹; R Wagner¹

¹Center of Cardiovascular and Transplant Surgery, Brno, Czech Republic

Introduction: Left ventricular assist device (LVAD) as a bridge to transplant strategy is well established. However, the implantation of LVAD is invasive and associated with significant peri-operative complications in these critically ill patients. Lower invasiveness of implantation might have the potential to enhance results of these high risk patients. The aim of this study is to present our two years experience with minimally invasive approach to implantation of left ventricular assist device HeartWare HVAD.

Methods: Seventeen patients underwent minimally invasive implantation of left ventricular assist device HeartWare HVAD between November 2013 and November 2015 as a bridge to heart transplantation in our centre. Sixteen patients were males, one patient was female. Mean age of patients was 57 \pm 8.9 years. Basic diseases were dilated cardiomyopathy in 13 patients (76%), ischemic cardiomyopathy in 4 patients (24%). The mean value of left ventricular ejection fraction was 13.5 \pm 3.8%, right ventricular ejection fraction was 30.9 \pm 5.4%. Access to the left ventricular apex was reached by small left anterior thoracotomy (approximately 8 cm incision). To access the ascending aorta we used upper J ministernotomy.

Results: Minimally invasive implantation was successful in all patients. In one patient closure of foramen ovale was simultaneously performed. Most patients (76%) were extubated on the first postoperative day. Only in one case (6%) a failure of the right ventricle occurred with the need for temporary percutaneous right-sided circulatory support device Centrimag. Overall thirty-day survival was 94%, one year survival was 82%. Nine patients (53%) underwent successfully heart transplantation, five patients (29%) remain on LVAD support.

Conclusion: Minimally invasive LVAD implantation is feasible, safe and allows easier re-entry for subsequent transplantation. There is also a promising tendency for lower incidence of perioperative right heart failure. After initial experience with this technique it has become the method of choice in our centre.

P1984

Impact of remote monitoring on clinical outcomes in chronic heart failure: our experience.

C Sticozzi¹; A Zanni¹; A Malagoli¹; L Rossi¹; U Corvi¹; G Villani¹; M Piepoli¹
¹Guglielmo Da Saliceto Hospital, Department of Cardiology, Piacenza, Italy

Introduction: The increasing worldwide prevalence of heart failure (HF) is associated with numerous and protracted hospital admissions. The increasing number of patients with implantable cardiac devices raises the need for more efficient outpatient follow-up care. Remote monitoring (RM) concept has been proposed to optimize medical management of the patients with chronic HF to decrease the hospitalizations.

Purpose: To assess the benefits on clinical outcomes of RM compared to standard outpatient follow-ups.

Methods: 558 consecutive outpatients with chronic HF with left ventricular ejection fraction (LVEF) <45% with single- or dual-chamber implantable cardioverter defibrillator (ICD) implanted (58.8% ischemic etiology, 66.8% primary prevention) were divided into a group of patients followed through standard outpatient visits (AMBULATORY group) and a group followed by the RM-system (REMOTE group). Emergency room accesses and delivered shocks were evaluated in both groups.

Results: During the 18-months follow-up, it was considerably reduced the number of emergency room accesses in the REMOTE group compared to the AMBULATORY group (38 and 125 respectively, $p = 0.05$). A comparable number of patients experienced one or more shocks (14.1 and 15 respectively in the AMBULATORY and REMOTE group, $p = 0.34$).

Conclusions: RM offers a unique opportunity to maintain device surveillance and improve patient outcomes in patients with chronic heart failure.

P1985

Role of non-invasive home telemonitoring (HTM) in diastolic heart failure treatment.

S Carugo¹; MC Centola²; AC Caretta²; SP Persampieri²; GF Ferrante²; LM Massironi²

¹Università degli Studi di Milano, Milan, Italy; ²San Paolo Hospital, Cardiology, Milan, Italy

Introduction: Heart Failure (HF) is the leading cause of hospitalization in older people and health costs are increasing. We sought to identify whether HTM improves therapies outcomes for patients with diastolic HF who are at high risk of hospitalization and death.

Purpose and Methods: We studied for 1 year patients with a recent clinical admission for HF with preserved left ventricular ejection fraction (LVEF) and with diastolic dysfunction. Patients sent and received data via internet with telematic support. HTM consisted of 6 months weekly remote monitoring of vital signs, blood pressure and ECG, with feed-back instructions for the management of drug therapy and way of life. Quality of life was measured by means of Minnesota Living with Heart Failure Questionnaire (MLHFQ). **Results:** We enrolled 30 patients from 55 to 90 years (mean 73.7, median 74, mode 61), males (66%), females (34%). The aetiology of diastolic heart disease was: hypertension (68%), post-ischemic (21%), post-myocardial inflammation (6%), post-ischemic associated with immunologic disease (5%). Mean LVEF at the beginning was 50.3% and after 6 months became 54.9%. The rate of mortality at 6 months was extremely low (5%) and the rate of hospitalization too (26%). Mean MLHFQ score at the beginning was 54.8 (30-76, range 46), after 6 months became 21.3 (5-70, range 65). Considering titration, beta blockers use increases from 67% to 88%, ACEi from 60% to 69%, AT1 from 47% to 80% and Diuretics from 90% to 98%. The rate of mortality at 6 months was extremely low (6%). With HTM patients in NYHA Class IV underwent: 48% in III, 37% in II-III, 5% in II and 5% remained stable in IV; patients in NYHA Class III became II (18%), II-III (18%) and 64% remained stable. We also observed after 1 ys a significant increase in home blood pressure control (MAP 150+30 mmHg vs 135+15.5 mmHg, $p < 0.001$).

Conclusions: The results of this study support the compliance and effectiveness of HTM for the management of diastolic HF in the early months after heart failure admission. In particular we obtained a successful optimization of the therapy according to Guidelines, a significant increase in LVEF, sensible decrease in III-IV NYHA patients, MLHFQ score and improvement in blood pressure control.

P1986

New possibilities of quadripolar left ventricular leads to optimise CRT

N Nikolay Ilov¹; A Nechepurenko¹; D Paskeev¹; E Kulikova¹; A Abdulkadyurov¹; E Daminina¹; M Markina¹; M Terenteva¹

¹Federal Center of Cardiovascular Surgery, Astrakhan, Russian Federation

The maximal value of cardiac resynchronization therapy (CRT) is developed when left ventricular (LV) stimulation is provided from the LV latest activation area (LAA). A quadripolar LV lead offers multiple additional pacing vectors (PV) to optimize CRT. The purpose of this study was to evaluate whether pacing from the pole of the LV

lead closest to the LAA evaluated by device based algorithm (DBA) could enhance cardiac output.

Methods: Six patients with ischemic (33%) and dilated (67%) cardiomyopathy (4 males, 54 (53; 57.3) years; NYHA III; LV EF 30 (25; 31)%; LBBB with QRS duration 140 (119; 156) ms) with implanted CRT-D featuring multipolar LV stimulation were included in the study for retrospective data analysis. Patients were equipped with quadripolar coronary sinus leads, implanted into an antero-lateral (1 patient) and lateral coronary sinus branch (5 patients). LV pacing evaluations were performed in all patients at baseline (BL) and during follow-up (FU) at 6 (FU1) and 7 months (FU2) after implantation. Cardiac output enhancement was estimated by transthoracic echocardiography. At FU1 the pole of the LV lead closest to the LAA was determined by DBA. LV PV was chosen according to these data. AV and VV delay optimization was performed using automatic device based optimization algorithm. All patients received optimal drug therapy including beta-blockers, ACE inhibitors and diuretics. Non-parametric statistical methods were used, all the quantitative characteristics were described as Me (IQ 25%; 75%).

Results: One patient died due to heart failure decompensation. At FU1 we registered an increasing of LV EF (from 29 (25; 31)% to 33 (32; 38)%, $p<0.05$) and an ESV decreasing (from 195 (170; 230) ml to 183 (156; 209) ml, $p=0.04$). According to a study protocol we changed LV PV at 80% of patients. In 1 case DBA showed LV LAA to be closer to basal LV lead pole (Proximal), in other cases it was closer to apical poles (Tip 1 or Mid 2). At FU2 we recorded further cardiac output enhancement: LV EF 40 (33; 47)%, ESV 141 (125; 159) ml ($p=0.03$).

Conclusions: DBA can determine a pole of quadripolar LV lead which is closest to LV LAA. Changing a PV according to these data may be a novel way to optimize CRT and to enhance cardiac output.

P1987

Quality of life and long follow-up efficacy of biventricular pacing in heart failure patients

G Savenkova¹; S Krivolapov¹; D Lebedev¹; S Popov¹

¹RI Cardiology, Heart Arrhythmias, Tomsk, Russian Federation

Atrial fibrillation (AF) and congestive heart failure (HF) are highly prevalent diseases in modern society, with considerable morbidity and mortality.

Aim: To assess heart failure (HF) long-term dynamics on biventricular pacing (BP) in patients with AF.

Methods: Study involved 127 patients (pat) (59 females), middle age 60.7 ± 10.1 years, all of them were on BP (CRT-D – 109 pat, 85/8%). Coronary artery disease had 51 pat (42/2%), Dilated cardiomyopathy had 76 (57.8%). NYHA HF stratification: III – 108 pat (85%); IV – 20 (15%). Sinus rhythm in 42 (33%) pat, drug resistant atrial fibrillation in 85 pat. EchoCG showed ventricular dyssynchrony in all pat. All patients were on optimal HF medication, pat with AF were anticoagulated. Pat with AF were performed AV-nodal ablation (63, 74/1%) or pulmonary vein isolation (22, 25/9%). QOL by SF-36 scores were assessed.

Results: After 36 ± 3.6 months positive dynamics was shown in 93 (73.2%): NYHA HF class decreased at average 1.4 ± 0.6 ; Ejection Fraction (EF) increased from $25.7 \pm 6.4\%$ to $33.5 \pm 5.2\%$; End diastolic volume (EDV) of left ventricle decreased on $77 \pm 8.4/3$ ml; lung circulation time decreased on 8.7 ± 3.6 s; 6 minute walking test distance increased on 45.5 ± 18.6 m. There also was improvement in quality of life (SF-36 questionnaire) in physical and mental functioning. Patients seemed to perform better in the physical functioning domain and possibly also in the general health domain. From the rest, 8 pat. died (total mortality 6.3%), 19 didn't show dynamics in NYHA HF class. Although, 6 of them showed an improvement in quality of life. For the follow-up period in 33 (26%) patients a ventricular tachycardia was registered, that wasn't revealed before implantation.

Conclusion: Biventricular pacing in patients with ventricular dyssynchrony on EchoCG decreases symptoms of HF, improves left ventricular function and quality of life in 73.2% of the pat. Responders had significantly better SF-36 scores than patients with advanced heart failure in terms "bodily pain," "general health perceptions" and "vitality."

P1988

The effects of CRT on arterial stiffness and ventricular-arterial coupling

E Edoardo Sciatti¹; E Vizzardi¹; I Bonadei¹; F Platto¹; M Metra¹

¹University of Brescia, Cardiology, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy

Background: cardiac resynchronization therapy (CRT) is indicated for patients with heart failure HF and left ventricular ejection fraction (LVEF) $<35\%$ in sinus rhythm and wide QRS. It can improve LVEF and reduce mortality. Arterial stiffness and ventricular-arterial coupling (VAC) are independent prognostic factors in HF patients. No studies to date have investigated the role of CRT regarding these parameters.

Purpose: we aimed at evaluating arterial stiffness and VAC before and early after CRT.

Methods: 23 patients scheduled for CRT were enrolled. Within 3 day before and at least 3 day after the procedure they underwent radial artery applanation tonometry to evaluate central blood pressures and augmentation index (Alx@75), and transthoracic echocardiography to calculate the aortic elastance (Ea), the end-systolic left ventricular elastance (Ees) and their ratio, namely VAC.

Results: mean age was 73 ± 11 years. 16 (69.6%) were male. LVEF was $32 \pm 17\%$. Hemodynamic parameters are reported in Table 1. After CRT there was a great improvement in central pressure and Ea. On the other hand, no effects were seen on left Alx@75, Ees or VAC. These results are independent from LVEF.

Conclusion: CRT is associated to an early improvement in central pressure and Ea, without effects on VAC or peripheral arterial stiffness. This may be due to a regularization of blood flow through the ascending aorta. Considering the prognostic role of these factors in patients with HF, CRT is of growing importance under different points of view.

Table 1

Variable	Before CRT	After CRT	p
Aortic SBP (mmHg)	113 ± 14	106 ± 12	0.028
Aortic DBP (mmHg)	76 ± 11	72 ± 10	0.054
Aortic MAP (mmHg)	91 ± 10	85 ± 9	0.016
Aortic PP (mmHg)	37 ± 14	33 ± 11	0.147
Alx@75 (%)	24 ± 16	20 ± 13	0.353
Stroke volume (mL)	58 ± 17	67 ± 22	0.101
Ea (mmHg/mL)	2.1 ± 0.7	1.7 ± 0.5	0.020
Ees (mmHg/mL)	2.5 ± 1.0	2.1 ± 0.9	0.131
VAC	0.9 ± 0.4	0.9 ± 0.4	0.961

SBP=systolic blood pressure; DBP=diastolic blood pressure; MAP=mean arterial pressure; PP=pulse pressure; Alx@75 augmentation index corrected for 75 bpm; Ea=aortic elastance; Ees=end-systolic left ventricular elastance; VAC=ventricular-arterial coupling

P1989

The Burden of scar and fibrosis is the strongest predictor for the early to midterm need for ICD-therapies in patients with primary prophylactic CRT-D

M Martin Grett¹

¹University Hospital St. Mary's Hospital Herne, Cardiology and Angiology, Herne, Germany

Purpose: Indications for primary prophylactic ICD-implantation as well as those for cardiac-resynchronization-therapy (CRT) are generally based on severe LV-dysfunction. A high number of pts with CRT-D will never profit from ICD-therapy but experience complications. A parameter independent from LVEF to predict which patient with CRT will need adequate ICD-therapies is required.

Methods: We studied 74 pts who underwent CRT-D implantation and had complete follow up of device interrogations at our institution for 3 years. Pts with secondary prophylactic indication for ICD or upgrade from existing devices were excluded. Following characteristics were investigated: modified Selvester-ECG-score (MSES), which correlates with LV scar burden and fibrosis, every one point raise counts for 3% additional scar or fibrosis), "true" left bundle branch block (LBBB, defined by the method of the modified Selvester-ECG-score), LVEF, ischemic (ICM) vs dilatative cardiomyopathy (DCM), myocardial infarction prior to implant (MI), sinus rhythm (SR) vs. atrial fibrillation (AF), occurrence of ICD-therapy.

Results: 25/74 pts suffered an adequate ICD-therapy. Calculation of the relative risk for the characteristic subgroups revealed the following results (table 1). Only 1 pt with a MSES ≤ 3 and LBBB suffered an ICD-therapy.

Conclusion: The burden of scar and fibrosis, measured by the modified Selvester-ECG-score is a promising approach to predict the necessity of ICD-therapy in pts with indication for CRT. It is superior to other routinely assessed parameters. Pts with low MSES and true LBBB are under the lowest risk.

	relative risk	confidence interval	p
SR vs. AF	0.82	0.41 - 1.64	0.57
DCM vs. ICM	0.87	0.46 - 1.65	0.67
EF $>25\%$ vs. $<25\%$	0.80	0.37 - 1.72	0.56
LBBB vs. no LBBB	0.54	0.29 - 0.99	0.05
MSES ≤ 3 vs. >3	0.21	0.07 - 0.65	<0.01

BETA BLOCKERS

P1990

Heart rate reduction or ventricular reverse remodeling associated with beta-blocker therapy is accompanied widespread, distinct changes in the beta1-adrenergic receptor gene signaling network

DP Kao¹; BD Lowes²; EM Gilbert³; W Minobe¹; C Goerg⁴; MA Hinterberg¹; R Zolty²; AD Robertson⁵; RA Quaife¹; MR Bristow¹

¹University of Colorado Denver, Cardiology, Denver, United States of America;

²University of Nebraska Medical Center, Cardiology, Omaha, United States of

America; ³University of Utah, Cardiology, Salt Lake City, United States of America;

⁴University of Denver, Computational Bioscience, Denver, United States of

America; ⁵University of Denver, Cardiology, Denver, United States of America

Background: Beta-blocker (BB) therapy of HF with reduced EF is lowers resting heart rate (HR). We hypothesize that changes in the beta-1-adrenergic receptor gene signaling network (B1GSN) are distinctly associated with HR lowering or reverse remodeling.

Objective: To describe HR response in reverse-remodeling and associated myocardial gene expression changes.

Methods: Forty-six nonischemic dilated cardiomyopathy patients were treated with BB for 12 months. Ventriculography and RV endomyocardial biopsies were performed at baseline, 3 and 12 months. LVEF response was defined as improvement of ≥ 8 EF units (EFU) at 12 months or ≥ 5 EFU at 3 months. mRNA expression was measured by microarray. Differences in gene expression change between LVEF Responders (Rs) and Nonresponders (NRs) were stratified by 3 month HR decrease above and below cohort median (18 bpm).

Results: In 30 (65%) Rs, EF increased by 21 ± 10 vs. 1 ± 5 EFU in NRs ($p < 0.001$). At 3 months, HR decreased by 18 ± 21 in Rs, vs. 5 ± 13 bpm in 16 NRs ($p < 0.001$). EF change correlated inversely with HR change at 3 months in all patients ($r = -0.44$, $p < 0.01$). There were 17 (37%) Rs with HR decrease > 18 bpm vs. 10 (22%) NRs with HR decrease < 18 bpm. Of 87 B1GSN genes, 46 (53%) were differentially expressed between these groups ($p < 0.05$) with 65 (75%) trending toward significance ($p < 0.10$). In comparison 1913/19586 (10%) non-B1GSN genes were differentially expressed ($p < 0.05$) and 3395 (17%) trended toward significance ($p < 0.01$). Favorable changes in B1GSN expression increased progressively from NR/HR decrease < 18 bpm to NR/HR decrease > 18 bpm to R/HR decrease < 18 bpm to R/HR decrease > 18 bpm (Figure).

Conclusions: The B1GSN remodeling subnetwork is strongly associated with HR reduction and LV reverse remodeling in response to beta-blockers.

B1-AR gene expression changes

P1991

Effect of beta blockers on exercise capacity in patients with heart failure undergoing cardiac rehabilitation

G M C Giuseppe M C Rosano¹; G Caminiti¹; G Campolongo¹; G Marazzi¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Background: β -blockers (β B) are the mainstay of medical therapy in heart failure. Aim of this study was to compare the exercise training response of patients with chronic heart failure (CHF) receiving or not β B therapy at admission.

Methods and Results: Sixty-two consecutive patients with CHF were included in a 3-week training program. Patients underwent a cardiopulmonary exercise and a 6 minute walk test (6MWT) test before and after training.

Oxygen uptake (VO₂) at peak exercise and at VT increased in both groups with a

trend towards a greater improvement in those patients not receiving β B but receiving ivabradine for heart rate control. A greater VT improvement was detected in patients not receiving β B but with heart rate < 70 bpm. A better improvement in exercise capacity was detected in those patients receiving $< 50\%$ of β B target dose.

Conclusions: β B therapy may impair the improvement in functional capacity obtainable with a rehabilitation program in patients with CHF.

P1992

Association of beta-blocker usage with mortality following myocardial infarction in patients with COPD: a propensity score analysis from the high-risk myocardial infarction database initiative

S Stefano Coiro¹; N Girerd²; P Rossignol²; JP Ferreira²; A Maggioni³; B Pitt⁴; I Tritto¹; G Ambrosio¹; K Dickstein⁵; F Zannad²

¹University of Perugia, Division of Cardiology, Ospedale Santa Maria della Misericordia, Perugia, Italy; ²Clinical Investigation Centre Pierre Drouin (CIC-P), Nancy, France; ³Associazione Nazionale Medici Cardiologi Ospedalieri Research Center, Florence, Italy; ⁴Cardiology Division, University of Michigan, Ann Arbor, United States of America; ⁵University of Bergen, Stavanger University Hospital, Bergen, Norway

Background/Introduction: Concerns that beta-blocker treatment may be harmful in patients with chronic obstructive disease (COPD) still limits their usage in this subset of patients, even in post-myocardial infarction (MI), where they have been shown to be highly effective in reducing mortality.

Purpose: The aim of the study was to assess the association between baseline beta-blocker intake and long-term prognosis of MI survivors with heart failure (HF) or with left ventricular dysfunction and a history of COPD.

Methods: In the 28,771 patients high risk MI collaborative database, we identified 1573 patients with a baseline history of COPD. We evaluated the association between beta-blocker usage at baseline (822 with a beta-blocker and $n = 751$ without) on the rate of all-cause death and cardiovascular death.

Results: By univariable Cox analysis, beta-blocker intake was associated with lower rates of both all-cause death (HR = 0.61, 0.51-0.75, $p < 0.0001$) and cardiovascular death (HR = 0.63, 0.51-0.78, $p < 0.0001$). After extensive adjustment for confounding including 24 baseline covariates, beta-blocker usage was associated with a lower risk in COPD patients (HR = 0.73, 0.60-0.90, $p = 0.002$ for all-cause death; HR = 0.77, 0.61-0.97, $p = 0.025$ for cardiovascular death) (Table). Propensity scores (PS), estimating probability of beta-blocker treatment on 24 baseline characteristics, were calculated; when entering these scores as covariate for adjustment in Cox models, the survival in the treatment group remained significantly higher. A cohort of 561 pairs of patients taking or not a beta-blocker was obtained by 1:1 nearest neighbor matching method. Among matched pairs of patients, treated group experienced less all-cause deaths (HR = 0.71, 0.56-0.89, $p = 0.003$) and cardiovascular deaths (HR = 0.76, 0.59-0.97, $p = 0.032$).

Conclusions: in the specific setting of a well-treated cohort of high-risk MI survivors, beta-blocker treatment was associated with better outcomes in patients with a history of COPD.

Cox proportional hazard models

	All-cause mortality HR (95%CI)	p-value	Cardiovascular death HR (95%CI)	p-value
Univariable analysis	0.61 (0.51-0.75)	< 0.0001	0.63 (0.51-0.78)	< 0.0001
Model 1	0.66 (0.54-0.80)	< 0.0001	0.68 (0.54-0.84)	< 0.0001

P1993

The effect of beta-blocker therapy in HF patients with high comorbidity burden: interpreting data in community setting

A Iorio¹; M Senni¹; A Gavazzi¹; C Concetta Di Nora²; E Zamboni²; G Barbati²; G Faganello³; G Pulignano³; G Sinagra²; A Di Lenarda³

¹Ospedale Papa Giovanni XXIII, Bergamo, Italy; ²University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; ³Cardiovascular Center A.S.S. 1 of Trieste, Trieste, Italy

Background: Older adults are often excluded from clinical trials. The benefit of HF-related treatments tested in younger trial populations may be diluted when applied to older adults with higher comorbidity burden in the clinical setting.

Purpose: To study whether the co-morbidity burden had an impact on the treatment effects of beta-blockers, we investigated the hazard ratios for outcome according to comorbidity burden in the community-based population.

Methods: From October 2009 to December 2013 we studied all consecutive ambulatory patients with HF whose ejection fraction had been assessed. Clinical variables were derived from the E-data chart for Outpatient Clinic collected in a regional Data Warehouse. Overall population were divided into groups with different co-morbidity burden (1, 2, ≥ 3 of comorbidities) taking into account 15 non cardiac comorbidities.

Results: The study population comprised 2,321 HF patients (mean age 78 \pm 8, 57% men). Of these, 914 (41 %) patients with LVEF $<50\%$ were identified as HFREF; 1,380 (59%) patients as HFpEF. The high mean age and comorbidity rates (mean 3.2 ± 2.5 ; 54% patients with ≥ 3 non cardiac comorbidities) were similarly between EF-HF phenotypes. 1198, 52% of overall population were treated with beta-blockers (536, 57% - HFREF; 662, 48% - HFpEF); 53% showed heart rate (HR) <70 bpm (73% in sinus rhythm). All cause mortality, HF hospitalization, non cardiovascular hospitalization significantly increased ($p < 0.0001$) with comorbidity burden irrespective of beta-blocker therapy. According to increased comorbidities rate, there was a progressive significant reduction of the effect of beta-blocker treatment for all-cause mortality and morbidity outcomes. No significant impact of beta-blocker was achieved in HF patients with ≥ 3 comorbidities for overall mortality, and morbidity end point (HF hospitalization, overall hospitalizations). This trend was maintained unchanged after adjustment for EF-HF phenotypes.

Conclusion: In an elderly real-world HF population, the high comorbidity burden may diluted the benefit of beta-blocker, even though HFREF.

P1994

Beta blockers upitration in patients with chronic heart failure and ICD/CRT-D: A single center study

D Daniele Masarone¹; G Limongelli¹; V De Stasio¹; E Ammendola¹; G Del Giorno¹; L Santangelo¹; M Rubino¹; S Tramonte¹; G Salerno¹; G Pacileo¹

¹Heart Failure Unit Second University of Naples, Naples, Italy

Background: Clinical trials have shown the unequivocal benefits of beta blockers (BBs) in patients with chronic heart failure with reduced ejection fraction (HFREF). These benefits include improved survival (30-35%) and a reduced need for hospitalization. Cardiac resynchronization therapy (CRT) has emerged as an important device-based therapy for symptomatic patients with HFREF despite optimal pharmacologic therapy. The extent to which BBs are being utilized in patients receiving implantable cardioverter defibrillator (ICD) and/or CRT is not well known.

Aims: In this study we evaluate the effect of BBs doses on clinical outcome in an unselected cohort of HFREF patients receiving ICD/CRT capable defibrillator system (CRT-D).

Methods: Adults who received their first ICD/CRT-D at our center between July 2008 and July 2015 were identified. Using hospital data, BBs use was determined at time of discharge, and during follow-up. A composite end point of cardiovascular mortality, CRT-D appropriate intervention (discharge or anti tachycardia pacing) and hospitalization for acute heart failure was recorded.

Results: The study cohort comprised 202 patients, 126 patients (62%) had an optimized BBs doses according to ESC guidelines (group A). 78 patients (38%) had a BBs doses higher than that recommended by European Society of Cardiology (ESC) guidelines (group B). The two groups were similar in terms of demographics characteristics, heart failure NYHA class, others pharmacologic HF therapy, and comorbidities. Comparing the two groups Group A have a better clinical outcome than group B (Table 1).

Conclusion: After ICD/CRT-D implantation, BBs therapy can be up-titrated, in a good percentage of patients, at higher doses than that recommended by international guidelines and this strategy confers advantages in terms of mortality and morbidity respect the use of standard doses.

Table 1

	Group A (n 126)	Group B (n 78)	P value
Overall cardiovascular events	95	20	$< 0,001$
Cardiovascular death	6	3	$< 0,001$
Acute heart failure related hospitalization	44	7	$< 0,001$
CRT-D appropriate intervention	45	10	$< 0,001$
Difference of cardiovascular events between the two study groups			

RENIN-ANGIOTENSIN-ALDOSTERONE ANTAGONISTS

P1995

Improvement in central haemodynamic parameters by association of angiotensin II receptors blockers and canrenone therapy in obese hypertensive patients

C A Carlos Alberto Paterno Marchioli¹

¹Centre of Cardiovascular Research Clinical and Instrumental, Foggia, Italy

Introduction: Hypertension and obesity are strong risk factors for heart failure (HF). It is associated with activation of the renin-angiotensin-aldosterone system (RAAS). Obesity is an inflammatory disease increased plasma aldosterone levels through leptin. A large body of evidence links aldosterone, now consider a major cardiovascular risk hormone, to development and progression of arterial stiffness, left ventricular hypertrophy, left ventricular post-load, and HF. Thiazide diuretics can activate the neurohormonal system, impair glucose metabolism, increase new-onset diabetes, and are potentially harmful.

Purpose: Could be obese hypertensive patients both sexes with normal kidney function, benefit from the association of Angiotensin II Receptors Blockers (ARBs) and canrenone (Cr) therapy better than with ARBs associated to hydrochlorothiazide (Hct).

Methods: In a retrospective cross-sectional study, data were collected from 448 obese hypertensive patients, normal kidney function, both sexes (female 64%), aimed to compare the effect of two therapy groups: ARBs+Cr (female/male average age 60/56) and ARBs+Hct (female/male average age 64/57). Were measured in female (ARBs+Cr/ARBs+Hct) BMI (36.3/35.6), and WC (107.8/108.3), and in male (ARBs+Cr/ARBs+Hct) BMI (33.2/33.8), and WC (112.1/113.4). The averages dose used in both genders were Cr 37 mg and Hct 16 mg. Were measured central haemodynamics parameters by the SphygmoCor System, according system's standard methods. Also was measured the difference between the observed values and the expected values of Augmentation Index (Diff-Alx) according to normal levels by age.

Results: The averages of BMI and WC were similar in both therapy groups. Interestingly, were found better results from ARBs+Cr than ARBs+Hct therapy, both female/male with the following differences (mmHg): Central Aortic Pressure (17.7/14.8), End-Systolic Pressure (15.5/15.3), Mean Arterial Pressure (12.3/11), Pulse Pressure (11.1/6.1), Augmentation Pressure (5.9/3.2), and Diff-Alx (6%/6.4%), with a statistically significant difference. Partly, this fact, could be explained by the phenomenon named "escape of aldosterone" by Hct.

Conclusions: In obese hypertensive patients, has been obtained better haemodynamic results by use ARBs+canrenone therapy. This association could prevent or reduce in short- and long-time the harmful effect of the RAAS, the development of HF and its serious complications such as atrial fibrillation.

P1996

Safety and benefits of the use of an uptitration protocol in patients with heart failure and reduced ejection fraction followed in an heart failure unit

A Giraldez¹; L Ruiz¹; S Gamaza¹; F Zafra¹; E Diaz¹; A Gutierrez¹; M Alba¹; E Gonzalez¹; A Del Rio¹; J Oneto¹

¹General Hospital de Jerez, Jerez, Spain

Background: Current guidelines recommend that patients with heart failure are enrolled in a multidisciplinary-care management programme to reduce the risk of heart failure hospitalization (level of recommendation IA). This will permit patients to reach dosages of Angiotensin converting enzyme inhibitors (ACEI), angiotensin receptor blockers (ARB) and beta blockers (BB) achieved in the randomised controlled trials that have demonstrated their efficacy

Purpose: To assess the influence of achieving higher dosages of recommended pharmacological treatment of heart failure with reduced ejection fraction, in terms of quality of life and safety, using a established protocol of uptitration

Methods: Data from 103 consecutive patients (80 men, 77.7%) referred to the Heart Failure Unit of our hospital between June 2014 and August 2015 were analyzed.. We used the Pearson correlation test to establish the relationship between doses of recommended pharmacological treatment and the incidence of worsening renal function (increase of serum creatinin) as well as with the quality of life, using the Minnesota Living with Heart Failure Questionnaire (MLHFQ)

Results: The etiology of the left ventricular dysfunction was ischaemic heart disease in 31.1% of patients, with a mean left ventricle ejection fraction of 30.8% (SD 8.7). An ACEI, ARB and BB were prescribed in 59.2, 34.9 and 96.1% of the cases, respectively. No relationship between dose of ACEI, ARB o BB and changes in serum creatinin was found. Only in two patients, an increase $>50\%$ regard the basal level was observed, and in only one was necessary to stop the ACEI. We found a correlation between dose of ACEI and lower score in the MLHFQ (meaning better quality of life) performed 6 months after uptitration

Conclusions: In our study, we have demonstrated that using a established protocol of uptitration of pharmacological treatment, designed by the physician and performed by specialized nurses, is safe and effective. In addition, reaching higher dosage of ACEI is related with a better quality of life in patients with heart failure and reduced ejection fraction

Table 1

	MLHFQ
BB Pearson Correlation Sig. (2-tailed) N	-0,108 0,405 99

P1997

Mineralocorticoid receptor antagonists: do we use them enough in very elderly patients with heart failure and severe left ventricular dysfunction?

ML Martín Mariscal¹; M Cortes García¹; A García Ropero¹; M López Castillo¹; J Palfy¹; A Romero Daza¹; M Taibo Urquía¹; J Farre Muncharaz¹

¹Foundation Jimenez Diaz, Cardiology, Madrid, Spain

Background and objectives: Mineralocorticoid receptor antagonists (MRAs) significantly reduce the risk of morbidity and mortality among patients with heart failure (HF) and severe left ventricular dysfunction (SLVD). In this study, we aimed to measure the use of this group of drugs among the elderly population.

Methods: Between 2008 and 2013, all patients aged >75 years revealed to have ejection fraction <35% following imaging studies were recruited by the cardiac imaging laboratory that had performed the analyses. Clinical variables and echocardiography results were gathered, among other data. A prospective follow-up study was performed by consulting either the electronic medical history of patients or by telephone interview.

Results: A total of 802 patients were included in the study. Men comprised 66.2% of all the participants, and the mean age was 82 ± 4.9 years. Mean ejection fraction (EF) was $28 \pm 6.5\%$. Ischemic etiology was found in 51.1% of the cases. Hypertension was observed in 79.2% of patients, while 31.3% were diabetic, and 35.7% presented chronic renal insufficiency (CRI). According to the New York Heart Association (NYHA) classification system, 55.4% of the patients were in Class II at the time of inclusion. The mean duration of follow-up was 32.7 ± 22.6 months. The percentage of deaths was 47.5%, and 61.84% of patients developed a cardiac event (death or admission due to HF).

At the conclusion of follow-up, 45.1% of patients were undergoing treatment with MRAs. Of all patients not receiving MRA treatment, in 24.3% the cause was presence of CRI that contraindicated use of the drugs or because of worsening of existing CRI. Treatment was suspended in 4.9% of cases due to hyperpotasemia, and 35.7% did not receive MRAs due to absence of clinical indication (i.e. NYHA Class I status, normalization of EF). MRA administration was indicated in as many as 29% of patients who did not receive the treatment.

Conclusions: MRAs were shown to be underused in our population of very elderly patients with HF and SLVD. This finding is due in part to the presence of side effects and comorbidities, although no justified cause was found in a high percentage of patients. Strict adherence to the care guidelines may lead to improved prognosis in this population.

P1998

Causes and impact on survival of omission of ACE-inhibitors and angiotensin II receptor blockers in heart failure.

P Pietro Ameri¹; G Ghigliotti¹; GM Secco¹; G De Blasi¹; F Torre²; GP Bezante²; P Chiarella²; C Brunelli¹; M Canepa¹

¹AOU IRCCS San Martino IST, University of Genova, Department of Internal Medicine, Genova, Italy; ²AOU IRCCS San Martino IST, Genova, Italy

Background: Large epidemiological studies have demonstrated that a sizable portion of patients with newly diagnosed heart failure (HF) are prescribed neither angiotensin-converting enzyme inhibitors (ACEi) nor angiotensin II receptor blockers (ARB), mainly because of concomitant kidney dysfunction, and that this therapeutic choice results in higher mortality. It is likely that this holds even more true when ACEi/ARB are withheld for a long period of time. However, there are few data to confirm this assumption. Furthermore, other reasons may also lead to the omission of ACEi/ARB.

Purpose: We investigated the correlates and the effect on survival of never-use vs. use of ACEi/ARB in a cohort of chronic HF patients referred to a single tertiary outpatient clinic in Italy.

Methods: Among all first visits between Jan. 1st 2004 and May 31st 2015, those with a serum creatinine concentration (sCr) available and <3.5 mg/dL were retrospectively selected. Patients not on ACEi/ARB at the time of both the first and the last visit were considered as never treated with ACEi/ARB. Clinical, biochemical, and echocardiographic data were compared between ACEi/ARB recipients and not. A multivariate logistic regression model with backward selection was created to

identify independent correlates of ACEi/ARB therapy. The risk of all-cause mortality was assessed by multivariate Cox regression and Kaplan-Meier analysis.

Results: Of 711 eligible patients, 117 (17.4%) never received ACEi/ARB. Compared to subjects on ACEi/ARB, never-users were older and more often women, had lower systolic blood pressure (SBP) and higher sCr, had more frequently an history of anemia and tumor and less frequently of ischemic heart disease (IHD), and were less commonly on β -blocker (all $p < 0.05$). In multivariate analysis, male gender (OR 0.41, 95%CI 0.26-0.66), SBP (0.98, 0.97-0.99), higher sCr (3.53, 2.26-5.52), a history of tumor (1.96, 1.07-3.58), the presence of IHD (0.62, 0.39-0.98) and β -blocker therapy (0.61, 0.37-0.99) were independently related to ACEi/ARB never-use. The same correlates were found when estimated glomerular filtration rate was substituted for sCr. At about 1-year follow-up, LVEF improved by $\geq 10\%$ in 30% vs. 17% of subjects on ACEi/ARB or not ($p = 0.005$), while sCr increased by more than 25% of baseline in 11% vs. 7%, respectively ($p = 0.20$). Overall mortality was 37% over a 5-year period (58 ± 30 months), and never-use of ACEi/ARB was associated with an almost 2-fold increased risk of death [adjusted HR 1.82, 1.33-2.50]. Patients not taking ACEi/ARB were more likely to die over the course of our extended follow-up (Figure 1).

Conclusions: In our population, a history of tumor and increased sCr were independent causes of ACEi/ARB omission. While renal function worsened similarly in ACEi/ARB recipients vs. not, never-use of ACEi/ARB was associated with lower rate of LV remodeling and dramatically raised risk of mortality.

Chronic heart failure induces changes in the serum blood profile of lipids containing choline - results of the validation study.

M Marta Marcinkiewicz-Siemion¹; K Ptaszynska-Kopczynska¹; M Ciborowski²; A Szpakowicz¹; A Lisowska¹; M Jasiewicz¹; E Waszkiewicz¹; A Kretowski²; WJ Musial¹; KA Kaminski¹

¹Medical University of Bialystok, Cardiology, Bialystok, Poland; ²Medical University of Bialystok, Clinical Research Centre, Bialystok, Poland

Introduction: Heart failure (HF) is a common clinical syndrome which constitutes the final stage of a variety of the cardiovascular diseases.

Aim: The use of untargeted metabolomics to identify and validate changes in the blood metabolites profile, occurring as a result of heart failure development.

Methods and Results: We prospectively studied a group of optimally treated patients with stable chronic HF (n=69) and subjects without the disease (n=40). Both groups were divided into the derivation (36 HF patients: 61.4 ± 13.9 yrs, 58% ischemic etiology-IE, ejection fraction-EF $23.6 \pm 6.3\%$, New York Heart Association Class - NYHA II/III 47/53% and 20 age-matched controls: 60.5 ± 12.8 yrs, EF $64.1 \pm 5.2\%$) and validation group (33 HF patients: 63.9 ± 10 yrs, 55% IE, EF $25.2 \pm 5\%$, NYHA II/III 36/64% and 20 age-, gender- and concomitant disease-matched controls: 65.5 ± 7 yrs, EF $58.6 \pm 5\%$). All of the enrolled patients were assessed clinically (NYHA class), biochemically (natriuretic peptide - BNP, C reactive protein - CRP, estimated glomerular filtration rate - eGFR) and echocardiographically (left ventricle EF). Acute and chronic inflammatory diseases (rheumatoid arthritis, diabetes mellitus, asthma) were excluded. Additional fasting serum samples were collected and fingerprinted by liquid chromatography-mass spectrometry (LC-QTOF-MS). Final identification of significant features, which occurred in both a derivation and validation study, was performed based on MS/MS spectra. In the validation study we focused on statistically significant lipids containing choline. Considering the derivation and validation studies lower levels of phosphatidylcholine-PC 34:4 ($-30 \pm 12\%$, $p = .002$), lysophosphatidylcholine-LysoPC 15:0 sn1 ($-26 \pm 10\%$, $p = .005$), LysoPC 14:0 sn1 ($-25 \pm 8\%$, $p = .008$), LysoPC 15:0 sn2 ($-22 \pm 6\%$, $p = .008$), LysoPC 20:3 ($-24 \pm 8\%$, $p = .009$), and LysoPC 14:0 sn2 ($-24 \pm 8\%$, $p = .012$) were characteristic for heart failure patients. LysoPC 20:3 and LysoPC 14:0 sn2 were moderately correlated with total blood cholesterol level ($r = -.40$, $r = -.38$; respectively). The

positive correlation ($r=.44$) between LysoPC 20:3 and low density lipoproteins (LDL) were also observed. There were no significant differences in the median intensity of each of the metabolites between patients treated with statins and those without the medication (for each metabolite, statin use vs no statin use $p>.05$).

Conclusions: Serum metabolites profile of stable HF subjects differ from controls especially in terms of decreased levels of lysophosphatidylcholines, its isomers and PC 34:4. Changes in LysoPC 20:3 and 14:0 sn2 may be dependent on total cholesterol and LDL metabolism.

How do we treat diabetic patients with heart failure?

JR Beramendi Calero¹; I Irene Rilo Miranda¹; S Garcia Gutierrez²; A Anton Ladislao²; L Quintas Ovejero³; C Goena Vives³; I Solla Ruiz¹; I Villanueva Benito¹; M Morillas Bueno²; F De La Cuesta Arzamendi¹

¹Hospital Donostia, San Sebastian, Spain; ²Hospital Galdakao-Usansolo, Bilbao, Spain; ³Hospital Comarcal de Mendara, Cardiology, Mendara, Spain

Purpose: If we try to assess if the treatment is adequate for heart failure in diabetic patients, using as quality index the percentage of patients treated with ACE inhibitor-ARA II and beta blockers.

Methods: Observational prospective cohort study including a total of 1824 patients presenting to emergency departments in acute decompensated heart failure (acute decompensated heart failure and chronic heart failure). Sociodemographic features, cardiovascular risk factors, comorbidities, history of heart disease (ischemic cardiomyopathy, valvular, arrhythmia) and analytical and echocardiographic data were collected during emergency episode and hospital admission. We compared the 1824 at discharge treatment in diabetic and non-diabetic patients diagnosed with heart failure admitted to three hospitals of our Health Service between 2011 and 2013. 609 patients (33.39%) were diabetic and 1215 (66.61%) patients were not diabetic.

Results: 338 (27.82%) non-diabetic patients (PND) and 185 (30.43%) diabetic patients (PD) treated with an ACE inhibitor ($p=0.24$). 272 (22.39%) PND and 173 (28.45%) PD treated with ARA II ($p=0.004$). 437 (35.97%) and NDP 255 (41.94%) PD treated with beta-blockers ($p=0.013$). 0.721 (59.34%) and NDP 410 (67.43%) PD treated with loop diuretics ($p=0.0008$). 379 (31.19%) PND and 235 (38.65%) were treated with antiplatelet PD ($p=0.001$). 418 (34.40%) and 349 PND (57.40%) PD treated with statins ($p<0.001$). 259 (21.32%) PND and 175 (28.78%) were treated with calcium antagonists PD ($p=0.0004$). There were no significant differences regarding treatment with digoxin, antiarrhythmics, ivabradine, aldosterone and anticoagulation among others. Associated cardiovascular risk factors: hypercholesterolemia in 65% vs 44% in PD PND ($p<0.0001$), hypertension in 90% vs 80% PND PD ($p<0.0001$) and obesity in PD 45.89% vs 32.97% in PND ($p=0.0002$). Ischemic etiology of heart failure: 30% vs 21% in PD in PND with $p<0.0001$

Conclusions: 1. There is not a minor use of ACEI-ARA II and beta blockers in diabetic patients compared to non-diabetics. On the contrary, there is a difference in favor to diabetics compared to non diabetics for treatment with ARBs and beta-blockers, with no significant differences in ACE.2. There are a greater number of diabetic patients treated with antihypertensives and statins because of the largest association of cardiovascular risk factors in diabetic patients.3. A greater number of diabetic patients treated with antiplatelets reflects the higher percentage of ischemic etiology of heart failure in these patients.

Determination of the metabolic syndrome risk factors in adults in turkey

S Oğuz¹; G Gulsah Camci¹; B Bayrak Ozarslan¹; A Dogan¹; T Karadag²

¹Marmara University, Health Science Faculty, Nursing Department, Istanbul, Turkey;

²Üsküdar University, Istanbul, Turkey

Background: Metabolic syndrome (MetS) is an important public health problem starting with insulin resistance and including systemic disorders such as abdominal obesity, glucose intolerance or diabetes mellitus, dyslipidemia, hypertension and coronary artery disease together. MetS continues to be an important cause of mortality and morbidity increasing day by day all around the world. In this growth, basic changes in the nutritional habits, increase in sedentary lifestyle and some hereditary features have a role.

Purpose: This study intended to determine the prevalence and risk factors of metabolic syndrome in adults in line with the diagnosis criteria determined by International Diabetes Foundation (IDF).

Methods: This study was conducted with a total of 201 persons who admitted to a family health center due to any health problem between June 2015 and August 2015. Fasting blood glucose, triglyceride, LDL-cholesterol and HDL-cholesterol measurements were obtained from the laboratory results of the patients. Weight, height, body mass index, waist circumference, blood pressure measurements, on the other hand, were obtained from the measurements made by the researchers. Number, percentage, average, frequency, standard deviation and chi-square were used in the statistical evaluation. Statistical significance was accepted as $p<0.05$.

Results: Age average of the individuals participating in the study was 58.5 ± 2 , 50.7% of which were male and 49.3% of which were female. Average of waist

circumference of the males was 98.2 ± 2 cm, average of HDL values was 38.2 ± 8 mg/dl; average of waist circumference of the females was 91.7 ± 17.8 cm and average of HDL values was 43.4 ± 11 mg/dl. Average of BMI of all the groups was 26.3 ± 5 , average of systolic blood pressure was 126.65 ± 20.85 , average of diastolic blood pressure was 77.59 ± 16.1 , average of triglyceride value was 169.9 ± 66 mg/dl, average of LDL values was 126.12 ± 37 , and average of fasting blood glucose was 116.35 ± 50.57 . MetS was present in 56.21% of the individuals according to IDF criteria. 63.68% of the individuals were under risk in terms of waist circumference, 67.66% and 58.7% of them were under risk in terms of HDL and triglyceride values, respectively. There was not any significant difference between the groups in terms of metabolic syndrome presence ($p=.62$). 82.3% of the individuals with MetS were equal to and above 50 years of age. There was not any significant difference between sexes in terms of metabolic syndrome presence ($p=.39$).

Conclusion: It was found that individuals participating in the study were under risk with regards to waist circumference, HDL values, triglyceride values and diabetes. The frequency of metabolic syndrome is high and increases with age.

P2002

The differences between two metabolic syndrome diagnostic criteria in predicting clinical severity and prognosis of acute myocardial infarction

Z Babic¹; M Marko Mornar Jelavic²; H Pintaric³

¹University Hospital "Sestre Milosrdnice", Coronary Care Unit, Zagreb, Croatia;

²Health Center Zagreb - East, Center for Internal Medicine and Dialysis, Zagreb, Croatia;

³University Hospital "Sestre Milosrdnice", Cardiac Catheterisation Laboratory, Zagreb, Croatia

Introduction: Metabolic syndrome (MetS) is defined as a group of interrelated factors (hyperglycemia, abdominal obesity, atherogenic dyslipidemia, hypertension, prothrombotic and proinflammatory states), which significantly increases the risk of coronary artery disease and other forms of atherosclerotic cardiovascular diseases.

Purpose: To investigate the importance of two MetS diagnostic criteria (the revised National Cholesterol Education Program - Adult Treatment Panel III (NCEP-ATP III) and International Diabetes Federation (IDF)) in predicting clinical severity and prognosis of acute ST-elevation myocardial infarction (STEMI).

Methods: This prospective study included 250 acute STEMI patients treated with primary percutaneous coronary intervention. They were classified into two groups (with/without MetS) which were analyzed by baseline (medical history and demography), severity (clinical presentation, laboratory, echocardiography, coronary angiography and in-hospital complications) and prognostic parameters (major adverse cardiovascular events (MACE) and sick leave duration (SLD) during 12-month follow up).

Results: MetS (NCEP-ATP III) patients (54.4%) had longer hospitalization, higher rates of total in-hospital complications, higher number of significantly stenosed coronary arteries (CAs), wider stents, higher rate of significantly stenosed proximal/middle CAs segments, and longer SLD ($p<0.05$). MetS (IDF) patients (58.8%) only had wider stents ($p<0.05$). MetS (NCEP-ATP III) increased the risk of total in-hospital complications and >1 significantly stenosed CAs ($p<0.05$). Hyperglycemia increased the risk of heart failure and the number of significantly stenosed CAs the risk of total MACE ($p<0.05$).

Conclusions: MetS (NCEP-ATP III) has a role in predicting acute STEMI severity (total in-hospital complications, severity of coronary disease), while MetS (IDF) have no influence on it. They all have no influence on prognosis (MACE and SLD).

P2003

Galectin-3 and metabolic syndrome components in non-diabetic patients with heart failure with preserved left ventricular ejection fraction

G Ganna Bolotskykh¹; I Rudyk¹; M Udovychenko¹

¹L.T.Malaya Institute of Therapy, Kharkiv, Ukraine

Background: Galectin-3 (Gal-3) is a marker of cardiac fibrosis and predicts incident heart failure. Recent studies suggested an important role for metabolic syndrome components in development and progression of heart failure with preserved left ventricular ejection fraction (HFpEF).

Purpose: To evaluate the association of circulating Gal-3 levels and metabolic syndrome components in non-diabetic patients with HFpEF.

Methods: Forty four non-diabetic patients (27 males and 17 females; mean age 60.45 ± 9.8 years) with HFpEF of ischemic genesis were examined. Patients with diabetes mellitus were excluded. The serum Gal-3, TNF-alpha, Nt-proBNP and insulin levels measured in serum by ELISA, according to manufacturer's instructions. Homeostasis Model Assessment (HOMA) index was calculated as a measure of IR at fasting state ($IR = \text{fasting glucose} \times \text{fasting insulin} / 22.5$). The echocardiographic parameters were measured with M- and B-mode and calculated following the American Guidelines of Echocardiography Society. Continuous variables are expressed as median (25th, 75th percentile). To distinguish the significance of the variation among the subjects for nonparametric data Spearman's correlation analysis and Mann-Whitney U test were used. The categorical variables were compared with a

χ^2 test. All statistical tests were 2-tailed, and $p < 0.05$ was considered statistically significant.

Results: Twenty two patients (50%) had Gal-3 serum levels above the median value of 3.13 ng/mL (interquartile range, 2.68–3.60). In the high Gal-3 levels group all patients were overweight. Compared with a low Gal-3 levels group there was significantly higher TNF α and glucose levels in the high Gal-3 levels group ($P = 0.001$, $P = 0.05$, respectively). Moreover, incidence of IR and co-occurrence cardiovascular risk factors in high Gal-3 levels group was significantly higher ($P < 0.05$, $c^2 = 5.53$, $P < 0.05$, $c^2 = 13.37$, respectively) compared with those in low Gal-3 levels group. Gal-3 levels were associated with systolic blood pressure (SBP) ($r = 0.371$, $P = 0.05$), higher SBP values were found in patients with higher levels of Gal-3. Gal-3 was also associated with diastolic dysfunction - E/A ratio ($r = -0.316$, $P = 0.05$). There were neither a significant correlation between Gal-3 levels and left ventricular ejection fraction and NTproBNP levels.

Conclusions: It was found, that increasing Gal-3 serum levels associated with higher incidence of metabolic syndrome components in non-diabetic patients with HFpEF. This fact may provide complementary information about mechanisms development and progression of HFpEF.

Research – ES Health Science Foundation, Cotignola, Italy

Background: Diabetes mellitus and heart failure (HF) are two common diseases that often coexist. However, despite the high frequency of diabetes among patients with HF, there are few contemporary, comparative data on the short- and long-term survival outcomes from multi-national cohorts of patients with and without diabetes who have been admitted to hospital for acute HF, out of the context of randomized clinical trials. Additionally, the few studies that explored the impact of diabetes on short- and long-term adverse outcomes in patients hospitalized for acute HF have reported discrepant results.

Purpose: To evaluate the short- and long-term prognostic impact of diabetes and elevated blood glucose levels at hospital admission for an acute HF episode.

Methods: We studied a multinational cohort of 6,926 hospitalized patients with acute HF included in a Society of Cardiology and a Heart Failure Association Long-Term HF Registry, of whom 49.4% ($n = 3,422$) had known or newly diagnosed diabetes. Two multivariable regression models were applied to estimate the risk associated with diabetes status in terms of in-hospital mortality (by logistic regression analysis), 1-year all-cause or cardiac mortality and 1-year re-hospitalization for HF (by Cox regression analysis).

Results: Compared with those without diabetes, patients with diabetes had higher cumulative rates of short- and long-term adverse outcomes that occurred independently of multiple clinical risk factors: in-hospital mortality (6.8 vs. 4.4%; adjusted HR - 1.79; 95% CI 1.31-2.44, $p < 0.001$), 1-year all-cause mortality (27.5 vs. 24.0%; adjusted-HR 1.179; 95% CI 1.03-1.32, $p = 0.014$) and 1-year re-hospitalizations for HF (23.2 vs. 18.5%; adjusted-hazard ratio 1.33; 95% CI 1.15-1.53, $p < 0.001$). Elevated blood glucose concentrations at hospital admission were powerfully prognostic for in-hospital mortality, but not for 1-year mortality or re-hospitalization rates, both in patients with and in those without diabetes.

Conclusion: Among patients hospitalized for acute HF, presence of diabetes is independently associated with an increased risk of short- and long-term mortality and re-hospitalizations for HF, underscoring the need for investigating a more individualized management of diabetes in this patient population.

The exercise has beneficial effects on circulating endotoxin levels in obese women.

S A Seon Ah Jin¹; JK Oh¹; MJ Kim¹; UL Choi¹; SW Seong¹; KT Ahn¹; SW

Choi¹; IW Seong¹; JO Jeong¹

¹Chungnam National University Hospital, Daejeon, Korea Republic of

Introduction: Obesity is worldwide pandemic and associated with high cardiovascular risk. Metabolic endotoxemia (ME) is thought to be involved in these associations as underlying molecular mechanism. ME triggers toll-like receptor 4-mediated inflammatory adipokines and leads to a chronic low grade inflammatory status,

which results in CV risk increase and target organ damage. Exercise is the best nonpharmacological treatment to improve prognosis for obesity.

Purpose: In this study, we examined the circulating endotoxin levels in Korean obese women and investigated effects of exercise on them.

Methods: Women ($n = 20$) who met obesity criteria of BMI 25 kg/m² or greater were included and participated in a resistance training exercise (with an intensity of 60-80% of their maximum heart rate, a frequency at least three days per week and duration of 30 minutes) for 12-weeks. After 0 (baseline) and 12 weeks, tests including anthropometric measurements, fasting blood samples and postprandial blood samples were conducted in all participants.

Results: In Korean obese women ($n = 20$, 27.9 ± 0.5 kg/m²), the fasting circulating endotoxin was 1.45 ± 0.11 EU/mL. Ingestion of a high calorie meal led to a peak level at 2 hour in endotoxin (1.78 ± 0.15 EU/mL for 2 hour; 1.75 ± 0.14 EU/mL for 4 hour, $p < 0.05$ vs. for 0 hour). After 12 week exercise, BMI and Hip circumference were reduced significantly. The total cholesterol at fasting, postprandial 2 and 4 hour was decreased significantly. Although the circulating endotoxin levels showed reduction at fasting state, they were not significant. The serum glucose and endotoxin levels at postprandial 2 hour were significantly declined in similar pattern (117.7 ± 6.4 at 0 week vs. 100.7 ± 5.1 mg/dL for glucose; 1.78 ± 0.15 at 0 week vs. 1.48 ± 0.06 EU/mL at 12 week for endotoxin, $p < 0.05$).

Conclusions: In conclusion, our data reports the circulating endotoxin levels in Korean obese women for the first time. Also, we suggest that exercise exerts beneficial effects on the endotoxin and it has an impact on the better prognosis in obese women who follow regular exercise.

(n = 20)	0 week	12 weeks	p value

Features of the diabetic population with acute heart failure in our reference area

I Irene Rilo Miranda¹; JR Beramendi Calero¹; S Garcia Gutierrez²; A Anton Ladislao²; L Quintas Ovejero³; C Goena Vives³; I Villanueva Benito¹; I Solla Ruiz¹; M Morillas Bueno²; F De La Cuesta Arzamendi¹

¹Hospital Donostia, San Sebastian, Spain; ²Hospital Galdakao-Usansolo, Bilbao,

Spain; ³Hospital Comarcal de Mendara, Cardiology, Mendara, Spain

Introduction: This study aims to determine the differential characteristics of patients with Diabetes Mellitus (DM) and acute heart failure admitted to the Emergency Services 3 hospitals in the Osakidetza network between 2011 and 2013.

Methods: Observational prospective cohort study including 1824 patients presenting to the emergency room of our hospital for acute decompensated heart failure. Outcome variables were considered short-term mortality and readmissions during 3 months.

Results: The sample included 1824 patients, of whom 609 are diabetics (33.39%). 47% were male and 51% female. The diabetic population was younger at the time of diagnosis :77.68 vs 80.58 years ($p < 0.0001$) and presented more cardiovascular risk factors: hypercholesterolemia 65% vs 44% ($p < 0.0001$), hypertension 90 % vs 80% ($p < 0.0001$) and obesity 45.89% vs 32.97% ($p = 0.0002$). In addition, diabetic patients more frequently have coronary artery disease as etiologic diagnoses (30% vs 21 % $p < 0.0001$) and higher comorbidity with the Charlson index significantly higher (3 vs. 2 vs. $p < 0.0001$) with a higher degree of chronic kidney disease (7.55% vs. 5.1% $p = 0.036$), anemia (27% vs. 19.84% $p = 0.0002$) and COPD (27.09% vs. 22.8%, $p = 0.0435$). Despite these data in our study we found no significant differences in short-term mortality (5.09% vs 4.44% with $p = 0.5371$), mortality at 3 months (11.66 vs 12.67% $p = 0.5336$) and readmissions (22.9% vs. 21.07% with $p = 0.3486$) compared to patients without diabetes.

Conclusions: Diabetic patients in our study had significantly more cardiovascular risk factors and greater comorbidity than non-diabetic patients. However, no significant differences were found in short-term mortality or readmissions in 3 months. However, we cannot say that the risk of poor outcome is higher in a longer time frame. It would require a longitudinal study to establish the risk of adverse outcomes in those patients for a longer period of time.

Right ventricular outflow tract m-mode echocg in congestive heart failure

M Mikheil Tsverava¹; DM Tsverava²¹Tbilisi Medical Academy, Tbilisi, Georgia Republic of; ²MediClub Georgia Tbilisi Clinic, Medicime, Tbilisi, Georgia Republic of

Right ventricle (RV) plays important role in Heart Failure. Inflow and outflow tracts of this chamber are functionally and morphologically different. The inflow tract of RV (RV in) was actively studied by different EchoCG methods in normal and pathologic state, but there is little information about RV outflow tract.

Aim: To investigate RV outflow tract (RVout) M-mode EchCG fractional shortening (FS%) in patients with congestive heart failure (HF).

Material and Methods: We studied 230 healthy volunteers and 110 patients with HF. RVout M-mode EchCG was registered from parasternal short axis view. It was measured RV outflow diastolic (RVd) and systolic (RVs) diameters. RVout FS% was calculated by formula (RVd-RVs)/RVd%.

Results: The RVd and RVs was significantly greater (30.4±4.9mm versus 33.6±5.4mm and 13.2±5.4mm versus 21.0±5.3mm respectively, p<0.001) and RV FS% was significantly lower (57.2±5.4% versus 37.6±10.4%, p<0.001) in patients with heart failure compared to normal persons. If we take for RV FS% <50% as reference point the sensitivity and specificity of this parameter in diagnosis of heart failure is 0.88 and 0.95 respectively.

Conclusion: In patients with HF the RV outflow tract systolic and diastolic diameters and FS% was significantly different compared to normal persons.

P2008

Right ventricular outflow tract tissue doppler parameters in congestive heart failure

M Tsverava¹¹Tbilisi Ilia Chavchavadze State University, Tbilisi, Georgia Republic of

Right ventricle (RV) plays important role in Heart Failure. Inflow and outflow tracts of this chamber are functionally and morphologically different. The outflow tract of RV (RVout) was actively studied by different EchoCG methods in normal and pathologic state, but there is little information about RV outflow tract.

Aim: To investigate RV outflow tract (RVout) pulsed wave TDI qualitative and quantitative parameters in patients with congestive heart failure (HF).

Material and Methods: We studied 140 healthy volunteers and 75 patients with HF. RVout pulsed wave TDI was registered from subcostal position with sample volume on RV lateral wall, near the pulmonary valve. RV in TDI was registered in apical 4 camber view with the sample volume positioned at lateral wall near the pulmonary valve.

Results: The pattern of TDI from RVout was quite different from pattern of TDI of RV free wall. It was characterized by prominent positive wave in isovolumic contraction period (Sict), high positive wave at the beginning of systole (S) with sharp decrease of velocity, prominent negative and positive waves during isovolumic relaxation period (Eict1 and Eict2) and two negative waves in diastole (E and A). The TDI waves of RVout were significantly greater in normal persons than corresponding waves on RVout TDI in patients with HF. The Sict (4.2±1.6 versus 6.5±1.9 cm/sec), S (7.7±2.0 versus 9.2±2.3 cm/sec), Eict1 (-4.0±1.7 versus -6.1±2.1 cm/sec) and E (5.1±1.8 versus 7.4±1.8 cm/sec) on TDI from RVout were significantly slower in HF group compared with normal persons (p<0.001).

Conclusion: In normal persons the TDI pattern of RV inflow and outflow tract is qualitatively and quantitatively different. In patients with HF the systolic and diastolic wave velocities were significantly lower compared to the normal persons.

P2009

2D speckle tracking of the left ventricle for early detection of myocardial involvement in patients with systemic sclerosis

I Ihnen Zairi¹; Z Jenifene¹; K Mzoughi¹; M Jabeur¹; F Benmoussa¹; S Kamoun¹; S Fennira¹; L Baili²; S Kraiem¹¹Habib Thameur Hospital, cardiology, Tunis, Tunisia; ²Habib Thameur Hospital, internal medicine, Tunis, Tunisia

Aims: Systemic sclerosis (SSc) is a connective tissue disease characterized by vascular inflammation and fibrosis. Visceral involvement particularly myocardial involvement is associated with poor prognosis. Two-dimensional speckle-tracking echocardiography is a useful sensitive tool to detect left ventricular systolic dysfunction that, so far, has not been diagnosed in SSc patients. The aim of this study was to evaluate deformation analyses derived from 2D speckle-tracking echocardiography for early detection of left ventricular dysfunction in patients with SSc.

Methods and results: 25 patients with SSc (53.64±13 years, LVEF (Left ventricular ejection fraction) 64.58±8.87 %) and 25 gender and age matched healthy subjects (35.8±8.72 years, LVEF 68.2±7.41%) underwent echocardiography with STE to assess global and regional left ventricular function. Despite a preserved and comparable LVEF, the global longitudinal strain of the left ventricle was significantly lower in the SSc group compared with controls: -17.42±1.62 vs. -19.24±8.85 (P<0.0001). This was mainly driven by a reduced strain in the medial and apical segments.

Conclusion: ventricular deformation analysis by 2D speckle-tracking echocardiography is a sensitive method to detect early left ventricular dysfunction in patients with SSc.

P2010

Left ventricular diastolic function: the effect of exercise training in young athletes

S Charfeddine¹; S Mallek¹; M Jabeur¹; D Abid¹; F Triki¹; L Abid¹; S Kammoun¹¹Hedi Chaker University Hospital, Cardiology department, Sfax, Tunisia

Introduction: Regular training induces structural myocardial adaptation, so-called "athlete's heart". The aim of this study was to assess the impact of regular sport activity in left ventricular (LV) diastolic function in young athletes.

Patients and methods: Thirty-three young athletes (football players) regularly trained at least three times a week for at least 9 months a year and 20 young controls were evaluated by 2D echocardiography (echo). The diastolic LV function was evaluated by 2D conventional echo parameters and Doppler method.

Results: All the found values were within the normal range. The LV End Diastolic Diameter (LVED 37.24±2.08 mm/m²) and the LV Mass index (LVMI 97.93±15.58 g/m²) were significantly higher in young athletes as compared with controls. There was no significant difference regarding the LV systolic function assessed by conventional echo parameters in the 2 study groups. Comparison of the standard transmitral Doppler parameters yielded similar E-wave and E-wave deceleration time for the 2 study groups. The A-wave was significantly lower in the athletes group (p<0.001) and the E/A ratio was significantly higher in athletes (E/A=2.10±0.49 versus 1.64±0.26, p<0.001). Comparison of TDI parameters measured from the lateral mitral annulus also demonstrated similar S' and E' rates for all 2 groups (p=0.377 and p=0.177, respectively). But there was no difference in the filling pressure in the 2 groups.

Conclusion: Conventional functional echocardiographic parameters could distinguish some adaptations in the athlete's heart and showed a different pattern of LV diastolic function in young footballers versus controls.

P2011

Carotid intima-media thickness and arterial stiffness are the best determinants of left atrial reservoir function

AO Ciobanu¹; R Dulgheru²; R Dragoi Galrinho³; SM Magda³; M Florescu¹; RC Rimbas¹; R Mincu³; D Dragos Vinereanu³¹University of Medicine and Pharmacy Carol Davila, Bucharest, Romania;²University Hospital of Liege (CHU), Liege, Belgium; ³University Emergency Hospital, Bucharest, Romania

Left atrium (LA) dysfunction is associated with atrial fibrillation and heart failure (HF). However, LA function is often neglected, as well as the potential role of medication for improving atrial function and subsequently lower HF incidence by targeting the arteries.

Aim: To test the hypothesis that LA reservoir function is related to the arterial function.

Methods: We studied 120 subjects (44±27 years, 63 males): 20 athletes, 20 normals, 20 patients with risk factors, 20 with growth hormone deficiency, 20 with multiple sclerosis, and 20 with dilated cardiomyopathy, with an ejection fraction (EF) from 12 to 76%. LA reservoir function was assessed from total LA strain (TLAS) and LA expansion index (LAEI), LA conduit function from positive global LA strain (pGLAS) and passive LA emptying fraction (PLAEF), while LA pump function from LA active emptying fraction; LV global systolic function from EF; longitudinal

systolic function from mitral annular systolic velocity (Sa) and MAPSE; LV diastolic function from mitral annular diastolic velocity (Ea). Arterial function was assessed from intima-media thickness (IMT) and stiffness parameters (elastic module - Ep and local wave speed - LWS); endothelial function from flow mediated dilation (FMD).

Results: All parameters of LA reservoir function correlated with both LV systolic and diastolic functions, FMD, and arterial stiffness (table), whereas LA conduit and pump functions correlated only for some of the parameters. By stepwise multivariate analysis, the best determinants of the LA reservoir function were Ea ($\beta = 0.40$) and IMT ($\beta = -0.37$) (both $p < 0.01$).

Conclusions: LA reservoir function is related to the LV longitudinal function, arterial stiffness, and endothelial function. This emphasizes the arterial-ventricular-atrial interaction, and role of medication in targeting both the heart and arteries, in an attempt to improve arterial and atrial function and prevent progression to HF.

The value of tissue doppler imaging in left ventricular diastolic function assessment

H Hortensia Gjergo¹; T Goda¹; A Simaku²; P Gjergo¹; S Qirko¹

¹University Hospital Center Mother Theresa, Tirana, Albania; ²Public Health Institute, Tirana, Albania

Background: Diastolic dysfunction is common in cardiac disease and contributes to the signs and symptoms of heart failure. Noninvasive assessment of diastolic filling by Doppler echocardiography provides important information about left ventricular (LV) status only in selected subset of patients.

The purpose of this study was to evaluate the reliability of different tissue Doppler imaging indexes in prediction of high LV filling pressures.

Methods: 105 patients underwent echocardiographic examination prior to cardiac catheterization. They were divided in two groups according to left ventricular end-diastolic pressure (LVEDP) and left ventricular ejection fraction (LVEF). LVEDP was obtained before coronary angiography and ventriculography. An elevated LV filling pressure was defined as LVEDP ≥ 16 mmHg. 42 patients had elevated LV filling pressures. Doppler signals from the mitral inflow and TDI of the mitral annulus were obtained.

Results: The parameters of transmitral flow correlated with LVEDP only when EF was reduced. In the subgroup of patients with normal EF, only E/E' ratio correlated with LVEDP. The ratio of E/E' showed a better correlation with LVEDP for all levels of systolic function. For predicting high LVEDP an E/E' ratio > 7.7 provided a sensitivity and specificity of 70%, E/(E' \times S') > 75 provided a sensitivity of 81% and a specificity of 58%, E'/A' \times S' > 10.4 provided a sensitivity of 49% and a specificity of 71%.

Conclusion: The E/E' ratio is the best predictor of LV filling pressure for all levels of systolic function, but it can't be used in isolation for the assessment of left ventricular diastolic dysfunction.

Correlation of TDI variables with LVEDP

Cardiac magnetic resonance late gadolinium enhancement in patients with genetic dilated cardiomyopathy

A Sousa¹; T Pinho²; P Canedo³; L Lopes⁴; O Azevedo⁵; A Madureira²; A Belo⁶; J Silva Cardoso²; JC Machado³; E Martins¹

¹Faculty of Medicine University of Porto, Porto, Portugal; ²Sao Joao Hospital, Porto, Portugal; ³Institute of Molecular Pathology and Immunology at the University of Porto, Porto, Portugal; ⁴Garcia de Orta Hospital, Lisbon, Portugal; ⁵Alto Ave Hospital Center, Guimaraes, Portugal; ⁶Portuguese Society of Cardiology, Lisbon, Portugal

Introduction: Dilated cardiomyopathy (DCM) has an estimated prevalence of 1:2500 in adult population, with genetic etiology explaining 30-50% of "idiopathic" cases. Genetic causality is difficult to identify because of the scarcity of distinctive red flags. In recent years, cardiac magnetic resonance (CMR) has emerged as a valuable imaging modality in this field. However, its utility in diagnosing genetic DCM remains largely unknown.

Purpose: In this work we aimed to describe CMR findings in genetically characterized DCM patients.

Methods: We included patients with idiopathic and familial DCM, that underwent a comprehensive CMR with a 3-T scanner (Siemens, Erlangen, Germany), as part of their diagnostic work-up. Left ventricular (LV) volumes, ejection fraction (LVEF) and mass were measured using dedicated software (ARGUS Software™, Siemens Healthcare Global). LV late gadolinium enhancement (LGE) presence, pattern and location were assessed; extensive fibrosis was defined as LGE presence in ≥ 3 LV segments. Molecular analysis included the search of mutations in LMNA/C, MYH7, MYBPC3, TNNT2, ACTC1, TPM1, CSRP3, TCAP, SGCD, PLN, MYL2, MYL3, TNNI3, TAZ and LBD3 genes. Pathogenicity was assessed by comparisons with mutations previously described, functional tests and segregations studies.

Results: We analyzed 73 patients, 46.6% with familial DCM, 52.8% men. Mean LVEF was $34 \pm 11\%$ and LV end-diastolic volume of 128 ± 34 mL. We identified 18 genetic variants in 17 distinct patients. Eleven patients presented variants with pathogenicity criteria. Comparing patients with or without genetic variants, we observed no difference in CMR parameters. Focusing on patients with mutations in MYBPC3, TNNT2 and MYH7 genes, we found only a trend toward an association of MYH7 mutations with LGE ($p = 0.057$) – with a significant predilection for septum involvement ($p = 0.042$), and with the presence of non-compaction ($p = 0.057$). There was no relationship between the remaining CMR variables.

Conclusion: LGE might have some utility in the clinical recognition of patients with genetic DCM, namely those with MYH7 mutations, although additional studies are warranted to confirm these findings. Nevertheless, the exclusion of other causes of LV dysfunction and the use of more recent CMR tools, as interstitial fibrosis assessment, support the continued exploration of this technique in the evaluation of genetic/familial DCM patients.

P2014

Acute coronary syndrome with normal coronary angiography: a gender issue?

M Marta Braga¹; H Nascimento¹; S M Oliveira¹; M Vasconcelos¹; T Pinho¹; R Rodrigues¹; A Madureira¹; P Dias¹; M J Maciel¹

¹Sao Joao Hospital, Porto, Portugal

Introduction: Acute coronary syndrome (ACS) with normal coronary angiography (CA) is a challenging medical condition with an uncertain prognosis. It has been reported that women are the most affected.

Purpose: The aim of this study was to compare women and men with ACS with normal/near-normal (stenosis <50%) CA (NCA) and describe the clinical profile, final diagnosis and outcome in these two groups.

Methods: This study was based on a retrospective analysis of 108 consecutive patients (pts) admitted in a tertiary centre from January 2007 to December 2014 with ACS suspected and NCA. All pts did a cardiac magnetic resonance (CMR) for additional evaluation. The pts were divided by gender.

Results: In our cohort, 56 (51.9 %) pts were female. The women were older than men (59.9 ± 14.5 years vs. 44.0 ± 15.4 , $p < 0.001$). Within cardiovascular risk factors, hypertension was more often in women (60.7% vs. 30.8%, $p = 0.002$), while smoking was more common in men (28.8% vs. 10.7%, $p = 0.017$). The presence of recent emotional stress was more often in women (30.4% vs. 5.8%, $p = 0.001$) and prior infectious symptoms were more common in men (40.4% vs. 7.1%, $p < 0.001$). The changes in initial EKG were similar in both groups. Mean value of maximal I troponin was greater in women, but without significance. The echocardiography showed moderated to severe left ventricular dysfunction in 33 patients, with no significantly difference according to sex. The findings in CA were no different as well. Myocardial edema and late enhancement in CMR was more common in men (48.1% vs. 23.2% $p = 0.007$; 80.8% vs. 48.2%, $p < 0.001$). Concerning to final diagnosis, ACS and Tako-Tsubo cardiomyopathy were more frequent in women (44.6% vs. 15.04%, $p = 0.001$ and 32.1% vs. 3.8%, $p < 0.001$, respectively). Acute myocarditis was more often in men (3.5 vs. 32.1%). During follow-up of 3.0 ± 2.0 years, readmission and all-causes mortality were rare, without differences between both genders.

Conclusions: Surprisingly, the number of female and male pts with ACS suspected and NCA did not differed significantly. While women were more hypertensive and had more often emotional stress factor, men were more smokers and had more frequently infectious symptoms. In work-up diagnosis, the most difference observed between both sexes was in CMR results, focusing the importance of this exam in etiologic diagnosis. ACS and Tako-Tsubo syndrome was the leading final diagnosis in women, while acute myocarditis was the main diagnosis in men.

P2015

Assessment of the left ventricle during heart failure : cardiac magnetic resonance or echocardiography ?

S Soufia Naccache¹; W Sdiri¹; R Tlili¹; S Longo¹; A Mokaddem¹; Y Ben Ameur¹; MR Boujnah¹

¹ Mongi Slim Teaching Hospital, La Marsa, Tunisia

Introduction: Echocardiography is commonly used to assess heart failure. This technique is facing many challenges that can be solved by the magnetic resonance imaging. However, this exam remains understudied in our country. Our objectives were to study the correlation between echocardiography and cardiac magnetic resonance imaging in evaluation of the left ventricle during heart failure.

Results: Thirty patients were collected consecutively. The mean age of our patients was 50 ± 16 years with a sex-ratio of 14. Ischemic cardiomyopathy was found in 50 % of cases. An atrial fibrillation was observed in 27% of patients. The mean follow-up was 11.53 months. The overall mortality rate was 17%. There was a good correlation between echocardiography and magnetic resonance imaging measurements of the diameters of the left ventricle with $r = 0.84$ and $p < 0.0001$. The correlation between the end-systolic and the end-diastolic volumes of the left ventricle was good with respectively $r = 0.66$ ($p < 0.0001$) and $r = 0.73$ ($p < 0.0001$). There was also good agreement between the 2 exams for measuring the ejection fraction of the left ventricle with $r = 0.73$ and $p < 0.0001$. The correlation between echocardiography and magnetic resonance imaging was good for the diagnosis of left ventricular hypertrophy with $r = 0.67$ and $p < 0.0001$. However, magnetic resonance imaging had a sensitivity of 70 % and a specificity of 100 % in comparison to echocardiography. Three left ventricular thrombi had not been detected by echocardiography. Myocardial fibrosis was observed in 73 % of cases. There was no correlation between fibrosis and the symptoms, diastolic function or mortality.

Conclusion: In our national context, magnetic resonance imaging allows reliable measurements of diameters, volumes and ejection fraction of the left ventricle with excellent correlation with echocardiography evaluation. This exam was showed to be the gold standard imaging technique for the detection of myocardial necrosis. The main limitation of magnetic resonance imaging remains its availability and cost.

P2016

Comparative study of coronary computed tomography versus coronary intravascular ultrasound and virtual histology for the diagnosis of cardiac allograft vasculopathy after heart transplantation

D Diego Rangel Sousa¹; N Romero-Rodriguez¹; I Esteve-Ruiz¹; M Sobrino-Marquez¹; MP Gotarredona-Serrano²; MP Villa-Gil-Ortega³; E Lage-Galle¹

¹ University Hospital of Virgen del Rocio, Heart Failure and Heart Transplantation Unit. Service of Cardiology, Seville, Spain; ² University Hospital of Virgen del Rocio, Cardiothoracic Image Unit, Seville, Spain; ³ University Hospital of Virgen del Rocio, Haemodynamic and Interventional Cardiology Unit, Seville, Spain

Background: Cardiac allograft vasculopathy (CAV) is currently one of the leading causes late graft-related death after heart transplantation (HT). CAV is characterized by diffuse and progressive coronary arteriopathy with concentric intimal hiperplasia. The exact pathophysiology of CAV remains poorly understood as the diagnosis is complex mainly at initial stages of the disease, when it is also usual lack of symptoms. Coronary angiography supported by intravascular ultrasound (IVUS) is widely used as the "gold standard" for routine surveillance to identify signs of CAV. Moreover, analysis of spectrum of the radiofrequency data obtained by IVUS has recently allowed the development of virtual histology techniques (IVUS-VH), bringing added value to the IVUS. Coronary computed tomography (cCT) has joined the diagnosis of ischemic heart disease by direct visualization of the coronary vessel wall and lumen, and identifying the presence of atherosclerosis and the stenosis degree.

Methods: 45 heart transplanted patients were prospectively included with a within-subject design in order to compare both tests (VH-IVUS vs cCT) and determine the diagnostic performance of cCT. 51% were male, ages 55 ± 9.6 years (range 32-70 years). Presence of CAV was defined as International Society for Heart and Lung Transplantation (ISHLT) score of ≥ 1 . Sensitivity and specificity found for the diagnosis of presence or absence of disease were 100%. When patients were adequately classified according to Stanford scale of CAV severity, sensitivity was 85.7%, specificity of 100%, positive predictive value of 100% and negative predictive value of 97.4%. The area under the ROC curve was 0.83

Conclusions: cCT have a high sensitivity, specificity and negative predictive value, which may support its inclusion in CAV screening protocols. cCT has also proven to be cost-effective, with direct costs attributable more than 10 times lower than the cost of IVUS, and has shown to be safe in patients undergoing HT.

The association of galectin-3 and clinical parameters in patients with chronic heart failure

K Karine Gyamdjan¹; ML Maximov¹

¹ I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Galectin-3 is a novel biomarker of fibrosis and cardiac remodeling that represents an intriguing link between inflammation and fibrosis.

Aim of the study: to assess the association of circulating galectin-3 levels with other clinical parameters and functional performance indicators of patients with chronic HF NYHA II-III.

Methods: 53 patients with HF NYHA II-III were enrolled into single-centre prospective cohort study. Patients underwent echocardiographic evaluation of cardiac structure as well as systolic and diastolic function. Estimated glomerular filtration rate (eGFR) was calculated using the standard 4-variable Modification of Diet in Renal Disease equation (MDRD). Plasma levels of galectin-3 and NT-proBNP were assessed at baseline. Galectin-3 levels were assessed on baseline samples, using enzyme-linked immunosorbent assay. The relationship between galectin-3 levels and other baseline variables of interest was analyzed using Pearson (Spearman for non-parametric data) correlation analysis. A $p < 0.05$ was regarded as statistically significant.

Results: Galectin-3 levels were associated with higher NYHA class (Table 1) and correlated to other risk factors such as, higher creatinine ($r = 0.26$, $p = 0.04$), higher NT-proBNP ($r = 0.30$, $p = 0.02$) and lower EF ($r = -0.26$, $p = 0.04$). Association was found between galectin-3 levels and scale of evaluation of clinical state in CHF (as modified Mareev VY 2000) ($p = 0.025$). Other variables, including age, sex, age, heart failure etiology, left ventricular myocardium mass, 6-min walk test were not significant independent predictors of galectin-3 levels.

Conclusion: in a small cohort of patients with systolic heart failure galectin-3 levels were associated with known markers of disease severity. Thus galectin-3 testing may provide prognostic information complementary to other established HF biomarkers, such as NT-proBNP.

Tab 1 Gal-3 and NYHA class association

Parameter	n	Gal-3, ng/ml, median	Gal-3, ng/ml, Q25	Gal-3, ng/ml, Q75
HF NYHA II	14	6,86	3,67	10,02
HF NYHA III	39	9,61	7,75	12,57

Association between neutrophil gelatinase-associated lipocalin (NGAL) and ventricular function in patients with chagas cardiomyopathy. Nephron or cardiomyocyte?

LE Luis Eduardo Echeverría¹; LS Calvo-Betancourt¹; ZM Roa-Díaz¹; LZ Rojas-Sánchez¹; RL Campo-Torrenegra¹; AM Redondo-Gelvez¹; AM Torres-Bustamante¹; MC Villamizar¹

¹Foundation Cardiovascular of Colombia, Heart failure and cardiac transplant, Floridablanca, Colombia

Purpose: The Neutrophil gelatinase-associated lipocalin (NGAL) is a 25kDa glycoprotein covalently linked to matrix metalloproteinase-9, produced by a variety of cells including respiratory cells, intestinal epithelial cells, endothelial cells, renal tubular cells and cardiomyocytes. In patients with chronic heart failure (CHF) elevated levels of NGAL are associated with worse functional class, higher levels of NT-proBNP, readmissions, and increased mortality. Global longitudinal strain (GLS) has proven to be a marker of myocardial dysfunction with a great prognostic value. In the present study, the correlation between the levels of NGAL and GLS in patients with chronic chagas disease was determined, which has not been previously reported in the literature.

Methods: Analytical cross-sectional study. Patients older than 18 years with chagas disease were included. Those patients with uncontrolled hypertension, diabetes, history of coronary artery disease and valvular disease were excluded. The GLS was established by speckle tracking electrocardiography and blood levels of NGAL were determined, both measures were taken the same day. A descriptive analysis was performed, the correlation between the GLS and NGAL was evaluated by scatter plot and Spearman's rank correlation coefficient. Finally, a multiple linear regression analysis adjusted by sex, age and Glomerular Filtration Rate (GFR) was performed.

Results: A total of 100 patients were analyzed, 55% (55/100) were men; the mean age was 61 years (SD ± 12 years); the median and interquartile range of LVEF was 42% (Q1 = 27; Q3 = 56), of NGAL was 96.5 ng / mL (Q1 = 69; Q3 = 145); of GLS was -12.6% (Q1 = -17.8; Q3 = -8.1); 40% (40/100) of the patients had a GFR <60 mL / min / 1.73 m². A positive correlation between GLS and NGAL values ($\rho = 0.584$, $p = 0.000$) was established; on the other hand, NGAL and LVEF presented a negative correlation ($\rho = -0.584$, $p = 0.000$). In addition, an association between GLS and NGAL ($\beta = 0.031$, $p = 0.005$) adjusted by sex, age and GFR was established.

Conclusions: NGAL is a biomarker traditionally used to determine tubular necrosis. In studies in patients with CHF it has shown to be an independent marker of mortality. In patients with Chagas cardiomyopathy, the GLS showed a moderate positive correlation with NGAL. The finding of an association between these two variables in a model adjusted for age, sex and GFR suggests that it is a marker of myocardial dysfunction in the presence or absence of renal dysfunction in chagas disease.

Low circulating microRNA levels in heart failure patients are associated with peripheral arterial disease

E L Vegter¹; E S Ovchinnikova¹; T Jaarsma²; D J Van Veldhuisen¹; E Berezikov³; P Van Der Meer¹; A A Voors¹

¹University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands; ²Linköping University, Faculty of medical and health sciences, Linköping, Sweden; ³European Research Institute for the Biology of Ageing, Groningen, Netherlands

Background: Several circulating microRNAs (miRNAs) were found to be downregulated in patients with heart failure. Further characterisation of the heart failure population and corresponding circulating miRNA profiles would be valuable for future clinical application of miRNAs as biomarkers. Here, we aimed to study differences

in these circulating miRNAs between heart failure patients with and without evidence of atherosclerotic disease.

Methods: A panel of 11 heart failure specific circulating miRNAs was measured with quantitative reverse transcription-polymerase chain reaction (qRT-PCR) in plasma from 114 patients hospitalized for heart failure, at time of discharge. MiRNA levels were compared in heart failure patients with different manifestations of atherosclerosis including coronary artery disease, stroke/transient ischemic attack and peripheral arterial disease. In addition, associations between differentially expressed miRNAs and biomarkers related to the atherosclerotic disease process were assessed.

Results: From the 114 heart failure patients, 54.5% had a medical history of coronary artery disease. Cerebrovascular disease was present in 13.2% of the patients and 21.1% had a prior diagnosis of peripheral arterial disease. There was no consistent trend in plasma levels of the selected miRNAs in patients with and without coronary artery disease, stroke and/or transient ischemic attack. In contrast, consistently lower levels of miRNAs were found in patients with peripheral arterial disease ($n = 24$), of which 7 miRNAs (miR-18a-5p, miR-30e-5p, miR-106a-5p, miR-27a-3p, miR-223-3p, miR-199a-3p and miR-652-3p) were significantly lower compared to heart failure patients without peripheral arterial disease. Further, low levels of these miRNAs were significantly associated with high levels of multiple biomarkers related to inflammation and endothelial dysfunction (ESAM, LTBR, PIGR, pentraxin-3, troy, syndecan-1, galectin-3, NGAL, GDF-15, RAGE, TNFR-1, VEGFR-1, neuropilin-1 and angiogenin).

Conclusion: A consistent pattern of low circulating miRNAs were found in heart failure patients with peripheral arterial disease. In addition, lower levels of miRNAs were related to higher levels of several biomarkers related to inflammation and endothelial dysfunction.

P2020

The influence of the standard heart failure treatment on the RDW variation in patients with decompensated heart failure

RN Siliste¹; A Chitroceanu²; R Ianula¹; D Spataru¹; D Isacoff¹

¹Coltea Clinical Hospital, Bucharest, Romania; ²University Emergency Hospital of Bucharest, Bucharest, Romania

Background and aim: Red blood cell distribution width (RDW), which is routinely reported in complete blood counts, is a measure of the variability in size of circulating erythrocytes. Studies have already shown that an increase in RDW is associated with a poor prognosis in patients with both acute and chronic heart failure (HF). The aim of our study was to determine the effect of the standard HF therapy on the RDW variation.

Material and method: 170 patients with acute decompensated CHF admitted in Cardiology Unit were included; mean age of the cohort 72.89 ± 11.11 years, 44% male, 55% with preserved ejection fraction. Age- and sex-matched 50 control subjects without HF were also evaluated. Patients with cancer, moderate to severe anemia, COPD, infectious diseases or autoimmune disorders were excluded from both groups.

Results: RDW was significantly higher in HF group compared to control group (13.64 ± 2.14 % vs. 12.61 ± 0.95 %, $p < 0.0001$), with a mean value of 14.23 ± 2.73 % in NYHA class IV patients. 83.53 % were treated with ACEI/ARBs, 78.25 % with beta-blockers, 75% with statins, 71.76 % with diuretics and 53.53 % with antialdosterone diuretics. RDW values were statistically significantly lower in patients treated with ACEI or ARBs (13.01 ± 1.48 % ± 2.70 vs. 13.39 %, $p = 0.009$) and higher in patients treated with loop (13.29 ± 1.19 % vs. 12.87 ± 1.34 %, $p = 0.004$) or antialdosterone diuretics (13.49 ± 2.12 % versus 12.81 ± 0.18 %, $p = 0.01$). There were no statistically significant differences between the values of RDW in patients treated with statin ($p = 0.07$), betablockers ($p = 0.693$), oral anticoagulants ($p = 0.122$) or antiplatelet therapy ($p = 0.126$).

Conclusion: RDW was significantly lower in patients receiving ACEI or ARBs suggesting the role of angiotensin on the mechanism involved in the RDW increase in patients with HF and the possible inhibitory effect of this class of drugs on these mechanisms.

P2021

Influence of body mass index on laboratory and biomarkers in acute heart failure patients

KW Strengh¹; JM Ter Maaten¹; JG Cleland²; M Metra³; MM Givertz⁴; P Ponikowski⁵; HL Hillege¹; DJ Van Veldhuisen¹; AA Voors¹; P Van Der Meer¹

¹University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands; ²National Heart and Lung Institute, Royal Brompton and Harefield Hospitals, Imperial College, London, United Kingdom; ³University of Brescia, Brescia, Italy; ⁴Brigham and Women's Hospital, Boston, United States of America; ⁵Wroclaw Medical University, Clinical Military hospital, Wroclaw, Poland

Background: It is known plasma concentrations of natriuretic peptide decline with obesity in patients with heart failure. Whether this is true for other biomarkers is unknown. We investigated biomarker profiles in acute heart failure across the body mass index (BMI) spectrum.

Methods: We acquired data and baseline plasma samples from 2033 patients in PROTECT; a trial comparing the effects of rolofylline to placebo in patients with acute heart failure, and measured 48 biomarkers, assessing multiple pathophysiological pathways. Patients were classified into four BMI groups (<25, 25-30, 30-35 and > 35 kg/m²).

Results: Of 2003 patients with known weight and height, the mean age was 70 ± 12 years and 67% were men. Patients with a higher BMI (> 35 kg/m²) had higher blood pressures, were younger and more often women. Median levels of BNP were 550 pg/ml in patients with a BMI <25 kg/m² and 319 pg/ml in patients with a BMI > 35 kg/m² ($p < 0.001$). Multivariable regression analysis revealed that BNP ($\beta = -0.250$, $p < 0.001$) and RAGE ($\beta = -0.095$, $p < 0.007$) were strongly inversely correlated to BMI, whereas higher levels of uric acid ($\beta = 0.164$, $p < 0.001$), proADM ($\beta = 0.171$, $p < 0.001$), creatinine ($\beta = 0.118$, $p = 0.003$), sodium ($\beta = 0.101$, $p = 0.006$) and bicarbonate ($\beta = 0.094$, $p = 0.009$) were associated with higher BMI. All betas are per standard deviation. Patients with a higher BMI had a lower 180-day mortality although this relationship was no longer significant on multivariable analysis.

Conclusions: When assessing the clinical utility of biomarkers for patients with acute heart failure, BMI should be taken into account. These findings suggest that these markers should be interpreted with caution in obese patients, and BMI should be included in multivariable analyses assessing the prognostic value of biomarkers in acute heart failure.

The role of circulating miR-21, miR-34a, miR-423, miR-208a and miR-499a in ischemic and dilated cardiomyopathy

A V Zaseeva¹; I V Zhironov¹; S N Tereschenko¹; A A Scvortcov¹; V P Masenko¹; A G Kochetov¹; R R Gimadiev¹; A A Abramov¹; O V Lyang¹

¹Russian Cardiology Research and Production Complex, Moscow, Russian Federation

Background: Despite growing evidence of the pivotal role of microRNAs in cardiovascular disease, primarily in aspect of myocardial remodeling, there is still great inconsistency about certain microRNA contribution to heart failure (HF), particularly of different origin. We assessed circulating levels of miR-21, miR-34a, miR-423 and two abundantly expressed in heart microRNAs - miR-208a and miR-499a in patients with HF with reduced ejection fraction (HFrEF) and healthy individuals.

Methods: We included patients with symptoms and signs of heart failure who had left ventricular ejection fraction (LVEF) ≤ 40%, 9 of whom had dilated cardiomyopathy (DCM) and 7 - ischemic one (ICM). The control group consisted of 10 healthy individuals. Circulating microRNAs levels were quantified by real-time reverse transcription polymerase chain reaction for all participants. Tissue microRNA levels were obtained from 2 myocardial biopsy samples of patients with DCM.

Results: 10 healthy individuals and 16 patients with HFrEF (10 males, aged 52 ± 16 years) were analyzed (LVEF % 32.6 ± 8.0). We found that plasma levels of miR-21, miR-34a and miR-423 were higher in the HF group when compared to control group ($p < 0.0001$, $p < 0.002$ and $p < 0.001$ respectively). On contrast, levels of muscle-specific microRNAs (miR-208a, miR-499a) were similar in both groups. The differences in microRNAs levels between patients with DCM and ICM did not reach statistical significance. Noticeably miR-423 appeared to be the only microRNA for which bioplat/plasma ratio was < 1 (0.54). Correlation analysis showed no significant association with both - LVEF and NYHA class.

Conclusions: These results suggest that miR-21, miR-34a and miR-423 may be novel diagnostic biomarkers for patients with HFrEF, while the implication of muscle-specific microRNAs may turn up beneficial in the setting of acute myocardial injury. The ability of these microRNAs to distinguish the etiology of HF was not approved.

Prognostic value of high sensitivity troponin-T to identify patients at risk of primary graft dysfunction after heart transplantation

A Ana Belen Mendez Fernandez¹; J Ordonez²; S Mirabet¹; J Galan³; ML Maestre³; V Brossa¹; L Lopez¹; T Koller²; A Sionis¹; E Roig¹

¹Hospital de la Santa Creu i Sant Pau, Department of Cardiology, Barcelona, Spain; ²Hospital de la Santa Creu i Sant Pau, Department of Biochemistry, Barcelona, Spain; ³Hospital de la Santa Creu i Sant Pau, Department of Anesthesiology, Barcelona, Spain

Primary graft dysfunction (PGD) after heart transplantation (HT) has a very high mortality especially if the left ventricle is involved. Early diagnosis is important to select the appropriate therapy to improve prognosis. The value of high sensitivity troponin T (hs-TnT) obtained at the arrival of the patient at the intensive care unit to identify patients at risk of PGD was analyzed in 71 HT. PGD was defined by hemodynamic compromise with systolic blood pressure < 90 mmHg and/or CI < 2.2 l/min/m², need of > 2 inotropic drugs or mechanical support and left ventricular dysfunction by echocardiography.

Mean recipient age was 54 ± 12 years (73% men) and mean donor age was 47 ± 11 years. Ischemic time was 200 ± 51 min. and cardiopulmonary bypass (CPB) 122 ± 31 min. Nine HT (13%) patients were diagnosed of having PGD post-HT, 8 with biventricular dysfunction. Four patients died, 2 with PGD (15%) and 2 without PGD (3%). Mean hs-TnT before HT was 158 ± 565 ng/L and post-HT 1621 ± 1269 ng/L. The area under the curve (ROC) of the hs-TnT to detect patients at risk of PGD was 0.86 ($p < 0.001$). A value of TnT-hs > 2000 ng/L had a sensitivity of 75% and specificity of 87% to identify patients at risk of PGD. Multivariate analysis identified hs-TnT > 2000 ng/L ($p < 0.02$) and CPB time ($p < 0.01$) as independent predictors of PGD.

Conclusions: hs-TnT > 2000 ng/L at intensive care admission after HT and prolonged CPB time were the most powerful predictors of PGD. Hs-TnT may be helpful to identify HT patients at risk of PGD and worse prognosis.

P2024

Galectin-3 in different phenotypes of heart failure

C Camilla Hage¹; A-C Bergman²; M Estonius²; E Donal³; C Linde¹; J-C Daubert³; L H Lund¹

¹Karolinska Institutet, Department of Medicine, Cardiology unit, Stockholm, Sweden; ²Karolinska Institute, Department of Laboratory Medicine, Stockholm, Sweden; ³Département de Cardiologie & CIC-IT U 804, Centre Hospitalier Universitaire de Rennes, Rennes, France

Purpose: Galectin-3 has in heart failure (HF) been linked to inflammation, fibrosis and ventricular remodeling. We investigated levels of galectin-3 and its correlation to disease severity and prognosis in HF with preserved (HFpEF) and reduced (HFrEF) ejection fraction.

Methods: Galectin-3 was measured in HFpEF patients with ejection fraction ≥ 45% (n = 86) and in advanced stable HFrEF, < 40% (n = 85), post left ventricular assist device (LVAD; n = 24) and post heart transplantation (HTx; n = 34). In HFpEF patients the composite endpoint consisted of HF hospitalization and death and in HFrEF, implantation of LVAD, HTx and death.

Results: Levels of galectin-3 was in HFpEF median (interquartile range) 17.1 (13.0;21.4) µg/L and in HFrEF 16.8 (13.0;21.4; $p = 0.825$) µg/L and decreased post LVAD 15.1 (11.1;17.9) and post HTx 12.2 (9.2;15.8) µg/L (HFrEF-LVAD-HTx $p = 0.0004$). In both HFpEF and HFrEF galectin-3 correlated with creatinine clearance but with NT-proBNP in HFrEF only (Table 1). Among comorbidities in HFpEF galectin-3 correlated with previous hypertension beta coefficient 0.21 (95% CI 0.00-0.42; $p = 0.048$) and in HFrEF with atrial fibrillation 0.26 (0.04-0.40; $p = 0.017$). Galectin-3, adjusted for age, gender and creatinine clearance, did not predict the composite endpoint in HFpEF (per log increase: 1.14, 0.47-2.77; $p = 0.776$) whereas in HFrEF it was numerically but not significantly associated with the composite endpoint (1.96, 0.83-4.62; $p = 0.125$).

Conclusions: HFpEF appears associated with increased galectin-3, which may reflect renal dysfunction but not HF prognosis. In HFrEF galectin-3 may more distinctively mirror the HF syndrome itself as demonstrated by falling levels after LVAD and HTx and may thus have a potential prognostic role.

Table 1

P2025

High-sensitivity troponins are the most effective predictors of mortality after heart transplantation when compared to other cardiac and renal biomarkers

The work was supported by the Ministry of Health of the Czech Republic (Grant number: AZV MZ 15-27579A).

J. Franeková¹; P. Secnik Jr¹; L. Hoskova²; E. Pokorna³; A. Jabor⁴

¹Institute for Clinical and Experimental Medicine (IKEM), Department of Laboratory Methods, Prague, Czech Republic; ²Institute for Clinical and Experimental Medicine (IKEM), Cardiology Department, Prague, Czech Republic; ³Institute for Clinical and Experimental Medicine (IKEM), Department of Organ Harvesting and Transplantation Databases, Prague, Czech Republic; ⁴Charles University of Prague, 3rd Faculty of Medicine, Prague, Czech Republic

Background: Troponins, natriuretic peptides, galectin-3, creatinine, cystatin C, and NGAL are recognized as biomarkers of heart and renal function and/or injury. However, careful selection of biomarkers with focus on the predictive power is necessary.

Purpose: We aimed to compare the prognostic power of selected cardiac and renal biomarkers in the early posttransplant period after heart transplantation (HTx).

Methods: In the prospective study, a total of 116 patients after heart transplantation (HTx) was evaluated. The group consisted of 97 men and 19 women. The standard immunosuppressant therapy was used together with other medication according to the common posttransplant regimen. Blood samples were taken on the 30th day after HTx, urine (for NGAL) on the 1st day after HTx. 11 patients (10 %) died during the first year after HTx, total mortality reached 16 % during follow-up period (up to 1800 days, 4.9 years). Total survival (together with the survival interval) was selected as the main end-point. BNP, galectin-3, cystatin C, hs-cTnI, and urinary NGAL were measured with Abbott Architect diagnostic kits, NT-proBNP and hs-cTnT were measured with Roche Elecsys diagnostic kits on Cobas 6000 analyzer.

Results: We tested 9 clinical variables (age, EuroScore, infection, sex, renal replacement therapy, diabetes mellitus, the use of ventricle assist device, BMI, smoking) and 8 laboratory variables (hs-TnI, hs-TnT, BNP, NT-proBNP, galectin-3, creatinine, cystatin C, NGAL) assessed before or up to 30 days after HTx. Cox proportional hazard regression analysis revealed 6 variables with significant hazard ratios (HR; 95% CI): diabetes mellitus (3.02; 1.2 – 7.6), BMI (1.14; 1.01 – 1.29), smoking (2.52; 1.11 – 5.59), hs-TnI (1.76; 1.12 – 2.77), hs-TnT (2.82; 1.44 – 5.50), NGAL (1.43; 1.1 – 1.87). Two multivariate Cox models based on four significant variables together with either hs-TnT or hs-TnI were tested. Only hs-TnT (HR 2.41; 1.10 – 5.29) or hs-TnI (HR 1.67; 1.05 – 2.66) were significant predictors of death.

Conclusions: Cardiac troponins measured with high-sensitivity methods 30 days after heart transplantation are the best predictors of prognosis when compared to other clinical and laboratory variables.

P2026

Prognostic utility of ST2 level as a predictor of clinical outcomes in incidental dialysis patients.

SM Seo¹; KY Lee²; HE Yoon¹; SJ Shin¹

¹Incheon St. Mary's Hospital, Incheon, Korea Republic of; ²Seoul St. Mary's Hospital, Seoul, Korea Republic of

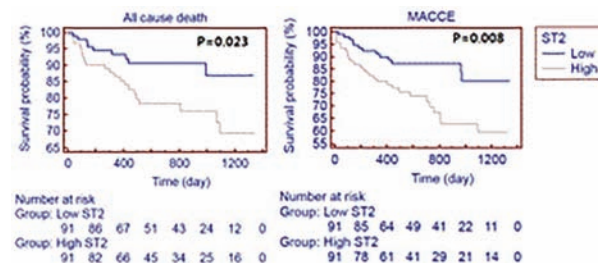

Background: The ST2 is associated with cardiac remodeling and tissue fibrosis. It is well known as a novel biomarker on predictor of cardiovascular events in patients with heart failure. In patients needed to start dialysis, 64–83% had congestive heart failure. However, the prognostic implications of serum ST2 level are unknown in incidental hemodialysis.

Methods: A total 182 patients undergoing incidental hemodialysis were consecutively enrolled from November 2011 to December 2014. We can analyze the serum ST2 level, and compared major adverse cardiac and cerebral events (MACCE)

including all-cause death, heart failure admission, acute coronary syndrome, and nonfatal stroke.

Results: Median follow up duration was 628 days (interquartile range 382 to 1,052 days). All patients were divided into two groups according to median ST2 level (59.5 ng/ml, interquartile range 40.0 to 102.5); high ST2 group (n=91) and low ST2 group (n=91). High ST2 group had significantly higher incidence of all-cause mortality, and composite of MACCE. High ST2 was a significant independent predictor of MACCE (adjusted hazard ratio 2.513, 95% confidence interval 1.02 to 6.20, p=0.046).

Conclusion: The higher ST2 is associated with higher cardiovascular and cerebral events in incidental dialysis patients. The serum ST2 level may serve as a predictor of cardiovascular and cerebral events in incidental dialysis patients.

Serum neprilysin and recurrent hospitalizations after acute heart failure

G Minana¹; J Nunez¹; E Nunez¹; A Carratala²; J Sanchis¹; J Lupon³; J Barallat⁴; MC Pastor⁴; D Pascual-Figal⁵; A Bayes-Genis³

¹University Hospital Clinic, Department of Cardiology, Valencia, Spain; ²University Hospital Clinic of Valencia, Department of Biochemistry, Valencia, Spain; ³Germans Trias i Pujol Hospital, Department of Cardiology, Badalona (Barcelona), Spain; ⁴Germans Trias i Pujol Hospital, Department of Biochemistry, Badalona (Barcelona), Spain; ⁵Hospital Clínico Universitario Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain

Background: Prediction of recurrent hospitalizations after an episode of acute heart failure (AHF) remains a challenge. The soluble form of neprilysin (sNEP) has been recently postulated as a promising biomarker in heart failure. We sought to evaluate the association between sNEP and long-term recurrent hospitalizations.

Methods: We measured at admission sNEP of 210 consecutive patients admitted for AHF. Negative binomial regression method was used to determine the association between sNEP and the risk of recurrent hospitalizations. Estimates were reported as incidence rate ratios (IRR).

Results: At a median follow-up of 2.1 years (IQR: 1.2-2.8), 94 deaths, 307 all-cause rehospitalizations in 144 patients (68.6%) and 130 AHF-rehospitalizations in 82 patients (39.1%) were recorded. The multivariable analysis showed that sNEP, from lower to higher quartile, had a stepwise increase of rates for both end-points, although with lesser effect on all cause-rehospitalizations. In reference to the first quartile, the IRRs for all-cause rehospitalizations were: Q2=0.96 (0.61-1.51); p=0.860, Q3=1.21 (0.77-1.88); p=0.407, and Q4=1.94 (1.28-2.94); p=0.002 [Omnibus p-value=0.004]. For AHF-rehospitalizations, the IRRs were: Q2=1.28

60154.	Clinical	Events	in	Patients	with	high	ST
	Low ST2 (n=91)	High ST2 (n=91)		Unadjusted HR (95% CI)	p value	Adjusted HR* (95% CI)	p value
All-cause death	9 (9.9)	21 (23.1)		2.41 (1.10-5.26)	0.021	2.62 (0.93-7.33)	0.067
Cardiac death	5 (5.5)	13 (14.3)		2.68 (0.96-7.53)	0.061	3.58 (0.73-17.5)	0.115
Heart failure admission	5 (5.5)	9 (9.9)		1.98 (0.66-5.91)	0.221		
Acute coronary syndrome	2 (2.2)	3 (3.3)		1.67 (0.28-10.0)	0.573		
Nonfatal stroke	1 (1.1)	3 (3.3)		3.09 (0.32-29.7)	0.329		
Composite of MACCE	13 (14.3)	28 (30.8)		1.59 (1.24-2.05)	0.012	2.52 (1.02-6.20)	0.046

*Adjusted covariates included age, sex, hypertension, diabetes mellitus, current smoker, BMI, ejection fraction, hemoglobin, albumin, C-reactive protein, high sensitivity troponin T, galectin-3, B type natriuretic peptide. HR = hazard ratio; CI = confidence interval

(0.63-2.58; $p=0.491$, $Q3=1.99$ (1.09-3.62); $p=0.024$, and $Q4=4.31$ (2.34-7.97); $p<0.001$ [Omnibus p -value <0.001].

Conclusion: In patients with AHF, sNEP was positively associated with long-term recurrent hospitalizations.

P2028

Plasma neutrophil gelatinase-associated lipocalin and long-term mortality in acute heart failure

A Paya-Chaume¹; G Minana¹; E Rumiz²; P Palau³; I Cardells¹; E Valero¹; V Bodi¹; E Nunez⁴; J Sanchez¹; J Nunez¹

¹University Hospital Clinic of Valencia, Cardiology, Valencia, Spain; ²University General Hospital of Valencia, Valencia, Spain; ³Hospital La Plana, Vila-Real, Spain; ⁴Research Foundation Hospital of Valencia (INCLIVA), Valencia, Spain

Background: Neutrophil gelatinase-associated lipocalin (NGAL) has emerged as a tubular marker related to early renal dysfunction. In heart failure (HF), contradictory results have been reported and some ambiguity still prevails about the prognostic utility of NGAL beyond standard prognosticators and traditional renal markers.

Purpose: We aimed to evaluate the independent ability of serum NGAL for predicting long-term mortality in patients admitted for acute HF (AHF).

Methods: 206 patients consecutively admitted for AHF were prospectively enrolled. Chronic kidney disease (CKD) was defined as $eGFR < 60$ ml/min/1.73m². Outcomes rates were depicted across NGAL median value and the presence of CKD using the Kaplan-Meier method. Multivariable analysis for all-cause mortality was performed by using regression Cox model. The discriminative accuracy and calibration of the model were assessed by the Harrell's C-statistic and the Hosmer-Lemeshow test, respectively

Results: During a median follow-up of 36 months (12-46), 97 deaths were registered (47.1%). 51% were female and 53.4% exhibited LVEF $> 50\%$. The median (interquartile range) for $eGFR$, BUN, serum creatinine and NGAL were 64.1 ml/min/1.73m² (37), 22.9 mg/dl (13.1), 1.02 mg/dl (0.5), and 85 ng/ml (98.7), respectively. NGAL above median showed higher rate of death (1.25 vs. 2.70 per 10 persons-year, $p<0.001$). Among renal biomarkers, BUN showed the higher discriminative accuracy followed by $eGFR$, creatinine, and NGAL (Harrell's C-statistics 0.650, 0.618, 0.612, and 0.610, respectively). When the sample was stratified across CKD, a differential prognostic effect was found. NGAL was related to long-term mortality in

patients without CKD but not in those with CKD (Figure 1). In the adjusted analysis, NGAL, dichotomized by its median, was borderline associated with risk of death in the whole sample (HR = 1.49; CI 95%:0.96-2.31, $p=0.077$). Likewise, in the univariate setting the differential prognostic effect of NGAL across CKD was also identified after adjustment (adjusted p -value for interaction = 0.021). In patients with CKD, NGAL above median did not show any prognostic effect (HR = 0.94; CI 95%:0.53-1.66, $p=0.818$); conversely, NGAL was powerfully associated with the risk of long-term mortality in those with $eGFR \geq 60$ ml/min/1.73m² (HR = 2.56; CI 95%:1.34-4.88, $p=0.004$). The final multivariate model showed an adequate discriminative ability and calibration (Harrell's C-statistics and Hosmer-Lemeshow were 0.720 and 0.811, respectively).

Conclusions: In patients admitted for AHF, circulating NGAL levels were associated with an increased long-term risk of death in patients with normal $eGFR$ but not in those with decreased renal function. Further studies are warranted in order to confirm present findings.

P2029

The lymphocyte count and neutrophil/lymphocyte ratio as independent predictors for cardiac events in heart failure only in ischemic heart disease patients

AD Farcas¹; MA Stoia¹; FP Anton¹; CM Goidescu¹; RD Ianos¹; SE

Susca-Hojda¹; IL Gavrilă¹; D Lutac¹; II Burian¹; L Vida-Simiti¹

¹University of Medicine and Pharmacy of Cluj Napoca, Department of Cardiology County Emergency Clinical Hospital Cluj, Cluj Napoca, Romania

Background: The predictive value of some biomarkers in heart failure (HF) is not well established. Recent data suggests that some specific types of leucocytes have different predictive value in cardiovascular risk. The predictive value is improved by using neutrophil/lymphocyte ratio (NLR).

Purpose: To evaluate the predictive values of white blood cell (WBC) count, WBC differential formula (WBC-DF) and NLR for cardiovascular events (cardiac adverse outcome and rehospitalisation) in heart failure patients with ischemic heart disease (IHF) and without ischemic heart disease (NIHF).

Methods: Our prospective study included 323 HF patients (185 with IHF and 138 with NIHF), NYHA class II-IV (66.7 ± 14.7 yrs), 47.3% male and 52.7% female. They signed informed consent and underwent clinical and laboratory assessment: lipid profile, N-terminal pro-brain natriuretic peptide (NT-proBNP), C reactive protein (CRP), total WBC, WBC-DF and NLR. The patients were followed for one year. The study methodology was approved by the Ethical Committee. Statistical data processing was performed with SPSS.

Results: There were no significant differences regarding gender, age and body mass index (BMI) between the subgroups. Patients with NIHF had significantly higher levels of total cholesterol and LDL-cholesterol ($p<0.001$) whereas patients with IHF had significantly higher levels of NT-proBNP ($p<0.001$), CRP ($p<0.005$), WBC ($7.68 \pm 3.07 \times 10^9/l$ vs $6.71 \pm 2.08 \times 10^9/l$, $p<0.005$), lymphocyte count ($16.9 \pm 10.2\%$ vs $13.8 \pm 10\%$, $p<0.05$), neutrophils index ($57.8 \pm 29.4\%$ vs $52.6 \pm 31.3\%$, $p<0.005$) and NLR values - 1.27 (1.2-1.36) vs 0.99 (0.4-1.15) ($p<0.02$). A significant difference between NLR values was found in patients in NYHA class II vs III, while no difference of NLR was found between patients in NYHA classes III and IV. A positive correlation between NLR and NT-proBNP level was found ($r=0.43$, $p<0.05$). The lymphocyte count, NLR and NYHA class ($p<0.001$) are independent predictors for the free interval until rehospitalisation for cardiovascular events. After adjusting for NYHA class, the lymphocyte count and NLR remained predictors only for IHF.

Conclusion: For patients in the same NYHA class, the lymphocyte count and NLR are independent predictors for cardiovascular events in IHF but not in NIHF.

P2030

Higher urinary hydrogen peroxide levels are associated with increased plasma renin activity and aldosterone concentration in patients with chronic heart failure

T. Sousa was supported by a Ciência 2008 Contract, funded by FCT and POPH/FSE (EC) and by a Postdoctoral fellowship from FCT (SFRH/BPD/112005/2015).

M. Reina-Couto¹; T. Sousa¹; M. Morato²; J. Carvalho¹; J. Afonso¹; P. Bettencourt³; A. Albino-Teixeira⁴

¹University of Porto, Faculty of Medicine, Porto, Portugal; ²University of Porto, Faculty of Pharmacy, Porto, Portugal; ³Sao Joao Hospital, Porto, Portugal; ⁴Institute of Molecular and Cell Biology, Porto, Portugal

Background: Renin-angiotensin-aldosterone system activation and oxidative stress are known to contribute to the pathogenesis of chronic heart failure (CHF) (1,2). Hydrogen peroxide (H₂O₂) is a non-radical oxidant and an established downstream mediator of RAAS activation that also appears to regulate the levels of RAAS components (3). Recent studies suggest that oxidative stress and H₂O₂ may stimulate renin release from juxtaglomerular cells (4,5).

Purpose: Therefore, we investigated the relationship between H₂O₂, oxidative stress and RAAS activation in patients with CHF.

Methods: Urinary H₂O₂, plasma and urinary isoprostanes, plasma renin activity and aldosterone concentration were evaluated by commercial kits in 60 CHF patients (New York Heart Association, NYHA, class I to IV) recruited from the Heart Failure Clinic of our hospital.

Results: Patients were first stratified into mild-to-moderate CHF (NYHA classes I and II) and severe CHF (NYHA classes III and IV). Severe CHF patients had higher levels of urinary isoprostanes (3.94 ± 0.68 vs 2.55 ± 0.34 ng/mg creatinine, $p < 0.01$) but no significant differences were observed in plasma isoprostanes (0.88 ± 0.10 vs 0.66 ± 0.05 ng/mL), urinary H₂O₂ (0.017 ± 0.0038 vs 0.012 ± 0.0015 micromol/mg creatinine), plasma renin activity (460.3 ± 158.2 vs 283.7 ± 112.2 microU/L) or aldosterone (16.58 ± 3.97 vs 10.56 ± 1.22 mg/dL). To evaluate the relationship between oxidative stress or H₂O₂ with RAAS activation, we analysed plasma renin activity or aldosterone levels by tertiles of urinary H₂O₂, urinary isoprostanes or plasma isoprostanes. Linear trend analyses revealed that both plasma renin activity and aldosterone increased across urinary H₂O₂ tertiles (Log plasma renin activity: 1st tertile: 1.82 ± 0.16 ; 2nd tertile: 2.10 ± 0.13 ; 3rd tertile: 2.39 ± 0.17 , $p = 0.012$; Log aldosterone: 1st tertile: 0.77 ± 0.10 ; 2nd tertile: 1.12 ± 0.07 ; 3rd tertile: 1.07 ± 0.06 , $p = 0.0089$). No differences in plasma renin activity or aldosterone were observed between tertiles of urinary or plasma isoprostanes.

Conclusion: Our results show that CHF patients with higher urinary excretion of H₂O₂ exhibit increased RAAS activation and thus reinforce the hypothesis of H₂O₂ being a modulator of renin release.

P2031

Correlation between N-terminal pro-brain natriuretic peptide levels and myocardial involvement detected with 2D speckle tracking echocardiography in systemic sclerosis

habib thameur hospital

I. Ihsen Zairi¹; K. Mzoughi¹; Z. Jenifene¹; M. Jabeur¹;

F. Benmoussa¹; S. Kamoun¹; S. Fennira¹; K. Sondos¹; L. Bail²

¹Habib Thameur Hospital, cardiology, Tunis, Tunisia; ²Habib Thameur Hospital, internal medicine, Tunis, Tunisia

Aims: Systemic sclerosis (SSc) is a severe tissue disorder characterized by frequent myocardial involvement which is associated with poor prognosis. The aim of this study is to identify the relation between serum levels of N-terminal pro-brain natriuretic peptide (BNP) and the severity of cardiac involvement assessed with 2D speckle tracking echocardiography (STE) in patients with systemic sclerosis (SSc).

Methods and results: 25 patients with SSc (53.64 \pm 13 years, LVF 64.58 \pm 8.87 %) and 25 gender and age-matched healthy subjects (35.8 \pm 8.72 years, LVF 68.2 \pm 7.41 %) underwent echocardiography with STE to assess global and regional ventricular function. Dosage of serum BNP was done for all patients and controls. There was a significant increase in the mean values of serum levels of BNP in SSc patients compared to controls ($p = 0.03$), parallel to an alteration of myocardial function assessed by 2D SST (left ventricle global longitudinal strain -17.42 \pm 1.62 vs. -19.24 \pm 8.85 ($P < 0.0001$). BNP values were correlated to ventricular strain impairment.

Conclusion: The results of this study provide confirmation that high BNP levels over time are associated with myocardial involvement progression.

P2032

Brain natriuretic peptide guided transthoracic doppler 2D echocardiography requests is cost saving and effective way to rule out heart failure.

C. B. Upadhyaya¹; G. Jenkins²; A. Wong³

¹Singleton Hospital, Cardiology, Swansea, United Kingdom; ²Regional Cardiac Centre Morriston Hospital, Swansea, United Kingdom; ³Princess of Wales Hospital, Bridgend, United Kingdom

Introduction: Brain Natriuretic Peptide (BNP) is a useful test to rule out heart failure with high negative predictive value. NICE guidelines(2) suggests referral for patients with suspected heart failure and a BNP level between 100 and 400 pg/ml (29–116 pmol/litre) or an NT-proBNP level between 400 and 2000 pg/ml (47–236 pmol/litre) to have echocardiography. ESC guidelines (1) suggests an optimal level of NT-proBNP of less than 300 pg/ml as a cut off point in patients presenting with acute onset or worsening of heart failure symptoms.

Purpose: To look at NT-proBNP and Echo requests in our health board to determine the number of inappropriate Echo requests in patients with NT-proBNP of less than 400 pg/ml.

Method: We reviewed the NT pro-BNP requests in our Health Board for 12 consecutive months. The criterion of NT pro-BNP level of less than 400 pg/ml was set according to the NICE Guidelines(2) for diagnosing heart failure. Local echo database was used to determine echo requests and its findings.

Results: 370 NT pro-BNP were requested during the study period. 300 (81%) and 274 (75%) requests with NT-proBNP level of less than 400 pg/ml and less than 300 pg/ml were done respectively. However, 137 and 121 echo requests were generated for assessment of left ventricular function, respectively, despite of these results. These echo requests are inappropriate and equates to around 35 echo sessions per year in the department. The estimated cost for these echo requests was €13500 (£10,275). The cost of BNP testing is around €13-18 (£10-15) per assay. Using BNP guided echo request to rule out heart failure will potentially save €10500 (£8000) per year and 35 echo sessions for our department. More importantly, all patients with NT pro BNP of less than 400pg/ml and without cardiac history, the echo findings for left ventricular function were normal.

Conclusion: Using BNP guided Echo request according to the NICE guideline(2) and ESC guidelines 2012(1) to rule out heart failure is cost effective and this retrospective analysis also showed that BNP of less than 400pg/ml essentially ruled out heart failure and thus can be used as a 'rule-out' test. Reference 1. ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure 2012 2 NICE Guidelines for Chronic heart failure 2010.

Table 1

NT proBNP levels	<300pg/ml	> 300pg/ml	<400 pg/ml	> 400pg/ml
Numbers of assays	278 /370	92/370	300/370	70/370
No. of Echo requests	121/278	69	137/300	51
% of inappropriate echo requests	43.5%		45.6%	

Table showing number of NT-proBNP assays ordered and number of echo requested. The inappropriate echo requests are in bold and underlined.

Prognostic value of serial b-type natriuretic peptide in hospitalized heart failure patients and mortality

BS Byungsu Yoo¹; SS Khanam¹; EH Choi¹; JY Kim¹; MC Cho²

¹Wonju College of Medicine, Yonsei University, Division of Cardiology, Department of Internal Medicine, Wonju, Korea Republic of; ²Chungbuk National University Hospital, Cheongju, Korea Republic of

Background: B-type natriuretic peptide (BNP) has prognostic significance in HF, and reduction of BNP level may be predicts clinical improvement or good clinical results. However, there is a limited data about role of follow-up BNP level. The aim of this study was to evaluate the prognostic impact of short-term follow up BNP and development of clinical outcome in heart failure patients.

Methods: We analyzed 733 hospitalized HF patients in the Wonju Christian Hospital Heart Failure Registry from April 2011 to December 2013. Among them 284 patients (age=72.8 \pm 12.2 years, Male=118, 41.5%) with concomitant measuring of BNP on admission and short-term follow-up period (within 2 month). We compared for the incidence of all-cause of mortality during the clinical follow-up (mean 764 days) according to the BNP quartiles on admission as an initial and short term follow up period

Results: The mean initial BNP was 1189.92 ± 1022.83 pg/ml and mean follow up BNP was 690.76 ± 884.06 pg/ml and mean follow up duration was (23.5 \pm 16.8) days. Multivariate analysis demonstrated a positive linear association between the risk of death and the BNP quartile. The patient with the highest quartile of follow up BNP (HR=4.360, Pvalue < 0.0001) was significantly associated with higher risk of the all cause mortality, compared to the patients with the lowest quartile of follow-up BNP level. However, the initial BNP was not significantly associated with all cause mortality. A multivariate Cox proportional hazards model analysis showed that follow up BNP was an independent association of all cause mortality after adjustment of covariates (HR=4.224, 95%CI 2.057-7.059). The Kaplan Meier curves also showed significant differences in the incidence of the primary endpoint between the 4 quartile groups according to fBNP (Log rank $p < 0.001$). Additionally (%) changes of BNP was also significantly associated with mortality.

Conclusions: Short-term follow up plasma BNP and also the percent changes of BNP level, not initial BNP level is a significant prognostic marker of heart failure and it's clinically useful to evaluate the clinical outcome

P2034

Embedding a specialist heart failure nurse into the general medicine teams to improve outcomes for patients with chronic heart failure

Department of Health, Victoria, Australia

A Andrea Ness¹; R Sanders¹; D Prior¹;

H Gock²; B Smith²

¹St Vincent's Hospital, Cardiology, Melbourne, Australia; ²St Vincent's Hospital, Department of Medicine, Melbourne, Australia

Introduction: Chronic heart failure remains a major public health issue with care costs estimated at \$1 billion per annum, mostly due to hospital admission and re-admission. Older patients are presenting to hospital with multiple comorbidities that impact on delivery of evidence-based treatment strategies.

Purpose: By embedding a specialist heart failure (HF) nurse within General Medicine, we aimed to streamline the patient journey, promote adherence to evidenced-based treatments, improve patient knowledge and reduce re-admission rates.

Method: Baseline demographic, treatment and clinical outcome data was collected between May and September 2014. Between March and September 2015, all patients admitted with a diagnosis of Acute Decompensated Heart Failure (ADHF) were prospectively identified. Throughout their hospital stay, a specialist HF nurse was involved in patient management and early follow up arranged. Outcomes post intervention were compared with baseline data.

Results: 124 consecutive patients were included at baseline and 215 post intervention. Mean age was 76 years and 54% were male. Post-intervention, 153 patients (71%) were admitted under General Medicine and 113 patients (53%) had a left ventricular ejection fraction <50% (HFrEF). Overall the mean HF knowledge score improved from 5.9 during at baseline to 8.2 on a 10-item survey of self-care behaviour. 30-day readmission rate was reduced from 37% to 21% ($p < 0.001$).

Conclusion: Hospitalised HF patients are elderly with a high prevalence of HFrEF. Unlike HFrEF, pharmacological strategies remain uncertain. However, symptomatic treatment, patient education and early review to detect signs of fluid retention appear to help keep these patients at home. Specialist HF nurse involvement in the care of patients admitted with ADHF can improve patient knowledge and self-management. A strategy including early review post-discharge either in clinic or the patient's local area results in reduced 30 day readmission rates.

P2035

A delphi study to update cardiac nursing core competencies.

A Annamaria Bagnasco¹; R Watson²; G Catania¹; F Timmins³; G Aleo¹; MP Zanini¹; L Sasso¹

¹University of Genoa, Health Sciences, Genoa, Italy; ²University of Hull, Hull, United Kingdom; ³Trinity College Dublin, Dublin, Ireland

Introduction: Following recent developments, such as the new health challenges due to the aging of the population, and the rapid scientific and technological advances of the last few years, cardiac nurses in Italy need to update and redefine their competencies and set new standards in line with the best international practices.

Purpose: The aim of this project is to elicit a national and international consensus around new core cardiac nursing competencies.

Methods: The Delphi technique - the main premise of which is based on the assumption that group opinion is more valid than individual opinion - was chosen to elicit national and international consensus around the core cardiac nursing competencies. In the present Delphi study, three rounds will be employed, during which questionnaires to elicit consensus on the core cardiac nursing competencies will be sent out to a panel of national and international cardiac nursing experts.

Results: Based on the most recent literature on cardiac nursing competencies and following preliminary debates with a panel of national and international experts, a prioritized list of 10 items has been produced and which, at the end of the three rounds of this Delphi study, will be presented at the conference with their significance and likely impact on the quality of cardiac nursing.

Conclusions: Important steps recently taken at a European level to identify a core curriculum that offers a European perspective for cardiovascular nursing education based in current health challenges. A broader perspective of cardiovascular competencies with a greater emphasis not only on stroke, peripheral vascular disease, but also prevention, and rehabilitation can support single countries to fulfil country-specific health care priorities. The results of the present study

will be used to develop a program for the self-assessment of cardiac nursing competencies.

P2036

Retrospective profile research of the patients evaluated for the inclusion on the cardiac transplant queue of a period of fifteen years.

FDC Fatima Das Does Cruz¹; CF Fukuoka¹; BFB Brito¹; BMS Santos¹; EAB Bocchi¹

¹Heart Institut, São Paulo, Brazil

Introduction: The cardiac transplant (CT) is a therapy indicated on the treatment of cardiac insufficiency (CI) when the drug therapy is not efficient. The selection and evaluation of the candidates to the transplant considers the stratification of prognostic variables and the comorbidities, as well as factors that could contraindicate or compromise the transplantation protocol.

Objectives: Analyse the patients' profile that were evaluated for the inclusion on the cardiac transplantation queue by the nurse. Variables: Gender, age, ethnicity, etiology of the disease, nationality, caregiver, education, family income, tabagism, alcohol and illicit drugs use, body mass index and co-morbidities such as hypertension, diabetes and dyslipidemia.

Methods: In the period 2000-2015 analyzed 1071 patients evaluated by nurses for inclusion cardiac transplant (CT) orthotopic, heterotopic retransplantation through in electronic medical records and physical consultation and nursing assessment forms filed with the heart failure unit.

Results: 63% of the patients evaluated were not included on the CT queue and 37% were included; 12% underwent a priority transplantation; 70% male, 71% white, 15% black, 13% mulattos, 1% yellow. Considering the etiology: 21.5% ischemic, 33% chagasic, 26% idiopathic, 4% valve, 0.5% restrictive, 1% vascular disease graft, 3% hypertensive, 2% hypertrophic cardiomyopathy, 0.2% congenital, 1.2% viral, 2% periparturient, 0.5% graft dysfunction, 5% other. Nationality: 38% from São Paulo, 62% other states; Originally from: 80% São Paulo, 20% other states; Caregiver: 52% spouse, 9% siblings, 13% children, 18% parents, 5% other relatives, 1% contracted, 2% without any caregiver; Education: 51% first grade, 21% high school, 14% higher education, 11% elementary school, 3% illiterate; Average family income between 700 ± 660 dollars; BMI: 24 ± 4 Kg/m²; Diabetes: 27%, Diabetes / insulin dependent: 51%; Dyslipidemia: 22%; High blood pressure: 43%; Alcohol use: 22% active, 19% abstemic, smoking: 7% active, 46% abstemic; Illicit drugs: 1% active, 3% abstemic; BMI: 24 ± 4 Kg/m²; re-transplant: 1% with a survival rate of 13.5%; heterotopic transplantation: 1% with survival rate of 12.5%; Double transplant (heart and kidney): 0.5% with survival rate of 20%.

Conclusion: The stratification criteria used for the patients inclusion on the CT queue are rigorous, which can be demonstrated by the number of patients evaluated and included on the queue. It was also observed that from the patients included on the queue, just a little percentage of them really underwent the transplant, due to the high morbi-mortality resulted by the CI. This study also demonstrates the high incidence of chagasic cardiomyopathy transplant indication. We obtained a high rate of patients with primary education level associated with a low family income. The vast majority of the population evaluated was insulin-dependent diabetic patients.

P2037

Adherence to heart failure treatment is generalizable across behaviors

B Barbara Riegel¹; CS Lee²; WV Dickson³

¹University of Pennsylvania, Philadelphia, United States of America; ²Oregon Health & Sciences University, Portland, OR, United States of America; ³New York University, New York, United States of America

Objective measurement of heart failure (HF) treatment adherence requires a variety of measures to obtain a full picture of behavior. Many of these measures are expensive, time-consuming, and burdensome to patients.

Purpose: We sought to identify the best objective means of quantifying adherence in HF by comparing adherence to medications and diet.

Methods: A sample of 280 adults with chronic HF was enrolled from three U.S. out-patient centers and followed for six months. We performed a secondary analysis of data collected at baseline on medication (by electronic monitoring) and dietary adherence (by 24-hour urine sodium (Na)). Growth mixture modeling was used to cluster and compare medication adherence and dietary adherence.

Results: We observed two distinct patterns of HF adherence (entropy = 0.86; probabilities ≥ 95%; $p < 0.001$ for all comparisons) (Figure). 57% of patients ($n = 159$) had HF medication adherence rates of approximately 90% and had urine Na levels <3g/day throughout 6 months of study (solid line=good adherence). The remaining 43% ($n = 121$) had HF medication adherence rates in the range of 70% and had 24-hour urine Na level consistently ≥ 3.5g/day (dashed line=poor adherence).

Conclusion: Patients with HF are either adherent to both prescribed medications and dietary sodium restriction or they are nonadherent. Objectively measuring adherence to both behaviors provides redundant information.

P2038

Rasch analysis of a heart failure self-care screening tool (Heart-FaST)

Nurses Board of Victoria Legacy Limited; ACU Faculty Research Grant; the Australian Government's Collaborative Research Networks (CRN) program J Jan Cameron¹; N Reynolds¹; C F Ski¹; D R Thompson¹

¹Australian Catholic University, Mary MacKillop Institute for Health Research, Melbourne, Australia

Background: Screening heart failure (HF) patients for self-care ability is advocated before applying education and support strategies. The Heart Failure Screening Tool (Heart-FaST) was developed specifically to assist nurses to identify patient barriers that impede engagement in self-care in three distinct domains: risk factors, cognitive and emotional functioning.

Purpose: To ascertain whether a total score, derived from the three domains of Heart-FaST, can be used as a valid measure of the overall construct of capacity to engage in self-care.

Methods: Heart-FaST was administered to 135 HF patients (X-age = 69, SD = 12; 40 females) enrolled in a multidisciplinary heart failure management program. A Rasch analysis examined fit to the Rasch model, rating scale performance, internal-consistency reliability, targeting, differential item functioning, local independence and unidimensionality.

Results: Components of the Hands and Numbers criteria of the Clock Drawing Task were amalgamated to circumvent the effect of local dependence. The Serial Sevens rating scale was reduced from three to five categories while the rating scale of the Emotional Functioning items was reduced from seven to two categories following evidence of threshold disorder. The fit of data to the Rasch model was acceptable following these modifications, after removing two items due to misfit and differential item functioning. Confirmation of the unidimensional nature of Heart-FaST was achieved via a test of unidimensionality that identified only 4% to 12% of participants with multidimensional response patterns. The final scale consisting of 22 items (scores range from 0 to 28; higher scores indicate higher risk for poor self-care) had adequate internal-consistency reliability ($\alpha = 0.64$).

Conclusions: Results provisionally support the use of Heart-FaST as an ordinal scale that is capable of differentiating two participant groups (low versus high risk) with respect to their capacity to engage in heart failure self-care.

P2039

Patient with heart failure and relatives attitudes towards using reflection cards during educational program.

G Gitte Ingwersen¹; JM Baekbo Gudiksen¹; S Hansen¹; EB Andersen¹

¹Roskilde Hospital, Cardiology Department, Roskilde, Denmark

Background: Chronic heart failure requires a complex treatment regime on a life-long basis. Medication, self-monitoring, diet and social isolation are challenging patient and resulting in readmissions. Educational program for patients with heart failure is individual and contains consultations with cardiologist, specialized trained nurse and if needed referred to physiotherapy, dietician, social worker and psychologist. A multidisciplinary group program, established in 2012., added to the individual program. To retain knowledge and support reflection on "daily knowledge and daily activity" is playing cards based on a formerly French heart failure game used in the group program.

Purpose: This study aims to evaluate patients and relatives attitudes towards using

reflection cards, during educational group program in the heart failure clinic in a Danish hospital.

Methods: This study is a cross-sectional study conducted October 2012 - June 2015(16 groups) and based on a formerly questionnaire by Hibbard et.al Patients referred to the heart clinic for the first time, is during the individual program offered to participate in the group program. Participants play once facilitated by a specialized trained nurse. Questionnaire answered, at final session. Respectively responded 96% (110/114) patients and 90% (38/42) relatives. Data presented using descriptive statistics.

Results: 96% (142/156) of participants agree or very much agree to the education giving knowledge and understandable. 92% agree or very much agree in being confident in following and understanding lifestyles changes. 77% (114/148) scores the reflection cards to 6-10 (score 1 = poor and 10 = excellent). 50% (74/142) added effect as: new learning, check understanding, giving more dialog and personal involvement. Score 2-6 given by 23% (34/148) with statements, the game is not as important. The group program with all 3 session rates to 6-10 by 95%(152/156) of the participants.

Conclusion: We find Patients attitudes towards the reflection cards very positively and several expressed that it leads to understanding and learning. The group program seems to facilitate reflection and understanding in lifestyle changes. Patient seem to have less contact to the clinic when both being in individual and group program but it calls for further investigation.

P2040

Socio-demographic and clinical determinants of poor self-care in patients with heart failure and diabetes mellitus

D Davide Ausili¹; P Rebora¹; S Di Mauro¹; B Riegel²; M Paturzo³; R Alvaro³; E Vellone³

¹Università Milano-Bicocca, Department of Medicine and Surgery, Monza, Italy;

²University of Pennsylvania, Philadelphia, United States of America; ³University of

Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy

Background: Patients with both Heart Failure (HF) and Diabetes Mellitus (DM) are at risk of severe adverse outcomes. Self-care is vital in both conditions. The effect of DM on HF self-care is unclear and determinants of poor self-care in HF-DM patients are unknown.

Objectives: To compare self-care of HF patients with and without DM; to estimate the effect of DM on self-care of HF patients; to identify socio-demographic and clinical determinants of self-care in HF-DM patients.

Methods: A multicentre cross-sectional observational study was conducted. 1192 adults with confirmed diagnosis of HF were enrolled. Socio-demographic and clinical data were collected from medical records. Self-care maintenance, management and confidence were measured by the Self-Care of Heart Failure Index (scores range 0-100; higher scores=better self-care). Self-care of HF-DM patients versus HF without DM was compared by linear regression. Multiple linear regressions were performed to estimate the effect of DM on self-care of HF patients and to identify determinants of self-care in HF-DM patients.

Results: 379 HF patients (31.8%) were affected by DM. Self-care was sub-optimal in HF patients with and without DM (means range from 53.2 to 55.6). Self-care maintenance ($p=0.13$), management ($p=0.21$) and confidence ($p=0.51$) were not statistically different between HF patients with versus without DM. No statistically significant associations were found between the presence of DM and self-care maintenance ($p=0.12$), management ($p=0.21$) or confidence ($p=0.51$) of HF patients. Number of medications ($p=0.04$), cognitive status ($p=0.04$), New York Heart Association (NYHA) functional class ($p=0.01$) and self-confidence ($p<0.01$) were determinants of self-care maintenance in HF-DM patients. Number of medications ($p=0.02$), cognitive status ($p=0.01$) and self-care confidence ($p<0.01$) were determinants of self-care management. Number of medications ($p=0.01$), cognitive status ($p<0.01$) and family income ($p=0.01$) were determinants of self-care confidence.

Conclusions: Self-care of HF-DM patients is poor but no worse than the self-care of HF patients without DM. HF-DM patients taking fewer medications, having low income, low self-care confidence, limited cognitive function and worse NYHA class are at higher risk of poor self-care. Future studies are needed to describe DM self-care in HF-DM patients, to develop and test interventions, and to evaluate the effect of DM self-care on HF-DM patients' outcomes.

P2041

Assessing the relationship between frailty syndrome and self-care in chronic heart failure

I Izabella Uchmanowicz¹; M Wleklík¹; M Lisiak¹; B Jankowska-Polanska¹

¹Health Science Faculty Wroclaw Medical University, Wroclaw, Poland

Introduction: Frailty syndrome frequently co-occurs with heart failure (HF), adversely affecting the course of the disease in various ways, such as restricting the patient's active participation in the treatment process. The optimization

of treatment and of patients' quality of life requires a methodical identification of predictors of decreased self-control and self-care capabilities in heart failure.

Purpose: The purpose of the study was to assess the correlation between two variables, frailty syndrome and self-care, in a group of chronic heart failure patients.

Material and methods: The study included 330 patients (148 female, 182 male; mean age \pm SD: 72.08 ± 7.92) with clinically confirmed chronic heart failure, hospitalized in the Cardiology Department. To obtain research material, the authors used two standardized research instruments: the Tilburg Frailty Indicator (TFI) for frailty syndrome assessment and The European Heart Failure Self-care Behavior Scale (EHFScBS) to evaluate self-care in HF. Correlations and differences at $p < 0.05$ were considered statistically significant.

Results: Frailty syndrome was identified in 86.67% of patients. Mean TFI score in the study group was $M \pm SD = 7.22 \pm 2.72$ points. Mean score in the physical component of the TFI was $M \pm SD = 4.12 \pm 1.82$ points, mean psychological component score was $M \pm SD = 1.79 \pm 0.98$ points; mean social component score was $M \pm SD = 1.30 \pm 0.93$ points. Mean self-care score was $M \pm SD = 37.93 \pm 7.34$ points. Multiple regression analysis showed that the score in the physical component of the TFI was a significant predictor for decreased self-care capabilities in HF ($\beta = -0.178$; $p = 0.01$).

Conclusions: 1. Lower scores in the physical component of the TFI are correlated with better self-care in heart failure. 2. The physical domain of the TFI is an independent predictor of self-care in heart failure.

P2042

Differential associations of somatic and cognitive depressive symptoms with vitamin D deficiency and cardiac event-free survival in patients with heart failure

E K Eun Kyeong Song¹; SM Kang²; YJ Lee³

¹University of Ulsan, College of Medicine, Department of Nursing, Ulsan, Korea Republic of; ²Severance Hospital, Cardiology Division, Yonsei Cardiovascular Center and Cardiovascular Research Institute, Seoul, Korea Republic of;

³University of Ulsan, Department of Thoracic and Cardiovascular Surgery, College of Medicine, Ulsan University Hospital, Ulsan, Korea Republic of

Background: Depressive symptoms and vitamin D deficiency independently predict shorter cardiac event-free survival in patients with heart failure (HF). There has been limited evidence on the differential association of specific symptoms of depression with cardiac events. However, whether specific symptoms of depression are associated with vitamin D deficiency and cardiac event-free survival in HF patients has not been examined.

Purpose: We hypothesized that somatic symptoms of depression would have higher risk for vitamin D deficiency and cardiac events compared to cognitive symptoms of depression.

Methods: A total of 204 patients with HF (age 63 ± 11 years, 33% female) completed the Patient Health Questionnaire-9 (PHQ-9) to assess depressive symptoms. Nutritional Analysis program were used to determine average daily intake of vitamin D through a 3-day food diary. Patients with $> 80\%$ probability of deficiency were defined as having a diet deficient in vitamin D. Patients were followed for 1 year to determine time to first event of hospitalization due to cardiac problems or cardiac death. Covariate data on age, gender, body mass index, New York Heart Association class, ejection fraction, comorbidities, and prescribed medications including anti-depressants were obtained from patient interview and review of medical records. Hypotheses were tested by hierarchical logistic and Cox proportional hazard regressions.

Results: The mean score \pm SD on somatic depressive symptoms of the PHQ-9 was 4.5 ± 3.3 ; on cognitive depressive symptoms, it was 2.6 ± 2.8 . Sixty patients (29.4%) had depressive symptoms indicating ≥ 10 of total PHQ-9 score. The average intake of vitamin D was 3.8 ± 2.7 mcg/day and 122 patients (59.8%) had vitamin D deficiency. During 1-year follow-up period, 11 patients (5.4%) died and 46 patients (22.5%) were hospitalized due to cardiac problems. After controlling for all covariates, somatic depressive symptoms (HR=1.10, 95% CI=1.01-1.19, $p = .025$) and vitamin D deficiency (HR=1.88, 95% CI=1.09-3.25, $p = .023$) predicted shorter cardiac event-free survival, but cognitive depressive symptoms (HR=1.10, 95% CI=0.99-1.21, $p = .064$) did not. In hierarchical logistic regression, somatic depressive symptoms ($\beta = 1.14$, $p = .036$) were associated with vitamin D deficiency, while there was no significant association of cognitive depressive symptoms ($\beta = 0.94$, $p = .388$) with vitamin D deficiency after controlling for all covariates.

Conclusions: In patients with HF, somatic depressive symptoms independently predicted shorter cardiac event-free survival, whereas cognitive depressive symptoms did not. This findings show that inadequate intake vitamin D is one possible mechanism to explain how somatic depressive symptoms contributed to adverse health outcomes for patients with HF. Future study is required to determine whether vitamin D adequacy could play a protective role in the impact of somatic depressive symptoms on cardiac events in patients with HF.

P2043

The effects of discharge planning on self-care ability in patients undergoing percutaneous transluminal coronary angioplasty in Iran.

N Nader Aghakhani¹; MAJID Najafi¹

¹Urmia University of Medical Sciences, Urmia, Iran (Islamic Republic of)

Introduction: Angioplasty is one of the most common methods for treatment coronary artery diseases. On the other hand-one of the major issues in improving quality of care is patient participation in the treatment and self-care which can, in most cases, including for patients coronary angioplasty treatment, especially for continuity of care after discharge considered.

Material and Method: Intervention group patients in the period of one month after discharge according to required two home visits are. One month after discharge demographic information questionnaire and the self-care ability by two groups of patients completed. Data analysis with software SPSS version 22 and using descriptive statistics done.

Results: The study was difference significant statistics there is no control and intervention groups ($P = 0.181$). Comparison averages of the self-care ability before and after the intervention in two group showed statistically significant differences ($p = 0.0001$). As a result of paired t-test showed that statistically significant differences in the control group ($P = 0.001$) and the intervention group ($P = 0.0001$) during one month after discharge to admission. However, the difference between the means of the scores obtained at the time of admission and one month after discharge is much greater in the intervention group than the control group.

Conclusion: Recommended health care providers and nurses by strengthening their self-care on discharge planning, improve the ability of self-care and reduce its complications in patients in coronary angioplasty.

P2044

Appropriateness of heart failure therapy in Bulgaria

T Katova¹; I Simova¹; I Bayraktarova²

¹National Heart Hospital, Department of Noninvasive Cardiovascular Imaging and Functional Diagnostics, Sofia, Bulgaria; ²National Heart Hospital, Clinic of Cardiology, Sofia, Bulgaria

Objective: Heart failure (HF) is a leading health and socio-economic problem worldwide. Guideline-recommended therapy could significantly improve morbidity and mortality in HF patients. It is not known, however, to what extent cardiologists are keeping with the guidelines regarding HF therapy. We aimed to evaluate the appropriateness of medical therapy in HF patients in Bulgaria with respect to current guidelines.

Methods: From October to November 2015 Bulgarian cardiologists filled anonymously and voluntarily a questionnaire, describing medical therapy of HF patients in their practice. 475 ambulatory patients were included in the registry. Mean age was 70 ± 10 years, 54% were male, concomitant diseases were as follows: arterial hypertension - 340 patients (72%), diabetes - 118 (5%), coronary artery disease - 305 (64%), cerebro-vascular disease - 91 (19%), atrial fibrillation - 135 (28%).

Results: Most of the patients (81%) were in functional class III, and the majority had pulmonary (58%) and peripheral (61%) congestion. 176 patients (37%) were prescribed an angiotensin-converting enzyme inhibitor (ACEi), 150 (32%) - angiotensin-receptor blocker (ARB), 299 (63%) - beta-blocker (BB) and 38 (8%) - aldosterone-receptor antagonist (ARA).

The dosages of most commonly prescribed HF medications were as follows (mg): enalapril - 18 ± 4 , perindopril - 8 ± 4 , ramipril - 7 ± 3 , valsartan - 166 ± 54 , candesartan - 17 ± 16 , olmesartan - 28 ± 11 , telmisartan - 69 ± 20 , bisoprolol 6 ± 5 , metoprolol - 61 ± 31 , carvedilol - 16 ± 12 , spironolactone 26 ± 9 .

Conclusions: A significant part of HF patients in Bulgaria do not receive appropriate and guideline-recommended medical therapy. Those who are prescribed ACEis, ARBs, BBs and ARAs are far from reaching the target dosages.

P2045

Characteristics of police patients with heart failure.

LS Secco¹; SM Mettini¹; DAF Fernandez¹; MB Baglioni¹; GC Cirone¹; MGM Masuelli¹; SMPG Pereiro Gonzalez¹

¹Hospital Center Churrua-Visca, Buenos Aires, Argentina

Intro: It's well known high prevalence in cardiovascular disease, and so in heart failure. At the police hospital, we saw this evolution in our patients (p). We make our own data base to analyse their characteristics.

Objectives: To define characteristics in p with decompensate heart failure (DHF) in our population.

Method: It is a prospective analysis of 370 p admitted for DHF, consecutively, in our Cardiology Service, from June 2012 to November 2015, with a median follow-up of 23 months (Q1 13 - Q3 33). Quantitative variables with normal distribution were expressed with medium and with standard deviation (analysed by Fisher's Test);

those with not normal distribution, were expressed with median (m) and quartiles (analysed by Mann Whitney's Test). Dichotomous variables were analysed by Chi2.

Results: We saw population with a m of 71 years old (Q1 62 - Q3 80), were predominately males (65.5%). In cardiovascular risk factors (CRF), we found 79.5% hypertension, 32.5% diabetics, 46.9% smokers, 35.9% dislipemics. Predominant etiology was ischemic one (36.1%). At admission 39.7% p had history of severe ventricular dysfunction; more frequent cause of decompensation was lack of treatment or non-compliance (30.3%), progression of underlying disease and arrhythmias were in 2° place (15.1% and 15.4%, respectively). With the echo, we found dilated ventricles (m diameters in diastole 56.3 mm, in systole 42 mm), m ejection fraction (EF) of 37% (35.1% p had EF < 35%, 49.5% EF < 45%), mild mitral regurgitation were observed in 45% p (31.7% moderate, 8.3% severe). 20.5% had history of myocardial infarction, 10% any device (pacemaker 9.2%). At labs, the m were abnormal values in glycemia (126 mg/ml), glomerular filtration rate (by MDRD 56.2 ml/min/1.73 m2 and by creatinine clearance in 24 hours 52 ml/min/1.73 m2), albumin (3.3 g/g). We remark that 68.7% p increased their serum creatinine during admission. At EKG, 55.7% had sinus rhythm, 37.2% had atrial fibrillation or flutter; QRS width had a m value of 100 msec; 25.5% showed LBBB. About pre hospital treatment, 59.9% received ACE inhibitors or ARB, 59% beta blockers, 17% aldosterone antagonists, 20.5% amiodarone, 49% diuretics. Mortality during admission was 4.6%, at the following-up was 35.2%. Readmissions were 25.6%.

Conclusions: We have an aged population, with high prevalence of CRF. Even known HF history, they have poor adherence to treatment. They have severe dysfunction, however have few p with devices. Most important co morbidity is renal dysfunction. We can improve the ambulatory treatment. We have no great differences in mortality and readmissions with international records.

P2046

Changing trends in heart failure hospitalizations 2010-2015 for patients with HFpEF and HFrEF

B Branimir Kanazirev¹; MSD Dimova¹; VZZ Zlateva¹; AAK Kirkorova¹; JKD Kashlov¹

¹Varna University Hospital, Varna, Bulgaria

Materials and methods: In 1615 hospitalized patients ejection fraction, mean age and percentage female gender were calculated during a period of six year from 2010 to 2015. Ejection fraction above 50% was considered preserved, below 40 % was considered reduced and in between was estimated as intermediate.

Results: Trends in hospitalization of patients with heart failure were observed with increase of mean age and increase of the percentage of hospitalized female gender. Concomitantly a tendency of increasing the percentage of patients with heart failure with preserved ejection fraction (HFpEF) and a decrease of the percentage of patients with heart failure with reduced ejection fraction (HFrEF) was noted. Patients with HF with intermediate EF also showed some variation during the years.

Conclusions: Although these changes did not reach statistical significance tendencies of changing trends in hospitalized patients are observed even in a relatively short period of time.

Mean Age and percentage of females admit

	2010	2011	2012	2013	2014	2015
Age	70,1	71,1	73,1	72,4	72,0	72,8
Females %	52	54	46	50	57,4	57,2

Hospitalized HF patients 2010-2015

Risk factor differences by geography, income level and ethnicity among patients with heart failure from eleven Asian regions (the asian-hf registry)

CSP Lam¹; THK Teng Miss W-T Tay²; I Anand³; S Zhang⁴; W Shimizu⁵; C Narasimhan S-W Park⁶; C-M Yu T-Ngarmukos⁷; R Omar E Reyes⁸; B Siswanto C-L Hung⁹; LH Ling A-R Richards¹⁰

¹National Heart Centre Singapore, Duke-National University of Singapore; Cardiovascular Research Institute, National University, Singapore, Singapore; ²National Heart Centre Singapore, Singapore, Singapore; ³University of Minnesota, VA Medical Center, Minneapolis, United States of America; ⁴Fu Wai Hospital, Beijing, China People's Republic of; ⁵Nippon Medical School, Department of Cardiovascular Medicine, Tokyo, Japan; ⁶CARE Hospitals, Korea University Hospital, Korea, Hyderabad, India; ⁷Princess Margaret Hospital, The Chinese University of Hong Kong; Ramathibodi Hospital, Mahidol University, Thailand, Hong Kong, Hong Kong SAR People's Republic of China; ⁸Institute Jantung Negara, Malaysia; Manila Doctors Hospital, Philippines, Kuala Lumpur, Malaysia; ⁹National Cardiovascular Center Harapan Kita, University of Indonesia, Jakarta; Mackay Memorial Hospital, Cardiology Division, Taipei, Jakarta, Indonesia; ¹⁰National University of Singapore, Cardiovascular Research Institute, National University of Singapore, Singapore, Singapore

Background: Rapid epidemiological transition has contributed to a surge in cardiovascular diseases, including heart failure (HF), in Asia.

Aim: To determine differences in risk factors based on geographic region, stage of economic development and ethnicity among Asian patients with HF

Methods: ASIAN-HF is a multicentre prospective registry of 5276 patients with HF with reduced ejection fraction (≤40%) from 11 Asian regions (China, Hong Kong, India, Indonesia, Japan, Korea, Malaysia, Philippines, Singapore, Taiwan, Thailand). We compared 3 key risk factors: ischaemic heart disease (IHD), hypertension (HTN) and diabetes mellitus (DM) by geographic region (by United Nations), income level (by WHO: Lower – Indonesia, Philippines, India; Middle – China, Thailand, Malaysia; Higher – Singapore, Hong Kong, Taiwan, South Korea, Japan) and ethnicity (Chinese [29.6%], Indian [31.3%], Malay [15.4%], Japanese [10.3%], Korean [6.0%], Thai [3.6%] and Indigenous South-East [SE] Asians [2.5%]).

Results: Mean age of Asian patients was strikingly low (60±13 years), with two-thirds <65 years old, yet 64% had 2 or more comorbidities. Patients from East Asia and higher income countries were older while Malays were the youngest ethnic group. IHD was prevalent in 58% overall; with highest prevalence in SE Asia (70%), and lowest in East Asia (44%). Prevalence was not related to income level, but strongly influenced by ethnicity (Indian [OR=3.1]; Malay [OR=1.6] and Thai [OR=1.7] vs Chinese). HTN was prevalent in 52% overall; with higher prevalence in higher income regions (OR=1.9 vs lower income). Malays (62%) and Chinese (58%) had the highest prevalence; but these ethnic differences were influenced by geography: Indians and Chinese from SE Asia had higher prevalence compared to Indians from South Asia (73% vs 38%) and Chinese from East Asia (67% vs 48%); all p = 0.001. DM was prevalent in 40% overall; with strikingly higher prevalence in higher income regions (OR=2.7 vs lower income), as well as geographic regions of SE Asia (46%) and South Asia (37%). Median duration of diabetes was 8 years (IQR 4-14). Indians (OR =3.1) and Malays (OR =1.67) had the highest adjusted odds of diabetes compared with Chinese, whereas Koreans had the lowest (OR = 0.67).

Conclusions: These first prospective multinational data demonstrate significant heterogeneity among Asian patients with HF, depending on geographic region, socioeconomic status, and ethnicity. These findings carry implications for managing the HF epidemic in Asia, and suggest that lifestyle, genetic and environmental factors are important considerations.

P2048

Pharmacotherapy for heart failure in adult patients with congenital heart disease: initial results from challenge registry

Hellenic Cardiological Society
G Giannakoulas¹; K Vasiladias²; A Frogoudakis³; A Tzifa⁴; C Ntellos⁵; D Parcharidou⁶; D Ntiloudi¹; H Kavouris¹; K Tsioufis⁷; S Rammos⁸

¹Ahepa University Hospital, Cardiology Department, Thessaloniki, Greece; ²General Hospital G. Papanikolaou, Cardiology Department, Thessaloniki, Greece; ³Attikon University Hospital, Cardiology Department, Athens, Greece; ⁴Mitera General Hospital, Department of Congenital Heart Disease, Athens, Greece; ⁵Tzaneio General Hospital of Piraeus, Cardiology Department, Athens, Greece; ⁶Interbalkan medical center, Cardiology Department, Thessaloniki, Greece; ⁷Hellenic Cardiological Society (HCS), Athens, Greece; ⁸Onassis Cardiac Surgery Center, Department of pediatric cardiology and adult congenital heart disease department, Athens, Greece

Introduction: As adult congenital heart disease (ACHD) population ages, prevalence of heart failure (HF) rises in these patients.

Purpose: We aimed to highlight the characteristics of ACHD patients who are under medical therapy for HF.

Methods: Data from February 2012 until October 2015 were collected from the national registry of ACHD in Greece (CHALLENGE). For severity of ACHD subtypes, Bethesda classification was used.

Results: A total of 1705 ACHD population were included in CHALLENGE registry, of which 286 (16.8%) were under HF medical treatment. Physicians were more likely to prescribe HF pharmacotherapy in ACHD patients with single ventricle (SV) (53%), followed by atrioventricular/ventriculoarterial (AV/VA) abnormal connections (29%), atrioventricular septal defect (AVSD) (28%) and tetralogy of Fallot (TOF) (20%). Regarding the elderly (> 60 years old) with CHD (n = 182), 76 patients (42%) were under HF treatment. Patients under medical treatment were older (45.2 vs 34.7 years, $p < 0.001$), more frequently males (52.8% vs 45.8%, $p < 0.001$), had more severe CHD (27.3% vs 10.3%, $p < 0.001$), were more symptomatic (NYHA III/IV 27.3% vs 4.5%, $p < 0.001$), underwent multiple (≥ 2) surgeries (34.6% vs 16.1%, $p < 0.001$) and were more frequently under antiarrhythmic medical therapy (40.2% vs 10.9%, $p < 0.001$).

Conclusion: In Greece, the most common forms of ACHD that required HF treatment were SV, AV/VA abnormal connections, AVSD and TOF. Patients with advanced age, male gender and more advanced disease were prone to be under HF medical therapy.

ACHD subtypes and HF pharmacotherapy

Heart failure awareness: a cross-sectional study on misconceptions and educational opportunities

G Burneikaite¹; G Grigaliunas¹; A Kavoliuniene²; J Celutkienė¹; R Maciunas¹; G Kaklauskaitė¹; E Lycholip¹; A Grigaliuniene¹; M Balciunas¹; S Stork³

¹Vilnius University, Faculty of Medicine, Vilnius, Lithuania; ²Lithuanian University of Health Sciences, Department of Cardiology, Medical Academy, Kaunas, Lithuania;

³University of Wuerzburg, Comprehensive Heart Failure Center (CHFC), Wuerzburg, Germany

Background: Heart failure (HF) is a growing cause of morbidity and mortality. The vast majority of HF patients lack basic comprehension of HF and self-care, which manifests itself in suboptimal outcomes in such patients.

Purpose: This study targeted at establishing the preexisting level of knowledge on HF in Lithuania and evaluating the effects of a single lecture on such knowledge.

Methods: A cross sectional survey study using an anonymous questionnaire designed by the German Competence Network Heart Failure (CNHF), provided to the participants prior to and after a standardized lecture on HF. The survey was conducted at five hospitals and two shopping malls, during public events. The CNHF questionnaire consisted of two sets of questions focusing on individual characteristics of the respondent and HF-related knowledge. A completion of the questionnaire was followed by a 20-minute standardized lecture on HF. The participants were given the opportunity to pose questions. After the lecture, the same questionnaire was completed for the second time. The gathered data was verified by a standardized procedure in Germany, and then transferred into a databank.

Results: A total of 1025 Lithuanian respondents, including patients, hospital employees, and shopping malls' visitors, participated in survey. The majority (60%) of the respondents were female. The rate of the participants with occupational experience in the medical field was 15%. The majority (79%) of the study population had heard about HF previously. Overall pre-existing HF-knowledge was insufficient. Only 44% of the respondents recognized the grim prognosis of HF once the patient needs hospitalization for HF. Evaluation of pre-existing knowledge also revealed that a whopping 58% of subjects who had worked in the medical field mistakenly perceived exercise as harmful for those with HF. Male participants were more prone to falsely attributing HF to normal process of ageing than their female counterparts

(58% and 42%, respectively, $p < 0.001$). The lecture significantly increased the rate of correct answers in most of the questions. Particularly notable gains were observed in those without prior medical experience.

Conclusions: The HF-knowledge in the mixed study population was lacking. The standardized lecture successfully improved theoretical HF-knowledge short-term. Long-lasting impact, however, remains unclear.

P2050

Differences of psychological features in patients with HF: results of a CAPS-LOCK HF (Complex Assessment of Psychological Status Located in Heart Failure) study

M Michal Orszulak¹; K Mizia-Stec¹; A Siennicka²; K Goscinska-Bis³; R Blaszczyk⁴; F Szymanski⁵; B Michalski⁶; K Ptaszynska-Kopczynska⁷; A Hryniewicz-Szymanska⁸; E Jankowska⁹

¹7th Public Hospital of the Silesian Medical University, I Departement of Cardiology, Katowice, Poland; ²Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland; ³7th Public Hospital of the Silesian Medical University, Department of Electrophysiology, Katowice, Poland; ⁴Medical University of Lublin, Department of Cardiology, Lublin, Poland; ⁵Medical University of Warsaw, Department of Cardiology, Warsaw, Poland; ⁶Medical University of Lodz, Department of Cardiology, Lodz, Poland; ⁷Medical University of Bialystok, Department of Cardiology, Bialystok, Poland; ⁸Medical University of Warsaw, Department of Cardiology, Hypertension and Internal Medicine, Warsaw, Poland; ⁹Military Hospital of Wroclaw, Department of Cardiology, Wroclaw, Poland

Background: It is likely that the psychological reaction towards heart failure (HF) differs between males and females, which may determine sex-oriented and aetiology-oriented treatment and recommendations.

Purpose: the aim of the study was to assess the psychological state of patients with HF with a reduced ejection fraction (HFrEF) with regard to gender and aetiology.

Methods: 758 patients with HFrEF (mean age – 64 ± 11 years, men – 79%, NYHA class III-IV – 40%, ischemic aetiology – 61%) were included in a prospective Polish multicenter Caps-Lock-HF study. Scores on five different self-report inventories: CISS (Coping Styles in Stressful Situations), MHLC (Multidimensional Health Locus of Control), GSES (Generalised Self-efficacy scale), BDI (Beck Depression Inventory) and a modified Mini-MAC (adjusted to HF) were compared between the sexes taking into account the aetiology of HFrEF.

Results: There were differences in the CISS scale and BDI score between the genders – women had higher scales of both the CISS (emotion- and avoidance-oriented) and BDI scores (general score – 14.2 ± 8.7 vs 12.3 ± 8.6 , $p < 0.05$; subscale – somatic score – 7.3 ± 3.7 vs 6.1 ± 3.7 , $p < 0.05$). In the ischemic subpopulation, women had higher BDI scores (general score and subscales – somatic and affective) than men. In the non-ischemic subpopulation the differences between genders were limited to the CISS avoidance-oriented subscale (women – 17.2 ± 3.8 vs men – 16.2 ± 3.4 , $p < 0.05$). In a multivariable analysis with demographic and clinical data as the dependent variables, female sex, NYHA class, atrial fibrillation and diabetes mellitus determined the BDI score. Similarly, in the ischemic subpopulation, the female sex, NYHA class and atrial fibrillation determined the BDI score, while in the non-ischemic population NYHA class was the only factor that influenced the BDI score. Adding the psychological data made a significant additional contribution to the prediction of depression status. The final model, which included the demographic, clinical and psychological data, correctly predicted the BDI score in 42.9% of the cases.

Conclusions: There are distinct differences in psychological features with regard to gender in patients with HFrEF. Women demonstrate less favourable psychological characteristics in the CISS and BDI scores. Gender-related differences in the BDI score are especially explicit in patients with an ischemic aetiology of HF. The BDI score is related to psychological predisposition.

P2051

Heart failure videos on a famous video-sharing website - the good, the bad, and the ugly: a study on the utility and education value for patients, healthcare practitioners and learners

N Bowers¹; CM Chow²

¹University of Toronto, Internal Medicine, Toronto, Canada; ²St. Michael's Hospital, Cardiology, Toronto, Canada

Introduction: Heart failure is a major international health issue, with over 23 million people worldwide living with heart failure, and a global economic cost of up to \$108 billion per annum. Patient education in heart failure is essential, as therapies become more complex and patient self-care becomes more important. A video-sharing website can be a source of resources on heart failure for both patient and medical education purposes.

Purpose: To investigate and characterize heart failure videos on this video-sharing website in terms of content and target audience, and to determine their use for patients, healthcare practitioners and learners.

Methods: On October 1st, 2015, it was queried for the search terms "congestive heart failure" and "heart failure." The first 10 pages of results were analyzed, each including 20 videos per page. Videos were analyzed by the authors for their source, target audience, utility for patients, relevance, number of views, advertisements, and content.

Results: A total of 200 videos were analyzed, the total views were 4,858,591 (average 24,293 views per video), and 159 videos were found to be relevant to medicine. Individuals of unknown credentials were the source of 32% of the videos, whereas educational companies and hospitals were the source of 16.5% and 11.5%, respectively. Healthcare practitioners and learners were the target audience of 71.7% of the relevant videos, whereas patients were the target audience in only 36.5%. Only 5% of the videos were misleading with endorsement of alternative treatments or treatments lacking evidence, and 16.5% of the videos contained advertisements.

Conclusion: This site is a popular video-sharing platform with many videos on heart failure. Most videos are relevant to medicine, but surprisingly the majority are intended for healthcare professionals and learners that may be too advanced for patients. Healthcare practitioners should be aware that users with unknown credentials upload a significant number of heart failure videos. The lack of a commonly agreed upon peer-review process and the lack of a proper rating system raise concerns with the accuracy of information being accessed by heart failure patients on the platform. A more objective and independent peer-reviewed guide on health-related videos would be extremely useful for the public and health professionals.

P2052

Right ventricular dysfunction and depressive symptoms in patients with chronic heart failure: clinical and pathophysiologic implications

I Alexanian¹; V Matzaraki²; J Parissis³; A Karavidas²; D Farmakis³; V Bistola³; S Lymperi¹; J Lekakis³; G Filippatos³

¹"Sotiria" Chest Diseases Hospital, Department of Cardiology, Athens, Greece;

²General Hospital of Athens G. Gennimatas, Department of Cardiology, Athens, Greece;

³Attikon University Hospital, Department of Cardiology, Athens, Greece

Introduction-Purpose: Depression is a common condition in chronic heart failure (CHF) and has been independently associated with an adverse prognosis. This study investigates the relationship of depressive symptomatology [estimated by Zung self-rating depression scale (Zung SDS)] with echocardiographic indices of right ventricular dysfunction in patients with CHF.

Methods: Zung SDS, functional questionnaires [Kansas City Cardiomyopathy Questionnaire (KCCQ) and Minnesota Living with Heart Failure Questionnaire (MLHFQ)], BNP, 6-minute walk test (6MWT) and a comprehensive echocardiographic study were assessed in 70 CHF patients. Thirty-three percent of patients had preserved left ventricular ejection fraction LVEF \geq 50% (HFPEF).

Results: Twenty-four patients (34%) were found to have symptoms of mild to severe depression (Zung SDS \geq 44). These patients were older (73.4 \pm 9.2 vs. 68.3 \pm 7.2 yrs, $p=0.014$), with significantly higher early mitral inflow velocity to early diastolic mitral annulus TDI velocity ratio (E/e') (14.9 \pm 3.1 vs. 10.2 \pm 2.5, $p<0.001$) and greater left atrial volume (63.6 \pm 12.2 vs. 54.8 \pm 10.7 ml, $p=0.003$) compared to those without depression. Moreover, they had greater right ventricular diameter (40.7 \pm 2.6 vs. 36.9 \pm 3.4 mm, $p<0.001$), higher systolic pulmonary artery pressure (PASP) (45.1 \pm 6.7 vs. 37.1 \pm 6.1 mmHg, $p<0.001$), lower systolic tricuspid annular TDI velocity (sRV) (8.2 \pm 1.1 vs. 11.2 \pm 1.7 cm/sec, $p<0.001$), lower early diastolic tricuspid annular TDI velocity (eRV) (7.1 \pm 2.1 vs. 8.7 \pm 2.4 cm/sec, $p=0.013$) and greater inferior vena cava diameter at end-expiration (22.1 \pm 2.9 vs. 17.7 \pm 3.2 mm, $p<0.001$) compared to HF patients without depression. They also exhibited worse overall summary KCCQ (28.3 \pm 6.1 vs. 47.9 \pm 15.9, $p<0.001$), higher total score MLHFQ (62.0 \pm 12.2 vs. 39.0 \pm 9.4, $p<0.001$), decreased 6MWD (257.1 \pm 78.00 vs. 397.7 \pm 84.2 m, $p<0.001$) and increased BNP (713.5 \pm 221.3 vs. 418.9 \pm 223.4 pg/ml, $p<0.001$). In multiple linear regression analysis, PASP (B: 0.389, 95%CI: 0.130-0.648, $P=0.004$) and sRV (B: -1.556, 95%CI: -2.399 to -0.713, $p=0.001$) were independent predictors of Zung SDS after adjusting for age and gender. ROC analysis revealed that a PASP cut-off value of 37.5 mmHg (91.7% sensitivity and 60.9% specificity, $p<0.001$) and sRV cut-off value of 9.5 cm/sec (80.0% sensitivity and 87.5% specificity, $p<0.001$) discriminated CHF patients with depression vs. those without.

Conclusion: RV dysfunction seems to play a role in the pathophysiology of depressive status in CHF. Echocardiographic indices of RV dysfunction are independent predictors of depressive symptomatology in these patients.

P2053

Factors related to the psychological changings in elderly patients suffering from chronic heart failure

VN Larina¹; EV Larina²; NK Runikhina¹

¹The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation; ²National Research University Higher School of Economics, Faculty of Social Sciences, Psychology, Moscow, Russian Federation

Introduction: Chronic diseases lead to restrictions in all areas of everyday life of patients, especially among elderly. This restrictions due to special conditions can become even more important than symptoms of an illness to a person. Moreover, serious health problems of a relative lead to essential changings in his family. Permanent therapy, frequent appeal for help and hospitalizations affect not only patient's psychological state, but his close surrounding's too. Relatives often don't understand the seriousness of the clinical state and life prognosis of the patient which form barrier to the relations. The purpose of the study was to assess the psychological changings of elderly patient suffering from chronic heart failure (CHF) and its associated factors.

Methods: Elderly outpatients (16 M, 26 F, aged 60-88 years), suffering from CHF II-IV functional class NYHA, completed validated questionnaires regarding their quality of life and emotional health. Due to the answer to the question 'Did your heart failure prevent you from living as you wanted during the past month (4 weeks) by making you feel you are a burden to your family or friends?' patients were divided in to two groups. Group 1 – patients with positive answer to the question, group 2 – patients with negative answer to the question. Statistical analysis was made using software packages SPSS 16.0.

Results: Patients of group 1 had higher education level ($n=12$, 92,3%), compared to patients of group 2 ($n=15$, 51,7%), $p=0,011$, and more severe symptoms of CHF ($=0,019$). QoL among patients of group 1 was 38,8 \pm 8,4 points compared to patients of group 2 (27,2 \pm 14,8 points), $=0,036$. Depression score was 9,0 \pm 2,9 among patients of group 1 and 5,7 \pm 2,9 – of group 2, $=0,008$. We found that depression state correlated with QoL worsening ($=0,007$, $r=0,43$). Feeling of burden for close surrounding correlated positively with higher level of education ($=0,014$, $r=2,56$), QoL worsening ($=0,034$, $r=0,34$), depression ($=0,005$, $r=0,44$), severe clinical status ($=0,029$, $r=2,26$); negatively – supporting from family ($=0,029$, $r=-2,20$). Feeling of burden increased by loneliness ($=0,029$, $r=-0,47$), depression ($=0,017$, $r=0,47$) and CHF duration ($=0,036$, $r=0,43$) among women, and only by education level – among man ($=0,037$, $r=0,52$).

Conclusion: 31% of elderly patients with CHF experienced feeling of burden for relatives which happened due to QoL worsening, depression, severe clinical status and lack of understanding of the close surrounding. Thus, the early psychological consulting of this patients, especially in the elderly, should be directed to the solution of family problems and saving of favorable climate for the patient, which will help him to stay positive and to prevent progress of depression.

P2054

Social support in patients with congestive heart failure after percutaneous coronary intervention

VA Vadim Kuznetsov¹; GS Pushkarev¹; EI Yaroslavskaya¹

¹Tyumen Cardiology Center, Tyumen, Russian Federation

Purpose: To assess the relationship between social support and clinical characteristics in patients with congestive heart failure (CHF) after percutaneous coronary intervention (PCI).

Methods: A total of 659 patients after PCI (520 males and 139 females, 78.9% vs 21.1%, respectively, mean age 58.0 \pm 8.8 years) were included in the study. Multi-dimensional Scale of Perceived Social Support (MSPSS) was used for measuring of social support level. Based on CHF severity assessed by NYHA all patients were divided into two groups: group 1 consisted of 520 patients with NYHA functional class I-II and group 2 included 139 patients with NYHA functional class III-IV.

Results: The mean values of the MSPSS were 70.9 \pm 11.2 scores for group 1 compared to 68.5 \pm 13.5 scores for group 2 ($=0.03$). Group 1 reported low social support level in 4.3%, moderate in 28.1% and high in 67.6% of patients, whereas in group 2 low, moderate and high social support levels were observed in 7.2%, 38.8% and 54.0% of patients, respectively ($=0.01$).

Multiple logistic regression analysis for confounding factors such as age, gender, smoking status, alcohol abuse, diabetes mellitus, arterial hypertension, office systolic and diastolic blood pressure, total cholesterol, left ventricular ejection fraction and severity of coronary lesions by SYNTAX score showed the independent association of CHF with social support levels (OR = 0.47; 95% CI 0.23-0.98).

Conclusion: Patients with CHF functional class III-IV more frequently had low and moderate social support levels, whereas high level was detected more frequently in patients with CHF functional class I-II. Severity of CHF was independently associated with social support levels.

P2055

How men with heart failure perceive male and female faces?

DP Daneł¹; A E Agnieszka Siennicka²; P Fedurek³; T Frackowiak⁴; A Dziedzic-Daneł²; P Sorokowski⁴; EA Jankowska²; B Pawłowski⁴

¹Polish Academy of Sciences, Anthropology Unit, Wrocław, Poland; ²Wrocław Medical University, Wrocław, Poland; ³University of Neuchâtel, Institute of Biology, Neuchâtel, Switzerland; ⁴University of Wrocław, Wrocław, Poland

The perception of face is particularly important for social functioning.

As health status may affect the perception of other people (and also their faces), we investigated if middle-aged men with heart failure (HF) evaluate facial and non-facial stimuli in a different way as compared to healthy, age-matched controls.

65 men with clinically confirmed HF (NYHA II, age: 58 ± 11 years) and 143 healthy men (age: 51 ± 14 years) evaluated the aesthetics of photographs using a 7-point scale (where 1 = the lowest score, 7 = the highest score). The set included 15 photographs (9x13 cm) of 10 adult faces (en-face or half-profiles; 5 women, 5 men) and 5 non-facial pictures (landscapes and animals taken from the Internet). Scores were averaged separately for men's faces, women's faces and non-facial stimuli in order to reflect how a particular individual perceive the aesthetics of men, women and non-facial stimuli presented in the photographs.

Comparing to healthy controls, HF patients rated the pictures presenting men and women using significantly higher scores: 4.29 ± 0.12 vs. 3.52 ± 0.07 ($p < 0.0001$) for pictures of men and 5.52 ± 0.10 vs. 4.82 ± 0.06 ($p = 0.0002$) for pictures of women. However, this effect did not occur for non-facial stimuli (5.27 ± 0.12 vs. 4.87 ± 0.08 , $p = 0.16$).

The observed differences in perception between healthy men and HF patients seem to be face-specific.

It may suggest that the range of non-somatic consequences of HF is very wide and it affects features important for patients' psycho-social functioning, essential for adequate social support and proper quality of life.

EXERCISE TESTING & TRAINING

P2056

prediction of exercise training effect of cardiac rehabilitation using rate pressure product, and peak METs and heart rate recovery on post revascularized patients

GR Glenn Rose Baceronia-Advincula¹; J Patawaran¹

¹ The Medical City, Cardiology, Manila, Philippines

Background: Training effect using rate-pressure product at a 5-metabolic equivalent workload (RPP5), and the change in estimated peak MET (METPK) during treadmill testing baseline fitness were found to be the best predictors of change in exercise tolerance after training. Heart rate recovery (HRR) and RPP5 are also measurable tools that can be used as an outcomes parameter.

Methods: Resting heart rate, systolic blood pressure and computed HRR, RPP5, and METPK during treadmill stress test (TST) at baseline and after completion phase II Cardiac rehabilitation were determined.

Results: A total of 41 patients were enrolled in the study. 61% were revascularized with percutaneous coronary angioplasty while 39% underwent coronary artery bypass graft. A significant improvement in exercise capacity in terms of METSpk was seen in the baseline TST compared with exit TST. Similarly there was an improvement trend in RPP and HRR at baseline TST compared with exit TST but was not statistically significant.

Conclusion: The significant improvement in terms of METpk is consistent with findings from previous studies that cardiac rehabilitation improves exercise tolerance. However baseline fitness appears to play a role in low training effect in patients under the NIH protocol. Similarly the comparison of the HRR and RPP in the baseline and exit TST showed an improvement trend.

A novel cardiopulmonary exercise testing prognosticating algorithm for heart failure patients with reduced and preserved ejection fraction

IYU Giverts¹; MG Poltavskaya¹; AA Doletsky¹; ON Dikur¹; MV Kuznetsova¹; EE Yakubovskaya¹; VP Sedov¹; DA Andreev¹; AL Syrkin¹

¹ I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Objectives: cardiopulmonary exercise testing (CPET) is a well known prognostic tool in chronic heart failure (CHF) but multitude of parameters impedes the interpretation of CPET in common practice. The aim of the study was to create a simple algorithm for predicting cardiovascular mortality (CVM) using CPET indices in optimally treated CHF patients with reduced and preserved left ventricular ejection fraction.

Methods: 111 optimally treated patients (83 men, 28 women, mean age 60.6 ± 12.8 years,) with CHF NYHA class I-III of various etiologies were enrolled in the study. 30,6% had preserved LVEF. After performing CPET the patients were followed up for 25.1 ± 9.7 months in average. Cardiovascular mortality (CVM) was considered the primary end-point. Using the method of classification and regression trees (C&RT) we analyzed the prognostic value of peak oxygen consumption (VO₂peak) and its derivatives (Weber class, % from predicted VO₂peak, oxygen uptake efficiency slope), ventilatory equivalent for carbon dioxide (VE/VCO₂), ventilatory class derived from VE/VCO₂, partial pressure of end-tidal carbon dioxide (PetCO₂) at rest and at the peak load, presence of exercise oscillatory ventilation, blood pressure (BP) and ECG response to exercise, heart rate (HR) recovery in 1 minute after test termination and the reason for test termination. Heart Failure Survival Score (HFSS) model combining VO₂ peak with LVEF, mean BP, serum sodium, presence of coronary heart disease, QRS width and resting HR was also included into analysis.

Results: CVM due to sudden cardiac death ($n = 7$) and progression of HF ($n = 13$) amounted 18,0%. According to C&RT analysis combination of HFSS and ventilatory class allowed to work out an algorithm accurately predicting CVM in 87,4% of cases. In patients with HFSS $\leq 6,61$ probability of cardiovascular death within 2 years amounted 72,7%, and with HFSS $> 6,61$ - 12,0%. Addition of ventilatory class specified the prognosis in patients with HFSS $> 6,61$ predicting CVM with probability of 7,7% in I-III ventilatory class and of 55,6% in IV ventilatory class. Addition of other CPET indices didn't adjust the prognosis.

Conclusions: In patients with CHF with both reduced and preserved LVEF combination of Heart Failure Survival Score based on VO₂ peak and ventilatory class provides a useful algorithm for predicting cardiovascular mortality.

P2058

The pattern of oscillatory ventilation during exercise and recovery in CPET is associated with the severity of chronic heart failure

N Panagopoulou¹; E Karatzanos¹; P Ferentinos¹; O Papazachou¹; S

Dimopoulos¹; A Tasoulis¹; A Ntalianis²; E Repasos²; S Nanas¹; A Sideris³

¹Cardiopulmonary Exercise Testing & Rehabilitation Laboratory, NKUA, Athens, Greece;

²National & Kapodistrian University of Athens, Department of

Therapeutics, School of Medicine, Athens, Greece; ³Evangelismos General

Hospital of Athens, 2nd Cardiology Department, Athens, Greece

Background/Introduction: Oscillatory ventilation (OV) in chronic heart failure (CHF) is described by the amplitude and the length of cyclic fluctuations in breathing. The clinical significance of the pattern of this phenomenon during exercise and during recovery has not been investigated yet.

Purpose: To investigate the relationship between OV characteristics during exercise and recovery phase of CPET with indices of CHF severity.

Methods: Ninety one consecutive patients with systolic CHF were analyzed (age: 55 ± 11 years, VO₂peak: 18 ± 6 ml/kg/min). All patients underwent a CPET. Cyclic fluctuations in ventilation with an amplitude during exercise greater than 15% of the average resting amplitude that lasted longer than 60% of total exercise duration, were considered as exercise OV. The same criteria applied for the recovery phase lasting 3 min. Length was also measured for each fluctuation. The average length (λ_{aver}) of exercise OV of each patient was used in the analysis. The median value of λ_{aver} (39.5 sec) of all exercise OV patients was used as cut off to define two groups [$\lambda_{aver}(1) \leq 39.5$ sec, $\lambda_{aver}(2) > 39.5$ sec]. Also, the average amplitude (haver) was similarly studied [median value: 6.1 L/min, haver(1) \leq , haver(2) $>$]. Parameters of CPET compared in each group were: VO₂peak, %VO₂peak predicted, VO₂ at anaerobic threshold (VO₂AT), ventilatory equivalent for CO₂ (VE/VCO₂slope), maximum ventilation (VEpeak), partial pressure of end-tidal carbon dioxide at anaerobic threshold (PetCO₂AT) and at maximal exertion (PetCO₂peak), maximum respiratory rate (RRmax), the first degree slope of VO₂ (VO₂/tslope) and heart rate (HRR) at the first minute of recovery. Values are expressed as means \pm SD.

Results: Fifty six patients exhibited exercise OV (62% of CHF). λ_{aver} groups differed on % VO₂peak predicted (62.8 ± 15.4 vs 41.5 ± 6.5 %, $p = 0.01$), VO₂AT (12.6 ± 4.5 vs 7.5 ± 3.3 mL/kg/min, $p = 0.04$), VE/VCO₂slope (34.1 ± 6.6 vs 49.2 ± 6.9 , $p < 0.01$), PetCO₂AT (33.5 ± 4.0 vs 26.7 ± 4.3 mmHg, $p < 0.01$), PetCO₂peak (31.5 ± 4.6 vs 18.3 ± 2.9 mmHg, $p < 0.01$) and on LVEF (33 ± 9 vs 22 ± 6 %, $p = 0.02$) comparing

$\Delta \text{aver}(1)$ vs $\Delta \text{aver}(2)$, respectively. haver groups were different in terms of VEpeak, RRmax and PetCO2peak in favor of haver(1) ($p < 0.05$). Thirty eight out of 56 exercise OV patients exhibited OV during exercise and recovery (42% of CHF, 68% of exercise OV).

Conclusions: Average length and amplitude of ventilatory oscillations seem to be significant parameters of exercise OV pattern related to the severity of CHF. Oscillatory ventilation is also present during the recovery phase. These results encourage further prospective studies in larger sample of patients.

P2059

A comparison of the effect of outpatient cardiac rehabilitation between acute heart failure and acute myocardial infarction

Y Okazaki¹; K Takabayashi¹; A Ikuta¹; R Fujita¹; S Kitaguchi¹; R Nohara¹
¹Hirakata Kohsai Hospital, Hirakata, Japan

Background: Cardiac rehabilitation (CR) is a comprehensive management of cardiac disease. Previous studies demonstrated CR improved functional capacity, but improvement rate of functional capacity in acute heart failure and acute myocardial infarction patients (pts) have not been well documented.

Purpose: The purpose of this study is to identify the characteristics of population to which CR is more beneficial.

Method: We have enrolled 152 pts with cardiopulmonary exercise testing (CPX). We compared the CPX variables between acute heart failure pts (AHF, $n = 73$) and acute myocardial infarction pts (AMI, $n = 79$), and with or without CR after 3 and 6 months.

Result: The pts with AHF were older than those with AMI (70.0 ± 11.9 vs. 66.6 ± 10.0 years old; $p < 0.01$) and had lower BMI (22.8 ± 3.6 vs. 24.0 ± 3.4 kg/m²; $p = 0.02$). They were more likely to have more co-morbidities; atrial fibrillation (44.3% vs. 39.0%; $p < 0.01$) and chronic kidney disease (45.3% vs. 22.8%; $p < 0.01$). There was no significant difference in gender of male, the prevalence of hypertension and diabetes between AHF and AMI pts (78.0% vs. 81.0%; $p = 0.59$, 69.8% vs. 74.5%; $p = 0.46$, 33.0% vs. 29.4%; $p = 0.58$, respectively). In pts with AHF, peak VO₂, VO₂/pulse and ejection fraction were lower at baseline (15.7 ± 4.3 vs. 18.2 ± 5.0 ml/kg/min; $p < 0.01$, 8.4 ± 2.7 vs. 9.6 ± 3.4 ml/bpm; $p < 0.01$, 48.2 ± 17.4 vs. 60.2 ± 10.0 %; $p < 0.01$, respectively). After 3 months, in pts with AHF, the improvement rate of peak VO₂ was higher in pts with CR than those without CR (18.5 ± 22.0 vs. 0.0 ± 15.9 % of improving; $p < 0.01$), but in patients with AMI, there was no significant improvement rate of peak VO₂ (12.2 ± 17.1 vs. 13.4 ± 20.3 % of improving; $p = 0.82$). These trend of improvement were sustained in 6 months (with AHF; 23.0 ± 26.7 vs. 3.7 ± 15.4 % of improving; $p < 0.01$, with AMI; 17.4 ± 15.2 vs. 16.5 ± 19.9 % of improving; $p = 0.86$). After the adjustment by age and gender in multiple logistic regression models, CR was independently associated with higher improvement rate in the pts with AHF after 3 and 6 months (20.0% of improving; 95% confidence interval 9.6-30.4, $p < 0.01$, 17.7% of improving; 95% confidence interval 4.0-31.4%, $p = 0.01$, respectively).

Conclusion: The pts with AHF had lower functional capacity, but higher improvement rate with CR than those with AMI after 3 and 6 months. CR was independently associated with higher improvement rate in the pts with AHF.

P2060

Non invasive cardiac output measurement in 500 healthy volunteers: validation of new normal values

C Carlo Vignati¹; G Cattadori²; S Farina¹; C Boiti¹; F Nicoli³; A Del Torto³; N Corrieri³; PG Agostoni¹

¹Cardiology Center Monzino IRCCS, Heart Failure Unit, Milan, Italy; ²San Giuseppe Hospital, Cardiac Rehabilitation Unit, Milan, Italy; ³University of Milan, Milan, Italy

Background: Cardiac output (CO) is a key parameter in the assessment of cardiac function, and its determination is critical to the diagnosis, treatment and prognostic evaluation of all heart diseases. In clinical practice, the determination of CO is limited by the fact that the validated techniques are invasive, expensive, and mainly performed at rest. Little information is available about CO during exercise.

Purpose: To assess the behavior of CO during maximal exercise in a large cohort of healthy subjects and to validate normal values.

Methods: 500 healthy subjects (age 44.9 ± 13.4 , range 18-77 years, 261 males, 239 females) were enrolled, and they underwent cardiopulmonary exercise testing with non-invasive measurement of cardiac output by inert gas rebreathing technique (Innocor).

Results: CO increased from 5.4 ± 1.5 l/min at rest to 13.2 ± 3.5 l/min at peak exercise in the total population, from 5.9 ± 1.5 to 15.3 ± 3.3 l/min in men and from 4.8 ± 1.2 to 11.0 ± 2.0 l/min in women.

Conclusions: the simultaneous measurement of CO and oxygen consumption (VO₂) at peak exercise in a large sample of healthy subjects resulted in an equation predictive of normal reference values of peak exercise cardiac output:

- total population: $\text{CO} = 4.4 \times \text{peak VO}_2 + 4.3$ ($R^2 = 0.7$)

- men: $\text{CO} = 4.9 \times \text{peak VO}_2 + 3.6$ ($R^2 = 0.5$)

- women: $\text{CO} = 4.3 \times \text{peak VO}_2 + 4.5$ ($R^2 = 0.5$)

P2061

The impact of aerobic exercise training with vascular occlusion in patients with chronic heart failure

Y Yasushi Tanaka¹

¹Yodogawa Christian Hospital, Osaka, Japan

Background: Aerobic exercise training is an important adjunct to medical therapy in patients with chronic heart failure (CHF), but the effect that aerobic exercise training with vascular occlusion in patients with CHF improves exercise capacity is unknown.

Purpose: The aim of this study was to evaluate the impact of aerobic exercise training with vascular occlusion in patients with CHF.

Methods: Forty patients with CHF due to Ischemic cardiomyopathy (New York Heart Association functional class I to II) were randomized to an interventional exercise group (IG, $n = 20$) or a control exercise group (CG, $n = 20$). Exercise was performed at an intensity of 40 to 60% of maximum Peak VO₂/W (PVO₂) for 15 min three times per week for 6 months. In IG, patients remained seated on the cycle ergometer saddle with their feet on the pedals, and the proximal end of thighs were applied by pneumatic tourniquets (width: 90mm, length 700mm) with appropriate pressure which was added 50-80 mmHg to the systolic pressure (209.5 ± 7.6 mmHg). We evaluated safety and effect of the intervention on exercise capacity, serum levels of brain natriuretic peptide (BNP) and thigh circumference (15cm above the patella).

Results: There were no differences between two groups at study entry (Age: 61.7 ± 11.2 vs. 61.7 ± 10.3 years; Height: 166.7 ± 7.4 vs. 167.1 ± 5.8 cm; Weight: 68.8 ± 10.1 vs. 69.8 ± 11.3 kg; Ejection Fraction: 48.6 ± 16.1 vs. 52.9 ± 16.2 %; PVO₂: 17.1 ± 3.8 vs. 15.9 ± 3.5 ml/kg/min; BNP: 128.5 ± 112.8 vs. 142.6 ± 183.3 pg/ml; Circumference of right thigh: 47.7 ± 6.0 vs. 47.9 ± 4.9 cm; Circumference of left thigh: 48.2 ± 6.1 vs. 47.8 ± 4.9 cm). Change of PVO₂ was significantly larger in IG than in CG (30.4% vs 16.5%, $p < 0.05$). Change of serum levels of BNP was significantly larger in IG than in CG (-58.9 ± 7.5 vs. 7.7 ± 7.0 pg/ml, $p < 0.05$). Change of circumference of right thigh was significantly larger in IG than in CG (1.9 ± 1.7 vs. -0.2 ± 1.2 cm, $p < 0.05$). Change of circumference of left thigh was significantly larger in IG than in CG (2.0 ± 1.6 vs. -0.1 ± 1.3 cm, $p < 0.05$).

Conclusion: These results suggest that aerobic exercise training with vascular occlusion can improve, without serious adverse events, exercise capacity, BNP and thigh circumference in patients with CHF.

PROGNOSIS

Neutrophil gelatinase-associated lipocalin in prediction of in-hospital heart failure and mortality in patients with acute myocardial infarction

N Sabanovic Bajramovic¹; M Kulic¹; A Durak Nalbant¹; E Hodic¹; N Resic¹; N Serdarevic²; M Dilic³; A Begic³; L Bragic¹; M Halilcevic¹

¹Clinical Center University of Sarajevo, Department of Cardiology, Sarajevo, Bosnia and Herzegovina; ²Clinical Center University of Sarajevo, Department of Clinical Chemistry and Biochemistry, Sarajevo, Bosnia and Herzegovina; ³Clinical Center University of Sarajevo, Department of Vascular diseases, Sarajevo, Bosnia and Herzegovina

Background: Neutrophil Gelatinase-Associated Lipocalin (NGAL) is a sensitive marker of acute kidney injury. It is considered as a novel biomarker for progressive inflammatory process in patients with coronary artery disease and from a pathophysiological perspective in many ways affects the prognosis after myocardial infarction.

Purpose: The aim of this study was to evaluate the role of NGAL in prediction of in-hospital heart failure and mortality in patients with ST-segment elevation myocardial infarction treated with fibrinolytic therapy.

Methods: We included 42 consecutive ST-segment elevation myocardial infarction patients treated with fibrinolytic therapy (alteplase). The median follow-up time was 7 days (interquartile range, 6 to 8 days). Blood samples were drawn immediately after admission prior to fibrinolytic administration. The end points were in-hospital heart failure ($n = 19$) and all-cause mortality ($n = 9$).

Results: Patients with high NGAL (≥ 134.05 µg/l; 75th percentile) had significantly increased risk of in-hospital heart failure and all-cause mortality compared to

patients with low NGAL ($\leq 134.05 \mu\text{g/l}$; 75th percentile), $p = 0.002$; $p = 0.001$, respectively.

High NGAL was an independent predictor of in-hospital heart failure and all-cause mortality (hazard ratio 2.88; 95% confidence interval: 1.6552-5.0112; $p = 0.0002$ and hazard ratio 6.45; 95% confidence interval: 1.9466-21.0147; $p = 0.0002$, respectively).

Conclusion: High plasma NGAL is significant independent predictor of in-hospital heart failure and all-cause mortality in ST-segment elevation myocardial infarction patients treated with fibrinolytic therapy.

P2063

Predictors of very short term (<72 hours) hospital admission or death in patients with decompensation of heart failure attended in primary care setting

J M Jose Maria Verdu¹; MA Munoz¹; L Pirretas¹; L Pifarre¹; MQ Guitart¹; C Enjuanes¹; AM Galan¹; MJ Gonzalez-Moneo¹; E Vinyoles¹; A Casado¹

¹Primary Care Research Institute (IDIAP), Barcelona, Spain

Background: Information about prognostic factors related to the heart failure patients attended in primary care is scarce.

Purpose: To identify predictive variables (easily measurables at primary care setting) related to a very short term (<72 hours) hospital admission or death in patients with decompensation of heart failure attended in primary care setting.

Methodology: HEFESTOS is a cohort study aimed at knowing the main triggers and the prognosis of some factors related to the heart failure decompensations attended in primary care setting. Heart failure patients attended as a consequence of an episode of decompensation from 1st, March to 31st December 2015 were included. The following variables were collected: age, sex, heart rate, blood pressure, NYHA class, days since the onset of symptoms, oxygen saturation, diuretic dose, crackles, ankle oedemas, paroxysmic dyspnea, pathological weight gain, orthopnea, hospital admission in the last year, causative factor of decompensation, comorbidity and ejection fraction. Logistic regression adjusting by age and sex were performed.

Results: a total of 177 consecutive patients were recruited (50.6% women), mean (SD) age was 81.4 (8.55) years. During the first 72 hours after the visit, 42 patients were hospitalized or died. Paroxysmic dyspnea (OR 3.6, 95% confidence interval 1.36-6.61), weight gain (OR 3.0, 95% confidence interval 1.36-6.69), heart rate > 100 beat/min (OR 3.35, 95% confidence interval 1.18-9.47) and breathing frequency > 25 breath/min (OR 2.36 95% confidence interval 1.08-5.18) were associated with a higher risk of very short term (<72 hours) hospital admission or death.

Conclusions: A small number of variables, easily measurables at primary care setting, may identify those patients who will be more probably to be hospitalized or death.

P2064

Factors influencing the occurrence of adverse cardiac events in patients with chronic heart failure

M Janusz-Jenczen¹; B Hornik¹; I Wlodarczyk¹; A Mlynarska¹

¹Medical University of Silesia, Department of Internal Nursing, Katowice, Poland

Background: Knowledge of factors influencing the occurrence of adverse cardiac events in patients with chronic heart failure helps to identify those, which should be covered with special care, educational programs and social support. The aim of this study was to determine the factors affecting the prognosis of patients with chronic heart failure, including the degree of compliance by patients with medical recommendations and treatment options used.

Patients and Methods: The study included 84 consecutive patients diagnosed with chronic heart failure, hospitalized in the Department of Cardiology in order diagnostic tests or due to decompensation of heart failure. The average age of the study population was 56.7 ± 10.9 years, the majority of respondents were male (77.4%). Participants were mainly in the III and IV NYHA functional class (56%, 25%) and mean left ventricular ejection fraction was 31, 6%. In univariate and multivariate assessment of risk of death and serious cardiovascular events (MACE) during the annual observation included demographic characteristics, laboratory, clinical, treatment adherence by patients and therapeutic methods used in the course of hospitalization.

Results: During the follow-up 15 patients died (17.9%) and 36 (42.9%) experienced MACE. In the study population 39.3% of patients were treated pharmacologically and in 60.7% additional methods of invasive treatment were used. Patients were characterized by a high degree of adherence of pharmacological (94%) and non-pharmacological recommendations, ie physical activity, limiting sodium and fluid intake in the diet, and recommendations related to self-control such as weight control did not achieve a satisfactory result (respectively 50%, 56.5%, 80%, 64.7%). Among patients in whom an improvement in NYHA class after 12 months occurred significantly more frequently surgical treatment were used. Risk factors for death were functional class IV NYHA, renal failure, low left ventricular ejection fraction, free marital status and low degree of acceptance rate of the disease. Risk factors for a serious cardiovascular event were: IV NYHA functional class, presence of peripheral edema,

low left ventricular ejection fraction, reduced systolic blood pressure, increased heart rate, urgent admission to hospital, patient age, a free marital state and low physical activity.

Conclusion: Patients with chronic heart failure are saddled with a high risk of death or other serious cardiovascular event. The majority of patients comply with the recommendations of pharmacology, while the smaller exhibit discipline in complying with the recommendations for dealing with drug-free. Factors influencing the prognosis is mainly clinical and demographic parameters. Adverse prognostic factor for failure to follow recommendations include lack of regular physical activity.

P2065

Alcohol consumption and heart failure in patients with previous revascularization; a substudy of the POP-HF study

P Predrag Mitrovic¹; B Stefanovic¹; M Radovanovic¹; N Radovanovic¹; D Rajic²; G Matic²; R Lasica¹; I Subotic²; N Mijic²; Z Vasiljevic¹

¹University Institute for Cardiovascular Diseases, CCS, School of Medicine, University of Belgrade, Belgrade, Serbia; ²Clinical Center of Serbia, Institute for Cardiovascular Diseases, Belgrade, Serbia

The prognosis of patients (pts) after coronary artery bypass surgery (CABS) has been noted in many studies, but there were no studies which analyzed prognosis of light-to-moderate alcohol consumers with heart failure (HF) after prior CABS. This substudy of POP-HF study (PostOperative Prognosis-Heart Failure study), aimed to evaluating the influence of light-to-moderate alcohol consumption on the HF expression in patients after prior CABS.

Methods: The effect of light-to-moderate alcohol consumption was assessed in 124 pts with HF after prior CABS (post bypass group) and control group of 560 pts with HF and without prior CABS, who were followed from April 1988 to December 2015.

Results: At baseline post bypass group was slightly younger ($p = 0.0442$), with more men ($p = 0.4320$) and with more pts with previous angina ($p = 0.0422$) and previous AMI ($p = 0.0399$). Control group of pts had more hyperlipidemia ($p = 0.0422$). Other baseline characteristics were similar in both groups of patients. After adjustment for cardiovascular risk factors by logistic regression, alcohol consumption displayed a protective effect against HF in post bypass group of patients, but not in control group of pts.

Conclusions: The effect of light-to-moderate alcohol consumption is associated with decreasing risk of HF in pts with prior CABS, but not in pts without prior CABS. This effect of light-to-moderate alcohol consumption is probably because of decreasing of cholesterol, triglycerides and fibrinogen, as well as physiological changes in coronary arteries and decreasing in sympathetic nervous system activity.

P2066

Transient loss of consciousness assessment in a University Hospital: from diagnosis to prognosis.

A R Godinho¹; M Silva¹; G Pestana¹; M Tavares-Silva¹; MJ Maciel¹; J Freitas¹

¹Sao Joao Hospital, Cardiology, Porto, Portugal

Introduction and objectives: Transient loss of consciousness is a symptom that has several differential etiologic diagnosis, causes significant morbidity and mortality and has a significant impact on quality of life. The purpose of this study was to access the diagnosis and prognosis of these patients admitted in a university hospital.

Methods: The study included 125 patients admitted in the emergency room and admitted to the hospital during the year 2013 with transient loss of consciousness. Patients were contacted by phone to evaluate the follow-up to 18 months from the date of admission for each patient.

Results: The cardiogenic syncope etiology was the most common cause of transient loss of consciousness (39.2%). The 18-month total mortality was 11.2% but 27.8% of patients with unexplained cause of transient loss of consciousness at discharge died ($p = 0.031$); 20% of patients had recurrent episodes of transient loss of consciousness, moreover 35.3% of patients with reflex syncope had recurrence ($p = 0.023$). 60% of patients who recurred had injuries and/or accidents. 20% of patients with recurrences gave up driving ($p = 0.019$).

Conclusion: Transient loss of consciousness results in significant morbidity and mortality, so the diagnosis should be done in a correct and timely manner, following standardized guidelines such as the European Society of Cardiology.

P2067

Prognostic factors and outcomes of Extracorporeal membrane oxygenation support in patients who suffered from cardiogenic shock.

DH Dong Hee Kim¹; JM Cho¹; HJ Hwang¹; IS Sohn¹; CB Park¹; ES Jin¹; CJ Kim¹

¹Kyung Hee University Hospital at Gangdong, Department of Cardiology, Seoul, Korea Republic of

Purpose: Extracorporeal oxygenation support (ECMO) has been employed as rescue therapy in patients with hemodynamic failure which were caused by cardiac problems. But mortality of the patients on ECMO remains high. So we investigated the predictors of mortality and outcomes in patients with cardiogenic shock who underwent ECMO.

Methods: The records of patients with refractory cardiogenic shock who had applied Extracorporeal oxygenation support were analyzed from May 1, 2006 to October 31, 2015 at Kyung Hee University Hospital at Gansong. Refractory cardiogenic shock was defined as sustained hypotension with ongoing tissue hypoperfusion despite of optimal fluid, vasopressor and inotropic therapy.

Results: A total of 40 patients with cardiogenic shock required ECMO during study period. Among these, 47.5% of patients (19/40) had successfully been weaned from the ECMO, and survival rate after the application of ECMO was 40.0% (16/40). The proportion of patients who received cardiopulmonary resuscitation was lower in survivor group compared to non-survivor group. (37.5% vs. 70.8%, $p=0.037$) Patients with cardiogenic shock caused by acute coronary syndrome showed poor survival rate compared to those with cardiogenic shock due to other origin such as valvular heart disease, cardiomyopathy and myocarditis. (31.2% vs. 66.7%, $p=0.028$) Serum lactic acid level at the time of initiation of ECMO was higher in non-survivors than survivors. (6.67 ± 7.09 vs. 11.44 ± 6.04 mg/dL, $p=0.003$) Finally, the peak levels of creatinine kinase-MB and troponin I during ECMO were higher in non-survivors than survivors despite of little differences of initial levels. (182.88 ± 119.71 vs. 97.08 ± 109.94 , $p=0.048$ and 48.06 ± 51.70 vs. 9.47 ± 14.58 , $p=0.017$, respectively)

Conclusion: High serum lactate level, high peak level of serum troponin and creatinine kinase-MB isoenzyme, existence of cardiopulmonary resuscitation events had significant impact on mortality of patients with cardiogenic shock. The patients with cardiogenic shock caused by acute coronary syndrome had poor prognosis compared to those with cardiogenic shock due to other cardiac disease, such as valvular heart disease, cardiomyopathy, myocarditis.

Clinical characteristics and parameters

	Survivor (n = 16)	Non-survivor (n = 24)	p
Lactic acid (mg/dL)	6.67 ± 7.09	11.44 ± 6.04	0.003
CPR events (%)	6 (37.5)	17 (70.8)	0.037
CK-MB (peak, mg/dL)	97.08 ± 109.94	182.88 ± 119.71	0.048
Troponin-I (peak, ng/mL)	9.47 ± 14.58	48.06 ± 51.70	0.017
Etiology (acute coronary syndrome, %)	5 (31.2)	16 (66.7)	0.028

Validation of the Seattle Heart Failure Model (SHFM) for mortality risk prediction in a portuguese population

A R Ana Rita Marinho¹; P Amador¹; T Duarte¹; C Sa¹; R Rodrigues¹; M Fonseca¹; R Caria¹

¹Hospital Center of Setubal, Setubal, Portugal

Introduction: Annual mortality rate in heart failure (HF) patients can range between 5 and 75%. The Seattle Heart Failure Model (SHFM) is a multivariate risk prediction model for mortality. It incorporates clinical, laboratory and therapeutic variables, widely available in clinical practice.

Purpose: To assess the performance of the SHFM in predicting mortality in a real-world cohort of Portuguese patients with HF.

Methods: Retrospective cohort study of ambulatory patients with chronic HF. The SHFM was applied in the first visit, using the online calculator (<http://depts.washington.edu/shfm>). In case of adding medications or devices to a patient's therapeutic regimen until a year after the first visit, the SHFM was calculated again according to those changes. Endpoint was all-cause mortality. Kaplan-Meier method estimated observed survival. Discrimination and calibration were assessed respectively by the area under the receiver-operating characteristic (ROC) curve and the Hosmer-Lemeshow (H-L) goodness-of-fit test and graph.

Results: During a median follow-up period of 24 months, 58 (26%) patients died. All variables used in the SHFM were analysed in groups with and without endpoint. The SHFM had adequate discrimination throughout the 5-year period (figure). Observed and predicted mortality were similar (table). The H-L chi-square statistic was 7.58 ($p=0.27$), 14.51 ($p=0.07$), 4.61 ($p=0.80$) at 1-, 2- and 5-year, respectively.

Conclusion: The SHFM was reliable in predicting mortality among Portuguese patients with HF. However absolute risk was overestimated at 1- and 2-year follow-up. Adding therapeutic changes until one year after the first visit decreased SHFM predicted mortality but had no statistically significance improvement in the discriminative capacity of the SHFM.

Performance of the SHFM

Time	Predicted mortality [SHFM]	Observed mortality (CI 95%)
1-year	6.5 %	5.4 % (2.8% - 9.4%)
1-year (after therapeutic alterations)	6.2 %	
2-year	15.9 %	9.2 % (6.1% - 14.9%)
2-year (after therapeutic alterations)	11.6 %	
5-year	28.1 %	27.3 % (21.2 % - 35.4%)
5-year (after therapeutic alterations)	28.0 %	

Performance of the SHFM in predicting mortality at 1-, 2- and 5-year in the first visit and after therapeutic alterations done until a year later. SHFM: Seattle Heart Failure Model. CI: Confidence interval.

Discriminative capacity of the SHFM

P2069

Prognostic significance of the echocardiographic assessment of inferior vena cava in chronic heart failure.

K Katarzyna Luczak¹; T Ciusur¹; J Drozd¹; K Piestrzeniewicz¹

¹Medical University of Lodz, Department of Cardiology, Lodz, Poland

Purpose: Diameter of the inferior vena cava (IVC) and the degree of its inspiratory collapse are used as echocardiographic indices of right atrial pressure. The aim of the study was to assess the relation between IVC diameter and late outcome in patients with chronic heart failure (CHF) with reduced left ventricular ejection fraction (EF) defined as EF < 40%.

Methods: 225 patients were enrolled in the study (median age: 68 years, female 44%). Clinical data, biochemical markers, and echocardiographic parameters were analysed. All patients underwent echocardiography with assessment of IVC diameter and the degree of its inspiratory collapse. The primary composite endpoint was cardiovascular death and rehospitalizations for acute heart failure decompensation.

Results: Patients with CHF in the highest tertile of IVC diameter had lower body mass index, were more likely to be in higher NYHA functional class, to have ischemic heart disease, atrial fibrillation, renal insufficiency, mitral and tricuspid regurgitation, right ventricular dysfunction, larger left and right atrial volumes, higher estimated pulmonary pressure and plasma NTproBNP blood level and were treated with higher doses of diuretics. There was a positive association between IVC diameter and NTproBNP ($r=0.68$; $p<0.05$). 34% of patients reached a primary endpoint at one year follow-up. In a multivariable regression model, higher NYHA functional class, right ventricular dysfunction and larger IVC diameter independently predicted poor outcome. A cut off value of an IVC diameter greater ≥ 22 mm predicted MACE with a sensitivity of 86% and a specificity of 72%.

Conclusion: In patients with CHF with reduced EF, larger IVC diameter identifies patients with worse outcome.

P2070

Comparative analysis of three prognostic scores in heart failure with reduced ejection fraction

P Pedro Freitas¹; C Aguiar¹; A Ferreira¹; A Ventosa¹; M Mendes¹

¹Hospital de Santa Cruz, Cardiology, Lisbon, Portugal

Background: Despite optimal treatment (drugs and devices) for heart failure, many patients continue to show disease progression, ultimately leading to death or cardiac transplantation. We evaluated and compared three scores for prognostic assessment of patients with heart failure and reduced ejection fraction (HF-REF).

Methods: We identified 200 HF-REF patients (EF < 40% at any point during medical follow-up) who underwent a cardiopulmonary exercise test (CPET) between 2003 and 2013 in a single center. For each patient, we calculated three scores (Heart Failure Survival Score - HFSS; Seattle Heart Failure Score - SHFS; Metabolic

Exercise Cardiac Kidney Indexes – MECKI) using data at the time of the CPET. ROC curve analyses were performed to evaluate and compare the prognostic accuracy of each score for the prediction of all-cause death or cardiac transplantation at 2-years after CPET (study endpoint).

Results: Mean age was 55.1 ± 10.7 years and 79.5% were male. The most common heart failure etiology was ischemic heart disease (45%). Median ejection fraction was 30% (interquartile range: 25%-35%). Sixty-six percent had implanted a device with defibrillator capability. During the 2-year follow-up after CPET, 18 patients died and 25 underwent cardiac transplantation. The MECKI score showed the best discriminative power for the study endpoint (see figure). The best cut-off value for the MECKI score was 14.46% (sensitivity 88.37%; specificity 86.62%; NPV 96.5%; PPV 64.4%).

Conclusion: In a contemporary population of patients with HF-REF, the MECKI score showed superior prognostic accuracy compared to the HFSS or the SHFS. The present study supports the use of the MECKI score when evaluating HF-REF patients for transplant candidacy.

Figure 1 - ROC curve analysis

P2071

One year prognostic value of Jung variable for acute heart failure in patients with acute ST elevation myocardial infarction treated invasively

A Aleksandra Vulin¹; R Jung¹; S Obradovic²; G Panic¹; J Dejanovic¹; V Ivanovic¹; I Ivanov¹; T Popov¹; S Petkovic - Curic³; D Penjaskovic⁴

¹Clinic of Cardiology, Institute of Cardiovascular diseases Vojvodina, Sremska Kamenica, Serbia; ²Military Medical Academy of Belgrade, Clinic for Emergency and Internal Medicine, Belgrade, Serbia; ³Specialistic internistic Medicine Practice "Serafim 023", Zrenjanin, Serbia; ⁴General Hospital Sremska Mitrovica, Sremska Mitrovica, Serbia

Background: Jung variable is a simple clinical risk index combining age, systolic blood pressure and heart rate. It is designed to be calculated quickly at first medical contact, and all potential subsequent risk stratifications points.

Aim: To determine the prognostic accuracy of Jung variable and established risk scores for one year acute heart failure in STEMI patients treated with percutaneous coronary intervention (pPCI), and to validate it in independent STEMI patients population.

Methods: Primary and validation prospective studies of consecutive patients were conducted in two tertiary hospitals. One-year acute heart failure (AHF) was assessed as end point of study. The Jung variable was calculated using the equation: $\text{systolic blood} / (\text{heart rate} \times \text{age}) \times 100$. The predictive value of Jung variable and TIMI, PAMI, and Zwolle scores were evaluated with Cox regression analysis, calibration of scores with Hosmer-Lemeshow test and the diagnostic accuracy of the scores was assessed using receiver operating characteristic curves, while scores were compared using the DeLong method.

Results: Out of 647 patients 70 (10.8%) died and 42 (6.5%) had AHF in primary, while out of 418 patients 33 (7.9%) died and 52 (12.4%) had AHF in validation study. In primary study Jung variable was univariate predictor of AHF, but PAMI score was independent predictor of AHF (1.207 (1.118-1.304); $p < 0.01$), while in validation study Jung variable was independent predictor of AHF (7.911 (3.910-16.005); $p < 0.01$). In a primary study, C-statistic and 95% confidence intervals of PAMI score was the biggest (0.690 (0.600-0.780)), but comparable to Jung variable (0.676 (0.58-0.766)), TIMI and Zwolle risk score ($p > 0.05$). C-statistic for predicting AHF in a validation study was the biggest for Zwolle score (0.876 (0.826-0.925)). C-statistic for Jung variable was well (0.732 (0.655-0.809)), but lower than AUC for other risk scores ($p < 0.05$). Hosmer-Lemeshow test of Jung variable in both studies was nonsignificant ($p > 0.05$).

Conclusion: Jung variable, simple, quickly determined at first medical contact, was predictor of one year AHF in primary and validation studies with STEMI patients treated with pPCI. Discriminatory capacity and calibration for Jung variable in both studies was good, comparable to TIMI, PAMI and Zwolle risk scores in primary study.

P2072

Hand-carried ultrasound assessment of the inferior vena cava at discharge for predicting readmission and mortality after hospitalization for acute decompensated heart failure

E Emilia Roy¹; R Costa¹; M Ciudad¹; C Rodriguez¹; P Carles¹; E Diaz De Mayorga¹; A Bautista¹; P Gil¹

¹University Hospital De La Princesa, Servicio de Medicina Interna, Madrid, Spain

Introduction: Congestion is one of the hallmarks of acute heart failure (HF) and can be measured by inferior vena cava (IVC) ultrasound study, that correlates well with right auricle pressures. IVC collapse at discharge after acute decompensated HF may be of use to predict patients' evolution.

Purpose: The aim of our study was to evaluate IVC collapse as mortality and readmission predictor in patients admitted with acute heart failure.

Methods: We performed prospective descriptive study with patients with acute HF as main diagnosis who required admission in a university hospital from July 2014 to February 2015. We performed IVC ultrasound at discharge and patients were classified as having IVC collapse $> 50\%$ or $\leq 50\%$. Anthropometric, clinical and analytical parameters were collected. We analyzed readmission and mortality as primary outcomes at 30 and 90 days.

Results: IVC ultrasound was performed in 145 patients during the study period, with a mean age of 85.5 ± 7 years, 40% males, and 84% with preserved systolic function. The most frequent comorbidities were hypertension (95%), diabetes (38%), atrial fibrillation (68%) and chronic kidney disease (38.6%). Mean follow-up period was 176 days (18-360 days). Readmission rates at 30 days and 90 days were 17% and 32% respectively, 61.5% due to HF. Mortality rates at 30 days and 90 days were 12 patients (8%) and 39 patients (27%), respectively, 15 of them because of HF. 44 patients had IVC collapse $\leq 50\%$ at discharge and had more HF readmissions than those patients with IVC collapse $> 50\%$ at 30 days (8 patients-21% vs 7 patients-7%; $p=0.06$) and 90 days (14 patients-42% vs 15 patients-18%; $p=0.009$), respectively. Mortality due to HF was higher among patients with IVC collapse $\leq 50\%$ both at 30 days (6 patients-14% vs 0, $p < 0.0001$) and 90 days (11 patients-28% vs 1 patient-1%; $p < 0.0001$).

Conclusions: IVC collapse at discharge after HF decompensation is a good predictor of death and HF readmission both at 30 and 90 days.

P2073

Gender-related risk of dying in patient after cardiac resynchronization

A Mlynarska¹; R Mlynarski²; J Biernat²; KS Golba¹

¹Medical University of Silesia, Katowice, Poland; ²Upper Silesian Cardiology Center, Katowice, Poland

Introduction: Risk of dying significantly increase in heart failure population qualified for cardiac resynchronization, there is a need to evaluate it.

Methods: 108 patients (20W; aged 74.9 ± 6.3) with advanced heart failure (NYHA II, III, IV ambulatory, left bundle branch block, QRS > 120 ms.) qualified for cardiac resynchronization device implantation were included into study. Patients were divided into groups depending on the type of implanted device. In all patients were assessed 1 and 3-year risk of dying with the use of the Heart Failure Risk Calculator – Maggic (Meta-Analysis Global Group in Chronic Heart Failure).

Results: Risk of dying within 1 year in all included patients was $21.4\% \pm 9.6\%$ and 3-years risk was $45.2\% \pm 15.7\%$. Risk of dying within 1 year for women was $16.2\% \pm 7.1\%$ compared to $22.5\% \pm 9.7\%$ for men; $p=0.010$. Risk of dying within 3 years in women was $22.5\% \pm 9.7\%$ compared to men $47.05\% \pm 15.67\%$; $p=0.000$. Average risks of dying according the type of CRT (pacemaker only versus cardioverter-defibrillator) are presented in the table below. In CRT-pacemaker men had significantly higher risk of dying within 1 year ($p=0.012$) and 3 years ($p=0.008$) compare to women. This relation was not observed for ICD-CRT.

Conclusion: Gender-related risk of dying for men is significantly higher if compare to the women. Type of CRT device do not influence risk of death

Risks of dying according type of CRT			
Score	CRT-pacemaker	ICD-CRT	p
Integer score [%]	26,88 ± 5,41	27,49 ± 5,48	0,626
1 years score [%]	20,66 ± 9,14	21,68 ± 9,74	0,639
3 years score [%]	43,88 ± 15,58	45,65 ± 15,8	0,621

Clinical impact of gender in mortality after transcatheter aortic valve implantation for severe aortic stenosis

E Munoz-Garcia¹; M Munoz-Garcia²; AJ Antonio Jesus Munoz Garcia³; AJ Dominguez-Franco³; JM Garcia-Pinilla³; MF Jimenez-Navarro³; JH Alonso-Briales³; JM Hernandez-Garcia³; E De Teresa-Galvan³

¹Department of Cardiology, Malaga, Spain; ²Complejo Hospitalario de Jaén, Division of Cardiology, Department of Pediatrics, Jaén, Spain; ³University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background: Transcatheter Aortic Valve Implantation (TAVI) is an effective alternative to surgical valve replacement in symptomatic patients with severe aortic stenosis at high or extreme surgical risk, but the impact of sex on outcomes remains unclear. The aim of this study was to examine sex differences in outcome after TAVI.

Methods: A total of 500 consecutive patients undergoing TAVI were evaluated. Differences in all-cause mortality were examined and the safety endpoints (vascular complications, stroke, myocardial infarction, acute kidney injury) according to the Valve Academic Research Consortium criteria.

Results: 295 patients (59%) were female. The prevalence of comorbidities was higher in men compared with women, including coronary artery disease, chronic obstructive pulmonary disease, chronic renal failure (55.6% vs. 34.2%, $p < 0.001$, 45.9% vs. 24.1%, $p = 0.001$ and 31.2% vs. 15.3%, $p = 0.001$, respectively). There were not significant differences in complications after TAVI, in-hospital mortality 4.4% for men vs. 3.1% for women, $p = 0.290$, vascular complications 2.9% vs. 6.8%, $p = 0.056$, stroke 3.4% vs. 3.4%, $p = 0.988$. After follow-up of 34.36 ± 23 months, the total mortality was similar in both sex, 25.9% vs. 21%, $p = 0.206$. Survival at 1, 2, 3, 4 y 5 years were slightly lower in men 87.6% vs. 91.64%, 81.4% vs. 86.4%, 76.9% vs. 81.7%, 70.4% vs. 79.2%, 64.8% vs. 73.5%, log Rank 2.3, $p = 0.126$. There was most total mortality in men 23.2% vs. 15.2%, [OR = 1.688 (95% CI 1.04-2.742), $p = 0.023$] and this results persisted for 2 years, [HR = 1.576 (1.019-2.438), $p = 0.042$].

Conclusions: Male sex is associated with worse comorbidities, but the results of procedure and long-term survival were similar in both sex

P2075

Predictive value of the shock index on long term mortality in patients treated with successful primary percutaneous coronary intervention

L Lidija Savic¹; I Mrdovic²; M Asanin²; G Krijanac²; R Lasica²; B Kastel²

¹Clinical Center of Serbia, Institute for Cardiovascular Disease, Belgrade, Serbia;

²Clinical Center of Serbia, Institute for Cardiovascular Disease, Emergency Hospital, Belgrade, Serbia

Purpose: Early identification of patients with ST-elevation myocardial infarction (STEMI) who are at risk for developing cardiogenic shock will allow more aggressive treatment strategy and approach. Preprocedural shock index (SI) measured invasively before primary percutaneous coronary intervention (pPCI) is a strong independent predictor of on in-hospital and medium-term mortality. The aim of this study is to analyse the predictive value of the SI at hospital admission on long-term mortality in patients treated with successful pPCI.

Method: We analysed 1619 consecutive STEMI patients who were treated with successful pPCI (postprocedural flow TIMI=3). SI was calculated at hospital admission, before pPCI (SI=heart rate/systolic blood pressure). A positive SI was defined as being above 1. The follow-up period was 5 years.

Results: Among analysed patients 1193 (74.1%) were male and 418 (25.9%) were female; the mean age of analysed patients was 58 years (IQR 51, 68). Positive SI at admission was identified in 80 (4.9%) patients. Patients with positive SI had significantly higher 5-year mortality as compared with patients with SI<1 –25% vs 4.89%, $p < 0.001$. In Cox regression model positive SI was an independent predictor of 5-year mortality: HR 2.76 (95%CI 1.32-6.21), $p = 0.003$. Positive SI remained an independent predictor of long-term mortality after excluding 38 (2.35%) patients who died during hospitalization - HR 2.29, 95%CI 1.21-3.96, $p = 0.014$. Other independent predictors of 5-year mortality were: ejection fraction <40% (HR 2.58, 95%CI 1.65-4.96, $p = 0.001$), age>65 years (HR 2.19, 95%CI 1.41-3.38, $p = 0.001$) and 3-vessel disease (HR 1.56, 95%CI 1.02-2.39, $p = 0.040$).

Conclusion: Positive shock index at hospital admission was the strongest independent predictor of 5-year mortality in STEMI patients treated with successful pPCI. This simple parameter may be used in everyday clinical practice for risk stratification during first contact with patients.

Meta-analysis about the effects of transcatheter closure of patent foramen ovale for secondary prevention of stroke or transient ischemic attack

C Ariano¹; R De Vecchis¹

¹Cardiology Unit, Presidio Sanitario Intermedio "Elena d'Aosta", Naples, Italy

Background: In recent years, a potential relationship between stroke, and patent foramen ovale (PFO) has emerged. Thus we decided to investigate the role of transcatheter closure of PFO on the recurrence of stroke.

Methods: PubMed and Embase databases were systematically searched from January 2000 to November 2015 for pertinent clinical studies. For inclusion in the meta-analysis, we decided to consider only randomized controlled trials (RCTs), that had compared transcatheter PFO closure with medical therapy in patients with previous cryptogenic stroke. The primary end-point was the composite of stroke and transient ischemic attack (TIA), and adverse cardiovascular events. Data were independently extracted on trial conduct quality, baseline characteristics, and efficacy and safety endpoints from published articles and appendices.

Results: After excluding 437 citations, we finally included a total of three RCTs of 2298 subjects with previous cryptogenic stroke or TIA, or systemic arterial embolism. PFO closure did not significantly reduce the risk of recurrent stroke/TIA (3.4% vs 5%; OR = 0.75; 95% CI: 0.53-1.12; $p = 0.13$); however, an increased risk of incident atrial fibrillation/flutter was detected (3.9% vs 1.2%; OR = 3.55; 95% CI: 1.85-6.75; $p < 0.0001$).

Conclusions: In this meta-analysis of RCTs performed in patients with PFO and previous cryptogenic stroke, transcatheter PFO closure did not significantly reduce the short-term incidence of recurrent stroke or TIA events compared with antithrombotic therapy.

P2077

Thromboembolic findings in heart failure patients submitted to necropsy

LKR Almeida¹; LFL Dinardi¹; TV Pereira¹; TS Barbosa¹; LA Benvenuti¹; SM Ayub-Ferreira¹; VS Victor Sarli Issa¹; EA Bocchi¹

¹Heart Institute (InCor) do Hospital das Clinicas da Faculdade de Medicina da Universidade São Paulo, Sao Paulo, Brazil

Introduction: Thromboembolic events carry/represent a significant portion of the morbidity of Heart Failure (HF). However, few studies have evaluated the occurrence of thrombotic and embolic events in patients with heart failure submitted to necropsy.

Methods: We analyzed 1241 autopsies performed from January 2000 through May 2005 in our hospital and selected 500 patients with diagnosis of heart failure, cardiogenic shock, or cardiomyopathy at autopsy. Patients with congenital heart diseases, pericardial diseases and postoperative shock were excluded. Clinical and autopsy diagnoses were confronted and discrepancies were categorized in classes I-IV in decreasing order of importance regarding therapy and prognosis; the causes of death according to specific clinical scenarios were explored.

Result: We studied 500 autopsies and found 250 patients with thromboembolic events at necropsy. Mean age of this group was 73.5 ± 10.6 years; 152 (60.8%) patients were male and 98 (39.2%) female. According to the analysis, 80 (32%) out 250 patients had a thromboembolic event as specific cause of death: acute myocardial infarction was present in 53 (66.3%) patients, pulmonary embolism in 18(22.5%) patients and systemic embolism in 6 (7.5%). A number of 180 thromboembolic events considered related to the cause of death were found in 119 patients. These main events were: 59 (32.7%)intracardiac thrombosis, 35 (19.4%) pulmonary embolism, 32 (17.7%) systemic embolism and 31(17.2%) acute myocardial infarction; 51 (20.4%) thromboembolic events were unrelated to death. Further analysis of 232 patients with retrievable clinical data found discrepancies between in vivo and post-mortem diagnoses in 191 (82.3%): class I discrepancies occurred in 56 (24.1%) patients, class II in 35 (15.1%), class III in 38 (16.4%) and class IV in 62 (26.7%). Pulmonary embolism was the cause of death of 24 (42.9%) patients with a class I discrepancy.

Conclusion: Thromboembolic events are frequently associated to death process in patients with heart failure. Pulmonary embolism is a major source of discrepancy between in vivo and post mortem diagnosis.

Serum activity of selenium in various phenotypes of heart failure: clinical and pathophysiologic implications

I Alexanian¹; J Parissis²; H Pantziou³; L Pappas⁴; S Lymperi¹; S Ioannidou³; A Sideris⁴; D Kremastinos²; J Lekakis²; G Filippatos²

¹"Sotiria" Chest Diseases Hospital, Department of Cardiology, Athens, Greece;

²Attikon University Hospital, Department of Cardiology, Athens, Greece;

³Evangelismos General Hospital of Athens, Laboratory of Biochemistry, Athens, Greece;

⁴Evangelismos General Hospital of Athens, 2nd Department of Cardiology, Athens, Greece

Introduction - Purpose: Emerging evidence suggests that promotion of adverse remodeling and clinical deterioration is possibly induced by micronutrient dyshomeostasis in heart failure (HF). Selenium (Se) is an essential trace element required for antioxidant defense, oxidative metabolism, regulation of gene expression and

thyroid hormones metabolism. The aim of this study was to assess serum Se concentrations in patients with HF.

Methods: We studied 69 patients, 75% male, aged 68 ± 11 years, 28% with preserved left ventricular ejection fraction (LVEF $\geq 40\%$), including 50 with acute HF (AHF) and 19 with chronic HF (CHF). Se concentration was assessed by atomic absorption spectrometer with the Graphite Tube Atomizer.

Results: Serum Se concentrations were $74.93 \pm 6.91 \mu\text{g/L}$. Serum Se did not differ between acute HF and chronic HF patients (74.88 ± 7.10 vs. $75.05 \pm 6.55 \mu\text{g/L}$, $p = 0.927$) and across different NYHA classes ($p = 0.971$). Serum Se was significantly lower in HF patients with reduced LVEF compared to those with preserved LVEF (73.61 ± 7.52 vs. $77.71 \pm 4.90 \mu\text{g/L}$, $p = 0.042$). In multiple linear regression analysis, only LVEF (B: 0.469, 95%CI: 0.153 – 0.785, $p = 0.005$) and myocardial injury biomarker troponin C (B: -3.246, 95%CI: -6.202 to -0.290, $p = 0.032$) were independently associated with serum Se after adjusting for age and sex.

Conclusion: Serum Se was significantly lower in HF patients with reduced LVEF in comparison to those with preserved LVEF. Systolic dysfunction and ongoing myocardial injury seems to be closely related with serum concentrations of Se in HF patients.

24-hour patterns of central and peripheral systolic blood pressure in the very elderly with heart failure with preserved ejection fraction

N Ezhova¹; A Alam²; Y Kotovskaya²; Z Kobalava²

¹M.V. Lomonosov Moscow State University, Moscow, Russian Federation;

²Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Circadian profile of central blood pressure (BP) and its relationship to peripheral diurnal rhythm of BP had not been investigated in the elderly population to the moment. The aim of current study was to investigate and compare 24-hour profiles of central and peripheral blood pressures in the very elderly via their simultaneous ambulatory monitoring. Parallel 24-h ambulatory aortic and brachial blood pressure monitoring was performed in 67 treated hypertensive subjects older than 80 years (mean age 84.1 ± 3.1 years, 25.5% male, mean clinic brachial SBP 134.8 ± 23.2 mm Hg) with HFpEF. We used oscillometric cuff-based device BPLab Vasotens. Patients with EF < 40%, atrial fibrillation and severe comorbidities were not included. 24-h, awake and sleep-time systolic, diastolic and pulse blood pressure in aorta and brachial artery were compared in subgroups divided according to the diurnal pattern of brachial systolic blood pressure (SBP). Dipper pattern was defined as relative decrease of mean SBP values of 10 to 20% at night, nondipper – less than 10% and reverse-dipper – as absent of nocturnal SBP reduction. The diurnal profiles of central systolic and pulse BPs run in parallel with those of peripheral BPs in patients with all types of dipping pattern and SBP amplification at night did not change significantly comparing to day-time values. Non-dipping or reverse-dipping SBP patterns appeared to be typical and were observed in 82.1% patients, while 50.7% participants had inadequate DBP dip < 10%. The proportionality of night-time SBP and DBP changes varied in different types of SBP diurnal profile. SBP and DBP decreased proportionally in dippers (ratio of DBP/SBP night-time reduction was 1.18) and disproportionately in non-dippers (the ratio was 2.6). In those patients with reverse-dipping pattern SBP and DBP changed in opposite directions at night. This disproportion in SBP and DBP night-time changes resulted in different intensity of PP night-time rise that was most evident in reverse-dippers. Relative nocturnal reduction of PP was $9.3 \pm 4.72\%$ in dippers, whereas non-dippers and reverse-dippers had relative PP increase of 6.2 ± 8.6 and $22.9 \pm 12.3\%$, respectively. The diurnal patterns of central and brachial BPs observed in very elderly treated hypertensives with HFpEF were almost parallel. PP amplification is similar in the day- and nighttime and this finding is different from previously observed PP amplification diurnal behavior in younger subjects. Proportionality of SBP and DBP sleep-time changes depends on dipping status and results in nocturnal PP increase in non- and reverse-dippers.

P2080

No association is observed between long- and short-term blood pressure variability in patients with controlled arterial hypertension without heart failure

E Elena Troitskaya¹; Y Kotovskaya¹; Z Kobalava¹

¹Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation

Background: Visit-to-visit blood pressure variability (BPV) is associated with cardiovascular disease risk. In view of the inconvenience of obtaining blood pressure at multiple visits to calculate visit-to-visit BPV, substituting BP variability from calculating short-term variability (intra-visit and 24-hours) may be a practical alternative. The aim of the study was to evaluate the associations between long-term (visit-to-visit) and short-term (intra-visit and 24-hours) BPV in patients with uncomplicated controlled arterial hypertension (AH).

Methods: 52 pts (20 men, age 58.9 ± 9.0 yrs; 4 smokers; 6 diabetics) with AH without HF were treated to target BP < 140/90 mmHg with combination of RAAS-inhibitor

and amlodipine for 14 months. Visit-to-visit BPV was calculated as SD for 5 visits during 8 months after target BP achievement. Intra-visit BPV was calculated as SD of 3 BP values at each visit. ABPM was performed before treatment and at the end of the study. $p < 0.05$ was considered significant.

Results: Baseline BP was $163.4 \pm 8.1/100.9 \pm 4.2$ mmHg; achieved- $123.7 \pm 9.7/76.8 \pm 6.7$ mmHg. Intra-visit systolic BPV varied from 0.8 to 7.0 mm Hg (mean 3.1 ± 1.1 mmHg), diastolic BPV – from 0.8 to 4.2 mmHg (mean 2.3 ± 0.7 mmHg). Daytime systolic BPV varied from 6 to 29 mm Hg, daytime diastolic BPV varied from 5 to 31 mm Hg. Nighttime systolic BPV varied from 5 to 18 mm Hg, nighttime diastolic BPV – from 4 to 23 mm Hg. Visit-to-visit systolic BPV after achievement of target BP varied from 1.79 mmHg to 16.79 mmHg (mean 7.2 ± 3.6 mmHg); (tertile I < 5.38; II 5.38 – 7.78; III > 7.78 mmHg). The groups were similar by age (56.6 ± 8.94 , II 59.4 ± 9 , III 60.7 ± 9.1 yrs, $p > 0.05$), gender, metabolic risk factors, baseline and achieved BP. Groups were also similar by intra-visit systolic BPV (3.0 ± 1.0 vs 3.4 ± 1.2 vs 3.0 ± 1.2 mmHg, respectively), intra-visit diastolic BPV (2.1 ± 0.8 vs 2.1 ± 0.4 vs 2.5 ± 0.9 mmHg, respectively); daytime systolic BPV (13.5 ± 3.8 vs 15.6 ± 2.9 vs 14.9 ± 5.1 mmHg), daytime diastolic BPV (14.0 ± 6.1 vs 13.6 ± 3.3 vs 12.3 ± 4.7 mmHg), nighttime systolic BPV (10.7 ± 2.9 vs 11.6 ± 3.1 vs 11.4 ± 3.1 mmHg) and nighttime diastolic BPV (8.2 ± 2.5 vs 10.2 ± 3.5 vs 9.9 ± 4.0 mmHg). No correlation was found between visit-to-visit and short-term blood pressure variability.

Conclusion: Absence of association between visit-to-visit blood pressure variability and short-term variability underlines the importance of its separate calculation in patients with uncomplicated controlled AH without HF.

P2081

Effect of treatment bisoprolol and verapamil on left ventricular diastolic function, arterial stiffness and cardiovascular coupling.

IA Orlova¹; M Vitsenia²; G Mikhaylov²; F Khezheva²

¹M.V. Lomonosov Moscow State University, Moscow, Russian Federation;

²Cardiology Research and Production Center, Moscow, Russian Federation

The purpose of the study was to compare the effect of treatment β -blocker bisoprolol and calcium antagonist verapamil on left ventricular diastolic function (DFLV), arterial stiffness and cardiovascular coupling (CVC) of patients with hypertension.

Materials and Methods: Included 60 patients (mean age 55 ± 12 years), 29 men, 31 women with hypertension I-II and heart rate ≥ 75 beat/min. Blood pressure (BP), resting heart rate (HR), pulse wave velocity on carotid-femoral (PWVcf), DFLV and CVC were evaluated at baseline and after 3 months of therapy with bisoprolol and verapamil.

Results: Both type of therapy significantly decreased SBP, DBP, HR. The changes of CVC and DFLV were not significant. PWVcf (-11.5%) was significantly decreased in the bisoprolol group. Bisoprolol showed antistiffening effect that was better than verapamil. Multivariate analysis showed a decrease in PWVcf is determined only by the type of therapy, but not the dynamics of systolic BP and HR.

Conclusion: Both drugs showed a comparable reduction in the blood pressure and HR. In direct comparison with bisoprolol showed a more pronounced effect on “surrogate” prognosis marker PWVcf compared with verapamil. CVC and DFLV dynamics were not found on both groups.

P2082

Study of association of vitamin D and hypertension in a South Asian cohort

nil

AK Pradhan¹; A Singh¹; S Priya¹

¹King George Medical University, Lucknow, India

Background: Hypertension continues to be a public health menace with substantial morbidity & mortality. The antihypertensive effect of vitamin D is attributed to its negative regulation of Renin-angiotensin-aldosterone system (RAAS), anti-oxidant and anti-angiogenic effects. Data regarding role of Vitamin D in Asian Indian population is meager.

Methods: One hundred two subjects with Essential hypertension who were Vitamin D naïve were enrolled from outpatient department. Ninety nine Healthy age and sex matched non-hypertensive controls were also taken for comparison. Serum Vitamin D level estimation was done in both groups via immunoabsorbant assay and deficiency defined as values < 20 ng/ml.

Results: Vitamin D deficiency was more prevalent among cases in comparison to controls (80.4% vs 67.7%, $p = 0.01$). The mean 25-OH vitamin D levels among cases was 15.15 ± 12.51 ng/ml versus a corresponding value of 33.59 ± 16.69 ng/ml among controls ($p = 0.0001$). We observed an inverse association between vitamin D levels and systolic blood pressure (p value = 0.01).

Conclusion: Vitamin D deficiency is linked to hypertension and may serve as cheap and efficient measure to cut down elevated BP and its complications.

P2083

Factors associated with left ventricle diastolic function in patients with arterial hypertension and mildly reduced kidney functionO Olena Torbas¹; YU Sirenko¹; G Radchenko¹; O Rekovets¹; S Kushnir¹; V Granich¹; A Dobrokhod¹¹NSC Institute of Cardiology M.D. Strazhesko, Symptomatic hypertension, Kiev, Ukraine

It has been shown that renal function impairment may potentiate left ventricle stiffening that may influence its diastolic function. We examined 52 patients with essential AH stage 2 (mean SBP 158.04 ± 2.24 mmHg, mean DBP 92.19 ± 2.15 mmHg; eGFR 86.2 ± 1.8 ; age 51.29 ± 2.24), 25 men and 27 women. We performed Doppler echocardiography according to local full protocol, LV diastolic function was determined by measuring velocity of the peak E and peak A of transmitral flow with determination of E/A, velocity of peak E' by tissue Doppler with determination of E/E', deceleration time (Dt) and isovolumic relaxation time (IVRT) measurement. eGFR was estimated using CKD-EPI formula. Also we used hematology and biochemical blood testing, urine analysis, microalbuminuria and urine creatinine excretion with albumin to creatinine excretion ratio (A/C). To assess the relationship between these values we used Spearman correlation analysis. The mean values were E/A 1.04 ± 0.06 , E/E' 7.58 ± 0.44 , Dt 253.9 ± 12.6 msec, IVRT 92.6 ± 3.9 msec. We found that E/E' was correlated with A/C ($r=0.38$ $p=0.046$), serum sodium ($r=0.341$ $p=0.038$) and with the quantity of leucocytes (Leu) in the urine portion ($r=0.396$ $p=0.037$). E/A was associated with serum potassium ($r=-0.385$ $p=0.035$), eGFR ($r=0.376$ $p=0.017$), uric acid ($r=-0.675$ $p=0.005$), the quantity of Leu in hematology ($r=-0.436$ $p=0.033$) and urine ($r=-0.456$ $p=0.013$) samples. Dt was associated with urine specific density ($r=0.313$ $p=0.039$), eGFR ($r=0.693$ $p=0.034$), erythrocyte sedimentation rate ($r=0.410$ $p=0.046$), quantity of Leu ($r=0.0576$ $p=0.001$) and erythrocytes ($r=0.387$ $p=0.042$) in urine portion. IVRT correlated with serum sodium ($r=0.374$ $p=0.019$) and potassium ($r=0.383$ $p=0.04$) concentration, eGFR ($r=0.412$ $p=0.011$) and blood hemoglobin concentration ($r=0.485$ $p=0.16$). In patients with arterial hypertension and started renal function impairment all the predictors found could be useful for the prognosis of the development of LV diastolic dysfunction.

P2084

Benefit of forty-eight-hour ambulatory blood pressure monitoring in hemodialysis populationK Mnif¹; F Jarraya¹; H Chaker¹; H Mahfoudh¹; S Feki¹; S Charfeddine²; L Abid²; S Kammoun²; K Kammoun¹; J Hachicha¹¹Hedi Chaker University Hospital, Nephrology, Sfax, Tunisia; ²Hedi Chaker University Hospital, Cardiology, Sfax, Tunisia

Introduction: Hypertension (HTN) is the second leading cause of end-stage renal disease (ESRD), and it present in up to 90% of ESRD patients irrespective of the etiology of kidney disease. Blood Pressure (BP) exhibits continuous variation during the day and the night, as a result of complex interactions between environmental, behavioral, and endogenous factors. Data derived from ambulatory BP monitoring (ABPM) allow better characterization of BP during everyday activities and sleep, and most importantly, better correlate with target organ damage, cardiovascular disease (CVD) risk, and long term patient prognosis than clinic BP.

Purpose: The aim of our work is to define the role of ABPM in hemodialysis (HD) patients and assess correlation of the results with the echocardiographic data.

Methods: The study has a cross-sectional design. We enrolled 17 patients from a single HD unit undergoing thrice weekly HD. We performed ABPM for 48 hours (day of dialysis (D1), day followin dialysis (D2)) in all patients. using an appropriately sized cuff, ABPM was recorded every 20 min during the day (6 a.m. to 10 p.m.) and every 30 min during the night (10 p.m. to 6 a.m.); using a BRAVO 24 HRABP SUN TECH MEDICAL MODEL 222-B properly calibrated and validated; in the non access arm. Dialysis unit BP recordings measured by the dialysis unit staff before and after dialysis were collected prospectively at the time of the patient visit. Two-dimensionnal- guided M-mode echocardiograms were performed 30 min before and 30 min after HD.

Conclusion(s): Our study confirms the high prevalence of BP abnormalities at the ABPM in HD population. Not only ABPM helps in the diagnosis and categorization of HTN, but can also provide prognostic. We suggest that ABPM should become the norm for the diagnosis of HTN and prognostic evaluation in chronic HD population.

Results: According to the collected BP before HD, 4 (23.5%) patients had HTN, against 10 (58.8%) according to the measure taken after HD. According to ABPM, we defined 4 categories of BP: 5 (29.4%) patients were normotensive, 4 (23.5%) were with sustained HTN, 4 (23.5%) with masked HTN and 4 (23.5%) with white-coat HTN. Systolic BP of 48 H correlated significantly with pre and post dialysis BP ($p < 0.05$). Pulse pressure (PP) of 48 H correlated significantly with pre and post dialysis BP ($p < 0.01$). The study of the variation of nocturnal BP objectified a dipper profile in 3 cases (17.6%), non-dipper in 12 cases (70.6%), inverted-dipper in 2 cases (11.8%). No cases of hyper-dipper was identified. Three patients (17.6%)

had echocardiographic left ventricle after HD from $318.41 \text{ g/m}^2 \pm 71.21$ to $261.95 \text{ g/m}^2 \pm 86.56$ ($p = 0.002$).

HFpEF – HEART FAILURE WITH PRESERVED EJECTION FRACTION

P2085

Association of Serum liver enzymes with E/Em ratio in patients with heart failure preserved ejection fraction (HFpEF)F Vakilian¹; DR FE Ghaderi¹; SOH Kasraee¹¹Mashad University of Medical Sciences, Cardiology Department, Mashad, Iran (Islamic Republic of)

Background: Prior studies have suggested the use of biomarkers that show diverse biological processes in systolic heart failure. Whether this can be applied for diastolic heart failure is unknown. In this prospective cross sectional study, we evaluated the relation of serum liver enzyme with echocardiography parameters in heart failure preserved ejection fraction (HFpEF) ($\text{EF} \geq 45\%$) and being compared with reduced ejection fraction (HFrEF).

Methods: Serum alanine transferases, aspartate transaminase, total and direct bilirubin were measured in 100 patients with stable chronic heart failure. Mean age of patients was 59.82 ± 14.35 (60% women, 48% HFpEF). There was no significant difference in liver function test in two groups. Transthoracic echocardiography was done in the same day. Association of a few echocardiographic systolic and diastolic indices with laboratory data was assessed.

Results: Similarly to past studies, we found significant relation between liver function test and echocardiography parameters in HFrEF (P value: 0.002). In HFpEF, while there was no significant relation of total and direct bilirubin to echocardiography parameters except we found significant correlation of serum transaminases with E/Em (P value: 0.02).

Conclusion: Liver dysfunction is not uncommon in HFpEF and is related to severity of systolic and diastolic dysfunction based on echocardiography findings. However, it is just E/Em ratio in significant relation to liver enzymes in HFpEF.

Table 1

	ESV(ml)	LVEDD(cm)	E/Em(ratio)	LAVI(ml/m ²)
ALT	0.24	0.6	0.02	0.84
AST	0.28	0.6	0.05	0.37

P2086

The relationship between arterial stiffness and left ventricular ejection fraction in heart failure.K Koji Takagi¹; N Sato¹; S Ishihara¹; W Shimizu²¹Nippon Medical School Musashi-Kosugi Hospital, Department of Internal Medicine and Cardiology, Kanagawa, Japan; ²Nippon Medical School, Department of Internal Medicine and Cardiology, Tokyo, Japan

Backgrounds: Heart failure (HF) is pandemic with high morbidity and mortality, and also is becoming a worldwide economic burden. Although many studies has been conducted to identify characteristics of patients with HF with reduced ejection fraction (HFrEF), characteristics and pathophysiologic features of patients with HF with preserved ejection fraction (HFpEF) remain unclear. Hypertension and diabetes mellitus are the most important risk factors for developing HFpEF, comprehensive risk factors are still lacking. Cardio-ankle vascular index (CAVI) has been widely applied to assess arterial stiffness in patients with known cardiovascular diseases. Therefore, we investigated the relationship between CAVI and several parameters of HFpEF.

Methods: We enrolled consecutive 108 patients who were hospitalized for acute heart failure and examined CAVI from April 2013 to March 2015. We excluded patients with atrial fibrillation, aortic regurgitation and also excluded the patients whose ankle brachial index was less than 0.9, because these patients' CAVI are unreliable. We defined the patient whose left ventricular ejection fraction (LVEF) was less than 40 as HFrEF, and the patient whose LVEF was more than 40 as HFpEF. Since CAVI is influenced by age and sex, we calculated CAVI using by regression formula as follows, $\text{CAVI} = 5.43 + 0.053 \times \text{age}$ for men, and $\text{CAVI} = 5.34 + 0.049 \times \text{age}$ for women (J Atheroscler Thromb 2011; 18: 924-938). We divided CAVI into three groups as follows, measured CAVI minus calculated CAVI is less than -0.5 are low

CAVI, is between -0.5 and +0.5 are matched CAVI and more than 0.5 are high CAVI.

Results: There is no differences in age (73 ± 11 , 72 ± 15), sex (male: 57.4%, 74.5%), serum Creatinine (0.99 ± 0.21 , 1.12 ± 1.6), serum potassium (4.22 ± 0.70 , 4.35 ± 0.59) between HFpEF and HFREF. Calculated CAVI was significantly higher in HFpEF compared with HFREF ($10.1[9.0-10.6]$, $9.3[8.28-10.38]$, $p=0.03$). There was statistically significant difference in LVEF between low CAVI and high CAVI ($31.5\%[22.0-50.0]$, $47.5\%[31.5-60.0]$, $p=0.03$).

Conclusion: Thus, the present study demonstrated that CAVI was closely related to HFpEF, suggesting that arterial stiffness might be involved in the development of HFpEF.

P2087

Relationship between left ventricle geometry and disorders of glucose metabolism in patients with heart failure with preserved ejection fraction

A Furman-Niedziejko¹; K Bury¹; K Golinska-Grzybala¹; M Wilczynska-Golonka¹; J Zalewski¹; J Nessler¹

¹Institute of Cardiology, Jagiellonian University, John Paul II Hospital, Dept of Coronary Disease, Krakow, Poland

Background: There are four types of left ventricular (LV) geometry: normal, concentric remodeling, eccentric hypertrophy and concentric hypertrophy. It has been shown that abnormal LV geometry significantly increase the risk of cardiovascular events. The most unfavorable prognostic implications are associated with concentric hypertrophy. Diabetes and prediabetes are also important risk factors of cardiovascular disease. Little is known about the association between disorders of glucose metabolism and LV geometry changes in patients with heart failure with preserved ejection fraction (HFPEF).

Purpose: The aim of this study was to evaluate the relationship between LV geometry and incidence of diabetes (DM) and prediabetes (PD) in patients with HFPEF.

Methods: 443 consecutive pts were enrolled based on HFPEF diagnosis. The pts were divided into two groups depending on disorders of glucose metabolism diagnosis: group A – 175 pts with DM or PD (118 M, mean age 64.3 ± 11.0 yrs), group B – 268 without DM or PD (189M, mean age 61.8 ± 10.9 yrs). LV function and structure parameters were analyzed based on transthoracic echocardiography. LV mass (LVM) was calculated from Devereux-Reichek formula, and LV mass index (LVMI) was calculated as the LVM divided by height to the power of 2.7. LV relative wall thickness (RWT) was calculated as diastolic intraventricular septal dimension (IVD) divided by LV diastolic dimension, both measured in the parasternal long axis.

Results: We found that the groups A and B were significantly different in respect to interventricular septum diastolic dimension-IVD (12.5 ± 2.5 vs. 11.6 ± 2.3 mm, $p=0.0001$), LVM (279 ± 101 vs. 257 ± 80 g, $p=0.009$), LVMI (69 ± 24 vs. 62 ± 18 g/m^{2.7}, $p=0.0007$) and RWT ratio (0.50 ± 0.13 vs. 0.47 ± 0.12 , $p=0.005$), as well as BMI (29.9 ± 4.7 vs. 26.9 ± 3.8 kg/m², $p<0.0001$) and waist circumference (103 ± 12 vs. 95 ± 11 cm, $p<0.0001$). Furthermore in the entire study population we found significant correlation between the level of blood glucose at admission and IVD ($r=0.14$, $p<0.05$), LVMI ($r=0.10$, $p<0.05$) and RWT ($r=0.10$, $p<0.05$). There was also association between waist circumference and LVMI ($r=0.28$, $p<0.001$).

Conclusions: The presence of glucose metabolism disorders in patients with HFPEF is associated with septal hypertrophy and increased LV mass and consequently may lead to LV concentric hypertrophy development.

P2088

Baseline hemodynamic characteristics of patients in the REDUCE elevated left atrial pressure in patients with heart failure trial

Corvia Medical Inc.

Nieuwegein, Netherlands; ⁶Medical University of Vienna, AKH – Vienna, Cardiology Clinic, Vienna, Austria; ⁷Auckland City Hospital, Auckland, New Zealand;

⁸University Hospital of Nantes, Nantes, France; ⁹The Alfred Hospital, Melbourne, Australia; ¹⁰Georg-August University, Göttingen, Germany

Introduction: Treatment of patients with heart failure with preserved ejection fraction (HFpEF) is challenging since there are no effective evidence-based therapies. While the underlying pathophysiology is complex, multifactorial and potentially variable between patients, an elevated pulmonary capillary wedge pressure (PAWP), particularly during exercise, is considered a key contributor to morbidity and exercise intolerance in all patients with HFpEF. The REDUCE LAP-HF trial is investigating the safety and effects of an interatrial septal shunt device designed to reduce left atrial pressure.

Purpose: The purpose of this study was to characterize the hemodynamic responses to exercise at baseline in patients upon enrollment into the REDUCE LAP-HF trial, with particular emphasis on changes in PAWP, central venous pressure (CVP) and their difference; it is the PAWP-CVP difference that would be the driving force for flow through an interatrial device to reduce PAWP.

Methods: Patients with HFpEF, as defined by LV ejection fraction (EF) $\geq 40\%$, New York Heart Association (NYHA) class II-IV, PAWP ≥ 15 mmHg at rest or ≥ 25 during supine bike exercise, and CVP < 15 mmHg at rest, were eligible for participation in this study. Pressures and cardiac outputs (CO, by thermodilution) were measured via standard right heart catheterization at rest and during symptom-limited supine bike exercise. All tests were read at a central core laboratory.

Results: 64 patients qualified for the study. Mean age was 69 ± 8.3 years and 65% were female. Patients exercised for an average of 7.3 ± 3.1 minutes to 42.5 ± 18.3 Watts with an increase of heart rate from 69.3 ± 14.4 to 95.8 ± 18.4 bpm and an increase of CO from 5.5 ± 1.6 to 8.7 ± 2.6 L/min. CVP increased from 9.0 ± 3.6 to 17.6 ± 5.8 mmHg and PAWP from 17.4 ± 5.2 to 34.3 ± 7.4 mmHg. Consequently, the PAWP-CVP difference increased from 8.3 ± 4.1 mmHg at rest to 16.7 ± 6.5 mmHg at peak exercise. All differences listed above were significant at $p < 0.001$.

Conclusion: HFpEF patients qualified for the REDUCE LAP-HF study exhibited marked increases in both PAWP and CVP during supine bicycle exercise. PAWP increased approximately twice as much as CVP so that the PAWP-CVP pressure gradient (the driving force for flow through an interatrial shunt) increased significantly. This suggests that the hemodynamic impact of such a shunt device would be significantly greater during exercise than at rest. Results of repeat hemodynamic exercise testing 6 months following shunt implant in these patients will elucidate the degree of PAWP reduction by this approach as well as its impact on exercise tolerance and morbidity.

GENE AND CELL THERAPY

Re-do cell base therapy in patients with chronic coronary artery disease

A Nemkov¹; B Afanasiev¹; S Bely¹; JU Nesteruk¹; V Lukashenko¹; V Komok¹; N Bunenkov¹; E Babenko¹; A Kalenichenko¹

¹St-Petersburg State Pavlov Medical University, St-Petersburg, Russian Federation

Background: Cell base therapy is a promising strategy for treatment of non-operable patients with coronary artery disease. Little is known about re-do cell base therapy in patients with chronic heart disease.

Purpose: Assessment of repeated administration of bone marrow cells in patients with chronic coronary artery disease 3-5 years after the first procedure.

Methods: Within 2003-2013 years 215 patients with non-operable coronary artery disease received cell based therapy - intracoronary administration of bone marrow cells. 15 of them had received the same re-do procedure 4-5 years later. Clinical observation, echocardiography (Echo-CG), single photon emissive tomography (SPECT) investigation were performed during 3 years after re-do procedure. Quality of life was assessed by SF36.

Results: 2 pts died during follow up (1 year and 2 year later). Functional improvement (decreasing of angina pectoris) noted 60% of patients 3-9 months after re-do procedure. Transplantation of bone marrow cells was associated with increasing in myocardial perfusion by SPECT at 12-month of follow-up. Echo-CG parameters did not change significantly, but patients with low ejection fraction had tendency to improving them during follow up. Coronarography revealed stable atherosclerotic damages in coronary arteries and increasing collateral blood flow.

Conclusion: Re-do intracoronary administration of bone marrow stem cells may be useful procedure in patients with non-operable coronary artery disease.

P2090

Gene polymorphism of beta receptors in patients with chronic heart failure

U Umida Kamilova¹; T Alieva²

¹Republican specialized scientific-practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan; ²Tashkent medical academy, Tashkent, Uzbekistan

Purpose: To examine of adenylate cyclase activity and gene polymorphism of beta (β) receptors in patients with chronic heart failure (CHF).

Methods: 72 male patients at the age of 40 to 55 years old with postinfarction cardio sclerosis (PICS) have been examined. All patients were divided into two groups: 1st group included 35 patients with CHF II FC and 2nd group included - 37 patients with CHF III FC by NYHA classification. Activity of adenylate cyclase erythrocytes was assessed by Solomon method (1979). Genetic typing was conducted by method of polymerase chain reaction (PCR).

Results: Initial density of erythrocyte beta2-adrenal receptors at patients with II FC CHF making up 27.7 ± 1.4 conventional units, while at patients with III FC CHF this index making up 30.8 ± 1.3 conventional units. ($P < 0.001$). At patients with II FC CHF basal activity of adenylate cyclase made up 4.15 ± 0.14 pmol/mg/min, with III FC CHF 3.56 ± 0.13 pmol/mg/min against 6.1 ± 0.19 pmol/mg/min of control group. At genetic typing it was noted that the most expressed reduce of basal activity was revealed in group Gly389 homozygote in comparison with group Arg389.

Conclusions: At CHF patients, in group of Gly389 homozygotes more expressed failures of adenylate cyclase system activity have been noticed.

S Roura¹; A Revilla³; JA San Roman³; C Galvez-Monton¹

¹Germans Trias i Pujol Health Sciences Research Institute, Badalona, Spain;

²Germans Trias i Pujol University Hospital, Badalona, Spain; ³University Hospital Clinic of Valladolid, Valladolid, Spain

Background: The present study evaluates the safety and efficacy of the Adipose Graft Transposition Procedure (AGTP) as a biological regenerative innovation for patients with a chronic myocardial scar. The adipose tissue surrounding the heart and pericardium may serve as an autologous biological matrix for salvaging this injured myocardium, as experiments in porcine models have suggested.

Methods: This prospective, randomized single-centre controlled study included 10 patients with established chronic transmural myocardial scars. Candidates for myocardial revascularization were randomly allocated into two treatment groups. In the control arm ($n=5$), the revascularizable area was treated with CABG and the non-revascularizable area was left untouched. Patients in the AGTP-treated arm ($n=5$) were treated with CABG and the non-revascularizable area was covered by a biological adipose graft. The primary endpoint was the appearance of adverse effects derived from the procedure including hospital admissions and death, and 24-hour Holter monitoring arrhythmias at baseline, 1 week, and 3 and 12 months. Secondary endpoints of efficacy were assessed by cardiac MRI.

Results: No differences in safety were observed between groups in terms of clinical or arrhythmic events. On follow-up MRI testing, participants in the AGTP-treated arm showed a borderline smaller left ventricular end systolic volume (LVESV; $p=0.09$) and necrosis ratio ($p=0.06$). The AGTP-treated patient with the largest necrotic area and most dilated chambers experienced a noted improvement in necrotic mass size (-10.8%), and ventricular volumes (LVEDV: -55.2 mL and LVESV: -37.8 mL at 1 year follow-up) after inferior AGTP.

Conclusions: Our results indicate that AGTP is safe and may be efficacious in selected patients. Further studies are needed to confirm its clinical value. (NCT01473433, AdiFlap Trial). Legend: Pericardial adipose tissue dissected and transposed onto the infarct.

Table 1

	AGTP-treated	Control				
	Baseline	3 mo.	12 mo.	Baseline	3 mo.	12 mo.

Impact of regional wall motion abnormality on myocardial infarction with mild cardiac troponin elevation is different according to the degree of left ventricular dysfunction

J Y Jae Yeong Cho¹; K H Kim¹; H J Yoon¹; Y Ahn¹; M H Jeong¹; J G Cho¹; J C Park¹; Y J Kim²; M C Cho³; H S Kim⁴

¹Chonnam National University Hospital, Cardiology, Gwangju, Korea Republic of;

²Yeungnam University Hospital, Daegu, Korea Republic of; ³Chungbuk National

University Hospital, Cheongju, Korea Republic of; ⁴Seoul National University

Hospital, Seoul, Korea Republic of

Background: Echocardiographic evaluation of regional wall motion abnormality (RWMA) is frequently performed in routine practice especially when cardiac enzyme elevation is indeterminate. We aimed to investigate whether RWMA in this patients have an impact on clinical outcomes in this category of patients.

Methods: Between November 2005 and August 2013, a total of 2,124 patients (64.7 ± 12.2 years, 1,371 males) with non-ST-segment elevation myocardial infarction enrolled. Patients were divided into two groups according to regional wall motion score (RWMS) [Group I ($n=598$): RWMS ≥ 24 , Group II ($n=1,526$): RWMS < 24]. Primary endpoint was composite of major adverse cardiac event (MACE) at 1 year. MACE was comprised of death, non-fatal myocardial infarction, stent thrombosis, target lesion revascularization, and target vessel revascularization. Cut off value of 24 points for MACE was defined by receiver operating characteristics (ROC) curve analysis (AUC: 0.586, $p < 0.0001$).

Results: There were no differences in baseline characteristics between the two groups except older age in group I (70.1 ± 12.2 vs. 66.3 ± 11.7 , $p < 0.0001$) and more males in group II (59.7% vs. 66.2% , $p=0.005$). Also medical histories such as hypertension, diabetes, and smoking showed no significant differences. However, left ventricular ejection fraction (LVEF) was significantly lower in group I than in group II ($44.3 \pm 11.3\%$ vs. $56.7 \pm 10.0\%$, $p < 0.0001$). Subgroup analysis was performed according to LVEF ($EF \geq 40\%$ vs. $EF < 40\%$). In-hospital mortality was different between groups regardless of LVEF ($EF \geq 40\%$: 2.0% vs. 1.1% , $p < 0.0001$, $EF < 40\%$: 8.1% vs. 5.8% , $p=0.025$). Group I showed significantly more 1-year MACE when LVEF $\geq 40\%$ (7.7% vs. 6.4% , $p=0.001$). When $EF < 40\%$, however, there was no difference in MACE between Group I and II (16.9% vs. 15.1% , $p=0.228$).

Conclusion: RWMA in NSTEMI patients with mild cardiac troponin elevation may predict higher in-hospital mortality regardless of LVEF, but could predict adverse long-term MACE only in preserved EF not in low EF.

P2093

Myocardial mechanics within 24 hour after successful reperfusion in acute ST segment elevation myocardial infarction are still compromised even in normal left ventricular ejection fraction

EJ Cho¹; JJ Kim¹; BH Whang¹; DB Kim¹; SW Jang¹; HK Jeon¹

¹Catholic University of Korea, Cardiology division, Seoul, Korea Republic of

Purpose: The necrotic phase of myocardial infarction, of which dominant pathologic processes are inflammation and necrosis, begins within a few hours and lasts for few days after ischemia. The myocardial mechanics during this critical period are still poorly understood. We aimed to evaluate myocardial mechanical alternation during necrotic phase of acute ST segment elevation myocardial infarction (STEMI) within 24 hour after successful primary percutaneous coronary intervention (PCI)

Methods: Total 33 acute STEMI patients were enrolled [age = 52 ± 17 years, 27 male (82%)] and compared with 28 normal control group of age and sex matched

[age=53±12 years, 23 male (82%)]. Primary PCIs were done to all subjects within 90 minutes of emergency room (ER) arrival to balloon inflation times to culprit lesions. Myocardial mechanics were measured using speckle tracking image on transthoracic echocardiography (TTE) examination within 24 hour of successful primary PCIs and compared with normal subjects.

Results: Averaged time duration from onset of chest pain to ER arrival time was 313.4±154.2 minutes and pain to balloon inflation time was 78.8±42.1 minutes. Cardiovascular risk factors were hypertension (n=18, 54.5%), diabetes mellitus (n=6, 18.2%), smoking (n=23, 69.7%) and family history (n=6, 18.2%). Culprit coronary lesions were left main (n=2), proximal left anterior descending (px LAD, n=13), mid LAD (n=7), px left circumflex artery (n=2), px right coronary artery (px RCA, n=4) and mid RCA (n=5). On the TTE examination, mean left ventricular ejection fraction (EF) was 56.6 ± 18.2 %. Left ventricular mechanics of global longitudinal strain (-16.2 vs. -23.2%, p<0.001), global circumferential strain (-15.3vs. -28.8%, p<0.001), Basal rotation (13.2 vs. 35.5°, p<0.001) and twist values (9.5 vs. 26.4°, p<0.001) in peak systolic periods were significantly lower than normal subjects.

Conclusion: Myocardial mechanical deteriorations in acute stage STEMI were still compromised within 24 hour after successful PCIs even with normal LV EF. Necrotic phase of myocardial infarction might on-going even after successful reperfusion and measurement of myocardial mechanic would provide comprehensive myocardial performances in this critical stage.

P2094

The added assessment of combined administration of carperitide and nicorandil for acute myocardial infarction patients with successful percutaneous coronary intervention

S Shinji Hisatake¹; S Kiuchi¹; T Kabuki¹; S Dobashi¹; T Oka¹; T Ikeda¹

¹Toho University, Department of Cardiovascular Medicine, Tokyo, Japan

Background: There are reports about validity of additional administration of carperitide or nicorandil for acute myocardial infarction (AMI) patients with successful recanalization therapy. However, there are no reports about efficacy of combined administration of both drugs.

Methods: Among 895 patients who hospitalized due to first-time AMI in the period between July 2008 and February 2015, sequent 80 patients who confirmed TIMI III by percutaneous coronary intervention (PCI) and gave consent became the subject of this study. The patients were divided into four groups; control group, low-dose(0.0125-0.025µg/kg/min) carperitide group, high-dose(0.05-0.2mg/kg/h) nicorandil group, and low-dose carperitide and high-dose nicorandil combined administration group. Immediately following PCI, each drug was continuously administrated for 72 hours and examined prospectively. We used left ventriculography to evaluate LVEF and LVEDVI, LVESVI at acute stage and at 6 months. Also we measured CPK at acute stage to proceed quantitative evaluation of myocardial infarction range.

Results: No significant difference was recognized in the time between onset of myocardial infarction and reperfusion, and the size of infarction in four studied groups. Also there were no significant differences in blood pressure and heart rate. Moreover, LVEF at chronic stage, LVEDVI and LVESVI were not significantly different between four groups.

Conclusion: There was no additional efficacy of combined administration of carperitide and nicorandil for AMI patients who succeeded revascularization by PCI at both acute and chronic stages.

P2095

Combined therapy of CAD accompanied by gastroduodenal pathology

Y Tarlovskaya¹; Z Simonova²; Y Balandina²

¹Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russian Federation;

²Kirov State Medical Academy, Kirov, Russian Federation

Purpose: To compare influence of gastroduodenal pathology therapy on clinical status of patients with angina pectoris stable.

Methods: 230 patients with angina pectoris stable, including 147 patients accompanied by gastroduodenal pathology H. pylori associated, were studied.

The patients were comparable according to age, sex and clinical status (p > 0.05). 67 (45.7%) patients of 147 has got duodenal ulcer, 29 (19.7%) - stomach ulcer, 51 (34.6%) - chronic gastritis, duodenitis.

The patients were divided in groups I, II or III.

Patients of group I (n=74) received basic therapy of angina pectoris stable and omeprazol/clarithromycin/amoxicillin. Patients of group II (n=63) - basic therapy and omeprazol. Patients of group III (n=93) - basic therapy of angina pectoris stable.

Results: Patients with CAD and gastroduodenal pathology have lower efficacy of nitroglycerin on anginal pain (60.5% versus 100%, X²=5.13, =0.024).

By the 24th week of treatment in group I the frequency of angina attacks decreased by 62.6 ± 4.2% (< 0.05). Weekly nitroglycerine consumption decreased by 70.4 ± 3.6% (p<0.01).

In group II the frequency of angina attacks decreased by 30.7 ± 4.6% (< 0.05), weekly nitroglycerine consumption decreased by 21.2 ± 5.6% (< 0.05).

In group III the frequency of angina attacks decreased by 29.5 ± 3.8% (< 0.05), weekly nitroglycerine consumption decreased by 44.1 ± 5.8% (< 0.05).

According to exercise tolerance test exercise tolerance increased from 72.5 ± 3.1 to 105.1 ± 6.1 W (p<0.01) (by 45.3 ± 3.2%, p<0.01) in group I, from 70.3 ± 2.1 to 89.1 ± 3.4 W (p<0.01) (by 26.5 ± 2.6%, p<0.01) in group II, from 110.4 ± 5.5 to 124.5 ± 2.8 W (p<0.001) (by 12.7 ± 3.8%, p<0.01) in group III.

In group I H.pylori eradication effectiveness was 95.9%. In group II occurred spontaneous eradication in 3.4% patients.

The relapse rate of gastroduodenal pathology within 24 weeks of observation in group I was 5.4%, in group II - 39.7% (c²=20.41, < 0.001).

Conclusions: The inclusion of eradication therapy in treatment for CAD patients accompanied by gastroduodenal pathology, associated with Helicobacter pylori, provides a quick reduction of dyspeptic disorders and an angina syndrome stabilization.

P2096

Clinical expression of acute myocardial infarction with and without ST segment elevation in a specific population

C Catia Costa¹; D Durao¹; M Leal¹

¹Hospital of Santarem, Cardiology, Santarem, Portugal

Introduction: Acute myocardial infarction (AMI) with and without ST segment elevation differs in clinical expression; these differences can be more prominent in some subgroups of patients.

Aims: Assess the differences between AMI with (STEMI) and without ST segment elevation (NSTEMI) in a specific population of women with an ejection fraction (EF) lesser than 40% (EF<40%).

Methods: Retrospective study, including 533 women with AMI and an EF<40%. The population was divided in two groups: A, including patients with NSTEMI (n=251); B, including patients with STEMI (n=282). Differences between groups were evaluated regarding the clinical profile.

Results: Group A was older than B, had more prevalence of comorbidities as hypertension, diabetes, dyslipidemia, chronic kidney disease and history of stroke (p<0.05) and higher prevalence of previous history of AMI, percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG) (p<0.001). Regarding reperfusion therapy (RT), CABG was more prevalent in group A and PCI in group B; the absence of RT was more prevalent in group A (p<0.001). Group B had more complications during hospital stay, namely cardiogenic shock, ventricular tachycardia and hospital death (p<0.05).

Conclusions: In this registry of patients with AMI and an EF<40%, patients with NSTEMI were older, had more comorbidities and were less treated with RT, similar to general population. Despite the reduced EF of both groups, patients with STEMI had higher hospital complications and mortality. This shows that the intrinsic pathophysiological process of the two types of AMI persist even when considering subsets of patients with particular characteristics.

P2097

Revascularisation of patients with acute myocardial infarction without ST segment elevation and an ejection fraction lesser than 40%, without high or very high risk criteria

C Catia Costa¹; D Durao¹; M Leal¹

¹Hospital of Santarem, Cardiology, Santarem, Portugal

Introduction: An ejection fraction (EF) lesser than 40% (EF<40%) constitutes a criteria for invasive stratification of patients with acute myocardial infarction (AMI) without ST elevation (NSTEMI) within the first 72h after hospital admission, if there are no more severe criteria requiring urgent coronary angiography (CA).

Aims: 1) Characterize a population with NSTEMI and an EF<40% in relation to the time interval to CA; 2) compare groups regarding their characteristics and prognosis.

Methods: Retrospective study, including 220 patients with NSTEMI and an EF<40%, without high or very high risk criteria for invasive stratification. The population was divided in three groups: A, patients that didn't perform CA (16.4%); B, patients who underwent CA in the first 72h of hospital admission (78.6%); C, patients who underwent CA after the first 72h (5.0%). Groups were compared regarding their characteristics.

Results: Group A had more prevalence of previous history of AMI and percutaneous coronary intervention (p<0.02). Group C had more signs of congestive heart failure (CHF), was treated with more diuretic therapy and non-invasive ventilation and had higher hospital duration of stay (p<0.05). Group B corresponded to the majority of patients. They had similar characteristics to group C, but had lesser signs of CHF (p0.002). There weren't differences between groups regarding death.

Conclusions: The majority of patients with EF<40% performed diagnostic CA within the first 72h recommended. Patients that didn't undergo CA had higher prevalence of known ischemic cardiomyopathy. The timing difference of CA between patients

who performed it was determined by the heart failure decompensation degree; however, this wasn't associated with differences in mortality.

P2098

Predictors of mid-term clinical outcome of patients treated for acute coronary syndrome

M Marija Vavlukis¹; B Pocašta¹; H Taravari¹; E Shehu¹; I Kotlar¹; F Janusevski¹; F Taneski¹; S Kedev¹

¹University Clinic for Cardiology, Skopje, Macedonia The Former Yugoslav Republic of

Aim of the study was to identify frequency, type of events and predictors of mid-term outcome in patients treated for acute coronary syndrome (ACS).

Methods: patients with ACS, were subjected to analyze with variables as: age, gender, risk factors, SBP and HR during ACS, type of MI, location, CAD severity, LV function, type of treatment, in-hospital morbidity, medications post discharge, type and time to event. Statistical analyze: descriptive and comparative analyze, uni and multivariate regression analyze, Caplan-Meier event free survival analyze.

Results: 269 patients treated for ACS, at mean age 63.1 ± 11.1 y., 176(65,4%) males and 93(34,6%) females, were followed up for mean 20.1 ± 10.2 months. A total of 69 cardiac events (CE) in 68(25,3%) patients during the 269pts./446 y. follow up were registered, 8(3%) of which cardiac deaths (CD). Ischemic events were the most frequent (40-14,9%): angina-10(3,7%), scheduled revascularization after ACS because of multivessel CAD-19(7,1%), and acute ischemic event leading to re-revascularization-11(4,1%) pts. Symptomatic heart failure-13(4,8%) pts. leading to CD in 5, 3(1,1%), ischemic CVI with one fatal event, atrial arrhythmias in 6(2,2%) and malignant ventricular arrhythmias in 4(1,5%) pts. one with fatal ending, and one sudden CD. 42(61,7%) out of 68 events occurred during the first 6 months after the ACS. Univariate predictors were: DAPT(dual antiplatelet treatment) after ACS: beta -2,369, $p=0,002$, exp(B) 0,094; EF(%): beta -0,062, $p=0,037$; age: beta 0,036, $p=0,022$; NSTEMI: beta 2,360, $p=0,005$, exp(B) 10,385; anemia: beta 1,192, $p=0,012$, exp(B) 3,293, and initial heart rate during ACS: beta 0,024, $p=0,005$. Multivariate analyze (logistic regression), identified four significant independent predictors: NSTEMI exp(B): 5,386, $p=0,056$; anemia: exp(B) 1,526, $p=0,024$; age: beta 0,040, $p=0,052$, and DAPT: beta -2,682, $p=0,002$, exp(B) 0,068;

Conclusion: being at advanced age, having NSTEMI MI and anemia during ACS, are independent negative predictors, while DAPT treatment was positive predictor of mid-term outcome after ACS. In terms of type of event, ischemic events predominated, especially in the first 6 month, leaving symptomatic heart failure fare behind.

P2099

Acute coronary dissection in a woman, due to emotional stress, presenting initially with a normal electrocardiogram and minimal elevation of troponin and causing an acute coronary syndrome.

P Zaglavira¹; N Karanikolas²; K Zabelis¹; G Bokos¹; P Tzevelekos¹; G Anagnostou¹; F Aivalioti¹; Z Karamigou¹; I Rentoukas¹; S Lympri¹

¹Sotiria Regional Chest Diseases Hospital, cardiology department, Athens, Greece;

²Sismanoglion Hospital, Cardiology, Athens, Greece

Introduction: Our case-report discerns an acute coronary syndrome after emotional stress, with no predisposing factors for coronary artery disease (CAD) and with subtle initial laboratory findings. The acute coronary syndrome turned out to be due to coronary dissection.

Purpose: Our report aims to show that low initial probability of CAD and subtle laboratory findings should not be the only clues to be evaluated when deciding about the hospitalization of a patient and subsequently the procession to coronary angiography.

Methods: The patient was a woman 65 years old, which presented with intense chest pain and dyspnea after a strong emotional stress. She had a normal electrocardiogram, a normal echocardiogram and a minimal troponin elevation in the grey zone area. She was hospitalized in the cardiac intensive care unit and antiischemic treatment was initiated. The symptoms had a clinical remission for three days and the troponin was stable for these days. But afterwards she had again intense chest pain and dyspnea with profound electrocardiographic changes, significant elevation of troponin, elevation of BNP and mild hypokinesia of the lateral wall. The patient underwent an urgent coronary angiography.

Results: Coronary angiography has shown acute coronary dissection at the circumflex coronary artery (at a distal site). No significant coronary artery stenosis was observed. No other intervention was undertaken and the patient was managed conservatively and stabilized. Nitrates, b-blockers, double antiplatelet treatment and mild diuresis was the mainstay of treatment. Tests for autoimmune diseases (arteritis etc) were negative. There were not indications for connective tissue metabolism disorders. Finally, the patient was discharged with a directive for frequent cardiologic evaluation, antiischemic treatment, and avoidance of emotional and physical stress.

Conclusions: The clinical picture and triggering factors, and not only the initial probability of CAD and laboratory findings, should be evaluated when deciding about hospitalization. The severity of symptoms should prompt us to careful and thorough follow up. Subtle initial laboratory findings may be due to small initial expansion of the dissection which subsequently became larger. It also should be noted that circumflex coronary artery ischemia, if distal, may not give electrocardiographic findings. Emotional stress causes not only tako-tsubo cardiomyopathy but also coronary artery dissection. Acute coronary dissection is a rare entity but should always be in our diagnostic armamentarium even after emotional stress.

Preamplified real-time RT-PCR analyses of endomyocardial biopsies by T-PreAmp

M Noutsias¹; P Schlattmann²; CV Pohl¹; T Kretschmar¹; VP Patil³; L Seres-Sturm¹; PC Schulze¹; B Horvath¹

¹University Hospital Jena, Department of Cardiology, KIM I, Jena, Germany;

²Institute of Medical Statistics, Friedrich-Schiller University Jena, Jena, Germany;

³Philipps University of Marburg, Genetics, Marburg, Germany

Background: Low RNA amounts and low expression of certain target genes limit conventional real-time RT-PCR analyses of endomyocardial biopsies (EMB). A novel T-preamplification technique (T-PreAmp) enables a robust PreAmp of multiple target genes (> 92 gene assays), by a mean Ct improvement around 7 cycles, and with a low inter- and intra-assay variance (<5%), with multiple advantages compared to the SSRT (sequence specific reverse transcription) preamplification technique.

Purpose: Systematic evaluation of publications on the establishment and application of T-PreAmp in EMB.

Results: Our literature survey identified 19 publications applying the T-PreAmp protocol. The T-PreAmp has been applied to cell cultures, blood cells, snap frozen and paraffin embedded tissues. In EMB, CDKN1B was ascertained as a novel housekeeping gene for myocardial tissues. T-PreAmp in EMB revealed a significant association between the immunohistological proof of DCMi and the expression of CD3d, CD3z and of the constant T-cell receptor beta region (TRBC). The criterion of significantly increased TRBC or CD3d expression was associated with differential expression of several T-cell related genes, cytokines, and genes involved in extracellular matrix (ECM). The quantification of functional T-cell markers revealed significantly increased expression of Th1- and CTL-specific genes, while genes indicating regulatory and anergic T-cells were not differentially expressed. Differential TRBV dominances in human DCMi have been associated to the PCR proof of various viral genomes. In a patient presenting with acute myocarditis and parvovirus B19 (B19V) viremia, TRBV11 dominance was identified in the peripheral

blood monocytes (PBMC), with Th1- and CTL-characteristic functional T-cell markers (i.e. T-bet, IFN, Perforin), whereas markers of regulatory T-cells were not differentially expressed.

Conclusions: T-PreAmp is a powerful tool for preamplification and robust expansion of comprehensive target gene expression analyses of EMB (up to 92 target genes per preamplification reaction). In gene expression analyses of EMB, the T-PreAmp technique elucidated a novel housekeeping gene for myocardial tissues (CDKN1B), and confirmed differential expression of several T-cell related genes, diverse cytokines identifying a dominance of Th1- and CTL-polarized immunity, and of ECM related genes, in EMB from DCMi-patients, while a "counter-balance" of regulatory T-cells was not discernible. The finding of virus-associated TRBV-dominance in EMB and PBMC indicates virus-induced proliferation of peptide-reactive T-cell populations, driven by viral antigen challenge.

P2101

Role of mitochondria in intraventricular conduction delay: association between TOMM40 polymorphism and left branch bundle block.

G Giuseppe Di Stolfo¹; S Mastroianno¹; D Seripa²; G Paroni²; C Gravina²; C D'ariento¹; G De Luca¹; DR Potenza¹; A Russo¹; R Fanelli¹

¹Scientific Institute Casa Sollievo della Sofferenza, Department of Cardiology, San Giovanni Rotondo, Italy; ²Casa Sollievo della Sofferenza Hospital, Geriatric and Gerontology Unit, San Giovanni Rotondo, Italy

Background: TOMM40 gene polymorphism (translocase of outer mitochondrial membrane 40) plays a critical role in mitochondrial dysfunction in Alzheimer's disease and cardiac preconditioning, by both impairing mitochondrial Ca²⁺ signaling and mtPTP (mitochondrial permeability transition pore) opening. At present only few investigations have explored polymorphism-related cardiac phenotype.

Objectives: The study aimed to examine the relationship between TOMM40 polymorphism and cardiac phenotype in patients affected by peripheral arterial disease.

Methods: TOMM40 polymorphism (rs2075650, AA and GX) were assessed in 198 consecutive patients, characterized for biochemical, electrocardiographic and echocardiographic parameters, traditional risk factors and history of myocardial infarction.

Results: We divided population in two groups, according to TOMM40 polymorphism (AA or GX), named AA group (165 pts) and GX group (33 pts). There was no difference between groups for the abovementioned factors, except for a greater prevalence of left bundle branch block (LBBB) in the GX group (χ^2 6.669, $p=0.010$); this difference persists also after correction for confounding factors.

Conclusions: This study showed an association between TOMM40 polymorphism and left branch bundle block, suggesting a role of mitochondria in intramitochondrial conduction delay.

Polymorphism Glu298Asp NOS-3 gene in patients with chronic heart failure

U Umida Kamilova¹; CHAROS Abdullaeva²

¹Republican specialized scientific-practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan; ²Tashkent medical academy, Tashkent, Uzbekistan

The purpose to study the features of polymorphism Glu298Asp NOS-3 gene in patients with chronic heart failure (CHF).

Methods: In patients with CHF 114 Uzbeks have been studied the genetic determinants of the development of endothelial dysfunction — alleles and genotypes Glu298Asp NOS-3 gene. The control group consisted of 75 healthy individuals — men of Uzbek nationality.

Results: Analysis of the distribution of genotypes Glu298Asp NOS-3 gene in patients with CHF showed: Glu/Glu — I in patients with CHF FC was 84.2% in patients with FC II — 70.4%, and FC III — 64.7% (Table 1). Glu/Asp genotype 3 patients met FC I — 15.3%, in 12 patients with FC II and —27.3% in 17 patients with FC III CHF —33.7%. In the group of healthy individuals Glu/Glu genotype occurred in 92%, Glu/Asp at 6.7%. Patients in the control group allele Glu was — 95.3%, and Alel Asp — 4.7%. Patients frequency vstechaemosti Glu — allele was distributed as follows: 92.1% in patients with CHF FC I, 84.1% in patients with class II and 81.4% in patients with FC III CHF.

Conclusions: Thus, the study of the distribution of alleles and genotypes Glu298Asp NOS-3 gene in patients with heart failure showed the progression of CHF depends on the polymorphism of this gene and gene Glu298Asp NOS-3 is effective prognostic markers.

Association of adrenomedullin and atrial natriuretic peptide with endothelial function and peripheral vascular resistance in heart failure subjects

E Economou¹; E Dimitropoulos¹; G Siasos¹; C Chrysoschoou¹; A Giannaki¹; E Zacharia¹; K Mourouzis¹; GA Papamikroulis¹; L Naar¹; D Tousoulis¹

¹University of Athens Medical School, 1st Cardiology Department, "Hippokraton" Hospital, Athens, Greece

Background: Adrenomedullin (ADM) is involved in vascular homeostasis and endothelial function. A-type natriuretic peptide (ANP) has potent diuretic, and vasodilating actions. Mid regional epitopes of these peptides (MR-proANP and MR-proADM) present increased plasma stability.

Purpose: To examine the association of MR-proANP and MR-proADM with indices of systolic and diastolic dysfunction in patients with chronic stable heart failure.

Methods: In this cohort study we enrolled 69 consecutive patients with stable chronic systolic heart failure in NYHA class 2 to 4. Endothelial function was evaluated by flow-mediated dilatation (FMD). Augmentation index (Aix) was measured as an index of arterial wave reflections. Serum levels of MR-proANP and MR-proADM were measured with ELISA.

Results: The mean age of the participant was 68 ± 10 years. In our study population there was no association between MR-proANP and MR-proADM with ejection fraction, while MR-proANP was associated with NYHA class ($\rho=0.24$, $p=0.04$). Importantly, we observe that MR-proADM was inversely associated with FMD ($r=-0.315$, $p=0.01$) and positively with Aix ($r=0.398$, $p=0.001$). However, MR-proANP was not associated neither with FMD ($r=0.03$, $p=0.8$) nor with Aix ($r=0.08$, $p=0.05$).

Conclusion: These findings confirm the different mechanisms involved in MR-proANP and MR-proADM secretion and revealed that MR-proADM is strongly associated not only with heart failure and ventricular filling pressures but also with endothelial function and peripheral vascular resistance.

Conclusion: These findings confirm the different mechanisms involved in MR-proANP and MR-proADM secretion and revealed that MR-proADM is strongly associated not only with heart failure and ventricular filling pressures but also with endothelial function and peripheral vascular resistance.

Mediterranean diet and erectile dysfunction

A Alexios Samentzas¹; D Papadimitriou¹; G Sionis¹; D Papasakakis¹; G Papagiannis¹; G Blazakis¹; P Stogiannos¹; V Mountaki¹; A Trikas¹

¹Elpis General Hospital, CARDIOLOGY, Athens, Greece

Introduction: Mediterranean Diet represents a way of life which combines longevity and a high quality of health. As far as the physiology of vessels is concerned, the application of this diet has shown that it can improve the good operation of the endothelium. The endothelial dysfunction is the main pathophysiological mechanism of the erectile dysfunction which influences dramatically the quality of life.

Purpose: We have studied the correlation between the Mediterranean Diet with the presence and rate of Erectile Dysfunction.

Methods: We studied 100 patients with Erectile Dysfunction without any history of cardiovascular disease (aged 52 ± 15 years) and 100 people without Erectile Dysfunction (test group), similar to age and danger factors. Erectile Dysfunction was evaluated based on the international questionnaire of sexual health (International Index of Erectile Dysfunction, IIEF). Low IIEF score shows severe Erectile Dysfunction. The degree of application of the Mediterranean Diet was found according to a special score (MED-DIET score, with a theoretic variation 0-55). High prices of this score show a great devotion to this kind of diet.

Results: Compared to the test group the patients with Erectile Dysfunction had considerably lower MED-DIET score ($P < 0.05$). All facts considered, MED-DIET score was positively related to erectile efficiency as this was expressed through IIEF score ($P < 0.01$). The relation of MED-DIET score with the IIEF score remained important as the age, the danger factors and the testosterone levels ($P < 0.05$) were examined.

Conclusion: This study showed that a poor, long-term application of the Mediterranean Diet has unfavorable effects on Erectile Dysfunction without taking into consideration the classic danger factors. A diet rich in fruit, pulses, vegetables, dried fruit and mainly olive oil combined with medium consumption of alcohol, especially between meals can be proven useful as far as the improvement of the vessels' functionality is concerned and also the erectile cardiovascular efficiency.

Dantrolene reduces cellular arrhythmogenic triggers in human atrial fibrillation and heart failure

S Steffen Pabel¹; N Hartmann¹; J Herting¹; TH Fischer¹; N Frey²; G Hasenfuss¹; S Sossalla¹

¹University Medical Center Gottingen (UMG), Dept. of Cardiology and Pneumology, Heart Center, Gottingen, Germany; ²University Medical Center of Schleswig-Holstein, Dept. of Internal Medicine III: Cardiology and Angiology, Kiel, Germany

Introduction: Cardiac type-2 ryanodine receptors (RyR2) play a pivotal role during excitation-contraction coupling. There is considerable evidence that abnormal, increased RyR2-mediated diastolic SR-Ca²⁺ release is linked to heart failure (HF) and arrhythmias such as atrial fibrillation (AF). Dantrolene (Dan), known as a drug for malignant hyperthermia, has been discussed to stabilize the cardiac RyR2. We thus aimed to investigate the effects of Dan on arrhythmogenic triggers and contractile function in human AF and HF myocardium.

Methods/Results: Human atrial cardiomyocytes (CM) were isolated from 7 patients with AF and left ventricular (LV) CM from 7 patients with end-stage HF. Functional measurements of SR Ca²⁺ leak were performed by confocal microscopy using Fluo-3 AM. In LV HF CM Dan (10 μM) caused a reduction of spark-frequency by 33 ± 16% ($p < 0.05$, n = 83 cells / 6 patients Dan vs. 94 cells / 6 patients control) leading to a reduction of the calculated diastolic SR-Ca²⁺-leak (frequency x width x duration x amplitude) by 76 ± 21% ($p < 0.05$, n = 83/6 vs. 94/6). Moreover, Dan decreased the frequency of Ca²⁺-waves and spontaneous Ca²⁺-transients by 52 ± 24% ($p < 0.05$, n = 102/6 vs. 109/6). The reduction of the arrhythmogenic diastolic SR-Ca²⁺-leak was further reproducible in atrial CM from patients with AF. Dan treatment in AF reduced the spark-frequency by 50 ± 19% ($p < 0.05$, n = 122/7 vs. 120/7) and the diastolic SR-Ca²⁺-leak by 56 ± 21% ($p < 0.05$, 122/7 vs. 120/7). Patch clamp experiments revealed that Dan abolishes cellular arrhythmogenic triggers (DADs and spontaneous APs) significantly in HF ($p < 0.05$ n = 16/7 vs. 19/7) and in AF ($p < 0.05$ n = 12/6 vs. 14/6). Importantly, Dan had no effect on action potential duration compared to control in AF and HF. The investigation of the effect of Dan on isometrically twitching muscle strips showed no significant alterations of systolic and diastolic force. Mean data of systolic force after drug-incubation was 5.6 ± 1.7 vs. 6.4 ± 2.8 mN/mm² for Dan and vehicle control, respectively (n.s., n = 5 each).

Conclusion: Dan beneficially altered calcium homeostasis in human HF and AF CM. Arrhythmogenic SR Ca²⁺ leak due to destabilized RyR2 was significantly decreased by Dan, and cellular arrhythmogenic triggers could be abolished. APD and contractility were not affected by Dan. Thus, Dantrolene as an already approved compound for malignant hyperthermia in men might be a potential antiarrhythmic compound for patients with AF and HF and merits clinical investigation.

Effects of atrial fibrillation on ventricular calcium cycling in human myocardium

German Research Foundation SFB 1002, Deutsche Herzstiftung e.V.

J Jonas Herting¹; N Hartmann¹; J Eiringhaus¹; S Pabel¹; G Hasenfuss¹; ST Sossalla¹; TH Fischer¹

¹Herzzentrum, Universitätsmedizin Göttingen, Göttingen, Germany

Atrial fibrillation (Afib) is the most common sustained arrhythmia, causing significant morbidity and mortality. In the atria it is associated with profound changes of cellular electrophysiology and Ca-handling. However, little is known about the effects of irregular heart rhythm itself on EC-coupling in the ventricle. This is of great relevance with regard to pathophysiological understanding and clinical treatment strategies. We isolated ventricular cardiomyocytes from patients with compensated cardiac hypertrophy (aortic stenosis) showing sinus rhythm (SiR) or persistent Afib (n = 4/4). Ca-cycling properties were investigated by epifluorescence microscopy (Fura2-AM). To our knowledge, these are the first measurements in this regard in human cells. Afib exhibited a tendency towards higher diastolic Ca-levels compared to SiR (B, n = 18/23, $P = 0.13$). The amplitude of systolic transients (0.5 Hz) was not altered (C, n = 18/23, $P = 0.41$), but elimination kinetics were slowed (D, RT 80, n = 17/22, $P < 0.01$) and the height of caffeine-induced Ca-transients was reduced in Afib (F, n = 12/12, $P < 0.05$) indicating a lower SR Ca-load. Elimination-kinetics of caffeine-induced Ca-transients were accelerated in Afib vs. SiR (G, RT80, n = 12/12, $P < 0.05$) suggesting increased NCX-activity. Conclusively, calculated SERCA2a-activity was diminished in Afib (H, n = 10/12, $P < 0.01$). Our findings have clear relevance as reduced SR Ca-load, SERCA2a-activity and increased NCX-activity are key-features of heart failure, but can obviously already be observed in patients with cardiac hypertrophy and Afib despite a still preserved ejection fraction. It may therefore be hypothesized that irregular ventricular excitation promotes pathologic alterations of Ca-homeostasis paving the way for contractile dysfunction and electric instability.

Pitx2 modulates atrial membrane potential, rendering atrial cells susceptible to antiarrhythmic drug treatment with sodium channel blockers

EUTRAF to PK, BHF to PK, Leducq Foundation to PK, PSIBS of UoB for TY to LF, DFG, and BIF fellowship to SMK
SM Kuhlmann¹; AP Holmes¹; F Syeda¹; TY Yu¹; S Tull¹; D Pavlovic¹; L Fabritz¹; P Kirchhof¹

¹University of Birmingham, Birmingham, United Kingdom

Purpose: Atrial fibrillation (AF) is common in heart failure patients and contributes to its morbidity and mortality, e.g. in tachycardia-induced cardiomyopathy. Common gene variants on chromosome 4q25, close to the PITX2 gene, predispose to AF, modify the response to antiarrhythmic drug (AAD) therapy, and alter left atrial PITX2 mRNA levels. We therefore studied how PITX2 modifies atrial electrophysiology and the response to AADs, making use of PITX2-deficient (Pitx2c^{-/-}) mice.

Methods: We assessed arrhythmias in isolated, perfused hearts, sharp electrode action potentials in superfused left atria, and sodium (INa) and potassium currents (Ito, IK1, IKACH) by whole-cell patch-clamp in isolated LA cells.

Results: Pitx2c^{-/-} left atria had shorter action potentials and a more positive resting membrane potential than WT ($P < 0.05$ (WT: -70.1 ± 0.7 mV, $n = 30$ cells. Pitx2c^{-/-}: -67.8 ± 0.7 mV; $n = 31$ cells)). Flecainide, but not sotalol, fully suppressed atrial arrhythmias in Pitx2c^{-/-} atria but not in WT, increasing post-repolarization refractoriness. INa amplitude or Nav1.5 channel expression were not different between genotypes. Different holding potentials affected INa equally in both genotypes at baseline and with flecainide (1 μ M), irrespective of genotype (Figure). Ito, IK1, or IKACH were not different in WT and Pitx2c^{-/-} LA (all $P > 0.2$). A comparable effect of LA holding potential (RMP) on the effect of flecainide was replicated in HEK cells expressing human Nav1.5 channels.

Conclusions: We identified a more depolarised resting membrane potential in mice with reduced PITX2c expression that markedly modulates the effects of sodium channel blockers. Our findings identify an altered resting membrane potential as an important modulator of antiarrhythmic drug efficacy.

P2109

The relation of atrial fibrillation to the severity of dyspnea in patients presenting to the emergency room

R Zeimaitė¹; V Juknevičius²; J Celutkienė²

¹Vilnius University, Vilnius, Lithuania; ²University Hospital Santariskiu Klinikos, Vilnius, Lithuania

Background/Introduction: Dyspnea is one of the most common symptoms presented by patients in the cardiac emergency rooms. As the etiology of dyspnea is multifactorial, from psychogenic causes to serious heart conditions, and the treatment stands upon eliminating the causing factor, various aspects should be considered when performing the differential diagnosis.

Purpose: We aimed to determine if the presence of atrial fibrillation (AF) is associated with the severity of dyspnea.

Methods: 151 consecutive patients admitted to the cardiac emergency room were included in the study. The inclusion criterion was dyspnea. Exploratory groups were defined based on cardiac rhythm at the time of admission: AF group and non-AF group and two subgroups regarding their heart rate (HR): moderate heart rate (MHR) group (HR < 90 beats per minute (bpm)) in AF group as well as in non-AF group and high heart rate (HHR) group (HR ≥ 90 bpm) accordingly in AF and non-AF groups. Patients were asked to fulfill the numerical and visual Borg dyspnea test charts in a scale from 1 to 10 points. Data was analysed using SPSS v23 statistical package. Independent samples T-test was used to compare the results amongst patient groups.

Results: Of 151 examined patients 68 (45%) were female and 83 (55%) male. 75 (49.7%) patients presented atrial fibrillation (tested by 12-lead electrocardiogram) at the time of admission, while 76 (50.3%) did not. Mean HR in AF group was 95.32 bpm while in non-AF group – 84.72 bpm. Study did not find a statistically significant difference between mean dyspnea points in AF (mean of dyspnea points – 6.4) and non-AF (6.56) patient groups, male (6.18) and female (6.63) groups as well as between two MHR (6 in MHR – non-AF, 7.13 in MHR – AF) and HHR (5.97 in HHR – non-AF, 6.82 in HHR – AF) subgroups – for both numerical and visual evaluations ($p > 0.05$).

Conclusion: Atrial fibrillation does not influence the subjective severity of dyspnea.

The value of exosomal miRNAs to predict clinical outcome in patients undergoing percutaneous mitral valve repair using MitraClip system

O M Galuszka¹; M Gast¹; A Stroux¹; X Wang¹; D Steffens¹; C Skurk¹; U Landmesser¹; W Poller¹; M Gross¹; M Kasner¹

¹Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany

Aims: Long-standing mitral regurgitation (MR) causes chronic volume overload eventually leading to left ventricular (LV) remodeling and heart failure. In the present study we aimed to assess the potential of a panel of echocardiographic parameters and miRNA biomarkers to predict clinical outcome and functional recovery after percutaneous mitral valve repair (PMVR) using the MitraClip system.

Methods: 67 patients (76 ± 6 y, 53% w) with heart failure symptoms (NYHA > 2) and moderate-to-severe MR (> 2) underwent PMVR. We performed conventional 2D echocardiography, including speckle tracking analysis before the procedure (BL) and at six-months follow-up (FU). Circulating exosomal miRNA abundance was determined after enrichment of exosomal microparticles from serum followed by Taqman PCR for quantification of specific miRNAs.

Results: Mitral valve repair resulted in increased effective stroke volume (SV) despite unchanged LV ejection fraction (EF), indicating recovery of overall cardiac performance. LV global longitudinal strain (GLS) revealed differing potential for recovery of contractility. Patient clinical recovery (defined NYHA class improvement) significantly correlated with exosomal miR-enc-1, miR-enc-2, and miR-enc-5; whereas post-procedural pulmonary artery pressure (PAP) with miR-enc-6 and miR-enc-7.

Conclusions: Possible predictive value of exosomal miRNAs regarding myocardial recovery requires further evaluation of candidate miRNAs in validation cohorts. Distinct exosomal miRNA profiles may differentiate functional disturbances in left ventricle vs. left atrium and pulmonary circulation vs. right ventricle, and thus progression of heart failure through different phases until the transition to irreversible myocardial damage. Clinical application of confirmed predictive miRNAs would enable further individualization of treatment decision based on a patient's likely individual response to therapy

Permanent pacemaker implantation in patients undergoing trans-catheter aortic valve implantation: 1st year single center experience

J C Joana Catarina Duarte Rodrigues¹; FS Saraiva²; MTS Tavares Silva¹; JCS Carlos Silva¹; RR Rodrigues¹; DM Magalhaes¹; PA Almeida¹; MC Campelo¹; PP Pinho³; MJM Julia Maciel¹

¹Sao Joao Hospital, Department of Cardiology, Porto, Portugal; ²Faculty of Medicine University of Porto, Physiology and Cardiothoracic Surgery, Porto, Portugal; ³Sao Joao Hospital, Department of Cardiothoracic Surgery, Porto, Portugal

Background: Transcatheter aortic valve implantation (TAVI) has been established as a treatment option for patients with symptomatic aortic valve stenosis who are not considered candidates for open surgery. However, the proximity of the aortic valve annulus to the conduction system is a known risk of conduction disturbances that requires monitoring and, in some cases, permanent cardiac pacing. The aim of this study was to assess the incidence rate of conduction disorders and the predictors of permanent pacemaker implantation in patients undergoing TAVI.

Methods: We conducted a retrospective observational study that included consecutive patients treated with TAVI in a single tertiary centre between November 2014 and November 2015. Baseline parameters, procedural characteristics as well as twelve-lead surface ECG before and shortly after TAVI were evaluated. A comparison between patients that required pacemaker with those who did not was done using a univariate analysis.

Results: A total of 41 patients (41.5 % male), 80 ± 7.4 years successfully underwent TAVI, 66% implanted the third-generation percutaneous self-expanding CoreValve. A permanent pacemaker was implanted in 9 (22%) of the patients, dual chamber in 89% of cases. The pacemaker was implanted on average at 7 ± 3 days following TAVI (range 3 to 12 days). When comparing patients who required pacemaker versus those who didn't, we found a higher prevalence of new auriculoventricular conduction disturbance after implantation of TAVI (67% vs. 19 %, $p = 0.011$). No other baseline electrocardiographic parameters or clinical characteristics associated with the need of permanent cardiac pacing (namely age, sex, intraventricular delay conduction disturbances previous or after TAVI) were found.

Conclusion: Cardiac conduction disturbances are common after TAVI and are associated with an increased risk of permanent pacemaker. Careful ECG monitoring may be necessary for as long as one week after TAVI due to a risk of atrioventricular conduction disturbances of more late onset. In our small group of patients only new-onset auriculoventricular conduction disturbances was found to be associated with permanent pacemaker requirement. Future research and registries with larger

groups of patients will allow to find independent predictors for pacemaker implantation.

Different response to cardiac resynchronization therapy in patients with congestive heart failure

AM Anna Soldatova¹; VA Kuznetsov¹; DV Krinichkin¹; TN Enina¹

¹Tyumen Cardiology Center, Tyumen, Russian Federation

The aim: The aim of the study was to evaluate clinical, morphological and functional features and mortality in patients with chronic heart failure (CHF) in patients with different time of the best response to cardiac resynchronization therapy (CRT).

Materials and methods: 122 patients (82.8% men) with CHF NYHA functional class III-IV (mean age 54.8±9.6 years). At baseline, 1 month, 3 months and each 6 months after implantation we evaluated clinical and echocardiographic parameters. In 28 patients the best decrease of left ventricular end-systolic volume (LVESV) was achieved up to 3 months (1.1±0.9 months, I group – 'early' response) and in 94 patients – after 3 month (22.6±14.9 months, II group – 'late' response). Groups did not differ in clinical characteristics, NYHA functional class, QRS duration and parameters of mechanical dyssynchrony.

Results: In the II group responders (decrease in LVESV ≥15%) were identified significantly more frequently (90.4% vs. 60.7%; p=0.001), all patients with decrease of LVESV ≥30% (superresponders) had 'late' response. During follow-up period (33.2±16.7 months) increase in left ventricular ejection fraction (LVEF) and decrease in LVESV were more evident in patients with 'late' response. In Kaplan-Meier analysis mortality in II group was significantly lower (3.2% vs 28.6%; p=0.001). Cox regression showed that LVESV (HR 1.012; 95% CI 1.004–1.021; P=0.005) and the time of response (HR 0.131; 95% CI 0.032–0.530; P=0.004) were associated with long-term mortality.

Conclusion: Patients with 'early' response to CRT show significantly lower improvement in LVEF and LVESV compared to patients with 'late' CRT response. 'Early' response and greater LVESV are associated with higher mortality rate.

P2113

The effect of biventricular stimulation in patients with chronic heart failure with moderate clinical manifestations

ES Atroschenko¹; YP Ostrovskiy¹; DV Romanovskiy¹; VA Sujayeva¹; OV Koshlataya¹; IV Sidorenko¹; VV Shumavets¹

¹Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Objective: to assess the effectiveness of CRT (cardiac resynchronisation therapy) implantation in patients with chronic heart failure NYHA functional class II.

Methods: 50 patients (pts) with ischemic (23 pts) or dilated cardiomyopathy (27 pts) complicated by CHF NYHA functional class (FC) II, LV EF below 35%, QRS duration 150 msec and more and with ECHO confirmed mechanic myocardial dyssynchrony were examined. All patients underwent the LV end-diastolic volume (LVEDV), LV end-systolic volume (LVESV), LV end-systolic diameter (LVESD), LVEF, LV end-diastolic diameter (LVEDD), interventricular delay, dyssynchrony index (TS-DS), all segments max delay were estimated by ECHO. The levels of BNP, the six-minute walk test (6MWT) and life quality (LQ) were measured initially and at 6 months after CRT implantation.

Results: At 6 months, LVEDV significantly decreased from 318,41±15,8 ml to 252,7±22,1ml (<0,05), LVESV decreased from 241,41±12,9 to 166,8±20,4 (<0,05), LVEF increased evidently from 24,17±0,85% to 35,5±2,3% (<0,05). Intracardiac hemodynamic changes were accompanied by decreased mechanic dyssynchrony event rate - there was trend to the evident decrease of inter-ventricular delay from 67,7±4,2 to 38,15±7,3 msec. (<0,05), TS-DS- from 65,5±5,1 to 56,3±6,2 msec. (<0,05), all segments max delay from 183,5±11,5 to 151,7±17,8 msec. (<0,05); improved LQ of patients: LQ evidently decreased from 59,9±1,67 scores to 37,1±2,5 scores (<0,05); 6 MWT increased from 393,8±2±15,07 m to 479,1±17,06 m; NT-proBNP decreased from 1442,4±277,8 to 627,37±301,5 (<0,05).

Conclusions: At 6 months biventricular heart stimulation evidently enhances heart haemodynamic and the clinical conditions of pts, improving exercise tolerance in pts with chronic heart failure NYHA functional class II.

P2114

Measurement of left ventricular ejection fraction in candidates to implantable cardioverter-defibrillator: echocardiography versus radionuclide ventriculography in 67 patients

C Katsanos¹; L Paccaloni¹; M Capponi¹; F Pellone¹; D Bela¹; C Palpacelli¹; GL Morgagni¹

¹Osp. Civile Macerata, AV3 Asur Marche, SC Cardiologia, Macerata, Italy

Background: conflicting results have been reported in the measurement of left ventricular ejection fraction (LVEF) by different techniques. That is of paramount importance when dealing with chronic heart failure (CHF) patients who may be candidates to implantable cardioverter-defibrillator (ICD).

Aim of the study: to assess the difference in measurement of LVEF derived either by echocardiography (Echo) or by radionuclide ventriculography (RNV) in the same CHF patients candidates to ICD implant.

Materials and methods: in the period between 2010 to 2014, 67 CHF patients (age 26-87 years, average 76 years, 54 males and 13 females), NYHA functional class III or IV were admitted in our department of cardiology and studied before ICD implant. LVEF was assessed using both techniques (Echo and RNV) during the same hospitalization; measurements were taken in the same day or in consecutive days without changes in clinical status or in drugs administration.

Results: the mean value of LVEF obtained by Echo was 37.61±11.5% (range 20-78%). The mean value of LVEF obtained by RNV was 35±12.5% (range 15-76%). The mean difference (Echo LVEF – RNV LVEF) was 2.6±6.7% (range 13-22%). The statistical analysis showed a linear correlation, statistically significant, between the LVEF measurements obtained by the two techniques (Figure 1); on the contrary the difference between the two means was not significant. depicts; When analysing data by a different statistical way, the Bland-Altman plot (Figure 2), we observed that values included in the confidence interval were far from the mean (15.7% and -10.5% respectively), despite a mild mean difference.

Conclusions: the present study showed a strong linear correlation between the values of LVEF obtained with the two techniques (Echo / RNV) as well as a trivial mean difference, therefore confirming the clinical usefulness of both. However, the wide range (26.2%) of mean differences found in our CHF patients, suggests to be cautious when deciding the appropriateness of ICD implant on the value of LVEF obtained only by one technique.

Figure

Endothelial dysfunction with continuous flow left ventricular assist device support: effects on the number and function of endothelial progenitor cells

T Hasin¹; E Lev²; D Leshem-Lev²; D Murninkas²; B Ben-Avraham²; M Abuhazira²; V Rubchevsky²; D Aravot²; R Kornowski²; T Ben-Gali²

¹Shaare Zedek Medical Center, Jerusalem, Israel; ²Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel

Background: Contemporary continuous flow left ventricular assist devices (Cf-LVADs) support non-pulsatile physiology. This was associated with impaired endothelial function and the common occurrence of vascular complications. The mechanism of endothelial dysfunction in patients on Cf-LVAD support has not been determined.

Methods: In this prospective observational study patients in stage D heart failure (HF) were evaluated before and at 1 and 3 months after Cf-LVAD implantation. We measured reactive hyperemia index (RHI) for endothelial function using peripheral arterial tonometry. Circulating endothelial progenitor cells (EPC) were identified using flow cytometry and represented as the proportion of mononuclear cells expressing VEGFR-2/CD133, or VEGFR-2/CD34. Functional aspects of EPCs were evaluated after 7 days of culture by identification of colony forming units and the MTT assay for viability of cells.

Results: Twenty-one patients supported with Cf-LVAD for more than 3 months were included. Patients were 62±7 years old, 18(86%) males and 14(67%) had ischemic etiology. Twelve (57%) were implanted with HeartMate II (Thoratec) and 9 (43%) received an HVAD (Heartware) LVAD. RHI and EPC results are shown in the table. At 3 months early EPCs (VEGFR-2/CD133) and MTT significantly increased. RHI at

3 months strongly correlated with EPCs at 1 month (spearman's -0.8 , $p \leq 0.001$ for both). Pre and post LVAD EPCs did not form colonies in culture.

Conclusion: While pre-operative endothelial dysfunction persists after surgery, EPCs increase in number but remain dysfunctional, suggesting possible damage caused by the Cf-LVAD circulation. Newer LVADs with maintained pulsatility may be more protective of endothelial physiology.

Variable	Pre-LVAD	1mo after LVAD	3mo after LVAD

¹University of Athens, School of Medicine, 3rd Cardiology Dept., Athens, Greece;

²Evangelismos Hospital, Athens, Greece; ³University of Athens, Athens, Greece

Background: We have developed a novel implantable counterpulsation LVAD, the Pressure-Unloading Left Ventricular Assist Device (PULVAD), designed to provide LV pressure unloading and diastolic aortic augmentation.

Purpose: To investigate the effects of PULVAD support on LV and myocardial perfusion in a porcine model of acute heart failure (AHF).

Methods: PULVAD comprises a pneumatically-driven pumping chamber implanted in the thoracic cavity and connected to the ascending aorta. The pump is ECG-synchronized to operate through inflation of the device air space during diastole (injecting blood into the aorta), and deflation just prior and during systole (sucking blood from the aorta into the device blood sac). Seven farm pigs were instrumented with Millar catheter, sonomicrometry crystals and a Doppler flow probe placed around the left anterior descending artery (LAD). Pigs underwent induction of AHF by LAD ligation for 60 minutes, followed by reperfusion. PULVAD was implanted in the thoracic cavity and connected to the ascending aorta. PULVAD was driven by the Arrow Autocath 2 Wave system console (a conventional intra-aortic balloon pump console) and was ECG-synchronized to provide LV pressure unloading along with aortic diastolic pressure augmentation. Traditional hemodynamics, indices of LV energy consumption, indices of LV mechanical performance and LAD blood flow were measured without and after brief (30-60 seconds) PULVAD support during reperfusion.

Results: PULVAD support induced a profound reduction in LV afterload, manifested as a significant decrease in systolic aortic pressure (from 99.2 ± 23.1 to 80.3 ± 24.6 mmHg, $p < 0.05$) and in end-diastolic aortic pressure (from 82.1 ± 24.4 to 59.9 ± 28.6 mmHg, $p < 0.05$). PULVAD support reduced LV energy consumption, manifested as a significant decrease in LV stroke work (from 2974 ± 1816 to 2406 ± 1686 mmHg*ml, $p < 0.05$), while concurrently improving LV mechanical performance (relative increase in ejection fraction: $27.4 \pm 42.1\%$; relative increase in stroke volume $23.5 \pm 39.0\%$, $p < 0.05$). PULVAD support significantly increased mean LAD blood flow (from 50.77 ± 23.44 to 64.64 ± 24.22 ml/min, $p < 0.05$), mainly by producing a dramatic augmentation in diastolic LAD blood flow (62.40 ± 31.45 ml/min to 98.28 ± 36.30 ml/min, $p < 0.05$).

Conclusions: PULVAD, a novel implantable counterpulsation LVAD, optimizes LV energetic performance (decreases energy consumption and concurrently improves mechanical performance) by LV unloading and augmentation of myocardial blood flow.

Limited increase of cardiac index and myocardial perfusion during dobutamine-stress in a porcine model of early HFpEF: a cardiac magnetic resonance imaging study.

A Alogna¹; M Manninger²; U Reiter³; G Reiter⁴; G Adelsmayr³; J Verderber²; M Fuchsjaeger³; D Scherr²; B Pieske¹; H Post¹

¹Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Medical University of Graz, Department of Cardiology, Graz, Austria; ³Medical University of Graz, Dept. of Radiology, Graz, Austria; ⁴Siemens AG, Healthcare Division, Graz, Austria

Introduction: Heart failure with preserved ejection fraction (HFpEF) evolves by accumulation of risk factors over time and still lacks a guideline therapy, in part due to the complex pathophysiology. An increased left ventricular stiffness at rest is the hemodynamic hallmark of the disease. However, most patients become symptomatic preferably during exercise, and a limited myocardial perfusion and contractility reserve may play a role. We therefore investigated left ventricular (LV) function and perfusion during dobutamine-stress in a previously established porcine model of hypertensive heart disease/early-stage HFpEF.

Methods and Materials: Five anesthetized deoxycorticosterone-acetate (DOCA)-salt induced early-stage HFpEF pigs and seven weight-matched controls underwent cardiac magnetic resonance imaging at rest and during dobutamine stress (heart-rate increase: $21 \pm 7\%$). Indices of left ventricular (LV) function were evaluated from cine short-axis images. Early-diastolic tissue velocity (E'), transmural velocity (E), and coronary sinus net-forward blood volume (CSV) were acquired from 4D phase-contrast measurements and evaluated by prototype software (4D-Flow). Global myocardial perfusion (GMP) and perfusion reserve (MPR) were estimated from rest/stress CSV and LV mass. Rest, stress, and rest-to-stress differences (in %) of parameters in DOCA and control animals were compared by t-test.

Results: Dobutamine increased LV ejection-fraction and decreased LV end-systolic volume in both groups ($p > 0.05$). E' was lower in DOCA at rest ($p = 0.019$) and during stress ($p = 0.025$), yielding higher E/E' at rest and stress (4.4 ± 0.9 vs 3.0 ± 0.5 and 4.6 ± 0.3 vs 3.6 ± 0.8 , all $p < 0.05$), indicating higher LV filling pressures in DOCA. Cardiac index increased less in DOCA pigs (graph), and the LV end-diastolic volume index decreased during dobutamine in DOCA (DOCA, $-20 \pm 11\%$; controls, $-5 \pm 11\%$; $p = 0.042$). GMP did not differ between groups at rest ($p = 0.538$), but increased less in DOCA-pigs during dobutamine, resulting in a reduced MPR (graph).

Conclusion: In a preclinical model of early-stage HFpEF, an impaired increase of cardiac index during dobutamine-stress was paralleled by a reduced myocardial perfusion reserve. Exercise induced myocardial ischemia may be a contributor to LV dysfunction in HFpEF.

P2118

Native myocardial T1 times are not necessarily increased with myocardial collagen: a preclinical study in hypertensive hypertrophic heart disease.

A Alogna¹; M Manninger²; U Reiter³; G Reiter⁴; D Zweiker²; D Scherr²; C Muehlhfeld⁵; M Fuchsjaeger³; B Pieske¹; H Post¹

¹Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; ²Medical University of Graz, Department of Cardiology, Graz, Austria; ³Medical University of Graz, Dept. of Radiology, Graz, Austria; ⁴Siemens AG, Healthcare Division, Graz, Austria; ⁵Hannover Medical School, Institute of Functional and Applied Anatomy, Hannover, Germany

Introduction: Heart failure with preserved ejection fraction (HFpEF) evolves by accumulation of risk factors over time and still lacks a guideline therapy, in part due to the complex pathophysiology. Myocardial fibrosis is one of the major contributors of left ventricular diastolic dysfunction, the classical hallmark of the disease. T1 mapping is a cardiac magnetic resonance technique that allows the detection of myocardial fibrosis. However, the accuracy of this technique in detecting increased interstitial collagen in the setting of early left ventricular (LV) remodelling needs to be further elucidated. We therefore aimed to investigate whether native left ventricular (LV) T1-times are increased with myocardial collagen in a previously established porcine model of hypertensive heart disease/early-stage HFpEF.

Methods and Materials: Five anesthetized deoxycorticosterone-acetate (DOCA)-salt induced hypertensive, hypertrophic pigs and three healthy animals underwent ECG-gated 3T magnetic resonance imaging, including assessment of LV mass and native myocardial T1-times (MOLLI protocol 5(5)5(5)5). After in-vivo measurements, animals were sacrificed and transmural biopsies were collected for stereological analysis. T1-maps were evaluated by manual segmentation according to the AHA 17-segment model. LV T1-times were calculated as averages from

segmental values. Stereological evaluation included myocardial volume fractions of interstitium (Vint/LV) and collagen (Vcoll/LV), as well as collagen volume related to the interstitium (Vcoll/int). Parameter means of DOCA and control animals were compared by t-test; relationships between parameters were analyzed with correlation analysis.

Results: LV mass was higher in DOCA pigs (DOCA, 134 ± 21 g; controls, 88 ± 2 g; $p < 0.001$). LV T1-times did not differ between groups (DOCA, 1161 ± 21 ms; controls, 1195 ± 36 ms; $p = 0.094$). Vcoll/int showed higher levels in DOCA (DOCA, $17 \pm 4\%$; controls, $8 \pm 3\%$; $p = 0.032$). Related to LV mass, Vint/LV (DOCA, $17 \pm 5\%$; controls, $21 \pm 2\%$; $p = 0.202$) and Vcoll/LV (DOCA, $2.7 \pm 0.8\%$; controls, $1.7 \pm 0.5\%$; $p = 0.109$) were not significantly different. Whereas myocardial T1-times did not correlate significantly with Vint/LV and Vcoll/int, the negative correlation with Vcoll/LV was significant ($r = -0.71$, $p = 0.047$).

Conclusion: Although interstitial collagen content is elevated in our large-animal model of early-stage HFpEF, LV T1-times did not differ. The effect of cardiomyocyte hypertrophy (decreased interstitial space) dominates native T1-times in a voxel rather than increased myocardial collagen content.

P2119

Challenging diagnosis in constrictive pericarditis

C Tarau¹

¹University of Medicine and Pharmacy of Cluj Napoca, Cluj Napoca, Romania

Background: Perhaps no cardiac disorder is as elusive as constrictive pericarditis (CP) mimicking diseases as divergent as MI to cirrhosis. The penalty for incorrect decision is direr, needless sternotomy vs. continued undiagnosed symptoms.

Methods: 65 years old patient with persistent atrial fibrillation, without notable medical history, with signs of right failure despite maximal treatment. Echocardiography with signs of pulmonary hypertension, normal left ventricular systolic function, bia-trial dilatation, define the diagnostic of rhythmic cardiopathy. For the patient sent for ablation to our center, a cardiac scanner was used before ablation.

Results: Cardiac CT highlights the evidence of extensive pericardial calcification associated with increasing of pericardial thickness, diagnosing the constrictive pericarditis. CMR evaluation revealed the presence of ventricular interdependence and tagged cine CMR showing no tethering and no adhesion of the thickened pericardium to the myocardium, making feasible the pericardectomy. Partial pericardectomy was performed. Anatomic pathological images revealed an idiopathic chronic calcified pericarditis.

Conclusions: Given the ability to define all segments of pericardium and its physiologic interaction of with the heart, CMR associated cardiac CT may as well be the new 'gold standard' of diagnosis.

P2120

Left ventricular remodeling in patients with type 2 diabetes mellitus

A Albana Doko Banushi¹; I Refatllari¹; V Paparisto¹; E Konda¹; J Dragoti¹; A Goda¹

¹University Hospital Center Mother Theresa, Tirana, Albania

Background: Many studies have emphasized the architectural changes and left ventricular (LV) remodeling as a result of myocardial chronic stress factors such as hypertension and diabetes, as well as the risk of progression to heart failure.

Purpose: To study the LV geometrical remodeling in patients with type 2 diabetes mellitus (T2DM) with or without hypertension (HT), without coronary artery disease, asymptomatic for heart failure, with normal ejection fraction (LV EF > 55 %).

Methods: 337 patients with T2DM (175 male, age 38-77 years) and 100 age-matched normal subjects (52 male) as a control group underwent echocardiography for the evaluation of LV dimensions, mass and remodeling. They were divided in three groups: control group – 100 normal subjects; T2DM alone group – 213 patients; T2DM + HT group – 124 patients.

Results: 37.1 % (79/213) of patients with T2DM versus 76.61% (95/124) of patients with T2DM+HT had an abnormal LV geometry ($p < 0.001$). A concentric remodeling was found in 17.84% (38/213) of patients with T2DM versus 17.74% (22/124) of patients with HT+T2DM ($p = ns$). 12.68% (27/213) of patients with T2DM versus 29.84% (37/124) of patients with T2DM+HT showed concentric hypertrophy ($p = 0.05$), whereas 6.57% (14/213) of patients with T2DM versus 29.03 % (36/124) of patients with HT+T2DM showed eccentric LV hypertrophy. ($p = 0.001$). An important statistical significance was noticed between the presence of T2DM and LV remodeling ($r = 0.49$; $p < 0.001$), as well as a strong relationship between the presence of T2DM+HT and LV remodeling ($r = 0.75$; $p < 0.001$).

Conclusions: Diabetes mellitus is an important factor on the LV geometrical remodeling. When only DM is present the most common remodeling type is the concentric remodeling, whereas when DM coexists with HT both concentric and eccentric hypertrophic models are similarly expressed.

P2121

Imaging cardiac hydatid cysts: 10 cases.

H Habiba Drissa¹; MERIEM Drissa¹; HAJER Malek¹; FETEN Yahia¹; ABIR Bouslimi¹; MEHDI Che¹

¹La Rabta University Hospital, adults cardiology, Tunis, Tunisia

Introduction and Purpose: Cardiac hydatid disease is rare. Rupture of a cardiac cyst is a serious complication. Diagnosis of cardiac hydatid cysts is often made using transthoracic echocardiography (TTE) and transesophageal echocardiography (TEE) provides details of the cysts. We report 10 cases of cardiac hydatidosis, review the modes of diagnosis, and stress the contribution of modern imaging techniques

Methods: we have collected ten cases of CH between 1990 and 2014. The average age of patients was 33 years and sex ratio = 0.3. We assessed retrospectively the clinical and echocardiography features of CH in consecutive Patients.

Results: symptom consisted on atypical chest pain in six patients, dyspnea in two cases and dizzy spell was noted in one case. One patient was asymptomatic. Electrocardiogram showed a disturbance of repolarization in six cases, conduction disorder in one case and pseudo-aspect of necrosis in two patients. Trans thoracic echocardiography coupled to trans esophageal way allowed diagnosis in all patients by showing uni-vesicular cyst in six cases, multi-vesicular cyst in three cases and calcified in one patient.. The cyst site was within the left ventricular wall in seven cases, pericardium in one patient and right ventricle in two cases. The Chest CT scan our MRI performed in four patients confirmed the echocardiography data. Serology for primitive CH was positive only in 5 cases. All patients underwent surgery with good immediate results. Echocardiograph findings correlated well with surgical findings. Echocardiography Follow up (Mean 50 months) eliminated recurrence of CH.

Conclusion: Transthoracic echocardiography suggests the initial diagnosis. CT and MRI provide details of the location and extension of the cardiac hydatidosis.

Effect of cardiac rehabilitation on progenitor endothelial cells in patients with heart failure

L Gatta¹; A Armani¹; F Molinari¹; G Marazzi¹; G Caminiti¹; C Mammi¹; C Vitale¹; G M C Giuseppe M C Rosano¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Background: Alterations in the matrix metalloproteinases levels (MMPs) and in the number of endothelial progenitor cells (EPCs) have been observed in chronic heart failure (CHF) patients. Design: We investigated the effect of a three-week cardiac rehabilitation (CR) program on the number of circulating CD34/KDR+ cells and on serum levels of MMPs in 21 CHF patients. In addition, we studied the effect of patients serum on colony forming units-endothelial cells (CFU-ECs) proliferation.

Methods: Peripheral blood and serum were obtained from patients with CHF undergoing CR at admission and at discharge. We measured CD34/KDR+ cells and serum levels of MMP-1 and tissue inhibitor of metalloproteinases (TIMP)-1 by ELISA. Moreover the function and number of CFU-EC colonies were evaluated in cultures performed with serum obtained before and after CR. Exercise tolerance before and after CR was assessed by 6-minute-walking-test (6MWT).

Results: At discharge, 6MWT distance and percentage of circulating CD34/KDR+ cells increase (0.35 ± 0.03 to 0.58 ± 0.04 ; $p < 0.05$ and 154 ± 27 to 233 ± 48 ; $p < 0.0001$, respectively). Conversely, serum concentrations of MMP-1 and TIMP-1 (11.4 ± 2.4 vs. 6.3 ± 1.1 ng/ml, $p < 0.01$ and 320.4 ± 41.2 vs. 167.2 ± 12.6 ng/ml, $p < 0.01$, respectively) decrease. Interestingly, we found an increase of CFU-EC proliferation in cultures performed with serum obtained at discharge.

Conclusions: In CHF patients, three-weeks CR increases the number of circulating EPCs, decreases serum levels of enzymes involved in matrix remodeling and increases serum ability to sustain CFU-EC proliferation. These findings support the hypothesis that CR positively affects the activity of factors involved in cardiovascular repair.

P2123

Effect of a cardiac rehabilitation program on circulating CD34/CD117 cells, their proliferation and, metalloproteinases profile in patients with heart failure

L Gatta¹; G M C Giuseppe M C Rosano¹; A Armani¹; F Molinari¹; G Marazzi¹; G Caminiti¹; M Volterrani¹

¹San Raffaele Pisana Hospital IRCCS, Rome, Italy

Aims: Circulating adult stem cells are thought to exert beneficial effects on re-endothelialization after endothelial injury. Aim of this study was to assess the effect of a cardiac rehabilitation program on mobilization of CD34/CD117 positive cells in the peripheral blood, changes in serum levels of Matrix Metallo Proteinases (MMP-1, MMP-2 and MMP-9), Tissue Inhibitor of Metallo Proteinase-1 (TIMP-1) and TNF- α and on the effect of patient's serum on EPC maturation in culture in patients with mild heart failure.

Methods: Blood and serum were collected from 14 patients with NYHA class II heart failure, undergoing an in-patient cycle of cardiac rehabilitation. PBMC were analysed by flow cytometry at admission and at discharge for CD34, KDR, CD117 and CXCR4 markers. Serum levels of MMP-1, MMP-2, MMP-9, TIMP-1 and TNF- α were detected by ELISA before and after rehabilitation. Culture of EPCs from healthy donors were performed with serum obtained from patients at admission and at discharge.

Results: Compared to baseline an increase in the percentage of CD34/CD117 positive cells was found at discharge. At discharge, all patients showed a significant decrease in serum concentrations of MMP-1 and TIMP-1. EPCs cultures showed a significant increase in CFU number in EPCs cultivated with serum from patients at discharge. We also found an inverse correlation between TNF- α plasma levels and CD34/KDR positive cells number in blood and between TNF- α and number of EPCs that adhere to activated HUVECs.

Conclusions: Physical training in patients with HF induces mobilization of bone marrow stem cells and modifies serum concentrations of TIMP-1 and MMP-1 that may favour vascular repair and inhibit left ventricular remodelling. Moreover functional assays as CFU number analysis, showed that proliferation of cells is influenced by factors that are modified in the serum of patients after rehabilitation. These results underlie new exercise-related beneficial effects in patients with heart failure.

P2124

Effect of exercise training on serum capacity to induce endothelial cell death in patients with chronic heart failure

C Mammi¹; M Caprio¹; L Gatta¹; A Feraco¹; G Caminiti¹; G Marazzi¹; C Vitale¹; M Volterrani¹; G M C Giuseppe M C Rosano¹

¹ San Raffaele Pisana Hospital IRCCS, Rome, Italy

Serum from patients with cardiovascular diseases increases apoptosis in human endothelial cells suggesting the importance of humoral factors in the progression of the disease. Aim of this study was to evaluate whether an in-hospital exercise training program (3 weeks) may influence the apoptotic capacity of sera from patients with chronic heart failure. HUVECs were incubated with a medium containing 20% serum from 39 patients with HF (NYHA II) obtained before and after either a three week exercise training program or at baseline and after three months in patients receiving standard care, and compared to 10 age-matched healthy donors (HD). Sera from CHF patients showed enhanced proapoptotic capacity compared to sera from HD as assessed by Cell Death Assay (HFA 67 \pm 5.4% and HFA-E 70 \pm 5.6% vs HD 23 \pm 5.8%; $p < 0.001$). In addition, the capacity of sera to trigger endothelial cells apoptosis in vitro was significantly reduced after physical activity (HFA-E 70 \pm 5.6% vs HFD-E 41 \pm 4.5%, $p < 0.001$). Apoptosis assessment performed by intracellular PI staining confirmed both the increased capacity of pre-training CHF sera to trigger programmed cell death compared to the healthy donors (HFA-E 42,14 \pm 1.9% vs HD 14,2 \pm 0.7% $p < 0.001$), as well as the ability of physical training to markedly reduce such activity (HFA-E 42,14 \pm 1.9 vs HFD-E 31,9 \pm 1.4%, $p < 0.001$). The reduction of DNA fragmentation after exercise training correlated with the improvement in functional capacity of patients. Moreover the expression of positive regulators of apoptosis proteins Bax and cleaved Caspase-3 was significantly reduced in HUVECs exposed to sera collected after rehabilitation. Likewise, circulating TNF- α , MMP1, TIMP1 and of the MMP-9/TIMP-1 ratio levels were significantly reduced after exercise training.

In conclusion, in-hospital supervised cardiovascular training program reduces the ability of serum-derived factors to induce endothelial cell death in patient with CHF.

P2125

Reference equations for the six-minute walk test in heart failure patients

G Garyfallia Pepera¹; L Ingle²; G Peperas³; GR Sandercock¹

¹ University of Essex, Colchester, United Kingdom; ² University of Hull, Department of Sport, Health and Exercise Science, Hull, United Kingdom; ³ General Hospital of Lamia, Lamia, Greece

Background: The six-minute walking test (6-MWT) is the most common exercise test, used to evaluate functional capacity and effects of therapeutic interventions on heart failure (HF) patients enrolled in cardiac rehabilitation (CR) programmes.

Purpose: The purpose of this study was to establish a reference equation to predict 6-MWT performance in HF population.

Methods: 80 HF patients (85% males; mean age 78 \pm 7 years), enrolled in a chronic disease assessment programme completed the 6-MWT. Baseline clinical assessment took place prior to testing and included stature, body mass, BMI, medical and pharmacological history, ventricular function and New York Heart Association (NYHA) functional class. Multinomial logistic regression was used to determine the factors associated with poor performance (≤ 300 m) in the 6-MWT. Threshold values were identified for dependent (total distance 300 m) and independent variables (age > 75 ; stature < 172 cm; BMI > 25 kg \cdot m⁻²; step length < 0.63 m; walking pace index < 50 %; resting heart rate < 80 beats min⁻¹; LVEF < 45 %). Odds ratios with 95 per cent confidence intervals (CI) were calculated.

Results: Mean 6MWT distance was 310 \pm 120 m. Age and stature were the only

variables which correlated significantly with test performance. In regression analysis, 42% of variance in 6MWT performance was accounted for by age, but stature was no longer a significant predictor: 6MWT distance (m) = 765 - (6 \times age), m. Multinomial logistic regression analysis showed that independent predictors of poor performance were: BMI ≥ 25 kg-m⁻² (OR = 13.1, 95% CI = 1.48 - 110) and age ≥ 75 years (OR = 5.1, 95% CI = 1.31 - 18.79).

Conclusions: Clinical variables such as ventricular function are unrelated to 6 minute walk test performance in heart failure patients. Old age and high BMI are, however, independent predictors of poor performance and should be accounted for when the test is used to categorise patients according to prognostic cut points. Test performance may be better expressed as a percentage of normal population values which account for age and BMI.

Differences between overweight/obese patients and normal weight patients with stable heart failure. A Possible link to survival benefit

R B Pharithi¹; EE Egom¹; AA Jago¹; A M Maher¹; SM Fahy¹; S Fall¹; V Maher¹

¹ The Adelaide and Meath Hospital, Tallaght, Heart Efficiency Unit, Cardiology Department, Dublin, Ireland

Background: Chronic heart failure (CHF) patients with increased body mass index (BMI) (overweight and obese) have better survival rates than their normal weight counterparts. It is not known what factors related to increased BMI underlie this benefit.

Objective: We aimed to assess how body composition, diet, exercise levels and functional capacity differed between obese/overweight and normal weight patients.

Methods: 106 patients with chronic stable heart failure were categorized according to their BMI. Anthropometric measurements, body composition (Tanita), fat mass and free fat mass, dietary 3 day records and functional assessments including 6 minute walk test, 3 day FitBit records and NYHA class were recorded.

Results: There were no differences in daily energy, fat, or carbohydrate consumption or activity levels between the groups. However, overweight and obese CHF patients have significantly increased fat mass, % fat, free fat mass and consumed more protein. Mean age 66.8 \pm 12.7. 72.2% (n = 78) were male and 27.8% (n = 30) were female.

Conclusion: Our study highlights that energy intake and activity levels do not differ significantly between overweight/obese and normal weight patients. However, the higher fat free mass and protein intake suggests differences in protein metabolism may be relevant to the survival benefit with higher BMI.

Left ventricular function in asymptomatic scleroderma patients about 25 cases

H Habiba Drissa¹; MERIEM Drissa¹; HAJER Malek¹; ABIR Bouslimi¹; MEHDI Cheour¹; SANA Helali¹; SAMIRA Kaabachi¹

¹ La Rabta University Hospital, adults cardiology, Tunis, Tunisia

Introduction and Purpose: Scleroderma has been associated with an increases risk of cardiovascular diseases. The aim of this study is to assess the systolic and diastolic function of the left ventricular (LV) in asymptomatic scleroderma patients.

Methods: We included 25 scleroderma patients without symptoms or signs of heart failure or angina (groupe I) and 25 healthy subjects (groupe II). The two groups had similar mean age, sex ratio, mean blood pressure and body mass index. All included subjects had no evidence of diabetes mellitus, valvular or ischemic heart diseases. We used standard echocardiography and tissue Doppler imaging (TDI).

Results: LV diastolic diameter and LV ejection fraction were similar in both group, however we observed lower mitral annulus systolic velocities measured by TDI in scleroderma patients (5.2 ± 0.7 cm/s vs 8.6 ± 0.9 cm/s, $p < 0.01$) reflecting subclinical LV systolic dysfunction. There was not significant difference in the ratio of early to late diastolic mitral filling velocities E/A and in deceleration time of E between the 2 groups. However mitral annulus early diastolic velocities Ea measured by TDI were markedly reduced in scleroderma patients (7.0 ± 1.1 cm/s vs 12.5 ± 1.4 cm/s, $p < 0.01$) WITH function. Diastolic impaired suggesting $p < 0.01$ 1.7 ± 1.9 vs 13.1 velocities Ea E of ratio higher.

Conclusion: This study shows the presence of systolic and diastolic dysfunction in asymptomatic scleroderma patients. Tissue Doppler imaging may provide a useful tool to monitor the disease process and treatment response of this subclinical myocardial dysfunction.

P2128

Platelet function parameters assessment by Multiplate aggregometry and leucocyte count in patients with acute coronary syndrome and lower ejection fraction

M Mirjana Isailovic-Kekovic¹; P Kekovic¹; P Cvetkovic²

¹Hospital Dr Aleksa Savic, Prokuplje, Serbia; ²Clinical Center of Nis, Nis, Serbia

Background: Acute coronary syndrome (ACS) is common and affects a significant number of people annually. Death occurs due to either arrhythmia or heart failure.

As leucocytosis is a hallmark of inflammatory reactions in patients with ACS, we investigated the relationship between leucocytosis on admission and left ventricular ejection fraction (LVEF) in patients with ACS. Platelets play a pivotal role in atherogenesis and its thrombotic complications such as those occurring in patients with ACS which is a platelet-driven process.

Purpose: To study platelet function parameters assessment by Multiplate aggregometry and leucocyte count in patients with ACS and lower ejection fraction.

Methods: A total of 82 patients with acute coronary syndrome (ACS) were considered for entry into the study. Leucocyte count was measured on Sysmex KX21N. Platelet function parameters-response to acetylsalicylic acid (ASPI test), clopidogrel (ADP test) and thrombin receptor activating peptide (TRAP test) were assessed by the Multiplate platelet function analyzer. Brain natriuretic peptide levels (BNP) were measured using a Triage meter pro biosite. Value of ejection fraction was measured by echocardiography.

Results: 82 patients were entered into the study (54 males, 28 females). In this group were 17 patients with left ventricular ejection fraction (LVEF) $< 40\%$ -group I and 65 patients with LVEF $> 40\%$ -group II. Mean age of patients in group I was 70.94 ± 10.09 , while in group II was 64.72 ± 10.55 . ($P < 0.05$). Mean leucocyte count in group I was $10.31 \pm 4.40 \times 10^9/l$, in group II was $8.10 \pm 2.81 \times 10^9/l$. ($P < 0.05$). Mean BNP in group I was 609.43 ± 396.14 pg/ml, in group II was 218.55 ± 279.95 pg/ml ($P < 0.05$). In I group value of ASPI test was 472.50 ± 303.34 AU*min, in II group ASPI test was 391.60 ± 256.83 AU*min. (NS). In I group value of ADP test was 659.43 ± 181.17 AU*min, in II group it was 533.63 ± 182.11 AU*min. ($P < 0.05$). In I group value of TRAP test was 1163.39 ± 284.94 AU*min, but in II group it was 1019.12 ± 266.98 AU*min. ($P < 0.05$).

Conclusion: Patients with ACS and LVEF $< 40\%$ were older than patients with ACS and LVEF $> 40\%$. Patients with ACS and LVEF $< 40\%$ had higher leucocyte count, BNP levels and higher values of ASPI, ADP and TRAP test than patients with ACS and LVEF $> 40\%$.
